- `dual` - bool (default: False): If True, also returns the corresponding decomposition of V under the action of the transpose of A. The factors are guaranteed to correspond.
- `is_diagonalizable` - if the matrix is known to be diagonalizable, set this to True, which might speed up the algorithm in some cases.

Note: If the base ring is not a field, the kernel algorithm is used.

OUTPUT:

- Sequence - list of pairs (V,t), where V is a vector spaces and t is a bool, and t is True exactly when the charpoly of self on V is irreducible.
- (optional) list - list of pairs (W,t), where W is a vector space and t is a bool, and t is True exactly when the charpoly of the transpose of self on W is irreducible.

EXAMPLES:

```
sage: A = matrix(ZZ, 4, [3,4,5,6,7,3,8,10,14,5,6,7,2,2,10,9])
sage: B = matrix(QQ, 6, range(36))
sage: B*11
[  0  11  22  33  44  55]
[ 66  77  88  99 110 121]
[132 143 154 165 176 187]
[198 209 220 231 242 253]
[264 275 286 297 308 319]
[330 341 352 363 374 385]
sage: A.decomposition()
[
(Ambient free module of rank 4 over the principal ideal domain Integer Ring, True)
]
sage: B.decomposition()
[
(Vector space of degree 6 and dimension 2 over Rational Field
Basis matrix:
[ 1  0 -1 -2 -3 -4]
[ 0  1  2  3  4  5], True),
(Vector space of degree 6 and dimension 4 over Rational Field
Basis matrix:
[ 1  0  0  0 -5  4]
[ 0  1  0  0 -4  3]
[ 0  0  1  0 -3  2]
[ 0  0  0  1 -2  1], False)
]
```

decomposition_of_subspace()

Suppose the right action of self on M leaves M invariant. Return the decomposition of M as a list of pairs (W, is_irred) where is_irred is True if the charpoly of self acting on the factor W is irreducible.

Additional inputs besides M are passed onto the decomposition command.

EXAMPLES:

```
sage: t = matrix(QQ, 3, [3, 0, -2, 0, -2, 0, 0, 0, 0]); t
[ 3  0 -2]
[ 0 -2  0]
[ 0  0  0]
sage: t.fcp('X')    # factored charpoly
(X - 3) * X * (X + 2)
sage: v = kernel(t*(t+2)); v    # an invariant subspace
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[0 1 0]
[0 0 1]
sage: D = t.decomposition_of_subspace(v); D
[
(Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[0 0 1], True),
(Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
```

```
[0 1 0], True)
]
sage: t.restrict(D[0][0])
[0]
sage: t.restrict(D[1][0])
[-2]
```

We do a decomposition over ZZ:

```
sage: a = matrix(ZZ,6,[0, 0, -2, 0, 2, 0, 2, -4, -2, 0, 2, 0, 0, 0, -2, -2, 0, 0, 2, 0, -2,
sage: a.decomposition_of_subspace(ZZ^6)
[
(Free module of degree 6 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1  0  1 -1  1 -1]
[ 0  1  0 -1  2 -1], False),
(Free module of degree 6 and rank 4 over Integer Ring
Echelon basis matrix:
[ 1  0 -1  0  1  0]
[ 0  1  0  0  0  0]
[ 0  0  0  1  0  0]
[ 0  0  0  0  0  1], False)
]
```

denominator()

Return the least common multiple of the denominators of the elements of self.

If there is no denominator function for the base field, or no LCM function for the denominators, raise a TypeError.

EXAMPLES:

```
sage: A = MatrixSpace(QQ,2)(['1/2', '1/3', '1/5', '1/7'])
sage: A.denominator()
210
```

A trivial example:

```
sage: A = matrix(QQ, 0,2)
sage: A.denominator()
1
```

Denominators are not defined for real numbers:

```
sage: A = MatrixSpace(RealField(),2)([1,2,3,4])
sage: A.denominator()
...
TypeError: denominator not defined for elements of the base ring
```

We can even compute the denominator of matrix over the fraction field of $\mathbf{Z}[x]$.

```
sage: K.<x> = Frac(ZZ['x'])
sage: A = MatrixSpace(K,2)([1/x, 2/(x+1), 1, 5/(x^3)])
sage: A.denominator()
x^4 + x^3
```

Here's an example involving a cyclotomic field:

```
sage: K.<z> = CyclotomicField(3)
sage: M = MatrixSpace(K,3,sparse=True)
sage: A = M([(1+z)/3,(2+z)/3,z/3,1,1+z,-2,1,5,-1+z])
sage: print A
[1/3*z + 1/3 1/3*z + 2/3       1/3*z]
[          1       z + 1          -2]
```

```
[          1           5       z - 1]
sage: print A.denominator()
3
```

density()

Return the density of self.

By density we understand the ration of the number of nonzero positions and the self.nrows() * self.ncols(), i.e. the number of possible nonzero positions.

EXAMPLE:

First, note that the density parameter does not ensure the density of a matrix, it is only an upper bound.

```
sage: A = random_matrix(GF(127),200,200,density=0.3)
sage: A.density()
5159/20000

sage: A = matrix(QQ,3,3,[0,1,2,3,0,0,6,7,8])
sage: A.density()
2/3

sage: a = matrix([[],[],[],[]])
sage: a.density()
0
```

derivative()

Derivative with respect to variables supplied in args.

Multiple variables and iteration counts may be supplied; see documentation for the global derivative() function for more details.

EXAMPLES:

```
sage: v = vector([1,x,x^2])
sage: v.derivative(x)
(0, 1, 2*x)
sage: type(v.derivative(x)) == type(v)
True
sage: v = vector([1,x,x^2], sparse=True)
sage: v.derivative(x)
(0, 1, 2*x)
sage: type(v.derivative(x)) == type(v)
True
sage: v.derivative(x,x)
(0, 0, 2)
```

det()

Synonym for self.determinant(...).

EXAMPLES:

```
sage: A = MatrixSpace(Integers(8),3)([1,7,3, 1,1,1, 3,4,5])
sage: A.det()
6
```

determinant()

Return the determinant of self.

ALGORITHM: For small matrices (n4), this is computed using the naive formula For integral domains, the charpoly is computed (using hessenberg form) Otherwise this is computed using the very stupid expansion by minors stupid *naive generic algorithm*. For matrices over more most rings more sophisticated algorithms can be used. (Type `A.determinant?` to see what is done for a specific matrix A.)

EXAMPLES:

```
sage: A = MatrixSpace(Integers(8),3)([1,7,3, 1,1,1, 3,4,5])
sage: A.determinant()
6
sage: A.determinant() is A.determinant()
True
sage: A[0,0] = 10
sage: A.determinant()
7
```

We compute the determinant of the arbitrary 3x3 matrix:

```
sage: R = PolynomialRing(QQ,9,'x')
sage: A = matrix(R,3,R.gens())
sage: A
[x0 x1 x2]
[x3 x4 x5]
[x6 x7 x8]
sage: A.determinant()
-x2*x4*x6 + x1*x5*x6 + x2*x3*x7 - x0*x5*x7 - x1*x3*x8 + x0*x4*x8
```

We create a matrix over $\mathbf{Z}[x, y]$ and compute its determinant.

```
sage: R.<x,y> = PolynomialRing(IntegerRing(),2)
sage: A = MatrixSpace(R,2)([x, y, x**2, y**2])
sage: A.determinant()
-x^2*y + x*y^2
```

TEST:

```
sage: A = matrix(5, 5, [next_prime(i^2) for i in range(25)])
sage: B = MatrixSpace(ZZ['x'], 5, 5)(A)
sage: A.det() - B.det()
0
```

We verify that trac 5569 is resolved (otherwise the following will hang for hours):

```
sage: d = random_matrix(GF(next_prime(10^20)),50).det()
sage: d = random_matrix(Integers(10^50),50).det()
```

echelon_form()

Return the echelon form of self.

INPUT:

- `matrix` - an element A of a MatrixSpace

OUTPUT:

- `matrix` - The reduced row echelon form of A, as an immutable matrix. Note that self is *not* changed by this command. Use A.echelonize() to change A in place.

EXAMPLES:

```
sage: MS = MatrixSpace(GF(19),2,3)
sage: C = MS.matrix([1,2,3,4,5,6])
sage: C.rank()
2
sage: C.nullity()
0
sage: C.echelon_form()
[ 1  0 18]
[ 0  1  2]
```

echelonize()

Transform self into a matrix in echelon form over the same base ring as self.

INPUT:

- `algorithm` - string, which algorithm to use (default: 'default')
- `'default'` - use a default algorithm, chosen by Sage
- `'strassen'` - use a Strassen divide and conquer algorithm (if available)
- `cutoff` - integer; only used if the Strassen algorithm is selected.

EXAMPLES:

```
sage: a = matrix(QQ,3,range(9)); a
[0 1 2]
[3 4 5]
[6 7 8]
sage: a.echelonize()
sage: a
[ 1  0 -1]
[ 0  1  2]
[ 0  0  0]
```

An immutable matrix cannot be transformed into echelon form. Use `self.echelon_form()` instead:

```
sage: a = matrix(QQ,3,range(9)); a.set_immutable()
sage: a.echelonize()
...
ValueError: matrix is immutable; please change a copy instead (use self.copy()).
sage: a.echelon_form()
[ 1  0 -1]
[ 0  1  2]
[ 0  0  0]
```

Echelon form over the integers is what is also classically often known as Hermite normal form:

```
sage: a = matrix(ZZ,3,range(9))
sage: a.echelonize(); a
[ 3  0 -3]
[ 0  1  2]
[ 0  0  0]
```

We compute an echelon form both over a domain and fraction field:

```
sage: R.<x,y> = QQ[]
sage: a = matrix(R, 2, [x,y,x,y])
sage: a.echelon_form()                # not very useful? -- why two copies of the same row?
[x y]
[x y]

sage: b = a.change_ring(R.fraction_field())
sage: b.echelon_form()                # potentially useful
[  1 y/x]
[  0   0]
```

Echelon form is not defined over arbitrary rings:

```
sage: a = matrix(Integers(9),3,range(9))
sage: a.echelon_form()
...
NotImplementedError: Echelon form not implemented over 'Ring of integers modulo 9'.
```

Involving a sparse matrix:

```
sage: m = matrix(3,[1, 1, 1, 1, 0, 2, 1, 2, 0], sparse=True); m
[1 1 1]
[1 0 2]
```

```
[1 2 0]
sage: m.echelon_form()
[ 1  0  2]
[ 0  1 -1]
[ 0  0  0]
sage: m.echelonize(); m
[ 1  0  2]
[ 0  1 -1]
[ 0  0  0]
```

eigenmatrix_left()

Return matrices D and P, where D is a diagonal matrix of eigenvalues and P is the corresponding matrix where the rows are corresponding eigenvectors (or zero vectors) so that P*self = D*P.

EXAMPLES:

```
sage: A = matrix(QQ,3,3,range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: D, P = A.eigenmatrix_left()
sage: D
[                  0                   0                   0]
[                  0 -1.348469228349535?                   0]
[                  0                   0  13.34846922834954?]
sage: P
[                   1                   -2                    1]
[                   1  0.3101020514433644? -0.3797958971132713?]
[                   1   1.289897948556636?   1.5797958971132712?]
sage: P*A == D*P
True
```

Because P is invertible, A is diagonalizable.

```
sage: A == (~P)*D*P
True
```

The matrix P may contain zero rows corresponding to eigenvalues for which the algebraic multiplicity is greater than the geometric multiplicity. In these cases, the matrix is not diagonalizable.

```
sage: A = jordan_block(2,3); A
[2 1 0]
[0 2 1]
[0 0 2]
sage: A = jordan_block(2,3)
sage: D, P = A.eigenmatrix_left()
sage: D
[2 0 0]
[0 2 0]
[0 0 2]
sage: P
[0 0 1]
[0 0 0]
[0 0 0]
sage: P*A == D*P
True
```

eigenmatrix_right()

Return matrices D and P, where D is a diagonal matrix of eigenvalues and P is the corresponding matrix where the columns are corresponding eigenvectors (or zero vectors) so that self*P = P*D.

EXAMPLES:

```
sage: A = matrix(QQ,3,3,range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: D, P = A.eigenmatrix_right()
sage: D
[                  0                   0                   0]
[                  0 -1.348469228349535?                   0]
[                  0                   0  13.348469228349543?]
sage: P
[                   1                    1                    1]
[                  -2   0.1303061543300932?   3.069693845669907?]
[                   1 -0.7393876913398137?   5.139387691339814?]
sage: A*P == P*D
True
```

Because P is invertible, A is diagonalizable.

```
sage: A == P*D*(~P)
True
```

The matrix P may contain zero columns corresponding to eigenvalues for which the algebraic multiplicity is greater than the geometric multiplicity. In these cases, the matrix is not diagonalizable.

```
sage: A = jordan_block(2,3); A
[2 1 0]
[0 2 1]
[0 0 2]
sage: A = jordan_block(2,3)
sage: D, P = A.eigenmatrix_right()
sage: D
[2 0 0]
[0 2 0]
[0 0 2]
sage: P
[1 0 0]
[0 0 0]
[0 0 0]
sage: A*P == P*D
True
```

eigenspaces()

Deprecated: Instead of eigenspaces, use eigenspaces_left

eigenspaces_left()

Compute left eigenspaces of a matrix.

If algebraic_multiplicity=False, return a list of pairs (e, V) where e runs through all eigenvalues (up to Galois conjugation) of this matrix, and V is the corresponding left eigenspace.

If algebraic_multiplicity=True, return a list of pairs (e, V, n) where e and V are as above and n is the algebraic multiplicity of the eigenvalue. If the eigenvalues are given symbolically, as roots of an irreducible factor of the characteristic polynomial, then the algebraic multiplicity returned is the multiplicity of each conjugate eigenvalue.

The eigenspaces are returned sorted by the corresponding characteristic polynomials, where polynomials are sorted in dictionary order starting with constant terms.

INPUT:

- `var` - variable name used to represent elements of the root field of each irreducible factor of the characteristic polynomial I.e., if var='a', then the root fields will be in terms of a0, a1, a2, ..., ak.

Warning: Uses a somewhat naive algorithm (simply factors the characteristic polynomial and computes kernels directly over the extension field).

TODO:

Maybe implement the better algorithm that is in dual_eigenvector in sage/modular/hecke/module.py.

EXAMPLES: We compute the left eigenspaces of a 3×3 rational matrix.

```
sage: A = matrix(QQ,3,3,range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: es = A.eigenspaces_left(); es
[
(0, Vector space of degree 3 and dimension 1 over Rational Field
User basis matrix:
[ 1 -2  1]),
(a1, Vector space of degree 3 and dimension 1 over Number Field in a1 with defining polynomi
User basis matrix:
[            1 1/15*a1 + 2/5 2/15*a1 - 1/5])
]
sage: es = A.eigenspaces_left(algebraic_multiplicity=True); es
[
(0, Vector space of degree 3 and dimension 1 over Rational Field
User basis matrix:
[ 1 -2  1], 1),
(a1, Vector space of degree 3 and dimension 1 over Number Field in a1 with defining polynomi
User basis matrix:
[            1 1/15*a1 + 2/5 2/15*a1 - 1/5], 1)
]
sage: e, v, n = es[0]; v = v.basis()[0]
sage: delta = e*v - v*A
sage: abs(abs(delta)) < 1e-10
True
```

The same computation, but with implicit base change to a field:

```
sage: A = matrix(ZZ,3,range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: A.eigenspaces_left()
[
(0, Vector space of degree 3 and dimension 1 over Rational Field
User basis matrix:
[ 1 -2  1]),
(a1, Vector space of degree 3 and dimension 1 over Number Field in a1 with defining polynomi
User basis matrix:
[            1 1/15*a1 + 2/5 2/15*a1 - 1/5])
]
```

We compute the left eigenspaces of the matrix of the Hecke operator T_2 on level 43 modular symbols.

```
sage: A = ModularSymbols(43).T(2).matrix(); A
[ 3  0  0  0  0  0 -1]
[ 0 -2  1  0  0  0  0]
[ 0 -1  1  1  0 -1  0]
[ 0 -1  0 -1  2 -1  1]
[ 0 -1  0  1  1 -1  1]
[ 0  0 -2  0  2 -2  1]
```

```
[ 0  0 -1  0  1  0 -1]
sage: A.base_ring()
Rational Field
sage: f = A.charpoly(); f
x^7 + x^6 - 12*x^5 - 16*x^4 + 36*x^3 + 52*x^2 - 32*x - 48
sage: factor(f)
(x - 3) * (x + 2)^2 * (x^2 - 2)^2
sage: A.eigenspaces_left(algebraic_multiplicity=True)
[
(3, Vector space of degree 7 and dimension 1 over Rational Field
User basis matrix:
[   1    0  1/7    0 -1/7    0 -2/7], 1),
(-2, Vector space of degree 7 and dimension 2 over Rational Field
User basis matrix:
[ 0  1  0  1 -1  1 -1]
[ 0  0  1  0 -1  2 -1], 2),
(a2, Vector space of degree 7 and dimension 2 over Number Field in a2 with defining polynomi
User basis matrix:
[      0       1       0      -1 -a2 - 1       1      -1]
[      0       0       1       0      -1       0 -a2 + 1], 2)
]
```

Next we compute the left eigenspaces over the finite field of order 11:

```
sage: A = ModularSymbols(43, base_ring=GF(11), sign=1).T(2).matrix(); A
[ 3  9  0  0]
[ 0  9  0  1]
[ 0 10  9  2]
[ 0  9  0  2]
sage: A.base_ring()
Finite Field of size 11
sage: A.charpoly()
x^4 + 10*x^3 + 3*x^2 + 2*x + 1
sage: A.eigenspaces_left(var = 'beta')
[
(9, Vector space of degree 4 and dimension 1 over Finite Field of size 11
User basis matrix:
[0 0 1 5]),
(3, Vector space of degree 4 and dimension 1 over Finite Field of size 11
User basis matrix:
[1 6 0 6]),
(beta2, Vector space of degree 4 and dimension 1 over Univariate Quotient Polynomial Ring ir
User basis matrix:
[           0            1            0 5*beta2 + 10])
]
```

TESTS:

Warnings are issued if the generic algorithm is used over inexact fields. Garbage may result in these cases because of numerical precision issues.

```
sage: R=RealField(30)
sage: M=matrix(R,2,[2,1,1,1])
sage: M.eigenspaces_left() # random output from numerical issues
[
(2.6180340, Vector space of degree 2 and dimension 0 over Real Field with 30 bits of precisi
User basis matrix:
[]),
(0.38196601, Vector space of degree 2 and dimension 0 over Real Field with 30 bits of precis
User basis matrix:
```

```
[])
]
sage: R=ComplexField(30)
sage: N=matrix(R,2,[2,1,1,1])
sage: N.eigenspaces_left() # random output from numerical issues
[
(2.6180340, Vector space of degree 2 and dimension 0 over Complex Field with 30 bits of prec
User basis matrix:
[]),
(0.38196601, Vector space of degree 2 and dimension 0 over Complex Field with 30 bits of pre
User basis matrix:
[])
]
```

eigenspaces_right()

Compute right eigenspaces of a matrix.

If algebraic_multiplicity=False, return a list of pairs (e, V) where e runs through all eigenvalues (up to Galois conjugation) of this matrix, and V is the corresponding right eigenspace.

If algebraic_multiplicity=True, return a list of pairs (e, V, n) where e and V are as above and n is the algebraic multiplicity of the eigenvalue. If the eigenvalues are given symbolically, as roots of an irreducible factor of the characteristic polynomial, then the algebraic multiplicity returned is the multiplicity of each conjugate eigenvalue.

The eigenspaces are returned sorted by the corresponding characteristic polynomials, where polynomials are sorted in dictionary order starting with constant terms.

INPUT:

- `var` - variable name used to represent elements of the root field of each irreducible factor of the characteristic polynomial I.e., if var='a', then the root fields will be in terms of a0, a1, a2, ..., ak.

Warning: Uses a somewhat naive algorithm (simply factors the characteristic polynomial and computes kernels directly over the extension field).

TODO: Maybe implement the better algorithm that is in dual_eigenvector in sage/modular/hecke/module.py.

EXAMPLES: We compute the right eigenspaces of a 3×3 rational matrix.

```
sage: A = matrix(QQ,3,3,range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: es = A.eigenspaces_right(); es
[
(0, Vector space of degree 3 and dimension 1 over Rational Field
User basis matrix:
[ 1 -2  1]),
(a1, Vector space of degree 3 and dimension 1 over Number Field in a1 with defining polynomi
User basis matrix:
[           1 1/5*a1 + 2/5 2/5*a1 - 1/5])
]
sage: es = A.eigenspaces_right(algebraic_multiplicity=True); es
[
(0, Vector space of degree 3 and dimension 1 over Rational Field
User basis matrix:
[ 1 -2  1], 1),
(a1, Vector space of degree 3 and dimension 1 over Number Field in a1 with defining polynomi
User basis matrix:
[           1 1/5*a1 + 2/5 2/5*a1 - 1/5], 1)
```

```
]
sage: e, v, n = es[0]; v = v.basis()[0]
sage: delta = v*e - A*v
sage: abs(abs(delta)) < 1e-10
True
```

The same computation, but with implicit base change to a field:

```
sage: A = matrix(ZZ,3,range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: A.eigenspaces_right()
[
(0, Vector space of degree 3 and dimension 1 over Rational Field
User basis matrix:
[ 1 -2  1]),
(a1, Vector space of degree 3 and dimension 1 over Number Field in a1 with defining polynomi
User basis matrix:
[           1 1/5*a1 + 2/5 2/5*a1 - 1/5])
]
```

TESTS: Warnings are issued if the generic algorithm is used over inexact fields. Garbage may result in these cases because of numerical precision issues.

```
sage: R=RealField(30)
sage: M=matrix(R,2,[2,1,1,1])
sage: M.eigenspaces_right() # random output from numerical issues
[(2.6180340,
Vector space of degree 2 and dimension 0 over Real Field with 30 bits of precision
User basis matrix:
[]),
(0.38196601,
Vector space of degree 2 and dimension 0 over Real Field with 30 bits of precision
User basis matrix:
[])]
sage: R=ComplexField(30)
sage: N=matrix(R,2,[2,1,1,1])
sage: N.eigenspaces_right() # random output from numerical issues
[(2.6180340,
Vector space of degree 2 and dimension 0 over Complex Field with 30 bits of precision
User basis matrix:
[]),
(0.38196601,
Vector space of degree 2 and dimension 0 over Complex Field with 30 bits of precision
User basis matrix:
[])]
```

eigenvalues()

Return a sequence of the eigenvalues of a matrix, with multiplicity. If the eigenvalues are roots of polynomials in QQ, then QQbar elements are returned that represent each separate root.

EXAMPLES:

```
sage: a = matrix(QQ, 4, range(16)); a
[ 0  1  2  3]
[ 4  5  6  7]
[ 8  9 10 11]
[12 13 14 15]
sage: sorted(a.eigenvalues(), reverse=True)
[32.464249196572982?, 0, 0, -2.464249196572981?]
```

```
sage: a=matrix([(1, 9, -1, -1), (-2, 0, -10, 2), (-1, 0, 15, -2), (0, 1, 0, -1)])
sage: a.eigenvalues()
[-0.9386318578049146?, 15.506554353532585?, 0.2160387521361705? - 4.713151979747493?*I, 0.216
```

A symmetric matrix a+a.transpose() should have real eigenvalues

```
sage: b=a+a.transpose()
sage: ev = b.eigenvalues(); ev
[-8.350660860579577?, -1.1072479013493797?, 5.718651326708515?, 33.739257435220437?]
```

The eigenvalues are elements of QQbar, so they really represent exact roots of polynomials, not just approximations.

```
sage: e = ev[0]; e
-8.350660860579577?
sage: p = e.minpoly(); p
x^4 - 30*x^3 - 171*x^2 + 1460*x + 1784
sage: p(e) == 0
True
```

To perform computations on the eigenvalue as an element of a number field, you can always convert back to a number field element.

```
sage: e.as_number_field_element()
(Number Field in a with defining polynomial y^4 - 2*y^3 - 507*y^2 + 4988*y - 8744,
-a + 8,
Ring morphism:
From: Number Field in a with defining polynomial y^4 - 2*y^3 - 507*y^2 + 4988*y - 8744
To:   Algebraic Real Field
Defn: a |--> 16.350660860579577?)
```

eigenvectors_left()

Compute the left eigenvectors of a matrix.

For each distinct eigenvalue, returns a list of the form (e,V,n) where e is the eigenvalue, V is a list of eigenvectors forming a basis for the corresponding left eigenspace, and n is the algebraic multiplicity of the eigenvalue.

EXAMPLES: We compute the left eigenvectors of a 3×3 rational matrix.

```
sage: A = matrix(QQ,3,3,range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: es = A.eigenvectors_left(); es
[(0, [
(1, -2, 1)
], 1),
(-1.348469228349535?, [(1, 0.3101020514433644?, -0.37975897113271 3?)], 1),
(13.34846922834954?, [(1, 1.289897948556636?, 1.579795897113272?)], 1)]
sage: eval, [evec], mult = es[0]
sage: delta = eval*evec - evec*A
sage: abs(abs(delta)) < 1e-10
True
```

eigenvectors_right()

Compute the right eigenvectors of a matrix.

For each distinct eigenvalue, returns a list of the form (e,V,n) where e is the eigenvalue, V is a list of eigenvectors forming a basis for the corresponding right eigenspace, and n is the algebraic multiplicity of the eigenvalue.

EXAMPLES: We compute the right eigenvectors of a 3×3 rational matrix.

```
sage: A = matrix(QQ,3,3,range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: es = A.eigenvectors_right(); es
[(0, [
(1, -2, 1)
], 1),
(-1.348469228349535?, [(1, 0.1303061543300932?, -0.7393876913398137?)], 1),
(13.34846922834954?, [(1, 3.069693845669907?, 5.139387691339814?)], 1)]
sage: eval, [evec], mult = es[0]
sage: delta = eval*evec - A*evec
sage: abs(abs(delta)) < 1e-10
True
```

elementary_divisors()

If self is a matrix over a principal ideal domain R, return elements d_i for $1 \leq i \leq k = \min(r, s)$ where r and s are the number of rows and columns of self, such that the cokernel of self is isomorphic to

$$R/(d_1) \oplus R/(d_2) \oplus R/(d_k)$$

with $d_i \mid d_{i+1}$ for all i. These are the diagonal entries of the Smith form of self (see smith_form()).

EXAMPLES:

```
sage: OE = EquationOrder(x^2 - x + 2, 'w')
sage: w = OE.ring_generators()[0]
sage: m = Matrix([ [1, w],[w,7]])
sage: m.elementary_divisors()
[1, -w + 9]
```

See Also:

smith_form()

exp()

Calculate the exponential of this matrix X, which is the matrix

$$e^X = \sum_{k=0}^{\infty} \frac{X^k}{k!}.$$

This function depends on maxima's matrix exponentiation function, which does not deal well with floating point numbers. If the matrix has floating point numbers, they will be rounded automatically to rational numbers during the computation. If you want approximations to the exponential that are calculated numerically, you may get better results by first converting your matrix to RDF or CDF, as shown in the last example.

EXAMPLES:

```
sage: a=matrix([[1,2],[3,4]])
sage: a.exp()
[-1/22*((sqrt(33) - 11)*e^sqrt(33) - sqrt(33) - 11)*e^(-1/2*sqrt(33) + 5/2)              2/3
[             1/11*(sqrt(33)*e^sqrt(33) - sqrt(33))*e^(-1/2*sqrt(33) + 5/2)  1/22*((sqrt(33)
sage: type(a.exp())
<type 'sage.matrix.matrix_symbolic_dense.Matrix_symbolic_dense'>

sage: a=matrix([[1/2,2/3],[3/4,4/5]])
sage: a.exp()
[-1/418*((3*sqrt(209) - 209)*e^(1/10*sqrt(209)) - 3*sqrt(209) - 209)*e^(-1/20*sqrt(209) + 13
[                  15/418*(sqrt(209)*e^(1/10*sqrt(209)) - sqrt(209))*e^(-1/20*sqrt(209) + 13
```

```
sage: a=matrix(RR,[[1,pi.n()],[1e2,1e-2]])
sage: a.exp()
[ 1/416296432702*((297*sqrt(382784569869489) + 208148216351)*e^(1/551700*sqrt(3827845698694
[                                      30000/208148216351*(sqrt(382784569869489)*e^(1/551700*
sage: a.change_ring(RDF).exp()
[42748127.3153 7368259.24416]
[234538976.138 40426191.4516]
```

fcp()

Return the factorization of the characteristic polynomial of self.

INPUT:

- `var` - (default: 'x') name of variable of charpoly

EXAMPLES:

```
sage: M = MatrixSpace(QQ,3,3)
sage: A = M([1,9,-7,4/5,4,3,6,4,3])
sage: A.fcp()
x^3 - 8*x^2 + 209/5*x - 286
sage: A = M([3, 0, -2, 0, -2, 0, 0, 0, 0])
sage: A.fcp('T')
(T - 3) * T * (T + 2)
```

find()

Find elements in this matrix satisfying the constraints in the function f. The function is evaluated on each element of the matrix .

INPUT:

- `f` - a function that is evaluated on each element of this matrix.
- `indices` - whether or not to return the indices and elements of this matrix that satisfy the function.

OUTPUT: If `indices` is not specified, return a matrix with 1 where f is satisfied and 0 where it is not. If `indices` is specified, return a dictionary with containing the elements of this matrix satisfying f.

EXAMPLES:

```
sage: M = matrix(4,3,[1, -1/2, -1, 1, -1, -1/2, -1, 0, 0, 2, 0, 1])
sage: M.find(lambda entry:entry==0)
[0 0 0]
[0 0 0]
[0 1 1]
[0 1 0]

sage: M.find(lambda u:u<0)
[0 1 1]
[0 1 1]
[1 0 0]
[0 0 0]

sage: M = matrix(4,3,[1, -1/2, -1, 1, -1, -1/2, -1, 0, 0, 2, 0, 1])
sage: len(M.find(lambda u:u<1 and u>-1,indices=True))
5

sage: M.find(lambda u:u!=1/2)
[1 1 1]
[1 1 1]
[1 1 1]
[1 1 1]
```

```
sage: M.find(lambda u:u>1.2)
[0 0 0]
[0 0 0]
[0 0 0]
[1 0 0]

sage: sorted(M.find(lambda u:u!=0,indices=True).keys()) == M.nonzero_positions()
True
```

get_subdivisions()

Returns the current subdivision of self.

EXAMPLES:

```
sage: M = matrix(5, 5, range(25))
sage: M.get_subdivisions()
([], [])
sage: M.subdivide(2,3)
sage: M.get_subdivisions()
([2], [3])
sage: N = M.parent()(1)
sage: N.subdivide(M.get_subdivisions()); N
[1 0 0|0 0]
[0 1 0|0 0]
[-----+---]
[0 0 1|0 0]
[0 0 0|1 0]
[0 0 0|0 1]
```

gram_schmidt()

Return the matrix G whose rows are obtained from the rows of self (=A) by applying the Gram-Schmidt orthogonalization process. Also return the coefficients mu ij, i.e., a matrix mu such that `(mu + 1)*G == A`.

OUTPUT:

- `G` - a matrix whose rows are orthogonal
- `mu` - a matrix that gives the transformation, via the relation `(mu + 1)*G == self`

EXAMPLES:

```
sage: A = matrix(ZZ, 3, [-1, 2, 5, -11, 1, 1, 1, -1, -3]); A
[ -1   2   5]
[-11   1   1]
[  1  -1  -3]
sage: G, mu = A.gram_schmidt()
sage: G
[     -1       2       5]
[ -52/5    -1/5      -2]
[  2/187  36/187 -14/187]
sage: mu
[     0      0      0]
[   3/5      0      0]
[  -3/5 -7/187      0]
sage: G.row(0) * G.row(1)
0
sage: G.row(0) * G.row(2)
0
sage: G.row(1) * G.row(2)
0
```

The relation between mu and A is as follows:

```
sage: (mu + 1)*G == A
True
```

hadamard_bound()

Return an int n such that the absolute value of the determinant of this matrix is at most 10^n.

This is got using both the row norms and the column norms.

This function only makes sense when the base field can be coerced to the real double field RDF or the MPFR Real Field with 53-bits precision.

EXAMPLES:

```
sage: a = matrix(ZZ, 3, [1,2,5,7,-3,4,2,1,123])
sage: a.hadamard_bound()
4
sage: a.det()
-2014
sage: 10^4
10000
```

In this example the Hadamard bound has to be computed (automatically) using mpfr instead of doubles, since doubles overflow:

```
sage: a = matrix(ZZ, 2, [2^10000,3^10000,2^50,3^19292])
sage: a.hadamard_bound()
12215
sage: len(str(a.det()))
12215
```

hessenberg_form()

Return Hessenberg form of self.

If the base ring is merely an integral domain (and not a field), the Hessenberg form will (in general) only be defined over the fraction field of the base ring.

EXAMPLES:

```
sage: A = matrix(ZZ,4,[2, 1, 1, -2, 2, 2, -1, -1, -1,1,2,3,4,5,6,7])
sage: h = A.hessenberg_form(); h
[    2  -7/2 -19/5    -2]
[    2   1/2 -17/5    -1]
[    0  25/4  15/2  5/2]
[    0     0  58/5     3]
sage: parent(h)
Full MatrixSpace of 4 by 4 dense matrices over Rational Field
sage: A.hessenbergize()
...
TypeError: Hessenbergize only possible for matrices over a field
```

hessenbergize()

Transform self to Hessenberg form.

The hessenberg form of a matrix A is a matrix that is similar to A, so has the same characteristic polynomial as A, and is upper triangular except possible for entries right below the diagonal.

ALGORITHM: See Henri Cohen's first book.

EXAMPLES:

```
sage: A = matrix(QQ,3, [2, 1, 1, -2, 2, 2, -1, -1, -1])
sage: A.hessenbergize(); A
[  2 3/2   1]
[ -2   3   2]
[  0  -3  -2]
```

```
sage: A = matrix(QQ,4, [2, 1, 1, -2, 2, 2, -1, -1, -1,1,2,3,4,5,6,7])
sage: A.hessenbergize(); A
[    2  -7/2 -19/5    -2]
[    2   1/2 -17/5    -1]
[    0  25/4  15/2   5/2]
[    0     0  58/5     3]
```

You can't Hessenbergize an immutable matrix:

```
sage: A = matrix(QQ, 3, [1..9])
sage: A.set_immutable()
sage: A.hessenbergize()
...
ValueError: matrix is immutable; please change a copy instead (use self.copy()).
```

image()

Return the image of the homomorphism on rows defined by this matrix.

EXAMPLES:

```
sage: MS1 = MatrixSpace(ZZ,4)
sage: MS2 = MatrixSpace(QQ,6)
sage: A = MS1.matrix([3,4,5,6,7,3,8,10,14,5,6,7,2,2,10,9])
sage: B = MS2.random_element()

sage: image(A)
Free module of degree 4 and rank 4 over Integer Ring
Echelon basis matrix:
[  1   0   0 426]
[  0   1   0 518]
[  0   0   1 293]
[  0   0   0 687]

sage: image(B) == B.row_module()
True
```

integer_kernel()

Return the integral kernel of this matrix.

Assume that the base field of this matrix has a numerator and denominator functions for its elements, e.g., it is the rational numbers or a fraction field. This function computes a basis over the integers for the kernel of self.

When kernels are implemented for matrices over general PID's, this function will compute kernels over PID's of matrices over the fraction field of the PID. (todo)

EXAMPLES:

```
sage: A = MatrixSpace(QQ, 4)(range(16))
sage: A.integer_kernel()
Free module of degree 4 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1  0 -3  2]
[ 0  1 -2  1]
```

The integer kernel even makes sense for matrices with fractional entries:

```
sage: A = MatrixSpace(QQ, 2)(['1/2',0,  0, 0])
sage: A.integer_kernel()
Free module of degree 2 and rank 1 over Integer Ring
Echelon basis matrix:
[0 1]
```

inverse()

Returns the inverse of self, without changing self.

Note that one can use the Python inverse operator to obtain the inverse as well.

EXAMPLES:

```
sage: m = matrix([[1,2],[3,4]])
sage: m^(-1)
[  -2    1]
[ 3/2 -1/2]
sage: m.inverse()
[  -2    1]
[ 3/2 -1/2]
sage: ~m
[  -2    1]
[ 3/2 -1/2]

sage: m = matrix([[1,2],[3,4]], sparse=True)
sage: m^(-1)
[  -2    1]
[ 3/2 -1/2]
sage: m.inverse()
[  -2    1]
[ 3/2 -1/2]
sage: ~m
[  -2    1]
[ 3/2 -1/2]
```

TESTS:

```
sage: matrix().inverse()
[]
```

is_one()

Return True if this matrix is the identity matrix.

EXAMPLES:

```
sage: m = matrix(QQ,2,range(4))
sage: m.is_one()
False
sage: m = matrix(QQ,2,[5,0,0,5])
sage: m.is_one()
False
sage: m = matrix(QQ,2,[1,0,0,1])
sage: m.is_one()
True
sage: m = matrix(QQ,2,[1,1,1,1])
sage: m.is_one()
False
```

is_scalar()

Return True if this matrix is a scalar matrix.

INPUT

- base_ring element a, which is chosen as self[0][0] if a = None

OUTPUT

- whether self is a scalar matrix (in fact the scalar matrix aI if a is input)

EXAMPLES:

```
sage: m = matrix(QQ,2,range(4))
sage: m.is_scalar(5)
False
sage: m = matrix(QQ,2,[5,0,0,5])
sage: m.is_scalar(5)
True
sage: m = matrix(QQ,2,[1,0,0,1])
sage: m.is_scalar(1)
True
sage: m = matrix(QQ,2,[1,1,1,1])
sage: m.is_scalar(1)
False
```

jordan_form()

Compute the Jordan canonical form of the matrix, if it exists.

This computation is performed in a naive way using the ranks of powers of A-xI, where x is an eigenvalue of the matrix A.

INPUT:

- `base_ring` - ring in which to compute the Jordan form.
- `sparse` - (default False) If sparse=True, return a sparse matrix.
- `subdivide` - (default True) If subdivide=True, the subdivisions for the Jordan blocks in the matrix are shown.
- `transformation` - (default False) If transformation=True, compute also the transformation matrix (see example below).

EXAMPLES:

```
sage: a = matrix(ZZ,4,[1, 0, 0, 0, 0, 1, 0, 0, 1, \
-1, 1, 0, 1, -1, 1, 2]); a
[ 1  0  0  0]
[ 0  1  0  0]
[ 1 -1  1  0]
[ 1 -1  1  2]
sage: a.jordan_form()
[2|0 0|0]
[-+---+-]
[0|1 1|0]
[0|0 1|0]
[-+---+-]
[0|0 0|1]
sage: a.jordan_form(subdivide=False)
[2 0 0 0]
[0 1 1 0]
[0 0 1 0]
[0 0 0 1]
sage: b = matrix(ZZ,3,range(9)); b
[0 1 2]
[3 4 5]
[6 7 8]
sage: b.jordan_form()
...
RuntimeError: Some eigenvalue does not exist in Integer Ring.
sage: b.jordan_form(RealField(15))
[-1.348|0.0000|0.0000]
[------+------+------]
[0.0000|0.0000|0.0000]
[------+------+------]
[0.0000|0.0000| 13.35]
```

If you need the transformation matrix as well as the Jordan form of self, then pass the option transformation=True.

```
sage: m = matrix([[5,4,2,1],[0,1,-1,-1],[-1,-1,3,0],[1,1,-1,2]]); m
[ 5  4  2  1]
[ 0  1 -1 -1]
[-1 -1  3  0]
[ 1  1 -1  2]
sage: jf, p = m.jordan_form(transformation=True)
sage: jf
[2|0|0 0]
[-+-+---]
[0|1|0 0]
[-+-+---]
[0|0|4 1]
[0|0|0 4]
sage: ~p * m * p
[2 0 0 0]
[0 1 0 0]
[0 0 4 1]
[0 0 0 4]
```

Note that for matrices over inexact rings, there can be problems computing the transformation matrix due to numerical stability issues in computing a basis for a kernel.

```
sage: b = matrix(ZZ,3,3,range(9))
sage: jf, p = b.jordan_form(RealField(15), transformation=True)
...
ValueError: cannot compute the transformation matrix due to lack of precision
```

TESTS:

```
sage: c = matrix(ZZ, 3, [1]*9); c
[1 1 1]
[1 1 1]
[1 1 1]
sage: c.jordan_form(subdivide=False)
[3 0 0]
[0 0 0]
[0 0 0]

sage: evals = [(i,i) for i in range(1,6)]
sage: n = sum(range(1,6))
sage: jf = block_diagonal_matrix([jordan_block(ev,size) for ev,size in evals])
sage: p = random_matrix(ZZ,n,n)
sage: while p.rank() != n: p = random_matrix(ZZ,n,n)
sage: m = p * jf * ~p
sage: mjf, mp = m.jordan_form(transformation=True)
sage: mjf == jf
True
sage: m = diagonal_matrix([1,1,0,0])
sage: jf,P = m.jordan_form(transformation=True)
sage: jf == ~P*m*P
True
```

kernel()

Return the (left) kernel of this matrix, as a vector space. This is the space of vectors x such that x*self=0. Use self.right_kernel() for the right kernel, while self.left_kernel() is equivalent to self.kernel().

INPUT: all additional arguments to the kernel function are passed directly onto the echelon call.

By convention if self has 0 rows, the kernel is of dimension 0, whereas the kernel is whole domain if self

has 0 columns.

Note: For information on algorithms used, see the documentation of `right_kernel()` in this class, or versions of right and left kernels in derived classes which override the ones here.

EXAMPLES:

A kernel of dimension one over **Q**:

```
sage: A = MatrixSpace(QQ, 3)(range(9))
sage: A.kernel()
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2  1]
```

A trivial kernel:

```
sage: A = MatrixSpace(QQ, 2)([1,2,3,4])
sage: A.kernel()
Vector space of degree 2 and dimension 0 over Rational Field
Basis matrix:
[]
```

Kernel of a zero matrix:

```
sage: A = MatrixSpace(QQ, 2)(0)
sage: A.kernel()
Vector space of degree 2 and dimension 2 over Rational Field
Basis matrix:
[1 0]
[0 1]
```

Kernel of a non-square matrix:

```
sage: A = MatrixSpace(QQ,3,2)(range(6))
sage: A.kernel()
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2  1]
```

The 2-dimensional kernel of a matrix over a cyclotomic field:

```
sage: K = CyclotomicField(12); a=K.0
sage: M = MatrixSpace(K,4,2)([1,-1, 0,-2, 0,-a**2-1, 0,a**2-1])
sage: M
[             1             -1]
[             0             -2]
[             0 -zeta12^2 - 1]
[             0  zeta12^2 - 1]
sage: M.kernel()
Vector space of degree 4 and dimension 2 over Cyclotomic Field of order 12 and degree 4
Basis matrix:
[               0                1                0     -2*zeta12^2]
[               0                0                1 -2*zeta12^2 + 1]
```

A nontrivial kernel over a complicated base field.

```
sage: K = FractionField(PolynomialRing(QQ, 2, 'x'))
sage: M = MatrixSpace(K, 2)([[K.1, K.0], [K.1, K.0]])
sage: M
[x1 x0]
[x1 x0]
sage: M.kernel()
Vector space of degree 2 and dimension 1 over Fraction Field of Multivariate Polynomial Ring
```

```
Basis matrix:
[ 1 -1]
```

We test a trivial left kernel over ZZ:

```
sage: id = matrix(ZZ, 2, 2, [[1, 0], [0, 1]])
sage: id.left_kernel()
Free module of degree 2 and rank 0 over Integer Ring
Echelon basis matrix:
[]
```

Another matrix over ZZ.

```
sage: a = matrix(ZZ,3,1,[1,2,3])
sage: a.left_kernel()
Free module of degree 3 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1  1 -1]
[ 0  3 -2]
```

Kernel of a large dense rational matrix, which will invoke the fast IML routines in matrix_integer_dense class. Timing on a 64-bit 3 GHz dual-core machine is about 3 seconds to setup and about 1 second for the kernel() call. Timings that are one or two orders of magnitude larger indicate problems with reaching specialized derived classes.

```
sage: entries = [[1/(i+j+1) for i in srange(500)] for j in srange(500)]
sage: a = matrix(QQ, entries)
sage: a.kernel()
Vector space of degree 500 and dimension 0 over Rational Field
Basis matrix:
0 x 500 dense matrix over Rational Field
```

kernel_on()

Return the kernel of self restricted to the invariant subspace V. The result is a vector subspace of V, which is also a subspace of the ambient space.

INPUT:

- V - vector subspace
- check - (optional) default: True; whether to check that V is invariant under the action of self.
- poly - (optional) default: None; if not None, compute instead the kernel of poly(self) on V.

OUTPUT:

- a subspace

Warning: This function does *not* check that V is in fact invariant under self if check is False. With check False this function is much faster.

EXAMPLES:

```
sage: t = matrix(QQ, 4, [39, -10, 0, -12, 0, 2, 0, -1, 0, 1, -2, 0, 0, 2, 0, -2]); t
[ 39 -10   0 -12]
[  0   2   0  -1]
[  0   1  -2   0]
[  0   2   0  -2]
sage: t.fcp()
(x - 39) * (x + 2) * (x^2 - 2)
sage: s = (t-39)*(t^2-2)
sage: V = s.kernel(); V
Vector space of degree 4 and dimension 3 over Rational Field
Basis matrix:
```

```
[1 0 0 0]
[0 1 0 0]
[0 0 0 1]
sage: s.restrict(V)
[0 0 0]
[0 0 0]
[0 0 0]
sage: s.kernel_on(V)
Vector space of degree 4 and dimension 3 over Rational Field
Basis matrix:
[1 0 0 0]
[0 1 0 0]
[0 0 0 1]
sage: k = t-39
sage: k.restrict(V)
[  0 -10 -12]
[  0 -37  -1]
[  0   2 -41]
sage: ker = k.kernel_on(V); ker
Vector space of degree 4 and dimension 1 over Rational Field
Basis matrix:
[   1 -2/7    0 -2/7]
sage: ker.0 * k
(0, 0, 0, 0)
```

left_eigenmatrix()

Return matrices D and P, where D is a diagonal matrix of eigenvalues and P is the corresponding matrix where the rows are corresponding eigenvectors (or zero vectors) so that P*self = D*P.

EXAMPLES:

```
sage: A = matrix(QQ,3,3,range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: D, P = A.eigenmatrix_left()
sage: D
[                  0                   0                   0]
[                  0 -1.348469228349535?                   0]
[                  0                   0  13.34846922834954?]
sage: P
[                   1                   -2                    1]
[                   1  0.3101020514433644? -0.3797958971132713?]
[                   1   1.289897948556636?   1.579795897113272?]
sage: P*A == D*P
True
```

Because P is invertible, A is diagonalizable.

```
sage: A == (~P)*D*P
True
```

The matrix P may contain zero rows corresponding to eigenvalues for which the algebraic multiplicity is greater than the geometric multiplicity. In these cases, the matrix is not diagonalizable.

```
sage: A = jordan_block(2,3); A
[2 1 0]
[0 2 1]
[0 0 2]
sage: A = jordan_block(2,3)
sage: D, P = A.eigenmatrix_left()
```

```
sage: D
[2 0 0]
[0 2 0]
[0 0 2]
sage: P
[0 0 1]
[0 0 0]
[0 0 0]
sage: P*A == D*P
True
```

left_eigenvectors()

Compute the left eigenvectors of a matrix.

For each distinct eigenvalue, returns a list of the form (e,V,n) where e is the eigenvalue, V is a list of eigenvectors forming a basis for the corresponding left eigenspace, and n is the algebraic multiplicity of the eigenvalue.

EXAMPLES: We compute the left eigenvectors of a 3×3 rational matrix.

```
sage: A = matrix(QQ,3,3,range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: es = A.eigenvectors_left(); es
[(0, [
(1, -2, 1)
], 1),
(-1.348469228349535?, [(1, 0.3101020514433644?, -0.3797958971132713?)], 1),
(13.34846922834954?, [(1, 1.289897948556636?, 1.579795897113272?)], 1)]
sage: eval, [evec], mult = es[0]
sage: delta = eval*evec - evec*A
sage: abs(abs(delta)) < 1e-10
True
```

left_kernel()

Return the left kernel of this matrix, as a vector space. This is the space of vectors x such that x*self=0. This is identical to self.kernel(). For a right kernel, use self.right_kernel().

INPUT:

- all additional arguments to the kernel function are passed directly onto the echelon call.

By convention if self has 0 columns, the kernel is of dimension 0, whereas the kernel is whole domain if self has 0 rows.

Note: For information on algorithms used, see the documentation of right_kernel() in this class, or versions of right and left kernels in derived classes which override the ones here.

EXAMPLES:

A left kernel of dimension one over $\mathbf{Q}$:

```
sage: A = MatrixSpace(QQ, 3)(range(9))
sage: A.left_kernel()
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2  1]
```

A trivial left kernel:

```
sage: A = MatrixSpace(QQ, 2)([1,2,3,4])
sage: A.left_kernel()
Vector space of degree 2 and dimension 0 over Rational Field
Basis matrix:
[]
```

Left kernel of a zero matrix:

```
sage: A = MatrixSpace(QQ, 2)(0)
sage: A.left_kernel()
Vector space of degree 2 and dimension 2 over Rational Field
Basis matrix:
[1 0]
[0 1]
```

Left kernel of a non-square matrix:

```
sage: A = MatrixSpace(QQ,3,2)(range(6))
sage: A.left_kernel()
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2  1]
```

The 2-dimensional left kernel of a matrix over a cyclotomic field:

```
sage: K = CyclotomicField(12); a=K.0
sage: M = MatrixSpace(K,4,2)([1,-1, 0,-2, 0,-a**2-1, 0,a**2-1])
sage: M
[             1             -1]
[             0             -2]
[             0 -zeta12^2 - 1]
[             0  zeta12^2 - 1]
sage: M.left_kernel()
Vector space of degree 4 and dimension 2 over Cyclotomic Field of order 12 and degree 4
Basis matrix:
[               0                1                0     -2*zeta12^2]
[               0                0                1 -2*zeta12^2 + 1]
```

A nontrivial left kernel over a complicated base field.

```
sage: K = FractionField(PolynomialRing(QQ, 2, 'x'))
sage: M = MatrixSpace(K, 2)([[K.1, K.0], [K.1, K.0]])
sage: M
[x1 x0]
[x1 x0]
sage: M.left_kernel()
Vector space of degree 2 and dimension 1 over Fraction Field of Multivariate Polynomial Ring
Basis matrix:
[ 1 -1]
```

Left kernel of a large dense rational matrix, which will invoke the fast IML routines in matrix_integer_dense class. Timing on a 64-bit 3 GHz dual-core machine is about 3 seconds to setup and about 1 second for the kernel() call. Timings that are one or two orders of magnitude larger indicate problems with reaching specialized derived classes.

```
sage: entries = [[1/(i+j+1) for i in srange(500)] for j in srange(500)]
sage: a = matrix(QQ, entries)
sage: a.left_kernel()
Vector space of degree 500 and dimension 0 over Rational Field
Basis matrix:
0 x 500 dense matrix over Rational Field
```

left_nullity()

Return the (left) nullity of this matrix, which is the dimension of the (left) kernel of this matrix acting from the right on row vectors.

EXAMPLES:

```
sage: M = Matrix(QQ,[[1,0,0,1],[0,1,1,0],[1,1,1,0]])
sage: M.nullity()
0
sage: M.left_nullity()
0

sage: A = M.transpose()
sage: A.nullity()
1
sage: A.left_nullity()
1

sage: M = M.change_ring(ZZ)
sage: M.nullity()
0
sage: A = M.transpose()
sage: A.nullity()
1
```

matrix_window()

Return the requested matrix window.

EXAMPLES:

```
sage: A = matrix(QQ, 3, range(9))
sage: A.matrix_window(1,1, 2, 1)
Matrix window of size 2 x 1 at (1,1):
[0 1 2]
[3 4 5]
[6 7 8]
```

We test the optional check flag.

```
sage: matrix([1]).matrix_window(0,1,1,1, check=False)
Matrix window of size 1 x 1 at (0,1):
[1]
sage: matrix([1]).matrix_window(0,1,1,1)
...
IndexError: matrix window index out of range
```

Another test of bounds checking:

```
sage: matrix([1]).matrix_window(1,1,1,1)
...
IndexError: matrix window index out of range
```

maxspin()

Computes the largest integer n such that the list of vectors $S = [v, v*A, ..., v*A^n]$ are linearly independent, and returns that list.

INPUT:

- `self` - Matrix
- `v` - Vector

OUTPUT:

- `list` - list of Vectors

ALGORITHM: The current implementation just adds vectors to a vector space until the dimension doesn't grow. This could be optimized by directly using matrices and doing an efficient Echelon form. Also, when the base is Q, maybe we could simultaneously keep track of what is going on in the reduction modulo p, which might make things much faster.

EXAMPLES:

```
sage: t = matrix(QQ, 3, range(9)); t
[0 1 2]
[3 4 5]
[6 7 8]
sage: v = (QQ^3).0
sage: t.maxspin(v)
[(1, 0, 0), (0, 1, 2), (15, 18, 21)]
sage: k = t.kernel(); k
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2  1]
sage: t.maxspin(k.0)
[(1, -2, 1)]
```

minimal_polynomial()

This is a synonym for `self.minpoly`

EXAMPLES:

```
sage: a = matrix(QQ, 4, range(16))
sage: a.minimal_polynomial('z')
z^3 - 30*z^2 - 80*z
sage: a.minpoly()
x^3 - 30*x^2 - 80*x
```

minors()

Return the list of all k-minors of self.

Let A be an m x n matrix and k an integer with 0 < k, k <= m, and k <= n. A k x k minor of A is the determinant of a k x k matrix obtained from A by deleting m - k rows and n - k columns.

The returned list is sorted in lexicographical row major ordering, e.g., if A is a 3 x 3 matrix then the minors returned are with for these rows/columns: [[0, 1]x[0, 1], [0, 1]x[0, 2], [0, 1]x[1, 2], [0, 2]x[0, 1], [0, 2]x[0, 2], [0, 2]x[1, 2], [1, 2]x[0, 1], [1, 2]x[0, 2], [1, 2]x[1, 2]].

INPUT:

- k - integer

EXAMPLE:

```
sage: A = Matrix(ZZ,2,3,[1,2,3,4,5,6]); A
[1 2 3]
[4 5 6]
sage: A.minors(2)
[-3, -6, -3]

sage: k = GF(37)
sage: P.<x0,x1,x2> = PolynomialRing(k)
sage: A = Matrix(P,2,3,[x0*x1, x0, x1, x2, x2 + 16, x2 + 5*x1 ])
sage: A.minors(2)
[x0*x1*x2 + 16*x0*x1 - x0*x2, 5*x0*x1^2 + x0*x1*x2 - x1*x2, 5*x0*x1 + x0*x2 - x1*x2 - 16*x1]
```

minpoly()

Return the minimal polynomial of self.

This uses a simplistic - and potentially very very slow - algorithm that involves computing kernels to determine the powers of the factors of the charpoly that divide the minpoly.

EXAMPLES:

```
sage: A = matrix(GF(9,'c'), 4, [1, 1, 0,0, 0,1,0,0, 0,0,5,0, 0,0,0,5])
sage: factor(A.minpoly())
(x + 1) * (x + 2)^2
sage: A.minpoly()(A) == 0
```

```
True
sage: factor(A.charpoly())
(x + 1)^2 * (x + 2)^2
```

The default variable name is x, but you can specify another name:

```
sage: factor(A.minpoly('y'))
(y + 1) * (y + 2)^2
```

norm()

Return the p-norm of this matrix, where p can be 1, 2, ∞, or the Frobenius norm.

INPUT:

- `self` - a matrix whose entries are coercible into CDF
- `p` - one of the following options:
- `1` - the largest column-sum norm
- `2 (default)` - the Euclidean norm
- `Infinity` - the largest row-sum norm
- `'frob'` - the Frobenius (sum of squares) norm

OUTPUT: RDF number

EXAMPLES:

```
sage: A = matrix(ZZ, [[1,2,4,3],[-1,0,3,-10]])
sage: A.norm(1)
13.0
sage: A.norm(Infinity)
14.0
sage: B = random_matrix(QQ, 20, 21)
sage: B.norm(Infinity) == (B.transpose()).norm(1)
True

sage: Id = identity_matrix(12)
sage: Id.norm(2)
1.0
sage: A = matrix(RR, 2, 2, [13,-4,-4,7])
sage: A.norm()
15.0

sage: A = matrix(CDF, 2, 3, [3*I,4,1-I,1,2,0])
sage: A.norm('frob')
5.65685424949
sage: A.norm(2)
5.47068444321
sage: A.norm(1)
6.0
sage: A.norm(Infinity)
8.41421356237
sage: a = matrix([[],[],[],[]])
sage: a.norm()
0.0
sage: a.norm(Infinity) == a.norm(1)
True
```

nullity()

Return the (left) nullity of this matrix, which is the dimension of the (left) kernel of this matrix acting from the right on row vectors.

EXAMPLES:

```
sage: M = Matrix(QQ,[[1,0,0,1],[0,1,1,0],[1,1,1,0]])
sage: M.nullity()
0
sage: M.left_nullity()
0

sage: A = M.transpose()
sage: A.nullity()
1
sage: A.left_nullity()
1

sage: M = M.change_ring(ZZ)
sage: M.nullity()
0
sage: A = M.transpose()
sage: A.nullity()
1
```

numerical_approx()

Return a numerical approximation of `self` as either a real or complex number with at least the requested number of bits or digits of precision.

INPUT:

- `prec` - an integer: the number of bits of precision
- `digits` - an integer: digits of precision

OUTPUT: A matrix coerced to a real or complex field with prec bits of precision.

EXAMPLES:

```
sage: d = matrix([[3, 0],[0,sqrt(2)]]) ;
sage: b = matrix([[1, -1], [2, 2]]) ; e = b * d * b.inverse();e
[ 1/2*sqrt(2) + 3/2 -1/4*sqrt(2) + 3/4]
[      -sqrt(2) + 3  1/2*sqrt(2) + 3/2]

sage: e.numerical_approx(53)
[ 2.20710678118655 0.396446609406726]
[ 1.58578643762690  2.20710678118655]

sage: e.numerical_approx(20)
[ 2.2071 0.39645]
[ 1.5858  2.2071]

sage: (e-I).numerical_approx(20)
[2.2071 - 1.0000*I           0.39645]
[           1.5858 2.2071 - 1.0000*I]

sage: M=matrix(QQ,4,[i/(i+1) for i in range(12)]);M
[    0   1/2   2/3]
[  3/4   4/5   5/6]
[  6/7   7/8   8/9]
[ 9/10 10/11 11/12]

sage: M.numerical_approx()
[0.000000000000000 0.500000000000000 0.666666666666667]
[0.750000000000000 0.800000000000000 0.833333333333333]
[0.857142857142857 0.875000000000000 0.888888888888889]
[0.900000000000000 0.909090909090909 0.916666666666667]
```

```
sage: matrix(SR, 2, 2, range(4)).n()
[0.000000000000000  1.00000000000000]
[ 2.00000000000000  3.00000000000000]
```

permanent()

Calculate and return the permanent of this $m \times n$ matrix using Ryser's algorithm.

Let $A = (a_{i,j})$ be an $m \times n$ matrix over any commutative ring, with $m \leq n$. The permanent of A is

$$\mathrm{per}(A) = \sum_{\pi} a_{1,\pi(1)} a_{2,\pi(2)} \cdots a_{m,\pi(m)}$$

where the summation extends over all one-to-one functions π from $\{1, \ldots, m\}$ to $\{1, \ldots, n\}$.

The product $a_{1,\pi(1)} a_{2,\pi(2)} \cdots a_{m,\pi(m)}$ is called diagonal product. So the permanent of an $m \times n$ matrix A is the sum of all the diagonal products of A.

Modification of theorem 7.1.1. from Brualdi and Ryser: Combinatorial Matrix Theory. Instead of deleting columns from A, we choose columns from A and calculate the product of the row sums of the selected submatrix.

INPUT:

- A - matrix of size m x n with m = n

OUTPUT: permanent of matrix A

EXAMPLES:

```
sage: M = MatrixSpace(ZZ,4,4)
sage: A = M([1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1])
sage: A.permanent()
24

sage: M = MatrixSpace(QQ,3,6)
sage: A = M([1,1,1,1,0,0,0,1,1,1,1,0,0,0,1,1,1,1])
sage: A.permanent()
36

sage: M = MatrixSpace(RR,3,6)
sage: A = M([1.0,1.0,1.0,1.0,0,0,0,1.0,1.0,1.0,1.0,0,0,0,1.0,1.0,1.0,1.0])
sage: A.permanent()
36.0000000000000
```

See Sloane's sequence OEIS A079908(3) = 36, "The Dancing School Problems"

```
sage: print sloane_sequence(79908)                # optional (internet connection)
Searching Sloane's online database...

```

```
sage: R.<x,y> = PolynomialRing(ZZ,2)
sage: A = MatrixSpace(R,2)([x, y, x^2, y^2])
sage: A.permanent()
x^2*y + x*y^2
```

AUTHORS:

- Jaap Spies (2006-02-16)
- Jaap Spies (2006-02-21): added definition of permanent

permanental_minor()

Calculates the permanental k-minor of a $m \times n$ matrix.

This is the sum of the permanents of all possible k by k submatrices of A.

See Brualdi and Ryser: Combinatorial Matrix Theory, p. 203. Note the typo $p_0(A) = 0$ in that reference! For applications see Theorem 7.2.1 and Theorem 7.2.4.

Note that the permanental m-minor equals $per(A)$.

For a (0,1)-matrix A the permanental k-minor counts the number of different selections of k 1's of A with no two of the 1's on the same line.

INPUT:

- `self` - matrix of size m x n with m = n

OUTPUT: permanental k-minor of matrix A

EXAMPLES:

```
sage: M = MatrixSpace(ZZ,4,4)
sage: A = M([1,0,1,0,1,0,1,0,1,0,10,10,1,0,1,1])
sage: A.permanental_minor(2)
114

sage: M = MatrixSpace(ZZ,3,6)
sage: A = M([1,1,1,1,0,0,0,1,1,1,1,0,0,0,1,1,1,1])
sage: A.permanental_minor(0)
1
sage: A.permanental_minor(1)
12
sage: A.permanental_minor(2)
40
sage: A.permanental_minor(3)
36
```

Note that if k == m the permanental k-minor equals per(A)

```
sage: A.permanent()
36

sage: A.permanental_minor(5)
0
```

For C the "complement" of A:

```
sage: M = MatrixSpace(ZZ,3,6)
sage: C = M([0,0,0,0,1,1,1,0,0,0,0,1,1,1,0,0,0,0])
sage: m, n = 3, 6
sage: sum([(-1)^k * C.permanental_minor(k)*factorial(n-k)/factorial(n-m) for k in range(m+1)
36
```

See Theorem 7.2.1 of Brualdi: and Ryser: Combinatorial Matrix Theory: per(A)

AUTHORS:

- Jaap Spies (2006-02-19)

pivot_rows()

Return the pivot row positions for this matrix, which are a topmost subset of the rows that span the row space and are linearly independent.

OUTPUT:

- `list` - a list of integers

EXAMPLES:

```
sage: A = matrix(QQ,3,3, [0,0,0,1,2,3,2,4,6]); A
[0 0 0]
[1 2 3]
[2 4 6]
sage: A.pivot_rows()
[1]
```

plot()

A plot of this matrix.

Each (ith, jth) matrix element is given a different color value depending on its relative size compared to the other elements in the matrix.

The tick marks drawn on the frame axes denote the (ith, jth) element of the matrix.

This method just calls `matrix_plot`. `*args` and `**kwds` are passed to `matrix_plot`.

EXAMPLES:

A matrix over ZZ colored with different grey levels:

```
sage: A = matrix([[1,3,5,1],[2,4,5,6],[1,3,5,7]])
sage: A.plot()
```

Here we make a random matrix over RR and use cmap='hsv' to color the matrix elements different RGB colors:

```
sage: A = random_matrix(RDF, 50)
sage: plot(A, cmap='hsv')
```

Another random plot, but over GF(389):

```
sage: A = random_matrix(GF(389), 10)
sage: A.plot(cmap='Oranges')
```

prod_of_row_sums()

Calculate the product of all row sums of a submatrix of A for a list of selected columns `cols`.

EXAMPLES:

```
sage: a = matrix(QQ, 2,2, [1,2,3,2]); a
[1 2]
[3 2]
sage: a.prod_of_row_sums([0,1])
15
```

Another example:

```
sage: a = matrix(QQ, 2,3, [1,2,3,2,5,6]); a
[1 2 3]
[2 5 6]
sage: a.prod_of_row_sums([1,2])
55
```

AUTHORS:

- Jaap Spies (2006-02-18)

randomize()

Randomize density proportion of the entries of this matrix, leaving the rest unchanged.

Note: We actually choose at random density proportion of entries of the matrix and set them to random elements. It's possible that the same position can be chosen multiple times, especially for a very small matrix.

INPUT:

- `density` - integer (default: 1) rough measure of the proportion of nonzero entries in the random matrix
- `*args, **kwds` - rest of parameters may be passed to the random_element function of the base ring.

EXAMPLES: We construct the zero matrix over a polynomial ring.

```
sage: a = matrix(QQ['x'], 3); a
[0 0 0]
[0 0 0]
[0 0 0]
```

We then randomize roughly half the entries:

```
sage: a.randomize(0.5)
sage: a
[      1/2*x^2 - x - 12 1/2*x^2 - 1/95*x - 1/2                         0]
[-5/2*x^2 + 2/3*x - 1/4                         0                         0]
[           -x^2 + 2/3*x                         0                         0]
```

Now we randomize all the entries of the resulting matrix:

```
sage: a.randomize()
sage: a
[     1/3*x^2 - x + 1              -x^2 + 1               x^2 - x]
[ -1/14*x^2 - x - 1/4           -4*x - 1/5 -1/4*x^2 - 1/2*x + 4]
[ 1/9*x^2 + 5/2*x - 3     -x^2 + 3/2*x + 1   -2/7*x^2 - x - 1/2]
```

We create the zero matrix over the integers:

```
sage: a = matrix(ZZ, 2); a
[0 0]
[0 0]
```

Then we randomize it; the x and y parameters, which determine the size of the random elements, are passed onto the ZZ random_element method.

```
sage: a.randomize(x=-2^64, y=2^64)
sage: a
[-12401200298100116246   1709403521783430739]
[ -4417091203680573707  17094769731745295000]
```

restrict()

Returns the matrix that defines the action of self on the chosen basis for the invariant subspace V. If V is an ambient, returns self (not a copy of self).

INPUT:

- `V` - vector subspace
- `check` - (optional) default: True; if False may not check that V is invariant (hence can be faster).

OUTPUT: a matrix

Warning: This function returns an nxn matrix, where V has dimension n. It does *not* check that V is in fact invariant under self, unless check is True.

EXAMPLES:

```
sage: V = VectorSpace(QQ, 3)
sage: M = MatrixSpace(QQ, 3)
sage: A = M([1,2,0, 3,4,0, 0,0,0])
sage: W = V.subspace([[1,0,0], [0,1,0]])
sage: A.restrict(W)
[1 2]
[3 4]
sage: A.restrict(W, check=True)
[1 2]
[3 4]
```

We illustrate the warning about invariance not being checked by default, by giving a non-invariant subspace. With the default check=False this function returns the 'restriction' matrix, which is meaningless as check=True reveals.

```
sage: W2 = V.subspace([[1,0,0], [0,1,1]])
sage: A.restrict(W2, check=False)
[1 2]
[3 4]
sage: A.restrict(W2, check=True)
...
ArithmeticError: subspace is not invariant under matrix
```

restrict_codomain()

Suppose that self defines a linear map from some domain to a codomain that contains V and that the image of self is contained in V. This function returns a new matrix A that represents this linear map but as a map to V, in the sense that if x is in the domain, then xA is the linear combination of the elements of the basis of V that equals v*self.

INPUT:

- V - vector space (space of degree `self.ncols()`) that contains the image of self.

See Also:

`restrict()`, `restrict_domain()`

EXAMPLES:

```
sage: A = matrix(QQ,3,[1..9])
sage: V = (QQ^3).span([[1,2,3], [7,8,9]]); V
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1  0 -1]
[ 0  1  2]
sage: z = vector(QQ,[1,2,5])
sage: B = A.restrict_codomain(V); B
[1 2]
[4 5]
[7 8]
sage: z*B
(44, 52)
sage: z*A
(44, 52, 60)
sage: 44*V.0 + 52*V.1
(44, 52, 60)
```

restrict_domain()

Compute the matrix relative to the basis for V on the domain obtained by restricting self to V, but not changing the codomain of the matrix. This is the matrix whose rows are the images of the basis for V.

INPUT:

- V - vector space (subspace of ambient space on which self acts)

See Also:

restrict()

EXAMPLES:

```
sage: V = QQ^3
sage: A = matrix(QQ,3,[1,2,0, 3,4,0, 0,0,0])
sage: W = V.subspace([[1,0,0], [1,2,3]])
sage: A.restrict_domain(W)
[1 2 0]
[3 4 0]
sage: W2 = V.subspace_with_basis([[1,0,0], [1,2,3]])
sage: A.restrict_domain(W2)
[ 1  2  0]
[ 7 10  0]
```

right_eigenmatrix()

Return matrices D and P, where D is a diagonal matrix of eigenvalues and P is the corresponding matrix where the columns are corresponding eigenvectors (or zero vectors) so that self*P = P*D.

EXAMPLES:

```
sage: A = matrix(QQ,3,3,range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: D, P = A.eigenmatrix_right()
sage: D
[                  0                   0                   0]
[                  0 -1.348469228349535?                   0]
[                  0                   0  13.34846922834954?]
sage: P
[                   1                    1                    1]
[                  -2   0.1303061543300932?   3.069693845669907?]
[                   1 -0.7393876913398137?   5.139387691339814?]
sage: A*P == P*D
True
```

Because P is invertible, A is diagonalizable.

```
sage: A == P*D*(~P)
True
```

The matrix P may contain zero columns corresponding to eigenvalues for which the algebraic multiplicity is greater than the geometric multiplicity. In these cases, the matrix is not diagonalizable.

```
sage: A = jordan_block(2,3); A
[2 1 0]
[0 2 1]
[0 0 2]
sage: A = jordan_block(2,3)
sage: D, P = A.eigenmatrix_right()
sage: D
[2 0 0]
[0 2 0]
[0 0 2]
sage: P
[1 0 0]
[0 0 0]
[0 0 0]
sage: A*P == P*D
True
```

right_eigenspaces()

Compute right eigenspaces of a matrix.

If algebraic_multiplicity=False, return a list of pairs (e, V) where e runs through all eigenvalues (up to Galois conjugation) of this matrix, and V is the corresponding right eigenspace.

If algebraic_multiplicity=True, return a list of pairs (e, V, n) where e and V are as above and n is the algebraic multiplicity of the eigenvalue. If the eigenvalues are given symbolically, as roots of an irreducible factor of the characteristic polynomial, then the algebraic multiplicity returned is the multiplicity of each conjugate eigenvalue.

The eigenspaces are returned sorted by the corresponding characteristic polynomials, where polynomials are sorted in dictionary order starting with constant terms.

INPUT:

- `var` - variable name used to represent elements of the root field of each irreducible factor of the characteristic polynomial I.e., if var='a', then the root fields will be in terms of a0, a1, a2, ..., ak.

Warning: Uses a somewhat naive algorithm (simply factors the characteristic polynomial and computes kernels directly over the extension field).

TODO: Maybe implement the better algorithm that is in dual_eigenvector in sage/modular/hecke/module.py.

EXAMPLES: We compute the right eigenspaces of a 3×3 rational matrix.

```
sage: A = matrix(QQ,3,3,range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: es = A.eigenspaces_right(); es
[
(0, Vector space of degree 3 and dimension 1 over Rational Field
User basis matrix:
[ 1 -2  1]),
(a1, Vector space of degree 3 and dimension 1 over Number Field in a1 with defining polynomi
User basis matrix:
[           1 1/5*a1 + 2/5 2/5*a1 - 1/5])
]
sage: es = A.eigenspaces_right(algebraic_multiplicity=True); es
[
(0, Vector space of degree 3 and dimension 1 over Rational Field
User basis matrix:
[ 1 -2  1], 1),
(a1, Vector space of degree 3 and dimension 1 over Number Field in a1 with defining polynomi
User basis matrix:
[           1 1/5*a1 + 2/5 2/5*a1 - 1/5], 1)
]
sage: e, v, n = es[0]; v = v.basis()[0]
sage: delta = v*e - A*v
sage: abs(abs(delta)) < 1e-10
True
```

The same computation, but with implicit base change to a field:

```
sage: A = matrix(ZZ,3,range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: A.eigenspaces_right()
[
(0, Vector space of degree 3 and dimension 1 over Rational Field
```

```
User basis matrix:
[ 1 -2  1]),
(a1, Vector space of degree 3 and dimension 1 over Number Field in a1 with defining polynomi
User basis matrix:
[           1 1/5*a1 + 2/5 2/5*a1 - 1/5])
]
```

TESTS: Warnings are issued if the generic algorithm is used over inexact fields. Garbage may result in these cases because of numerical precision issues.

```
sage: R=RealField(30)
sage: M=matrix(R,2,[2,1,1,1])
sage: M.eigenspaces_right() # random output from numerical issues
[(2.6180340,
Vector space of degree 2 and dimension 0 over Real Field with 30 bits of precision
User basis matrix:
[]),
(0.38196601,
Vector space of degree 2 and dimension 0 over Real Field with 30 bits of precision
User basis matrix:
[])]
sage: R=ComplexField(30)
sage: N=matrix(R,2,[2,1,1,1])
sage: N.eigenspaces_right() # random output from numerical issues
[(2.6180340,
Vector space of degree 2 and dimension 0 over Complex Field with 30 bits of precision
User basis matrix:
[]),
(0.38196601,
Vector space of degree 2 and dimension 0 over Complex Field with 30 bits of precision
User basis matrix:
[])]
```

right_eigenvectors()

Compute the right eigenvectors of a matrix.

For each distinct eigenvalue, returns a list of the form (e,V,n) where e is the eigenvalue, V is a list of eigenvectors forming a basis for the corresponding right eigenspace, and n is the algebraic multiplicity of the eigenvalue.

EXAMPLES: We compute the right eigenvectors of a 3×3 rational matrix.

```
sage: A = matrix(QQ,3,3,range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: es = A.eigenvectors_right(); es
[(0, [
(1, -2, 1)
], 1),
(-1.348469228349535?, [(1, 0.1303061543300932?, -0.7393876913398137?)], 1),
(13.34846922834954?, [(1, 3.069693845669907?, 5.139387691339814?)], 1)]
sage: eval, [evec], mult = es[0]
sage: delta = eval*evec - A*evec
sage: abs(abs(delta)) < 1e-10
True
```

right_kernel()

Return the right kernel of this matrix, as a vector space. This is the space of vectors x such that self*x=0. A left kernel can be found with self.left_kernel() or just self.kernel().

INPUT: all additional arguments to the kernel function are passed directly onto the echelon call.

By convention if self has 0 columns, the kernel is of dimension 0, whereas the kernel is whole domain if self has 0 rows.

ALGORITHM:

Elementary row operations do not change the right kernel, since they are left multiplication by an invertible matrix, so we instead compute the kernel of the row echelon form. More precisely, there is a basis vector of the kernel that corresponds to each non-pivot column. That vector has a 1 at the non-pivot column, 0's at all other non-pivot columnss, and for each pivot column, the negative of the entry at the non-pivot column in the row with that pivot element.

Note: Preference is given to left kernels in that the generic method name `kernel()` returns a left kernel. However most computations of kernels are implemented as right kernels.

EXAMPLES:

A right kernel of dimension one over $\mathbb{Q}$:

```
sage: A = MatrixSpace(QQ, 3)(range(9))
sage: A.right_kernel()
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2  1]
```

A trivial right kernel:

```
sage: A = MatrixSpace(QQ, 2)([1,2,3,4])
sage: A.right_kernel()
Vector space of degree 2 and dimension 0 over Rational Field
Basis matrix:
[]
```

Right kernel of a zero matrix:

```
sage: A = MatrixSpace(QQ, 2)(0)
sage: A.right_kernel()
Vector space of degree 2 and dimension 2 over Rational Field
Basis matrix:
[1 0]
[0 1]
```

Right kernel of a non-square matrix:

```
sage: A = MatrixSpace(QQ,2,3)(range(6))
sage: A.right_kernel()
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2  1]
```

The 2-dimensional right kernel of a matrix over a cyclotomic field:

```
sage: K = CyclotomicField(12); a=K.0
sage: M = MatrixSpace(K,2,4)([1,-1, 0,-2, 0,-a**2-1, 0,a**2-1])
sage: M
[            1            -1             0            -2]
[            0 -zeta12^2 - 1             0  zeta12^2 - 1]
sage: M.right_kernel()
Vector space of degree 4 and dimension 2 over Cyclotomic Field of order 12 and degree 4
Basis matrix:
[      1  4/13*zeta12^2 - 1/13      0 -2/13*zeta12^2 + 7/13]
[      0                    0      1                    0]
```

A nontrivial right kernel over a complicated base field.

```
sage: K = FractionField(PolynomialRing(QQ, 2, 'x'))
sage: M = MatrixSpace(K, 2)([[K.1, K.0], [K.1, K.0]])
sage: M
[x1 x0]
[x1 x0]
sage: M.right_kernel()
Vector space of degree 2 and dimension 1 over Fraction Field of Multivariate Polynomial Ring
Basis matrix:
[ 1 x1/(-x0)]
```

Right kernel of a large dense rational matrix, which will invoke the fast IML routines in matrix_integer_dense class. Timing on a 64-bit 3 GHz dual-core machine is about 3 seconds to setup and about 1 second for the kernel() call. Timings that are one or two orders of magnitude larger indicate problems with reaching specialized derived classes.

```
sage: entries = [[1/(i+j+1) for i in srange(500)] for j in srange(500)]
sage: a = matrix(QQ, entries)
sage: a.right_kernel()
Vector space of degree 500 and dimension 0 over Rational Field
Basis matrix:
0 x 500 dense matrix over Rational Field
```

right_nullity()

Return the right nullity of this matrix, which is the dimension of the right kernel.

EXAMPLES:

```
sage: A = MatrixSpace(QQ,3,2)(range(6))
sage: A.right_nullity()
0

sage: A = matrix(ZZ,3,range(9))
sage: A.right_nullity()
1
```

rook_vector()

Returns rook vector of this matrix.

Let A be a general m by n (0,1)-matrix with $m \leq n$. We identify A with a chessboard where rooks can be placed on the fields corresponding with $a_{ij} = 1$. The number $r_k = p_k(A)$ (the permanental k-minor) counts the number of ways to place k rooks on this board so that no two rooks can attack another.

The rook vector is the list consisting of $r_0, r_1, \ldots, r_m$.

The rook polynomial is defined by $r(x) = \sum_{k=0}^{m} r_k x^k$.

INPUT:

- `self` - m by n matrix with m = n
- `check` - True or False (default), optional

OUTPUT: rook vector

EXAMPLES:

```
sage: M = MatrixSpace(ZZ,3,6)
sage: A = M([1,1,1,1,0,0,0,1,1,1,1,0,0,0,1,1,1,1])
sage: A.rook_vector()
[1, 12, 40, 36]

sage: R.<x> = PolynomialRing(ZZ)
sage: rv = A.rook_vector()
sage: rook_polynomial = sum([rv[k] * x^k for k in range(len(rv))])
sage: rook_polynomial
36*x^3 + 40*x^2 + 12*x + 1
```

AUTHORS:

- Jaap Spies (2006-02-24)

row_module()

Return the free module over the base ring spanned by the rows of self.

EXAMPLES:

```
sage: A = MatrixSpace(IntegerRing(), 2)([1,2,3,4])
sage: A.row_module()
Free module of degree 2 and rank 2 over Integer Ring
Echelon basis matrix:
[1 0]
[0 2]
```

row_space()

Return the row space of this matrix. (Synonym for self.row_module().)

EXAMPLES:

```
sage: t = matrix(QQ, 3, range(9)); t
[0 1 2]
[3 4 5]
[6 7 8]
sage: t.row_space()
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1  0 -1]
[ 0  1  2]

sage: m = Matrix(Integers(5),2,2,[2,2,2,2]);
sage: m.row_space()
Vector space of degree 2 and dimension 1 over Ring of integers modulo 5
Basis matrix:
[1 1]
```

set_block()

Sets the sub-matrix of self, with upper left corner given by row, col to block.

EXAMPLES:

```
sage: A = matrix(QQ, 3, 3, range(9))/2
sage: B = matrix(ZZ, 2, 1, [100,200])
sage: A.set_block(0, 1, B)
sage: A
[  0 100   1]
[3/2 200 5/2]
[  3 7/2   4]
```

We test that an exception is raised when the block is out of bounds:

```
sage: matrix([1]).set_block(0,1,matrix([1]))
...
IndexError: matrix window index out of range
```

smith_form()

If self is a matrix over a principal ideal domain R, return matrices D, U, V over R such that D = U * self * V, U and V have unit determinant, and D is diagonal with diagonal entries the ordered elementary divisors of self, ordered so that $D_i \mid D_{i+1}$. Note that U and V are not uniquely defined in general, and D is defined only up to units.

INPUT:

- `self` - a matrix over an integral domain. If the base ring is not a PID, the routine might work, or else it will fail having found an example of a non-principal ideal. Note that we do not call any methods

to check whether or not the base ring is a PID, since this might be quite expensive (e.g. for rings of integers of number fields of large degree).

ALGORITHM: Lifted wholesale from http://en.wikipedia.org/wiki/Smith_normal_form

See Also:

`elementary_divisors()`

AUTHORS:

- David Loeffler (2008-12-05)

EXAMPLES:

An example over the ring of integers of a number field (of class number 1):

```
sage: OE = NumberField(x^2 - x + 2,'w').ring_of_integers()
sage: w = OE.ring_generators()[0]
sage: m = Matrix([ [1, w],[w,7]])
sage: d, u, v = m.smith_form()
sage: (d, u, v)
([     1      0]
[     0 -w + 9], [ 1  0]
[-w  1], [ 1 -w]
[ 0  1])
sage: u * m * v == d
True
sage: u.base_ring() == v.base_ring() == d.base_ring() == OE
True
sage: u.det().is_unit() and v.det().is_unit()
True
```

An example over the polynomial ring QQ[x]:

```
sage: R.<x> = QQ[]; m=x*matrix(R,2,2,1) - matrix(R, 2,2,[3,-4,1,-1]); m.smith_form()
([            1             0]
[            0 x^2 - 2*x + 1], [    0    -1]
[    1 x - 3], [    1 x + 1]
[    0     1])
```

An example over a field:

```
sage: m = matrix( GF(17), 3, 3, [11,5,1,3,6,8,1,16,0]); d,u,v = m.smith_form()
sage: d
[1 0 0]
[0 1 0]
[0 0 0]
sage: u*m*v == d
True
```

Some examples over non-PID's work anyway:

```
sage: R = EquationOrder(x^2 + 5, 's') # class number 2
sage: s = R.ring_generators()[0]
sage: matrix(R, 2, 2, [s-1,-s,-s,2*s+1]).smith_form()
([     1      0]
[     0 -s - 6],
[   -1    -1]
[    s s - 1],
[    1 s + 1]
[    0     1])
```

Others don't, but they fail quite constructively:

```
sage: matrix(R,2,2,[s-1,-s-2,-2*s,-s-2]).smith_form()
...
ArithmeticError: Ideal Fractional ideal (2, s + 1) not principal
```

Empty matrices are handled safely:

```
sage: m = MatrixSpace(OE, 2,0)(0); d,u,v=m.smith_form(); u*m*v == d
True
sage: m = MatrixSpace(OE, 0,2)(0); d,u,v=m.smith_form(); u*m*v == d
True
sage: m = MatrixSpace(OE, 0,0)(0); d,u,v=m.smith_form(); u*m*v == d
True
```

Some pathological cases that crashed earlier versions:

```
sage: m = Matrix(OE, [[2*w,2*w-1,-w+1],[2*w+2,-2*w-1,w-1],[-2*w-1,-2*w-2,2*w-1]]); d, u, v =
True
sage: m = matrix(OE, 3, 3, [-5*w-1,-2*w-2,4*w-10,8*w,-w,w-1,-1,1,-8]); d,u,v = m.smith_form(
True
```

solve_left()

If self is a matrix A, then this function returns a vector or matrix X such that $XA = B$. If B is a vector then X is a vector and if B is a matrix, then X is a matrix.

INPUT:

- B - a matrix
- check - bool (default: True) - if False and self is nonsquare, may not raise an error message even if there is no solution. This is faster but more dangerous.

EXAMPLES:

```
sage: A = matrix(QQ,4,2, [0, -1, 1, 0, -2, 2, 1, 0])
sage: B = matrix(QQ,2,2, [1, 0, 1, -1])
sage: X = A.solve_left(B)
sage: X*A == B
True
```

solve_right()

If self is a matrix A, then this function returns a vector or matrix X such that $AX = B$. If B is a vector then X is a vector and if B is a matrix, then X is a matrix.

Note: In Sage one can also write A \backslash B for A.solve_right(B), i.e., Sage implements the "the MATLAB/Octave backslash operator".

INPUT:

- B - a matrix or vector
- check - bool (default: True) - if False and self is nonsquare, may not raise an error message even if there is no solution. This is faster but more dangerous.

OUTPUT: a matrix or vector

See Also:

solve_left()

EXAMPLES:

```
sage: A = matrix(QQ, 3, [1,2,3,-1,2,5,2,3,1])
sage: b = vector(QQ,[1,2,3])
sage: x = A \ b; x
(-13/12, 23/12, -7/12)
sage: A * x
(1, 2, 3)
```

We solve with A nonsquare:

```
sage: A = matrix(QQ,2,4, [0, -1, 1, 0, -2, 2, 1, 0]); B = matrix(QQ,2,2, [1, 0, 1, -1])
sage: X = A.solve_right(B); X
[-3/2  1/2]
[  -1    0]
[   0    0]
[   0    0]
sage: A*X == B
True
```

Another nonsingular example:

```
sage: A = matrix(QQ,2,3, [1,2,3,2,4,6]); v = vector([-1/2,-1])
sage: x = A \ v; x
(-1/2, 0, 0)
sage: A*x == v
True
```

Same example but over $\mathbf{Z}$:

```
sage: A = matrix(ZZ,2,3, [1,2,3,2,4,6]); v = vector([-1,-2])
sage: A \ v
(-1, 0, 0)
```

An example in which there is no solution:

```
sage: A = matrix(QQ,2,3, [1,2,3,2,4,6]); v = vector([1,1])
sage: A \ v
...
ValueError: matrix equation has no solutions
```

A ValueError is raised if the input is invalid:

```
sage: A = matrix(QQ,4,2, [0, -1, 1, 0, -2, 2, 1, 0])
sage: B = matrix(QQ,2,2, [1, 0, 1, -1])
sage: X = A.solve_right(B)
...
ValueError: number of rows of self must equal number of rows of B
```

We solve with A singular:

```
sage: A = matrix(QQ,2,3, [1,2,3,2,4,6]); B = matrix(QQ,2,2, [6, -6, 12, -12])
sage: X = A.solve_right(B); X
[ 6 -6]
[ 0  0]
[ 0  0]
sage: A*X == B
True
```

We illustrate left associativity, etc., of the backslash operator.

```
sage: A = matrix(QQ, 2, [1,2,3,4])
sage: A \ A
[1 0]
[0 1]
sage: A \ A \ A
[1 2]
[3 4]
sage: A.parent()(1) \ A
[1 2]
[3 4]
sage: A \ (A \ A)
[  -2    1]
[ 3/2 -1/2]
```

```
sage: X = A \ (A - 2); X
[ 5 -2]
[-3  2]
sage: A * X
[-1  2]
[ 3  2]
```

Solving over a polynomial ring:

```
sage: x = polygen(QQ, 'x')
sage: A = matrix(2, [x,2*x,-5*x^2+1,3])
sage: v = vector([3,4*x - 2])
sage: X = A \ v
sage: X
((-8*x^2 + 4*x + 9)/(10*x^3 + x), (19*x^2 - 2*x - 3)/(10*x^3 + x))
sage: A * X == v
True
```

Solving a system over the p-adics:

```
sage: k = Qp(5,4)
sage: a = matrix(k, 3, [1,7,3,2,5,4,1,1,2]); a
[    1 + O(5^4) 2 + 5 + O(5^4)     3 + O(5^4)]
[    2 + O(5^4)     5 + O(5^5)     4 + O(5^4)]
[    1 + O(5^4)     1 + O(5^4)     2 + O(5^4)]
sage: v = vector(k, 3, [1,2,3])
sage: x = a \ v; x
(4 + 5 + 5^2 + 3*5^3 + O(5^4), 2 + 5 + 3*5^2 + 5^3 + O(5^4), 1 + 5 + O(5^4))
sage: a * x == v
True
```

subdivide()

Divides self into logical submatrices which can then be queried and extracted. If a subdivision already exists, this method forgets the previous subdivision and flushes the cache.

INPUT:

- `row_lines` - None, an integer, or a list of integers
- `col_lines` - None, an integer, or a list of integers

OUTPUT: changes self

Note: One may also pass a tuple into the first argument which will be interpreted as (row_lines, col_lines)

EXAMPLES:

```
sage: M = matrix(5, 5, prime_range(100))
sage: M.subdivide(2,3); M
[ 2  3  5| 7 11]
[13 17 19|23 29]
[--------+-----]
[31 37 41|43 47]
[53 59 61|67 71]
[73 79 83|89 97]
sage: M.subdivision(0,0)
[ 2  3  5]
[13 17 19]
sage: M.subdivision(1,0)
[31 37 41]
[53 59 61]
[73 79 83]
sage: M.subdivision_entry(1,0,0,0)
31
```

```
sage: M.get_subdivisions()
([2], [3])
sage: M.subdivide(None, [1,3]); M
[ 2| 3  5| 7 11]
[13|17 19|23 29]
[31|37 41|43 47]
[53|59 61|67 71]
[73|79 83|89 97]
```

Degenerate cases work too.

```
sage: M.subdivide([2,5], [0,1,3]); M
[| 2| 3  5| 7 11]
[|13|17 19|23 29]
[+--+-----+-----]
[|31|37 41|43 47]
[|53|59 61|67 71]
[|73|79 83|89 97]
[+--+-----+-----]
sage: M.subdivision(0,0)
[]
sage: M.subdivision(0,1)
[ 2]
[13]
sage: M.subdivide([2,2,3], [0,0,1,1]); M
[|| 2|| 3  5  7 11]
[||13||17 19 23 29]
[++--++-----------]
[++--++-----------]
[||31||37 41 43 47]
[++--++-----------]
[||53||59 61 67 71]
[||73||79 83 89 97]
sage: M.subdivision(0,0)
[]
sage: M.subdivision(2,4)
[37 41 43 47]
```

AUTHORS:

- Robert Bradshaw (2007-06-14)

subdivision()

Returns in immutable copy of the (i,j)th submatrix of self, according to a previously set subdivision.

Before a subdivision is set, the only valid arguments are (0,0) which returns self.

EXAMPLE:

```
sage: M = matrix(3, 4, range(12))
sage: M.subdivide(1,2); M
[ 0  1| 2  3]
[-----+-----]
[ 4  5| 6  7]
[ 8  9|10 11]
sage: M.subdivision(0,0)
[0 1]
sage: M.subdivision(0,1)
[2 3]
sage: M.subdivision(1,0)
[4 5]
[8 9]
```

It handles size-zero subdivisions as well.

```
sage: M = matrix(3, 4, range(12))
sage: M.subdivide([0],[0,2,2,4]); M
[+-----++-----+]
[| 0  1|| 2  3|]
[| 4  5|| 6  7|]
[| 8  9||10 11|]
sage: M.subdivision(0,0)
[]
sage: M.subdivision(1,1)
[0 1]
[4 5]
[8 9]
sage: M.subdivision(1,2)
[]
sage: M.subdivision(1,0)
[]
sage: M.subdivision(0,1)
[]
```

subdivision_entry()

Returns the x,y entry of the i,j submatrix of self.

EXAMPLES:

```
sage: M = matrix(5, 5, range(25))
sage: M.subdivide(3,3); M
[ 0  1  2| 3  4]
[ 5  6  7| 8  9]
[10 11 12|13 14]
[--------+-----]
[15 16 17|18 19]
[20 21 22|23 24]
sage: M.subdivision_entry(0,0,1,2)
7
sage: M.subdivision(0,0)[1,2]
7
sage: M.subdivision_entry(0,1,0,0)
3
sage: M.subdivision_entry(1,0,0,0)
15
sage: M.subdivision_entry(1,1,1,1)
24
```

Even though this entry exists in the matrix, the index is invalid for the submatrix.

```
sage: M.subdivision_entry(0,0,4,0)
...
IndexError: Submatrix 0,0 has no entry 4,0
```

subs()

EXAMPLES:

```
sage: var('a,b,d,e')
(a, b, d, e)
sage: m = matrix([[a,b], [d,e]])
sage: m.substitute(a=1)
[1 b]
[d e]
sage: m.subs(a=b, b=d)
```

```
[b d]
[d e]
```

symplectic_form()

Find a symplectic form for self if self is an anti-symmetric, alternating matrix defined over a field.

Returns a pair (F, C) such that the rows of C form a symplectic basis for self and F = C * self * C.transpose().

Raises a ValueError if not over a field, or self is not anti-symmetric, or self is not alternating.

Anti-symmetric means that $M = -M^t$. Alternating means that the diagonal of M is identically zero.

A symplectic basis is a basis of the form $e_1, \ldots, e_j, f_1, \ldots f_j, z_1, \ldots, z_k$ such that

- $z_i M v^t = 0$ for all vectors v
- $e_i M {e_j}^t = 0$ for all i, j
- $f_i M {f_j}^t = 0$ for all i, j
- $e_i M {f_i}^t = 1$ for all i
- $e_i M {f_j}^t = 0$ for all i not equal j.

See the example for a pictorial description of such a basis.

EXAMPLES:

```
sage: E = matrix(QQ, 8, 8, [0, -1/2, -2, 1/2, 2, 0, -2, 1, 1/2, 0, -1, -3, 0, 2, 5/2, -3, 2,
[   0 -1/2   -2  1/2    2    0   -2    1]
[ 1/2    0   -1   -3    0    2  5/2   -3]
[   2    1    0  3/2   -1    0   -1   -2]
[-1/2    3 -3/2    0    1  3/2 -1/2 -1/2]
[  -2    0    1   -1    0    0    1   -1]
[   0   -2    0 -3/2    0    0  1/2   -2]
[   2 -5/2    1  1/2   -1 -1/2    0   -1]
[  -1    3    2  1/2    1    2    1    0]
sage: F, C = E.symplectic_form(); F
[ 0  0  0  0  1  0  0  0]
[ 0  0  0  0  0  1  0  0]
[ 0  0  0  0  0  0  1  0]
[ 0  0  0  0  0  0  0  1]
[-1  0  0  0  0  0  0  0]
[ 0 -1  0  0  0  0  0  0]
[ 0  0 -1  0  0  0  0  0]
[ 0  0  0 -1  0  0  0  0]
sage: F == C * E * C.transpose()
True
```

tensor_product()

Returns the tensor product of two matrices.

EXAMPLES:

```
sage: M1=Matrix(QQ,[[-1,0],[-1/2,-1]])
sage: M2=Matrix(ZZ,[[1,-1,2],[-2,4,8]])
sage: M1.tensor_product(M2)
[  -1    1   -2|   0    0    0]
[   2   -4   -8|   0    0    0]
[--------------+--------------]
[-1/2  1/2   -1|  -1    1   -2]
[   1   -2   -4|   2   -4   -8]
sage: M2.tensor_product(M1)
[  -1    0|   1    0|  -2    0]
[-1/2   -1| 1/2    1|  -1   -2]
[---------+---------+---------]
```

```
[   2    0|  -4    0|  -8    0]
[   1    2|  -2   -4|  -4   -8]
```

trace()

Return the trace of self, which is the sum of the diagonal entries of self.

INPUT:

- `self` - a square matrix

OUTPUT: element of the base ring of self

EXAMPLES:

```
sage: a = matrix(3,range(9)); a
[0 1 2]
[3 4 5]
[6 7 8]
sage: a.trace()
12
sage: a = matrix({(1,1):10, (2,1):-3, (2,2):4/3}); a
[  0   0   0]
[  0  10   0]
[  0  -3 4/3]
sage: a.trace()
34/3
```

visualize_structure()

Write a PNG image to 'filename' which visualizes self by putting black pixels in those positions which have nonzero entries.

White pixels are put at positions with zero entries. If 'maxsize' is given, then the maximal dimension in either x or y direction is set to 'maxsize' depending on which is bigger. If the image is scaled, the darkness of the pixel reflects how many of the represented entries are nonzero. So if e.g. one image pixel actually represents a 2x2 submatrix, the dot is darker the more of the four values are nonzero.

INPUT:

- `filename` - either a path or None in which case a filename in the current directory is chosen automatically (default:None)

maxsize - maximal dimension in either x or y direction of the resulting image. If None or a maxsize larger than max(self.nrows(),self.ncols()) is given the image will have the same pixelsize as the matrix dimensions (default: 512)

EXAMPLE:

```
sage: M = random_matrix(CC, 4)
sage: M.visualize_structure()
```

wiedemann()

Application of Wiedemann's algorithm to the i-th standard basis vector.

INPUT:

- `i` - an integer
- `t` - an integer (default: 0) if t is nonzero, use only the first t linear recurrence relations.

IMPLEMENTATION: This is a toy implementation.

EXAMPLES:

```
sage: t = matrix(QQ, 3, range(9)); t
[0 1 2]
[3 4 5]
[6 7 8]
sage: t.wiedemann(0)
```

```
x^2 - 12*x - 18
sage: t.charpoly()
x^3 - 12*x^2 - 18*x
```

cmp_pivots()
Compare two sequences of pivot columns.

- If x is shorter than y, return -1, i.e., x < y, "not as good".
- If x is longer than y, x > y, "better".
- If the length is the same then x is better, i.e., x > y if the entries of x are correspondingly >= those of y with one being greater.

decomp_seq()
This function is used internally be the decomposition matrix method. It takes a list of tuples and produces a sequence that is correctly sorted and prints with carriage returns.

EXAMPLES:

```
sage: from sage.matrix.matrix2 import decomp_seq
sage: V = [(QQ^3, 2), (QQ^2, 1)]
sage: decomp_seq(V)
[
(Vector space of dimension 2 over Rational Field, 1),
(Vector space of dimension 3 over Rational Field, 2)
]
```

32.8 Generic Asymptotically Fast Strassen Algorithms

Sage implements asymptotically fast echelon form and matrix multiplication algorithms.

class int_range()
Useful class for dealing with pivots in the strassen echelon, could have much more general application

AUTHORS:

- Robert Bradshaw

intervals()

to_list()

strassen_echelon()
Compute echelon form, in place. Internal function, call with M.echelonize(algorithm="strassen") Based on work of Robert Bradshaw and David Harvey at MSRI workshop in 2006.

INPUT:

- A - matrix window
- cutoff - size at which algorithm reverts to naive gaussian elemination and multiplication must be at least 1.

OUTPUT: The list of pivot columns

EXAMPLE:

```
sage: A = matrix(QQ, 7, [5, 0, 0, 0, 0, -1, 0, 0, 1, 0, 0, 0, 0, 0, -1, 3, 1, 0, -1, 0, 0, -1
sage: B = A.copy(); B._echelon_strassen(1); B
[ 1  0  0  0  0  0  0]
[ 0  1  0 -1  0  1  0]
[ 0  0  1  0  0  0  0]
[ 0  0  0  0  1  0  0]
[ 0  0  0  0  0  0  1]
[ 0  0  0  0  0  0  0]
[ 0  0  0  0  0  0  0]
sage: C = A.copy(); C._echelon_strassen(2); C == B
True
sage: C = A.copy(); C._echelon_strassen(4); C == B
True

sage: n = 32; A = matrix(Integers(389),n,range(n^2))
sage: B = A.copy(); B._echelon_in_place_classical()
sage: C = A.copy(); C._echelon_strassen(2)
sage: B == C
True
```

TESTS:

```
sage: A = matrix(Integers(7), 4, 4, [1,2,0,3,0,0,1,0,0,1,0,0,0,0,0,1])
sage: B = A.copy(); B._echelon_in_place_classical()
sage: C = A.copy(); C._echelon_strassen(2)
sage: B == C
True

sage: A = matrix(Integers(7), 4, 4, [1,0,5,0,2,0,3,6,5,1,2,6,4,6,1,1])
sage: B = A.copy(); B._echelon_in_place_classical()
sage: C = A.copy(); C._echelon_strassen(2)
sage: B == C
True
```

AUTHORS:

- Robert Bradshaw

strassen_window_multiply()

Multiplies the submatrices specified by A and B, places result in C. Assumes that A and B have compatible dimensions to be multiplied, and that C is the correct size to receive the product, and that they are all defined over the same ring.

Uses strassen multiplication at high levels and then uses MatrixWindow methods at low levels. EXAMPLES: The following matrix dimensions are chosen especially to exercise the eight possible parity combinations that ocould ccur while subdividing the matrix in the strassen recursion. The base case in both cases will be a (4x5) matrix times a (5x6) matrix.

```
sage: A = MatrixSpace(Integers(2^65), 64, 83).random_element()
sage: B = MatrixSpace(Integers(2^65), 83, 101).random_element()
sage: A._multiply_classical(B) == A._multiply_strassen(B, 3)
True
```

AUTHORS:

- David Harvey

32.9 Minimal Polynomials of Linear Recurrence Sequences

AUTHORS:

- William Stein

berlekamp_massey(a)

Use the Berlekamp-Massey algorithm to find the minimal polynomial of a linearly recurrence sequence a.

The minimal polynomial of a linear recurrence $\{a_r\}$ is by definition the unique monic polynomial g, such that if $\{a_r\}$ satisfies a linear recurrence $a_{j+k} + b_{j-1}a_{j-1+k} + \cdots + b_0 a_k = 0$ (for all $k \geq 0$), then g divides the polynomial $x^j + \sum_{i=0}^{j-1} b_i x^i$.

INPUT:

- `a` - a list of even length of elements of a field (or domain)

OUTPUT:

- `Polynomial` - the minimal polynomial of the sequence (as a polynomial over the field in which the entries of a live)

EXAMPLES:

```
sage: berlekamp_massey([1,2,1,2,1,2])
x^2 - 1
sage: berlekamp_massey([GF(7)(1),19,1,19])
x^2 + 6
sage: berlekamp_massey([2,2,1,2,1,191,393,132])
x^4 - 36727/11711*x^3 + 34213/5019*x^2 + 7024942/35133*x - 335813/1673
sage: berlekamp_massey(prime_range(2,38))
x^6 - 14/9*x^5 - 7/9*x^4 + 157/54*x^3 - 25/27*x^2 - 73/18*x + 37/9
```

32.10 Base class for dense matrices

TESTS:

```
sage: R.<a,b> = QQ[]
sage: m = matrix(R,2,[0,a,b,b^2])
sage: loads(dumps(m)) == m
True
```

class **Matrix_dense**()

antitranspose()

Returns the anittranspose of self, without changing self.

EXAMPLES:

```
sage: A = matrix(2,3,range(6)); A
[0 1 2]
[3 4 5]
sage: A.antitranspose()
[5 2]
[4 1]
[3 0]
```

```
sage: A.subdivide(1,2); A
[0 1|2]
[---+-]
[3 4|5]
sage: A.antitranspose()
[5|2]
[-+-]
[4|1]
[3|0]
```

apply_map()

Apply the given map phi (an arbitrary Python function or callable object) to this dense matrix. If R is not given, automatically determine the base ring of the resulting matrix.

INPUT: sparse – True to make the output a sparse matrix; default False

- phi - arbitrary Python function or callable object
- R - (optional) ring

OUTPUT: a matrix over R

EXAMPLES:

```
sage: m = matrix(ZZ, 3, range(9))
sage: k.<a> = GF(9)
sage: f = lambda x: k(x)
sage: n = m.apply_map(f); n
[0 1 2]
[0 1 2]
[0 1 2]
sage: n.parent()
Full MatrixSpace of 3 by 3 dense matrices over Finite Field in a of size 3^2
```

In this example, we explicitly specify the codomain.

```
sage: s = GF(3)
sage: f = lambda x: s(x)
sage: n = m.apply_map(f, k); n
[0 1 2]
[0 1 2]
[0 1 2]
sage: n.parent()
Full MatrixSpace of 3 by 3 dense matrices over Finite Field in a of size 3^2
```

If self is subdivided, the result will be as well:

```
sage: m = matrix(2, 2, srange(4))
sage: m.subdivide(None, 1); m
[0|1]
[2|3]
sage: m.apply_map(lambda x: x*x)
[0|1]
[4|9]
```

If the map sends most of the matrix to zero, then it may be useful to get the result as a sparse matrix.

```
sage: m = matrix(ZZ, 3, 3, range(1, 10))
sage: n = m.apply_map(lambda x: 1//x, sparse=True); n
[1 0 0]
[0 0 0]
[0 0 0]
sage: n.parent()
Full MatrixSpace of 3 by 3 sparse matrices over Integer Ring
```

TESTS:

```
sage: m = matrix([])
sage: m.apply_map(lambda x: x*x) == m
True

sage: m.apply_map(lambda x: x*x, sparse=True).parent()
Full MatrixSpace of 0 by 0 sparse matrices over Integer Ring
```

apply_morphism()

Apply the morphism phi to the coefficients of this dense matrix.

The resulting matrix is over the codomain of phi.

INPUT:

- `phi` - a morphism, so phi is callable and phi.domain() and phi.codomain() are defined. The codomain must be a ring.

OUTPUT: a matrix over the codomain of phi

EXAMPLES:

```
sage: m = matrix(ZZ, 3, range(9))
sage: phi = ZZ.hom(GF(5))
sage: m.apply_morphism(phi)
[0 1 2]
[3 4 0]
[1 2 3]
sage: parent(m.apply_morphism(phi))
Full MatrixSpace of 3 by 3 dense matrices over Finite Field of size 5
```

We apply a morphism to a matrix over a polynomial ring:

```
sage: R.<x,y> = QQ[]
sage: m = matrix(2, [x,x^2 + y, 2/3*y^2-x, x]); m
[          x     x^2 + y]
[2/3*y^2 - x           x]
sage: phi = R.hom([y,x])
sage: m.apply_morphism(phi)
[          y     y^2 + x]
[2/3*x^2 - y           y]
```

transpose()

Returns the transpose of self, without changing self.

EXAMPLES: We create a matrix, compute its transpose, and note that the original matrix is not changed.

```
sage: M = MatrixSpace(QQ,  2)
sage: A = M([1,2,3,4])
sage: B = A.transpose()
sage: print B
[1 3]
[2 4]
sage: print A
[1 2]
[3 4]

sage: A.subdivide(None, 1); A
[1|2]
[3|4]
sage: A.transpose()
[1 3]
[---]
[2 4]
```

32.11 Base class for sparse matrices

class Matrix_sparse()

antitranspose()

apply_map()

Apply the given map phi (an arbitrary Python function or callable object) to this matrix. If R is not given, automatically determine the base ring of the resulting matrix.

INPUT: sparse – False to make the output a dense matrix; default True

- phi - arbitrary Python function or callable object
- R - (optional) ring

OUTPUT: a matrix over R

EXAMPLES:

```
sage: m = matrix(ZZ, 10000, {(1,2): 17}, sparse=True)
sage: k.<a> = GF(9)
sage: f = lambda x: k(x)
sage: n = m.apply_map(f)
sage: n.parent()
Full MatrixSpace of 10000 by 10000 sparse matrices over Finite Field in a of size 3^2
sage: n[1,2]
2
```

An example where the codomain is explicitly specified.

```
sage: n = m.apply_map(lambda x:x%3, GF(3))
sage: n.parent()
Full MatrixSpace of 10000 by 10000 sparse matrices over Finite Field of size 3
sage: n[1,2]
2
```

If we didn't specify the codomain, the resulting matrix in the above case ends up over ZZ again:

```
sage: n = m.apply_map(lambda x:x%3)
sage: n.parent()
Full MatrixSpace of 10000 by 10000 sparse matrices over Integer Ring
sage: n[1,2]
2
```

If self is subdivided, the result will be as well:

```
sage: m = matrix(2, 2, [0, 0, 3, 0])
sage: m.subdivide(None, 1); m
[0|0]
[3|0]
sage: m.apply_map(lambda x: x*x)
[0|0]
[9|0]
```

If the map sends zero to a non-zero value, then it may be useful to get the result as a dense matrix.

```
sage: m = matrix(ZZ, 3, 3, [0] * 7 + [1,2], sparse=True); m
[0 0 0]
[0 0 0]
[0 1 2]
sage: parent(m)
Full MatrixSpace of 3 by 3 sparse matrices over Integer Ring
sage: n = m.apply_map(lambda x: x+polygen(QQ), sparse=False); n
```

```
[    x     x     x]
[    x     x     x]
[    x x + 1 x + 2]
sage: parent(n)
Full MatrixSpace of 3 by 3 dense matrices over Univariate Polynomial Ring in x over Rational
```

TESTS:

```
sage: m = matrix([], sparse=True)
sage: m.apply_map(lambda x: x*x) == m
True

sage: m.apply_map(lambda x: x*x, sparse=False).parent()
Full MatrixSpace of 0 by 0 dense matrices over Integer Ring
```

Check that we don't unnecessarily apply phi to 0 in the sparse case:

```
sage: m = matrix(QQ, 2, 2, range(1, 5), sparse=True)
sage: m.apply_map(lambda x: 1/x)
[  1 1/2]
[1/3 1/4]
```

Test subdivisions when phi maps 0 to non-zero:

```
sage: m = matrix(2, 2, [0, 0, 3, 0])
sage: m.subdivide(None, 1); m
[0|0]
[3|0]
sage: m.apply_map(lambda x: x+1)
[1|1]
[4|1]
```

apply_morphism()

Apply the morphism phi to the coefficients of this sparse matrix.

The resulting matrix is over the codomain of phi.

INPUT:

- `phi` - a morphism, so phi is callable and phi.domain() and phi.codomain() are defined. The codomain must be a ring.

OUTPUT: a matrix over the codomain of phi

EXAMPLES:

```
sage: m = matrix(ZZ, 3, range(9), sparse=True)
sage: phi = ZZ.hom(GF(5))
sage: m.apply_morphism(phi)
[0 1 2]
[3 4 0]
[1 2 3]
sage: m.apply_morphism(phi).parent()
Full MatrixSpace of 3 by 3 sparse matrices over Finite Field of size 5
```

change_ring()

Return the matrix obtained by coercing the entries of this matrix into the given ring.

Always returns a copy (unless self is immutable, in which case returns self).

EXAMPLES:

sage: A = matrix(QQ['x,y'], 2, [0,-1,2*x,-2], sparse=True); A [0 -1] [2*x -2] sage: A.change_ring(QQ['x,y,z']) [0 -1] [2*x -2]

Subdivisions are preserved when changing rings:

```
sage: A.subdivide([2],[]); A
[  0  -1]
[2*x  -2]
[-------]
sage: A.change_ring(RR['x,y'])
[                  0  -1.00000000000000]
[2.00000000000000*x  -2.00000000000000]
[-----------------------------------]
```

charpoly()

Return the characteristic polynomial of this matrix.

Note - the generic sparse charpoly implementation in Sage is to just compute the charpoly of the corresponding dense matrix, so this could use a lot of memory. In particular, for this matrix, the charpoly will be computed using a dense algorithm.

EXAMPLES:

```
sage: A = matrix(ZZ, 4, range(16), sparse=True)
sage: A.charpoly()
x^4 - 30*x^3 - 80*x^2
sage: A.charpoly('y')
y^4 - 30*y^3 - 80*y^2
sage: A.charpoly()
x^4 - 30*x^3 - 80*x^2
```

transpose()

Returns the transpose of self, without changing self.

EXAMPLES: We create a matrix, compute its transpose, and note that the original matrix is not changed.

```
sage: M = MatrixSpace(QQ,  2, sparse=True)
sage: A = M([1,2,3,4])
sage: B = A.transpose()
sage: print B
[1 3]
[2 4]
sage: print A
[1 2]
[3 4]
```

32.12 Dense Matrices over a general ring

class **Matrix_generic_dense**()

The Matrix_generic_dense class derives from Matrix, and defines functionality for dense matrices over any base ring. Matrices are represented by a list of elements in the base ring, and element access operations are implemented in this class.

EXAMPLES:

```
sage: A = random_matrix(Integers(25)['x'],2); A
[    x^2 + 12*x + 2   4*x^2 + 13*x + 8]
[ 22*x^2 + 2*x + 17 19*x^2 + 22*x + 14]
sage: type(A)
<type 'sage.matrix.matrix_generic_dense.Matrix_generic_dense'>
sage: A == loads(dumps(A))
True
```

32.13 Sparse Matrices over a general ring

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: M = MatrixSpace(QQ['x'],2,3,sparse=True); M
Full MatrixSpace of 2 by 3 sparse matrices over Univariate Polynomial Ring in x over Rational Field
sage: a = M(range(6)); a
[0 1 2]
[3 4 5]
sage: b = M([x^n for n in range(6)]); b
[  1   x x^2]
[x^3 x^4 x^5]
sage: a * b.transpose()
[            2*x^2 + x           2*x^5 + x^4]
[      5*x^2 + 4*x + 3 5*x^5 + 4*x^4 + 3*x^3]
sage: pari(a)*pari(b.transpose())
[2*x^2 + x, 2*x^5 + x^4; 5*x^2 + 4*x + 3, 5*x^5 + 4*x^4 + 3*x^3]
sage: c = copy(b); c
[  1   x x^2]
[x^3 x^4 x^5]
sage: c[0,0] = 5; c
[  5   x x^2]
[x^3 x^4 x^5]
sage: b[0,0]
1
sage: c.dict()
{(0, 1): x, (1, 2): x^5, (0, 0): 5, (1, 0): x^3, (0, 2): x^2, (1, 1): x^4}
sage: c.list()
[5, x, x^2, x^3, x^4, x^5]
sage: c.rows()
[(5, x, x^2), (x^3, x^4, x^5)]
sage: loads(dumps(c)) == c
True
sage: d = c.change_ring(CC['x']); d
[    5.00000000000000   1.00000000000000*x 1.00000000000000*x^2]
[1.00000000000000*x^3 1.00000000000000*x^4 1.00000000000000*x^5]
sage: latex(c)
\left(\begin{array}{rrr}
5 & x & x^{2} \\
x^{3} & x^{4} & x^{5}
\end{array}\right)
sage: c.sparse_rows()
[(5, x, x^2), (x^3, x^4, x^5)]
sage: d = c.dense_matrix(); d
[  5   x x^2]
[x^3 x^4 x^5]
sage: parent(d)
Full MatrixSpace of 2 by 3 dense matrices over Univariate Polynomial Ring in x over Rational Field
sage: c.sparse_matrix() is c
True
sage: c.is_sparse()
True
```

class Matrix_generic_sparse()

The Matrix_generic_sparse class derives from Matrix, and defines functionality for sparse matrices over any base ring. A generic sparse matrix is represented using a dictionary with keys pairs (i, j) and values in

the base ring.

The values of the dictionary must never be zero.

Matrix_sparse_from_rows()

INPUT:

- X - nonempty list of SparseVector rows

OUTPUT: Sparse_matrix with those rows.

EXAMPLES:

```
sage: V = VectorSpace(QQ,20,sparse=True)
sage: v = V(0)
sage: v[9] = 4
sage: from sage.matrix.matrix_generic_sparse import Matrix_sparse_from_rows
sage: Matrix_sparse_from_rows([v])
[0 0 0 0 0 0 0 0 0 4 0 0 0 0 0 0 0 0 0 0]
sage: Matrix_sparse_from_rows([v, v, v, V(0)])
[0 0 0 0 0 0 0 0 0 4 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 4 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 4 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
```

32.14 Dense matrices over $\mathbb{Z}/n\mathbb{Z}$ for n small.

AUTHORS:

- William Stein
- Robert Bradshaw

This is a compiled implementation of dense matrices over $\mathbf{Z}/n\mathbf{Z}$ for n small.

EXAMPLES:

```
sage: a = matrix(Integers(37),3,range(9),sparse=False); a
[0 1 2]
[3 4 5]
[6 7 8]
sage: a.rank()
2
sage: type(a)
<type 'sage.matrix.matrix_modn_dense.Matrix_modn_dense'>
sage: a[0,0] = 5
sage: a.rank()
3
sage: parent(a)
Full MatrixSpace of 3 by 3 dense matrices over Ring of integers modulo 37

sage: a^2
[ 3 23 31]
[20 17 29]
[25 16  0]
sage: a+a
[10  2  4]
```

```
[ 6  8 10]
[12 14 16]

sage: b = a.new_matrix(2,3,range(6)); b
[0 1 2]
[3 4 5]
sage: a*b
...
TypeError: unsupported operand parent(s) for '*': 'Full MatrixSpace of 3 by 3 dense matrices over Ri
sage: b*a
[15 18 21]
[20 17 29]

sage: a == loads(dumps(a))
True
sage: b == loads(dumps(b))
True

sage: a.echelonize(); a
[1 0 0]
[0 1 0]
[0 0 1]
sage: b.echelonize(); b
[ 1  0 36]
[ 0  1  2]
```

We create a matrix group and coerce it to GAP:

```
sage: M = MatrixSpace(GF(3),3,3)
sage: G = MatrixGroup([M([[0,1,0],[0,0,1],[1,0,0]]), M([[0,1,0],[1,0,0],[0,0,1]])])
sage: G
Matrix group over Finite Field of size 3 with 2 generators:
 [[[0, 1, 0], [0, 0, 1], [1, 0, 0]], [[0, 1, 0], [1, 0, 0], [0, 0, 1]]]
sage: gap(G)
Group(
[ [ [ 0*Z(3), Z(3)^0, 0*Z(3) ], [ 0*Z(3), 0*Z(3), Z(3)^0 ], [ Z(3)^0, 0*Z(3),
          0*Z(3) ] ],
  [ [ 0*Z(3), Z(3)^0, 0*Z(3) ], [ Z(3)^0, 0*Z(3), 0*Z(3) ],
      [ 0*Z(3), 0*Z(3), Z(3)^0 ] ] ])
```

TESTS:

```
sage: M = MatrixSpace(GF(5),2,2)
sage: A = M([1,0,0,1])
sage: A - int(-1)
[2 0]
[0 2]
sage: B = M([4,0,0,1])
sage: B - int(-1)
[0 0]
[0 2]
sage: Matrix(GF(5),0,0, sparse=False).inverse()
[]
```

class **Matrix_modn_dense**()

charpoly()

Returns the characteristic polynomial of self.

INPUT:

- `var` - a variable name
- `algorithm` - 'generic' 'linbox' (default)

EXAMPLES:

```
sage: A = Mat(GF(7),3,3)(range(3)*3)
sage: A.charpoly()
x^3 + 4*x^2

sage: A = Mat(Integers(6),3,3)(range(9))
sage: A.charpoly()
x^3
```

ALGORITHM: Uses LinBox if self.base_ring() is a field, otherwise use Hessenberg form algorithm.

determinant()

Return the determinant of this matrix.

EXAMPLES:

```
sage: m = matrix(GF(101),5,range(25))
sage: m.det()
0

sage: m = matrix(Integers(4), 2, [2,2,2,2])
sage: m.det()
0
```

TESTS:

```
sage: m = random_matrix(GF(3), 3, 4)
sage: m.determinant()
...
ArithmeticError: self must be a square matrix
```

echelonize()

Puts self in row echelon form.

INPUT:

- `self` - a mutable matrix
- `algorithm` - 'linbox' - uses the C++ linbox library
- `'gauss'` - uses a custom slower $O(n^3)$ Gauss elimination implemented in Sage.
- `'all'` - compute using both algorithms and verify that the results are the same (for the paranoid).
- `**kwds` - these are all ignored

OUTPUT:

- self is put in reduced row echelon form.
- the rank of self is computed and cached
- the pivot columns of self are computed and cached.
- the fact that self is now in echelon form is recorded and cached so future calls to echelonize return immediately.

EXAMPLES:

```
sage: a = matrix(GF(97),3,4,range(12))
sage: a.echelonize(); a
[ 1  0 96 95]
[ 0  1  2  3]
[ 0  0  0  0]
sage: a.pivots()
[0, 1]
```

hessenbergize()
Transforms self in place to its Hessenberg form.

lift()
Return the lift of this matrix to the integers.
EXAMPLES:

```
sage: a = matrix(GF(7),2,3,[1..6])
sage: a.lift()
[1 2 3]
[4 5 6]
sage: a.lift().parent()
Full MatrixSpace of 2 by 3 dense matrices over Integer Ring
```

Subdivisions are preserved when lifting:

```
sage: a.subdivide([], [1,1]); a
[1||2 3]
[4||5 6]
sage: a.lift()
[1||2 3]
[4||5 6]
```

list()
Return list of elements of self.
EXAMPLES:

```
sage: w = matrix(GF(19), 2, 3, [1..6])
sage: w.list()
[1, 2, 3, 4, 5, 6]
sage: w.list()[0].parent()
Finite Field of size 19
```

TESTS:

```
sage: w = random_matrix(GF(3),100)
sage: w.parent()(w.list()) == w
True
```

matrix_window()
Return the requested matrix window.
EXAMPLES:

```
sage: a = matrix(GF(7),3,range(9)); a
[0 1 2]
[3 4 5]
[6 0 1]
sage: type(a)
<type 'sage.matrix.matrix_modn_dense.Matrix_modn_dense'>
```

We test the optional check flag.

```
sage: matrix(GF(7),[1]).matrix_window(0,1,1,1)
...
IndexError: matrix window index out of range
sage: matrix(GF(7),[1]).matrix_window(0,1,1,1, check=False)
Matrix window of size 1 x 1 at (0,1):
[1]
```

minpoly()

Returns the minimal polynomial of self.

INPUT:

- var - a variable name
- algorithm - 'generic' 'linbox' (default)

randomize()

Randomize density proportion of the entries of this matrix, leaving the rest unchanged.

EXAMPLES:

```
sage: A = matrix(GF(5), 5, 5, 0)
sage: A.randomize(0.5); A
[0 0 0 2 0]
[0 3 0 0 2]
[4 0 0 0 0]
[4 0 0 0 0]
[0 1 0 0 0]
sage: A.randomize(); A
[3 3 2 1 2]
[4 3 3 2 2]
[0 3 3 3 3]
[3 3 2 2 4]
[2 2 2 1 4]
```

rank()

Return the rank of this matrix.

EXAMPLES:

```
sage: m = matrix(GF(7),5,range(25))
sage: m.rank()
2
```

Rank is not implemented over the integers modulo a composite yet.

```
sage: m = matrix(Integers(4), 2, [2,2,2,2])
sage: m.rank()
...
NotImplementedError: Echelon form not implemented over 'Ring of integers modulo 4'.
```

32.15 Sparse matrices over $\mathbb{Z}/n\mathbb{Z}$ for n small.

This is a compiled implementation of sparse matrices over $\mathbf{Z}/n\mathbf{Z}$ for n small.

TODO: - move vectors into a pyrex vector class - add _add_ and _mul_ methods.

EXAMPLES:

```
sage: a = matrix(Integers(37),3,3,range(9),sparse=True); a
[0 1 2]
[3 4 5]
```

```
[6 7 8]

class Matrix_modn_sparse()

density()

Return the density of self, i.e., the ratio of the number of nonzero entries of self to the total size of self.

EXAMPLES:

```
sage: A = matrix(QQ,3,3,[0,1,2,3,0,0,6,7,8],sparse=True)
sage: A.density()
2/3
```

Notice that the density parameter does not ensure the density of a matrix; it is only an upper bound.

```
sage: A = random_matrix(GF(127),200,200,density=0.3, sparse=True)
sage: A.density()
257/1000
```

lift()

Return lift of this matrix to a sparse matrix over the integers.

EXAMPLES: sage: a = matrix(GF(7),2,3,[1..6], sparse=True) sage: a.lift() [1 2 3] [4 5 6] sage: a.lift().parent() Full MatrixSpace of 2 by 3 sparse matrices over Integer Ring

Subdivisions are preserved when lifting:

```
sage: a.subdivide([], [1,1]); a
[1|2 3]
[4|5 6]
sage: a.lift()
[1|2 3]
[4|5 6]
```

matrix_from_columns()

Return the matrix constructed from self using columns with indices in the columns list.

EXAMPLES:

```
sage: M = MatrixSpace(GF(127),3,3,sparse=True)
sage: A = M(range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: A.matrix_from_columns([2,1])
[2 1]
[5 4]
[8 7]
```

matrix_from_rows()

Return the matrix constructed from self using rows with indices in the rows list.

INPUT:

- rows - list or tuple of row indices

EXAMPLE:

```
sage: M = MatrixSpace(GF(127),3,3,sparse=True)
sage: A = M(range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: A.matrix_from_rows([2,1])
[6 7 8]
[3 4 5]
```

p

rank()

Compute the rank of self.

INPUT:

- `gauss` - if True LinBox' Gaussian elimination is used. If False 'Symbolic Reordering' as implemented in LinBox is used. If 'native' the native Sage implementation is used. (default: False)

EXAMPLE:

```
sage: A = random_matrix(GF(127),200,200,density=0.01,sparse=True)
sage: r1 = A.rank(gauss=False)
sage: r2 = A.rank(gauss=True)
sage: r3 = A.rank(gauss='native')
sage: r1 == r2 == r3
True
sage: r1
155
```

ALGORITHM: Uses LinBox or native implementation.

REFERENCES:

- Jean-Guillaume Dumas and Gilles Villars. 'Computing the Rank of Large Sparse Matrices over Finite Fields'. Proc. CASC'2002, The Fifth International Workshop on Computer Algebra in Scientific Computing, Big Yalta, Crimea, Ukraine, 22-27 sept. 2002, Springer-Verlag, http://perso.ens-lyon.fr/gilles.villard/BIBLIOGRAPHIE/POSTSCRIPT/rankjgd.ps

Note: For very sparse matrices Gaussian elimination is faster because it barly has anything to do. If the fill in needs to be considered, 'Symbolic Reordering' is usually much faster.

swap_rows()

transpose()

Return the transpose of self.

EXAMPLE:

```
sage: A = matrix(GF(127),3,3,[0,1,0,2,0,0,3,0,0],sparse=True)
sage: A
[0 1 0]
[2 0 0]
[3 0 0]
sage: A.transpose()
[0 2 3]
[1 0 0]
[0 0 0]
```

visualize_structure()

Write a PNG image to 'filename' which visualizes self by putting black pixels in those positions which have nonzero entries.

White pixels are put at positions with zero entries. If 'maxsize' is given, then the maximal dimension in either x or y direction is set to 'maxsize' depending on which is bigger. If the image is scaled, the darkness of the pixel reflects how many of the represented entries are nonzero. So if e.g. one image pixel actually represents a 2x2 submatrix, the dot is darker the more of the four values are nonzero.

INPUT:

- `filename` - either a path or None in which case a filename in the current directory is chosen automatically (default:None)
- `maxsize` - maximal dimension in either x or y direction of the resulting image. If None or a maxsize larger than max(self.nrows(),self.ncols()) is given the image will have the same pixelsize as the matrix dimensions (default: 512)

32.16 Dense matrices over the integer ring.

AUTHORS:

- William Stein
- Robert Bradshaw

EXAMPLES:

```
sage: a = matrix(ZZ, 3,3, range(9)); a
[0 1 2]
[3 4 5]
[6 7 8]
sage: a.det()
0
sage: a[0,0] = 10; a.det()
-30
sage: a.charpoly()
x^3 - 22*x^2 + 102*x + 30
sage: b = -3*a
sage: a == b
False
sage: b < a
True
```

TESTS:

```
sage: a = matrix(ZZ,2,range(4), sparse=False)
sage: loads(dumps(a)) == a
True
sage: Matrix(ZZ,0,0).inverse()
[]
```

class Matrix_integer_dense()

Matrix over the integers.

On a 32-bit machine, they can have at most $2^{32} - 1$ rows or columns. On a 64-bit machine, matrices can have at most $2^{64} - 1$ rows or columns.

EXAMPLES:

```
sage: a = MatrixSpace(ZZ,3)(2); a
[2 0 0]
[0 2 0]
[0 0 2]
sage: a = matrix(ZZ,1,3, [1,2,-3]); a
[ 1  2 -3]
sage: a = MatrixSpace(ZZ,2,4)(2); a
...
TypeError: nonzero scalar matrix must be square
```

BKZ()

Block Korkin-Zolotarev reduction.

INPUT:

- `fp` - 'fp' - double precision: NTL's FP or fpLLL's double
- `'qd'` - quad doubles: NTL's QP
- `'qd1'` - quad doubles: uses quad_float precision to compute Gram-Schmidt, but uses double precision in the search phase of the block reduction algorithm. This seems adequate for most purposes, and is faster than 'qd', which uses quad_float precision uniformly throughout.
- `'xd'` - extended exponent: NTL's XD

- 'rr' - arbitrary precision (default)
- block_size - specifies the size of the blocks in the reduction. High values yield shorter vectors, but the running time increases exponentially with block_size. block_size should be between 2 and the number of rows of self (default: 10)
- prune - The optional parameter prune can be set to any positive number to invoke the Volume Heuristic from [Schnorr and Horner, Eurocrypt '95]. This can significantly reduce the running time, and hence allow much bigger block size, but the quality of the reduction is of course not as good in general. Higher values of prune mean better quality, and slower running time. When prune == 0, pruning is disabled. Recommended usage: for block_size = 30, set 10 = prune = 15.
- use_givens - use Given's orthogonalization. This is a bit slower, but generally much more stable, and is really the preferred orthogonalization strategy. For a nice description of this, see Chapter 5 of [G. Golub and C. van Loan, Matrix Computations, 3rd edition, Johns Hopkins Univ. Press, 1996].

EXAMPLE:

```
sage: A = Matrix(ZZ,3,3,range(1,10))
sage: A.BKZ()
[ 0  0  0]
[ 2  1  0]
[-1  1  3]
sage: A = Matrix(ZZ,3,3,range(1,10))
sage: A.BKZ(use_givens=True)
[ 0  0  0]
[ 2  1  0]
[-1  1  3]

sage: A = Matrix(ZZ,3,3,range(1,10))
sage: A.BKZ(fp="fp")
[ 0  0  0]
[ 2  1  0]
[-1  1  3]
```

LLL()

Returns LLL reduced or approximated LLL reduced lattice R for this matrix interpreted as a lattice.

A lattice $(b_1, b_2, ..., b_d)$ is (δ, η) -LLL-reduced if the two following conditions hold:

- For any $i > j$, we have $|mu_{i,j}| <= \eta$,
- For any $i < d$, we have $\delta |b_i^*|^2 <= |b_{i+1}^* + mu_{i+1,i} b_i^*|^2$,

where $mu_{i,j} =< b_i, b_j^* > / < b_j^*, b_j^* >$ and b_i^* is the i-th vector of the Gram-Schmidt orthogonalisation of $(b_1, b_2, ..., b_d)$.

The default reduction parameters are $\delta = 3/4$ and $eta = 0.501$. The parameters δ and η must satisfy: $0.25 < \delta <= 1.0$ and $0.5 <= \eta < sqrt(\delta)$. Polynomial time complexity is only guaranteed for $\delta < 1$.

The lattice is returned as a matrix. Also the rank (and the determinant) of self are cached if those are computed during the reduction. Note that in general this only happens when self.rank() == self.ncols() and the exact algorithm is used.

INPUT:

- delta - parameter as described above (default: 3/4)
- eta - parameter as described above (default: 0.501), ignored by NTL
- algorithm - string (default: "fpLLL:wrapper") one of the algorithms mentioned below
- fp
  - None - NTL's exact reduction or fpLLL's wrapper
  - 'fp' - double precision: NTL's FP or fpLLL's double
  - 'qd' - quad doubles: NTL's QP
  - 'xd' - extended exponent: NTL's XD or fpLLL's dpe

–'rr' - arbitrary precision: NTL'RR or fpLLL's MPFR

- prec - precision, ignored by NTL (default: auto choose)
- early_red - perform early reduction, ignored by NTL (default: False)
- use_givens - use Givens orthogonalization (default: False) only applicable to approximate reductions and NTL. This is more stable but slower.
  Also, if the verbose level is = 2, some more verbose output is printed during the calculation if NTL is used.
  AVAILABLE ALGORITHMS:
- NTL:LLL - NTL's LLL + fp
- fpLLL:heuristic - fpLLL's heuristic + fp
- fpLLL:fast - fpLLL's fast
- fpLLL:wrapper - fpLLL's automatic choice (default)

OUTPUT: a matrix over the integers

EXAMPLE:

```
sage: A = Matrix(ZZ,3,3,range(1,10))
sage: A.LLL()
[ 0  0  0]
[ 2  1  0]
[-1  1  3]
```

We compute the extended GCD of a list of integers using LLL, this example is from the Magma handbook:

```
sage: Q = [ 67015143, 248934363018, 109210, 25590011055, 74631449, \
            10230248, 709487, 68965012139, 972065, 864972271 ]
sage: n = len(Q)
sage: S = 100
sage: X = Matrix(ZZ, n, n + 1)
sage: for i in xrange(n):
...       X[i,i + 1] = 1
sage: for i in xrange(n):
...       X[i,0] = S*Q[i]
sage: L = X.LLL()
sage: M = L.row(n-1).list()[1:]
sage: M
[-3, -1, 13, -1, -4, 2, 3, 4, 5, -1]
sage: add([Q[i]*M[i] for i in range(n)])
-1
```

ALGORITHM: Uses the NTL library by Victor Shoup or fpLLL library by Damien Stehle depending on the chosen algorithm.

REFERENCES:

- ntl.mat_ZZ or sage.libs.fplll.fplll for details on the used algorithms.

LLL_gram()

LLL reduction of the lattice whose gram matrix is self.

INPUT:

- M - gram matrix of a definite quadratic form

OUTPUT:

- U - unimodular transformation matrix such that U.transpose() * M * U is LLL-reduced.

ALGORITHM: Use PARI

EXAMPLES:

```
sage: M = Matrix(ZZ, 2, 2, [5,3,3,2]) ; M
[5 3]
[3 2]
sage: U = M.LLL_gram(); U
[-1  1]
[ 1 -2]
sage: U.transpose() * M * U
[1 0]
[0 1]
```

Semidefinite and indefinite forms raise a ValueError:

```
sage: Matrix(ZZ,2,2,[2,6,6,3]).LLL_gram()
...
ValueError: not a definite matrix
sage: Matrix(ZZ,2,2,[1,0,0,-1]).LLL_gram()
...
ValueError: not a definite matrix
```

BUGS: should work for semidefinite forms (PARI is ok)

antitranspose()

Returns the antitranspose of self, without changing self.

EXAMPLES:

```
sage: A = matrix(2,3,range(6))
sage: type(A)
<type 'sage.matrix.matrix_integer_dense.Matrix_integer_dense'>
sage: A.antitranspose()
[5 2]
[4 1]
[3 0]
sage: A
[0 1 2]
[3 4 5]

sage: A.subdivide(1,2); A
[0 1|2]
[---+-]
[3 4|5]
sage: A.antitranspose()
[5|2]
[-+-]
[4|1]
[3|0]
```

charpoly()

INPUT:

- `var` - a variable name
- `algorithm` - 'linbox' (default) 'generic'

Note: Linbox charpoly disabled on 64-bit machines, since it hangs in many cases.

EXAMPLES:

```
sage: A = matrix(ZZ,6, range(36))
sage: f = A.charpoly(); f
x^6 - 105*x^5 - 630*x^4
sage: f(A) == 0
True
sage: n=20; A = Mat(ZZ,n)(range(n^2))
```

```
sage: A.charpoly()
x^20 - 3990*x^19 - 266000*x^18
sage: A.minpoly()
x^3 - 3990*x^2 - 266000*x
```

decomposition()

Returns the decomposition of the free module on which this matrix A acts from the right (i.e., the action is x goes to x A), along with whether this matrix acts irreducibly on each factor. The factors are guaranteed to be sorted in the same way as the corresponding factors of the characteristic polynomial, and are saturated as ZZ modules.

INPUT:

- `self` - a matrix over the integers
- `**kwds` - these are passed onto to the decomposition over QQ command.

EXAMPLES:

```
sage: t = ModularSymbols(11,sign=1).hecke_matrix(2)
sage: w = t.change_ring(ZZ)
sage: w.list()
[3, -1, 0, -2]
```

determinant()

Return the determinant of this matrix.

INPUT:

- `algorithm`
  - **`'default'` – use 'pari' when number of rows less than 50;** otherwise, use 'padic'
  - `'padic'` - uses a p-adic / multimodular algorithm that relies on code in IML and linbox
  - `'linbox'` - calls linbox det (you *must* set proof=False to use this!)
  - `'ntl'` - calls NTL's det function
  - `'pari'` - uses PARI
- `proof` - bool or None; if None use proof.linear_algebra(); only relevant for the padic algorithm.
  Note: It would be *VERY VERY* hard for det to fail even with proof=False.
- `stabilize` - if proof is False, require det to be the same for this many CRT primes in a row. Ignored if proof is True.

ALGORITHM: The p-adic algorithm works by first finding a random vector v, then solving A*x = v and taking the denominator d. This gives a divisor of the determinant. Then we compute $\det(A)/d$ using a multimodular algorithm and the Hadamard bound, skipping primes that divide d.

TIMINGS: This is perhaps the fastest implementation of determinants in the world. E.g., for a 500x500 random matrix with 32-bit entries on a core2 duo 2.6Ghz running OS X, Sage takes 4.12 seconds, whereas Magma takes 62.87 seconds (both with proof False). With proof=True on the same problem Sage takes 5.73 seconds. For another example, a 200x200 random matrix with 1-digit entries takes 4.18 seconds in pari, 0.18 in Sage with proof True, 0.11 in Sage with proof False, and 0.21 seconds in Magma with proof True and 0.18 in Magma with proof False.

EXAMPLES:

```
sage: A = matrix(ZZ,8,8,[3..66])
sage: A.determinant()
0

sage: A = random_matrix(ZZ,20,20)
sage: D1 = A.determinant()
sage: A._clear_cache()
sage: D2 = A.determinant(algorithm='ntl')
sage: D1 == D2
True
```

Next we try the Linbox det. Note that we must have proof=False.

```
sage: A = matrix(ZZ,5,[1,2,3,4,5,4,6,3,2,1,7,9,7,5,2,1,4,6,7,8,3,2,4,6,7])
sage: A.determinant(algorithm='linbox')
...
RuntimeError: you must pass the proof=False option to the determinant command to use Linbox'
sage: A.determinant(algorithm='linbox',proof=False)
-21
sage: A._clear_cache()
sage: A.determinant()
-21
```

A bigger example:

```
sage: A = random_matrix(ZZ,30)
sage: d = A.determinant()
sage: A._clear_cache()
sage: A.determinant(algorithm='linbox',proof=False) == d
True
```

echelon_form()

Return the echelon form of this matrix over the integers, also known as the hermit normal form (HNF).

INPUT:

- `algorithm`
  - **'default' - max 10 rows or columns: pari with flag 0** max 75 rows or columns: pari with flag 1 larger – use padic algorithm
  - **'padic' - an asymptotically fast p-adic modular algorithm,** If your matrix has large coefficients and is small, you may also want to try this.
  - 'pari' - use PARI with flag 1
  - 'pari0' - use PARI with flag 0
  - 'pari4' - use PARI with flag 4 (use heuristic LLL)
  - **'ntl' - use NTL (only works for square matrices of** full rank!)
- `proof` - (default: True); if proof=False certain determinants are computed using a randomized hybrid p-adic multimodular strategy until it stabilizes twice (instead of up to the Hadamard bound). It is *incredibly* unlikely that one would ever get an incorrect result with proof=False.
- `include_zero_rows` - (default: True) if False, don't include zero rows
- `transformation` - if given, also compute transformation matrix; only valid for padic algorithm
- `D` - (default: None) if given and the algorithm is 'ntl', then D must be a multiple of the determinant and this function will use that fact.

OUTPUT:

- `matrix` - the Hermite normal form (=echelon form over ZZ) of self.

Note: The result is *not* cached.

EXAMPLES:

```
sage: A = MatrixSpace(ZZ,2)([1,2,3,4])
sage: A.echelon_form()
[1 0]
[0 2]

sage: A = MatrixSpace(ZZ,5)(range(25))
sage: A.echelon_form()
[  5   0  -5 -10 -15]
[  0   1   2   3   4]
[  0   0   0   0   0]
[  0   0   0   0   0]
[  0   0   0   0   0]
```

TESTS: Make sure the zero matrices are handled correctly:

```
sage: m = matrix(ZZ,3,3,[0]*9)
sage: m.echelon_form()
[0 0 0]
[0 0 0]
[0 0 0]
sage: m = matrix(ZZ,3,1,[0]*3)
sage: m.echelon_form()
[0]
[0]
[0]
sage: m = matrix(ZZ,1,3,[0]*3)
sage: m.echelon_form()
[0 0 0]
```

The ultimate border case!

```
sage: m = matrix(ZZ,0,0,[])
sage: m.echelon_form()
[]
```

Note: If 'ntl' is chosen for a non square matrix this function raises a ValueError.
Special cases: 0 or 1 rows:

```
sage: a = matrix(ZZ, 1,2,[0,-1])
sage: a.hermite_form()
[0 1]
sage: a.pivots()
[1]
sage: a = matrix(ZZ, 1,2,[0,0])
sage: a.hermite_form()
[0 0]
sage: a.pivots()
[]
sage: a = matrix(ZZ,1,3); a
[0 0 0]
sage: a.echelon_form(include_zero_rows=False)
[]
sage: a.echelon_form(include_zero_rows=True)
[0 0 0]
```

Illustrate using various algorithms.:

```
sage: matrix(ZZ,3,[1..9]).hermite_form(algorithm='pari')
[1 2 3]
[0 3 6]
[0 0 0]
sage: matrix(ZZ,3,[1..9]).hermite_form(algorithm='pari0')
[1 2 3]
[0 3 6]
[0 0 0]
sage: matrix(ZZ,3,[1..9]).hermite_form(algorithm='pari4')
[1 2 3]
[0 3 6]
[0 0 0]
sage: matrix(ZZ,3,[1..9]).hermite_form(algorithm='padic')
[1 2 3]
[0 3 6]
[0 0 0]
sage: matrix(ZZ,3,[1..9]).hermite_form(algorithm='default')
```

```
[1 2 3]
[0 3 6]
[0 0 0]
```

The 'ntl' algorithm doesn't work on matrices that do not have full rank.:

```
sage: matrix(ZZ,3,[1..9]).hermite_form(algorithm='ntl')
...
ValueError: ntl only computes HNF for square matrices of full rank.
sage: matrix(ZZ,3,[0] +[2..9]).hermite_form(algorithm='ntl')
[1 0 0]
[0 1 0]
[0 0 3]
```

elementary_divisors()

Return the elementary divisors of self, in order.

Warning: This is MUCH faster than the smith_form function.

The elementary divisors are the invariants of the finite abelian group that is the cokernel of *left* multiplication of this matrix. They are ordered in reverse by divisibility.

INPUT:

- `self` - matrix
- `algorithm` - (default: 'pari')
  - `'pari'`: works robustly, but is slower.
  - `'linbox'` - use linbox (currently off, broken)

OUTPUT: list of integers

Note: These are the invariants of the cokernel of *left* multiplication:

```
sage: M = Matrix([[3,0,1],[0,1,0]])
sage: M
[3 0 1]
[0 1 0]
sage: M.elementary_divisors()
[1, 1]
sage: M.transpose().elementary_divisors()
[1, 1, 0]
```

EXAMPLES:

```
sage: matrix(3, range(9)).elementary_divisors()
[1, 3, 0]
sage: matrix(3, range(9)).elementary_divisors(algorithm='pari')
[1, 3, 0]
sage: C = MatrixSpace(ZZ,4)([3,4,5,6,7,3,8,10,14,5,6,7,2,2,10,9])
sage: C.elementary_divisors()
[1, 1, 1, 687]

sage: M = matrix(ZZ, 3, [1,5,7, 3,6,9, 0,1,2])
sage: M.elementary_divisors()
[1, 1, 6]
```

This returns a copy, which is safe to change:

```
sage: edivs = M.elementary_divisors()
sage: edivs.pop()
6
sage: M.elementary_divisors()
[1, 1, 6]
```

See Also:

smith_form()

frobenius()

Return the Frobenius form (rational canonical form) of this matrix.

INPUT: flag -an integer:

- 0 - (default) return the Frobenius form of this matrix.
- 1 - return only the elementary divisor polynomials, as polynomials in var.
- 2 - return a two-components vector [F,B] where F is the Frobenius form and B is the basis change so that $M = B^{-1}FB$.
- var - a string (default: 'x')

INPUT:

- flag - 0 (default), 1 or 2 as described above

ALGORITHM: uses pari's matfrobenius()

EXAMPLE:

```
sage: A = MatrixSpace(ZZ, 3)(range(9))
sage: A.frobenius(0)
[ 0  0  0]
[ 1  0 18]
[ 0  1 12]
sage: A.frobenius(1)
[x^3 - 12*x^2 - 18*x]
sage: A.frobenius(1, var='y')
[y^3 - 12*y^2 - 18*y]
sage: A.frobenius(2)
([ 0  0  0]
[ 1  0 18]
[ 0  1 12],
[    -1      2     -1]
[     0  23/15 -14/15]
[     0  -2/15   1/15])
sage: a=matrix([])
sage: a.frobenius(2)
([], [])
sage: a.frobenius(0)
[]
sage: a.frobenius(1)
[]
sage: B = random_matrix(ZZ,2,3)
sage: B.frobenius()
...
ArithmeticError: frobenius matrix of non-square matrix not defined.
```

AUTHORS:

- Martin Albrect (2006-04-02)

TODO: - move this to work for more general matrices than just over Z. This will require fixing how PARI polynomials are coerced to Sage polynomials.

gcd()

Return the gcd of all entries of self; very fast.

EXAMPLES:

```
sage: a = matrix(ZZ,2, [6,15,-6,150])
sage: a.gcd()
3
```

height()

Return the height of this matrix, i.e., the max absolute value of the entries of the matrix.

OUTPUT: A nonnegative integer.

EXAMPLE:

```
sage: a = Mat(ZZ,3)(range(9))
sage: a.height()
8
sage: a = Mat(ZZ,2,3)([-17,3,-389,15,-1,0]); a
[ -17    3 -389]
[  15   -1    0]
sage: a.height()
389
```

hermite_form()

Return the Hermite normal form of self.

This is a synonym for `self.echelon_form(...)`. See the documentation for `self.echelon_form` for more details.

EXAMPLES:

```
sage: A = matrix(ZZ, 3, 5, [-1, -1, -2, 2, -2, -4, -19, -17, 1, 2, -3, 1, 1, -4, 1])
sage: E, U = A.hermite_form(transformation=True)
sage: E
[   1    0   52 -133  109]
[   0    1   19  -47   38]
[   0    0   69 -178  145]
sage: U
[-46   3  11]
[-16   1   4]
[-61   4  15]
sage: U*A
[   1    0   52 -133  109]
[   0    1   19  -47   38]
[   0    0   69 -178  145]
sage: A.hermite_form()
[   1    0   52 -133  109]
[   0    1   19  -47   38]
[   0    0   69 -178  145]
```

TESTS: This example illustrated trac 2398.

```
sage: a = matrix([(0, 0, 3), (0, -2, 2), (0, 1, 2), (0, -2, 5)])
sage: a.hermite_form()
[0 1 2]
[0 0 3]
[0 0 0]
[0 0 0]
```

index_in_saturation()

Return the index of self in its saturation.

INPUT:

- `proof` - (default: use proof.linear_algebra()); if False, the determinant calculations are done with proof=False.

OUTPUT:

- `positive integer` - the index of the row span of this matrix in its saturation

ALGORITHM: Use Hermite normal form twice to find an invertible matrix whose inverse transforms a matrix with the same row span as self to its saturation, then compute the determinant of that matrix.

EXAMPLES:

```
sage: A = matrix(ZZ, 2,3, [1..6]); A
[1 2 3]
[4 5 6]
sage: A.index_in_saturation()
3
sage: A.saturation()
[1 2 3]
[1 1 1]
```

insert_row()

Create a new matrix from self with.

INPUT:

- index - integer
- row - a vector

EXAMPLES:

```
sage: X = matrix(ZZ,3,range(9)); X
[0 1 2]
[3 4 5]
[6 7 8]
sage: X.insert_row(1, [1,5,-10])
[  0   1   2]
[  1   5 -10]
[  3   4   5]
[  6   7   8]
sage: X.insert_row(0, [1,5,-10])
[  1   5 -10]
[  0   1   2]
[  3   4   5]
[  6   7   8]
sage: X.insert_row(3, [1,5,-10])
[  0   1   2]
[  3   4   5]
[  6   7   8]
[  1   5 -10]
```

is_LLL_reduced()

Return True if this lattice is (δ, η)-LLL reduced. See self.LLL for a definition of LLL reduction.

INPUT:

- delta - parameter as described above (default: 3/4)
- eta - parameter as described above (default: 0.501)

EXAMPLE:

```
sage: A = random_matrix(ZZ, 10, 10)
sage: L = A.LLL()
sage: A.is_LLL_reduced()
False
sage: L.is_LLL_reduced()
True
```

kernel_matrix()

The options are exactly like self.kernel(...), but returns a matrix A whose rows form a basis for the left kernel, i.e., so that A*self = 0.

This is mainly useful to avoid all overhead associated with creating a free module.

EXAMPLES:

```
sage: A = matrix(ZZ, 3, 3, [1..9])
sage: A.kernel_matrix()
[-1  2 -1]
```

Note that the basis matrix returned above is not in Hermite/echelon form.

```
sage: A.kernel()
Free module of degree 3 and rank 1 over Integer Ring
Echelon basis matrix:
[ 1 -2  1]
```

We compute another kernel:

```
sage: A = matrix(ZZ, 4, 2, [2, -1, 1, 1, -18, -1, -1, -5])
sage: K = A.kernel_matrix(); K
[-17 -20  -3   0]
[  7   3   1  -1]
```

K is a basis for the left kernel:

```
sage: K*A
[0 0]
[0 0]
```

We illustrate the LLL flag:

```
sage: L = A.kernel_matrix(LLL=True); L
[  7   3   1  -1]
[  4 -11   0  -3]
sage: K.hermite_form()
[ 1 64  3 12]
[ 0 89  4 17]
sage: L.hermite_form()
[ 1 64  3 12]
[ 0 89  4 17]
```

Two kernel matrices via PARI, one of full rank:

```
sage: B = matrix(ZZ, [[2,-1,1],[1,-1,0],[-5,4,-1],[-8,6,-2]])
sage: B.kernel_matrix(algorithm='pari')
[ 1  1 -1  1]
[ 0  2  2 -1]
sage: C = matrix(ZZ, [[1,1,2],[1,1,4]])
sage: D = C.kernel_matrix(algorithm='pari'); D
[]
sage: D.ncols()
2
```

minpoly()

INPUT:

- `var` - a variable name
- `algorithm` - 'linbox' (default) 'generic'

Note: Linbox charpoly disabled on 64-bit machines, since it hangs in many cases.

EXAMPLES:

```
sage: A = matrix(ZZ,6, range(36))
sage: A.minpoly()
x^3 - 105*x^2 - 630*x
sage: n=6; A = Mat(ZZ,n)([k^2 for k in range(n^2)])
sage: A.minpoly()
x^4 - 2695*x^3 - 257964*x^2 + 1693440*x
```

pivots()

Return the pivot column positions of this matrix as a list of Python integers.

This returns a list, of the position of the first nonzero entry in each row of the echelon form.

OUTPUT:

- `list` - a list of Python ints

EXAMPLES:

```
sage: n = 3; A = matrix(ZZ,n,range(n^2)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: A.pivots()
[0, 1]
sage: A.echelon_form()
[ 3  0 -3]
[ 0  1  2]
[ 0  0  0]
```

prod_of_row_sums()

Return the product of the sums of the entries in the submatrix of self with given columns.

INPUT:

- `cols` - a list (or set) of integers representing columns of self.

OUTPUT: an integer

EXAMPLES:

```
sage: a = matrix(ZZ,2,3,[1..6]); a
[1 2 3]
[4 5 6]
sage: a.prod_of_row_sums([0,2])
40
sage: (1+3)*(4+6)
40
sage: a.prod_of_row_sums(set([0,2]))
40
```

randomize()

Randomize density proportion of the entries of this matrix, leaving the rest unchanged.

The parameters are the same as the integer ring's random_element function.

If x and y are given, randomized entries of this matrix to be between x and y and have density 1.

INPUT:

- `self` - a mutable matrix over ZZ
- `density` - a float between 0 and 1
- `x, y` - if not None are passed to ZZ.random_element function as the upper and lower endpoints in the uniform distribution
- `distribution` - would also be passed into ZZ.random_element if given

OUTPUT:

- `None` - the matrix is modified in place

EXAMPLES:

```
sage: A = matrix(ZZ, 2,3, [1..6]); A
[1 2 3]
[4 5 6]
sage: A.randomize()
sage: A
```

```
[-8  2  0]
[ 0  1 -1]
sage: A.randomize(x=-30,y=30)
sage: A
[  5 -19  24]
[ 24  23  -9]
```

rank()

Return the rank of this matrix.

OUTPUT:

- nonnegative integer - the rank

Note: The rank is cached.

ALGORITHM: First check if the matrix has maxim posible rank by working modulo one random prime. If not call Linbox's rank function.

EXAMPLES:

```
sage: a = matrix(ZZ,2,3,[1..6]); a
[1 2 3]
[4 5 6]
sage: a.rank()
2
sage: a = matrix(ZZ,3,3,[1..9]); a
[1 2 3]
[4 5 6]
[7 8 9]
sage: a.rank()
2
```

Here's a bigger example - the rank is of course still 2:

```
sage: a = matrix(ZZ,100,[1..100^2]); a.rank()
2
```

rational_reconstruction()

Use rational reconstruction to lift self to a matrix over the rational numbers (if possible), where we view self as a matrix modulo N.

INPUT:

- N - an integer

OUTPUT:

- matrix - over QQ or raise a ValueError

EXAMPLES: We create a random 4x4 matrix over ZZ.

```
sage: A = matrix(ZZ, 4, [4, -4, 7, 1, -1, 1, -1, -12, -1, -1, 1, -1, -3, 1, 5, -1])
```

There isn't a unique rational reconstruction of it:

```
sage: A.rational_reconstruction(11)
...
ValueError: Rational reconstruction of 4 (mod 11) does not exist.
```

We throw in a denominator and reduce the matrix modulo 389 - it does rationally reconstruct.

```
sage: B = (A/3 % 389).change_ring(ZZ)
sage: B.rational_reconstruction(389) == A/3
True
```

right_kernel()

Return the right kernel of this matrix, as a module over the integers. This is the saturated ZZ-module spanned by all the column vectors v such that self*v = 0.

INPUT:

- `algorithm` - 'padic': a new p-adic based algorithm 'pari': use PARI
- `LLL` - bool (default: False); if True the basis is an LLL reduced basis; otherwise, it is an echelon basis.
- `proof` - None (default: proof.linear_algebra()); if False, impacts how determinants are computed.

By convention if self has 0 columnss, the right kernel is of dimension 0, whereas the right kernel is the whole domain if self has 0 rows.

EXAMPLES:

```
sage: M = MatrixSpace(ZZ,2,4)(range(8))
sage: M.right_kernel()
Free module of degree 4 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1  0 -3  2]
[ 0  1 -2  1]
```

saturation()

Return a saturation matrix of self, which is a matrix whose rows span the saturation of the row span of self. This is not unique.

The saturation of a $\mathbf{Z}$ module M embedded in $\mathbf{Z}^n$ is the a module S that contains M with finite index such that $\mathbf{Z}^n/S$ is torsion free. This function takes the row span M of self, and finds another matrix of full rank with row span the saturation of M.

INPUT:

- `p` - (default: 0); if nonzero given, saturate only at the prime p, i.e., return a matrix whose row span is a $\mathbf{Z}$-module S that contains self and such that the index of S in its saturation is coprime to p. If p is None, return full saturation of self.
- `proof` - (default: use proof.linear_algebra()); if False, the determinant calculations are done with proof=False.
- `max_dets` - (default: 5); technical parameter - max number of determinant to compute when bounding prime divisor of self in its saturation.

OUTPUT:

- `matrix` - a matrix over ZZ

Note: The result is *not* cached.

ALGORITHM: 1. Replace input by a matrix of full rank got from a subset of the rows. 2. Divide out any common factors from rows. 3. Check max_dets random dets of submatrices to see if their gcd (with p) is 1 - if so matrix is saturated and we're done. 4. Finally, use that if A is a matrix of full rank, then $hnf(transpose(A))^{-1} * A$ is a saturation of A.

EXAMPLES:

```
sage: A = matrix(ZZ, 3, 5, [-51, -1509, -71, -109, -593, -19, -341, 4, 86, 98, 0, -246, -11,
sage: A.echelon_form()
[      1       5    2262   20364   56576]
[      0       6   35653  320873  891313]
[      0       0   42993  386937 1074825]
sage: S = A.saturation(); S
[  -51 -1509   -71  -109  -593]
[  -19  -341     4    86    98]
[   35   994    43    51   347]
```

Notice that the saturation spans a different module than A.

```
sage: S.echelon_form()
[ 1  2  0  8 32]
[ 0  3  0 -2 -6]
[ 0  0  1  9 25]
```

```
sage: V = A.row_space(); W = S.row_space()
sage: V.is_submodule(W)
True
sage: V.index_in(W)
85986
sage: V.index_in_saturation()
85986
```

We illustrate each option:

```
sage: S = A.saturation(p=2)
sage: S = A.saturation(proof=False)
sage: S = A.saturation(max_dets=2)
```

smith_form()

Returns matrices S, U, and V such that S = U*self*V, and S is in Smith normal form. Thus S is diagonal with diagonal entries the ordered elementary divisors of S.

Warning: The elementary_divisors function, which returns the diagonal entries of S, is VASTLY faster than this function.

The elementary divisors are the invariants of the finite abelian group that is the cokernel of this matrix. They are ordered in reverse by divisibility.

EXAMPLES:

```
sage: A = MatrixSpace(IntegerRing(), 3)(range(9))
sage: D, U, V = A.smith_form()
sage: D
[1 0 0]
[0 3 0]
[0 0 0]
sage: U
[ 0  1  0]
[ 0 -1  1]
[-1  2 -1]
sage: V
[-1  4  1]
[ 1 -3 -2]
[ 0  0  1]
sage: U*A*V
[1 0 0]
[0 3 0]
[0 0 0]
```

It also makes sense for nonsquare matrices:

```
sage: A = Matrix(ZZ,3,2,range(6))
sage: D, U, V = A.smith_form()
sage: D
[1 0]
[0 2]
[0 0]
sage: U
[ 0  1  0]
[ 0 -1  1]
[-1  2 -1]
sage: V
[-1  3]
[ 1 -2]
sage: U * A * V
```

```
[1 0]
[0 2]
[0 0]
```

Empty matrices are handled sensibly (see trac #3068):

```
sage: m = MatrixSpace(ZZ, 2,0)(0); d,u,v = m.smith_form(); u*m*v == d
True
sage: m = MatrixSpace(ZZ, 0,2)(0); d,u,v = m.smith_form(); u*m*v == d
True
sage: m = MatrixSpace(ZZ, 0,0)(0); d,u,v = m.smith_form(); u*m*v == d
True
```

See Also:

elementary_divisors()

stack()

Return the matrix self on top of other: [self] [other]

EXAMPLES:

```
sage: M = Matrix(ZZ, 2, 3, range(6))
sage: N = Matrix(ZZ, 1, 3, [10,11,12])
sage: M.stack(N)
[ 0  1  2]
[ 3  4  5]
[10 11 12]
```

symplectic_form()

Find a symplectic basis for self if self is an anti-symmetric, alternating matrix.

Returns a pair (F, C) such that the rows of C form a symplectic basis for self and F = C * self * C.transpose().

Raises a ValueError if self is not anti-symmetric, or self is not alternating.

Anti-symmetric means that $M = -M^t$. Alternating means that the diagonal of M is identically zero.

A symplectic basis is a basis of the form $e_1, \ldots, e_j, f_1, \ldots f_j, z_1, \ldots, z_k$ such that

- $z_i M v^t = 0$ for all vectors v
- $e_i M {e_j}^t = 0$ for all i, j
- $f_i M {f_j}^t = 0$ for all i, j
- $e_i M {f_i}^t = 1$ for all i
- $e_i M {f_j}^t = 0$ **for all** i **not equal** j.

The ordering for the factors $d_i | d_{i+1}$ and for the placement of zeroes was chosen to agree with the output of smith_form.

See the example for a pictorial description of such a basis.

EXAMPLES:

```
sage: E = matrix(ZZ, 5, 5, [0, 14, 0, -8, -2, -14, 0, -3, -11, 4, 0, 3, 0, 0, 0, 8, 11, 0, 0
[  0  14   0  -8  -2]
[-14   0  -3 -11   4]
[  0   3   0   0   0]
[  8  11   0   0   8]
[  2  -4   0  -8   0]
sage: F, C = E.symplectic_form()
sage: F
[ 0  0  1  0  0]
[ 0  0  0  2  0]
[-1  0  0  0  0]
[ 0 -2  0  0  0]
```

```
[ 0  0  0  0  0]
sage: F == C * E * C.transpose()
True
sage: E.smith_form()[0]
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 2 0 0]
[0 0 0 2 0]
[0 0 0 0 0]
```

transpose()

Returns the transpose of self, without changing self.

EXAMPLES:

We create a matrix, compute its transpose, and note that the original matrix is not changed.

```
sage: A = matrix(ZZ,2,3,xrange(6))
sage: type(A)
<type 'sage.matrix.matrix_integer_dense.Matrix_integer_dense'>
sage: B = A.transpose()
sage: print B
[0 3]
[1 4]
[2 5]
sage: print A
[0 1 2]
[3 4 5]

sage: A.subdivide(None, 1); A
[0|1 2]
[3|4 5]
sage: A.transpose()
[0 3]
[---]
[1 4]
[2 5]
```

clear_mpz_globals()

gmp_randrange()

init_mpz_globals()

tune_multiplication()

Compare various multiplication algorithms.

INPUT:

- `k` - integer; affects numbers of trials
- `nmin` - integer; smallest matrix to use
- `nmax` - integer; largest matrix to use
- `bitmin` - integer; smallest bitsize
- `bitmax` - integer; largest bitsize

OUTPUT:

- `prints what doing then who wins` - multimodular or classical

EXAMPLES:

```
sage: from sage.matrix.matrix_integer_dense import tune_multiplication
sage: tune_multiplication(2, nmin=10, nmax=60, bitmin=2,bitmax=8)
10 2 0.2
...
```

32.17 Dense matrices over the rational field.

EXAMPLES:

We create a 3x3 matrix with rational entries and do some operations with it.

```
sage: a = matrix(QQ, 3,3, [1,2/3, -4/5, 1,1,1, 8,2, -3/19]); a
[    1   2/3  -4/5]
[    1     1     1]
[    8     2 -3/19]
sage: a.det()
2303/285
sage: a.charpoly()
x^3 - 35/19*x^2 + 1259/285*x - 2303/285
sage: b = a^(-1); b
[ -615/2303  -426/2303   418/2303]
[ 2325/2303  1779/2303  -513/2303]
[-1710/2303   950/2303    95/2303]
sage: b.det()
285/2303
sage: a == b
False
sage: a < b
False
sage: b < a
True
sage: a > b
True
sage: a*b
[1 0 0]
[0 1 0]
[0 0 1]
```

TESTS:

```
sage: a = matrix(QQ,2,range(4), sparse=False)
sage: loads(dumps(a)) == a
True
```

class MatrixWindow()

class Matrix_rational_dense()

antitranspose()

Returns the antitranspose of self, without changing self.

EXAMPLES:

```
sage: A = matrix(QQ,2,3,range(6))
sage: type(A)
<type 'sage.matrix.matrix_rational_dense.Matrix_rational_dense'>
```

```
sage: A.antitranspose()
[5 2]
[4 1]
[3 0]
sage: A
[0 1 2]
[3 4 5]

sage: A.subdivide(1,2); A
[0 1|2]
[---+-]
[3 4|5]
sage: A.antitranspose()
[5|2]
[-+-]
[4|1]
[3|0]
```

change_ring()

Create the matrix over R with entries the entries of self coerced into R.

EXAMPLES:

```
sage: a = matrix(QQ,2,[1/2,-1,2,3])
sage: a.change_ring(GF(3))
[2 2]
[2 0]
sage: a.change_ring(ZZ)
...
TypeError: matrix has denominators so can't change to ZZ.
sage: b = a.change_ring(QQ['x']); b
[1/2  -1]
[  2   3]
sage: b.parent()
Full MatrixSpace of 2 by 2 dense matrices over Univariate Polynomial Ring in x over Rational
```

TESTS:

Make sure that subdivisions are preserved when changing rings:

```
sage: a = matrix(QQ, 3, range(9))
sage: a.subdivide(2,1); a
[0|1 2]
[3|4 5]
[-+---]
[6|7 8]
sage: a.change_ring(ZZ).change_ring(QQ)
[0|1 2]
[3|4 5]
[-+---]
[6|7 8]
sage: a.change_ring(GF(3))
[0|1 2]
[0|1 2]
[-+---]
[0|1 2]
```

charpoly()

Return the characteristic polynomial of this matrix.

INPUT:

- `var` - 'x' (string)
- `algorithm` - 'linbox' (default) or 'generic'

OUTPUT: a polynomial over the rational numbers.

EXAMPLES:

```
sage: a = matrix(QQ, 3, [4/3, 2/5, 1/5, 4, -3/2, 0, 0, -2/3, 3/4])
sage: f = a.charpoly(); f
x^3 - 7/12*x^2 - 149/40*x + 97/30
sage: f(a)
[0 0 0]
[0 0 0]
[0 0 0]
```

column()

Return the i-th column of this matrix as a dense vector.

INPUT:
- `i` - integer
- `from_list` - ignored

EXAMPLES:

```
sage: matrix(QQ,2,[1/5,-2/3,3/4,4/9]).column(1)
(-2/3, 4/9)
sage: matrix(QQ,2,[1/5,-2/3,3/4,4/9]).column(1,from_list=True)
(-2/3, 4/9)
sage: matrix(QQ,2,[1/5,-2/3,3/4,4/9]).column(-1)
(-2/3, 4/9)
sage: matrix(QQ,2,[1/5,-2/3,3/4,4/9]).column(-2)
(1/5, 3/4)
```

decomposition()

Returns the decomposition of the free module on which this matrix A acts from the right (i.e., the action is x goes to x A), along with whether this matrix acts irreducibly on each factor. The factors are guaranteed to be sorted in the same way as the corresponding factors of the characteristic polynomial.

Let A be the matrix acting from the on the vector space V of column vectors. Assume that A is square. This function computes maximal subspaces W_1, ..., W_n corresponding to Galois conjugacy classes of eigenvalues of A. More precisely, let f(X) be the characteristic polynomial of A. This function computes the subspace $W_i = ker(g_(A)^n)$, where g_i(X) is an irreducible factor of f(X) and g_i(X) exactly divides f(X). If the optional parameter is_diagonalizable is True, then we let W_i = ker(g(A)), since then we know that ker(g(A)) = $ker(g(A)^n)$.

If dual is True, also returns the corresponding decomposition of V under the action of the transpose of A. The factors are guarenteed to correspond.

INPUT:

- `is_diagonalizable` - ignored
- `dual` - whether to also return decompositions for the dual
- `algorithm`
  - 'default': use default algorithm for computing Echelon forms
  - 'multimodular': much better if the answers factors have small height
- `height_guess` - positive integer; only used by the multimodular algorithm
- `proof` - bool or None (default: None, see proof.linear_algebra or sage.structure.proof); only used by the multimodular algorithm. Note that the Sage global default is proof=True.

Note: IMPORTANT: If you expect that the subspaces in the answer are spanned by vectors with small height coordinates, use algorithm='multimodular' and height_guess=1; this is potentially much faster than the default. If you know for a fact the answer will be very small, use algorithm='multimodular', height_guess=bound on height, proof=False.

You can get very very fast decomposition with proof=False.

EXAMPLES:

```
sage: a = matrix(QQ,3,[1..9])
sage: a.decomposition()
[
(Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2  1], True),
(Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1  0 -1]
[ 0  1  2], True)
]
```

denominator()

Return the denominator of this matrix.

OUTPUT: a Sage Integer

EXAMPLES:

```
sage: b = matrix(QQ,2,range(6)); b[0,0]=-5007/293; b
[-5007/293         1         2]
[         3         4         5]
sage: b.denominator()
293
```

determinant()

Return the determinant of this matrix.

INPUT:

- `proof` - bool or None; if None use proof.linear_algebra(); only relevant for the padic algorithm.
- `algorithm`:

  "default" – use PARI for up to 7 rows, then use integer
  "pari" – use PARI
  "integer" – clear denominators and call det on integer matrix

Note: It would be *VERY VERY* hard for det to fail even with proof=False.

ALGORITHM: Clear denominators and call the integer determinant function.

EXAMPLES:

```
sage: m = matrix(QQ,3,[1,2/3,4/5, 2,2,2, 5,3,2/5])
sage: m.determinant()
-34/15
sage: m.charpoly()
x^3 - 17/5*x^2 - 122/15*x + 34/15
```

echelon_form()

INPUT:

- `algorithm`
  - 'default' (default): use heuristic choice
  - 'padic': an algorithm based on the IML p-adic solver.
  - 'multimodular': uses a multimodular algorithm the uses linbox modulo many primes.
  - 'classical': just clear each column using Gauss elimination
- `height_guess, **kwds` - all passed to the multimodular algorithm; ignored by the p-adic algorithm.
- `proof` - bool or None (default: None, see proof.linear_algebra or sage.structure.proof). Passed to the multimodular algorithm. Note that the Sage global default is proof=True.

OUTPUT: self is no in reduced row echelon form.

EXAMPLES:

```
sage: a = matrix(QQ, 4, range(16)); a[0,0] = 1/19; a[0,1] = 1/5; a
[1/19  1/5    2    3]
[   4    5    6    7]
[   8    9   10   11]
[  12   13   14   15]
sage: a.echelon_form()
[      1       0       0 -76/157]
[      0       1       0  -5/157]
[      0       0       1 238/157]
[      0       0       0       0]
sage: a.echelon_form(algorithm='multimodular')
[      1       0       0 -76/157]
[      0       1       0  -5/157]
[      0       0       1 238/157]
[      0       0       0       0]
```

echelonize()

INPUT:

- algorithm
- 'default' (default): use heuristic choice
- 'padic': an algorithm based on the IML p-adic solver.
- 'multimodular': uses a multimodular algorithm the uses linbox modulo many primes.
- 'classical': just clear each column using Gauss elimination
- height_guess, **kwds - all passed to the multimodular algorithm; ignored by the p-adic algorithm.
- proof - bool or None (default: None, see proof.linear_algebra or sage.structure.proof). Passed to the multimodular algorithm. Note that the Sage global default is proof=True.

OUTPUT:

- matrix - the reduced row echelon for of self.

EXAMPLES:

```
sage: a = matrix(QQ, 4, range(16)); a[0,0] = 1/19; a[0,1] = 1/5; a
[1/19  1/5    2    3]
[   4    5    6    7]
[   8    9   10   11]
[  12   13   14   15]
sage: a.echelonize(); a
[      1       0       0 -76/157]
[      0       1       0  -5/157]
[      0       0       1 238/157]
[      0       0       0       0]

sage: a = matrix(QQ, 4, range(16)); a[0,0] = 1/19; a[0,1] = 1/5
sage: a.echelonize(algorithm='multimodular'); a
[      1       0       0 -76/157]
[      0       1       0  -5/157]
[      0       0       1 238/157]
[      0       0       0       0]
```

height()

Return the height of this matrix, which is the maximum of the absolute values of all numerators and denominators of entries in this matrix.

OUTPUT: an Integer

EXAMPLES:

```
sage: b = matrix(QQ,2,range(6)); b[0,0]=-5007/293; b
[-5007/293         1         2]
[         3         4         5]
sage: b.height()
5007
```

invert()

Compute the inverse of this matrix.

Warning: This function is deprecated. Use `inverse` instead.

EXAMPLES:

```
sage: a = matrix(QQ,3,range(9))
sage: a.invert()
...
ZeroDivisionError: input matrix must be nonsingular
```

minpoly()

Return the minimal polynomial of this matrix.

INPUT:

- `var` - 'x' (string)
- `algorithm` - 'linbox' (default) or 'generic'

OUTPUT: a polynomial over the rational numbers.

EXAMPLES:

```
sage: a = matrix(QQ, 3, [4/3, 2/5, 1/5, 4, -3/2, 0, 0, -2/3, 3/4])
sage: f = a.minpoly(); f
x^3 - 7/12*x^2 - 149/40*x + 97/30
sage: a = Mat(ZZ,4)(range(16))
sage: f = a.minpoly(); f.factor()
x * (x^2 - 30*x - 80)
sage: f(a) == 0
True

sage: a = matrix(QQ, 4, [1..4^2])
sage: factor(a.minpoly())
x * (x^2 - 34*x - 80)
sage: factor(a.minpoly('y'))
y * (y^2 - 34*y - 80)
sage: factor(a.charpoly())
x^2 * (x^2 - 34*x - 80)
sage: b = matrix(QQ, 4, [-1, 2, 2, 0, 0, 4, 2, 2, 0, 0, -1, -2, 0, -4, 0, 4])
sage: a = matrix(QQ, 4, [1, 1, 0,0, 0,1,0,0, 0,0,5,0, 0,0,0,5])
sage: c = b^(-1)*a*b
sage: factor(c.minpoly())
(x - 5) * (x - 1)^2
sage: factor(c.charpoly())
(x - 5)^2 * (x - 1)^2
```

prod_of_row_sums()

randomize()

Randomize density proportion of the entries of this matrix, leaving the rest unchanged.

If x and y are given, randomized entries of this matrix have numerators and denominators bounded by x and y and have density 1.

INPUT:

- density – number between 0 and 1 (default: 1)
- num_bound – numerator bound (default: 2)
- den_bound – denominator bound (default: 2)
- distribution – None or '1/n' (default: None); if '1/n' then num_bound, den_bound are ignored and numbers are chosen using the GMP function mpq_randomize_entry_recip_uniform

EXAMPLES:

```
sage: a = matrix(QQ,2,4); a.randomize(); a
[ 0 -1  2 -2]
[ 1 -1  2  1]
sage: a = matrix(QQ,2,4); a.randomize(density=0.5); a
[ -1  -2   0   0]
[  0   0 1/2   0]
sage: a = matrix(QQ,2,4); a.randomize(num_bound=100, den_bound=100); a
[ 14/27  21/25  43/42 -48/67]
[-19/55  64/67 -11/51     76]
sage: a = matrix(QQ,2,4); a.randomize(distribution='1/n'); a
[      3     1/9     1/2     1/4]
[      1    1/39       2 -1955/2]
```

rank()

Return the rank of this matrix.

EXAMPLES:: sage: matrix(QQ,3,[1..9]).rank() 2 sage: matrix(QQ,100,[1..100^2]).rank() 2

right_kernel()

Return the right kernel of this matrix, as a vector space over QQ. For a left kernel use self.left_kernel() or just self.kernel().

INPUT:

- algorithm - 'padic' (or 'default'): use IML's p-adic nullspace algorithm
- anything else - passed on to the generic echelon-form based algorithm.
- **kwds - passed onto to echelon form algorithm in the echelon case.

EXAMPLES:

A non-trivial right kernel over the rationals::

```
sage: A = matrix(QQ, [[2,1,-5,-8],[-1,-1,4,6],[1,0,-1,-2]])
sage: A.right_kernel()
Vector space of degree 4 and dimension 2 over Rational Field
Basis matrix:
[   1    0   -2  3/2]
[   0    1    1 -1/2]
```

A trivial right kernel, plus left kernel (via superclass)::

```
sage: M=Matrix(QQ,[[1/2,3],[0,1],[1,1]])
sage: M.right_kernel()
Vector space of degree 2 and dimension 0 over Rational Field
Basis matrix:
[]
sage: M.left_kernel()
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[   1 -5/2 -1/2]
```

row()

Return the i-th row of this matrix as a dense vector.

INPUT: • `i` - integer
• `from_list` - ignored

EXAMPLES:

```
sage: matrix(QQ,2,[1/5,-2/3,3/4,4/9]).row(1)
(3/4, 4/9)
sage: matrix(QQ,2,[1/5,-2/3,3/4,4/9]).row(1,from_list=True)
(3/4, 4/9)
sage: matrix(QQ,2,[1/5,-2/3,3/4,4/9]).row(-2)
(1/5, -2/3)
```

set_row_to_multiple_of_row()
Set row i equal to s times row j.
EXAMPLES:

```
sage: a = matrix(QQ,2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: a.set_row_to_multiple_of_row(1,0,-3)
sage: a
[ 0  1  2]
[ 0 -3 -6]
```

transpose()
Returns the transpose of self, without changing self.
EXAMPLES:
We create a matrix, compute its transpose, and note that the original matrix is not changed.

```
sage: A = matrix(QQ,2,3,xrange(6))
sage: type(A)
<type 'sage.matrix.matrix_rational_dense.Matrix_rational_dense'>
sage: B = A.transpose()
sage: print B
[0 3]
[1 4]
[2 5]
sage: print A
[0 1 2]
[3 4 5]

sage: A.subdivide(None, 1); A
[0|1 2]
[3|4 5]
sage: A.transpose()
[0 3]
[---]
[1 4]
[2 5]
```

clear_mpz_globals()

gmp_randrange()

init_mpz_globals()

32.18 Dense matrices over the Real Double Field using NumPy

EXAMPLES:

```
sage: b=Mat(RDF,2,3).basis()
sage: b[0]
[1.0 0.0 0.0]
[0.0 0.0 0.0]
```

We deal with the case of zero rows or zero columns:

```
sage: m = MatrixSpace(RDF,0,3)
sage: m.zero_matrix()
[]
```

TESTS:

```
sage: a = matrix(RDF,2,range(4), sparse=False)
sage: loads(dumps(a)) == a
True
sage: MatrixSpace(RDF,0,0).zero_matrix().inverse()
[]
```

AUTHORS:

- Jason Grout (2008-09): switch to numpy backend, factored out the Matrix_double_dense class
- Josh Kantor
- William Stein: many bug fixes and touch ups.

class Matrix_real_double_dense()

Class that implements matrices over the real double field. These are supposed to be fast matrix operations using C doubles. Most operations are implemented using numpy which will call the underlying BLAS on the system.

EXAMPLES:

```
sage: m = Matrix(RDF, [[1,2],[3,4]])
sage: m**2
[ 7.0 10.0]
[15.0 22.0]
sage: n= m^(-1); n
[-2.0  1.0]
[ 1.5 -0.5]
```

To compute eigenvalues the use the functions left_eigenvectors or right_eigenvectors

```
sage: p,e = m.right_eigenvectors()
```

the result of eigen is a pair (p,e), where p is a list of eigenvalues and the e is a matrix whose columns are the eigenvectors.

To solve a linear system Ax = b where A = [[1,2],[3,4]] and b = [5,6].

```
sage: b = vector(RDF,[5,6])
sage: m.solve_left(b)
(-4.0, 4.5)
```

See the commands qr, lu, and svd for QR, LU, and singular value decomposition.

32.19 Dense matrices over the Complex Double Field using NumPy

EXAMPLES:

```
sage: b=Mat(CDF,2,3).basis()
sage: b[0]
[1.0   0   0]
[  0   0   0]
```

We deal with the case of zero rows or zero columns:

```
sage: m = MatrixSpace(CDF,0,3)
sage: m.zero_matrix()
[]
```

TESTS:

```
sage: a = matrix(CDF,2,[i+(4-i)*I for i in range(4)], sparse=False)
sage: loads(dumps(a)) == a
True
sage: Mat(CDF,0,0).zero_matrix().inverse()
[]
```

AUTHORS:

- Jason Grout (2008-09): switch to numpy backend
- Josh Kantor
- William Stein: many bug fixes and touch ups.

class Matrix_complex_double_dense()

Class that implements matrices over the real double field. These are supposed to be fast matrix operations using C doubles. Most operations are implemented using numpy which will call the underlying BLAS on the system.

EXAMPLES:

```
sage: m = Matrix(CDF, [[1,2*I],[3+I,4]])
sage: m**2
[-1.0 + 6.0*I       10.0*I]
[15.0 + 5.0*I 14.0 + 6.0*I]
sage: n= m^(-1); n
[  0.333333333333 + 0.333333333333*I   0.166666666667 - 0.166666666667*I]
[ -0.166666666667 - 0.333333333333*I 0.0833333333333 + 0.0833333333333*I]
```

To compute eigenvalues the use the functions left_eigenvectors or right_eigenvectors

```
sage: p,e = m.right_eigenvectors()
```

the result of eigen is a pair (p,e), where p is a list of eigenvalues and the e is a matrix whose columns are the eigenvectors.

To solve a linear system Ax = b where A = [[1,2] and b = [5,6] [3,4]]

```
sage: b = vector(CDF,[5,6])
sage: m.solve_left(b)
(2.66666666667 + 0.666666666667*I, -0.333333333333 - 1.16666666667*I)
```

See the commands qr, lu, and svd for QR, LU, and singular value decomposition.

CHAPTER

THIRTYTHREE

MODULES

33.1 Abstract base class for modules

class Module()

Generic module class.

category()

Return the category to which this module belongs.

endomorphism_ring()

Return the endomorphism ring of this module in its category.

is_atomic_repr()

True if the elements have atomic string representations, in the sense that they print if they print at s, then -s means the negative of s. For example, integers are atomic but polynomials are not.

is_Module()

Return True if x is a module.

EXAMPLES:

```
sage: from sage.modules.module import is_Module
sage: M = FreeModule(RationalField(),30)
sage: is_Module(M)
True
sage: is_Module(10)
False
```

is_VectorSpace()

Return True if x is a vector space.

EXAMPLES:

```
sage: from sage.modules.module import is_Module, is_VectorSpace
sage: M = FreeModule(RationalField(),30)
sage: is_VectorSpace(M)
True
sage: M = FreeModule(IntegerRing(),30)
sage: is_Module(M)
True
sage: is_VectorSpace(M)
False
```

33.2 Free modules

Sage supports computation with free modules over an arbitrary commutative ring. Nontrivial functionality is available over $\mathbf{Z}$ and fields. All free modules over an integral domain are equipped with an embedding in an ambient vector space and an inner product, which you can specify and change.

Create the free module of rank n over an arbitrary commutative ring R using the command `FreeModule(R,n)`. Equivalently, `R^n` also creates that free module.

The following example illustrates the creation of both a vector space and a free module over the integers and a submodule of it. Use the functions `FreeModule`, `span` and member functions of free modules to create free modules. *Do not use the FreeModulexxx constructors directly.*

EXAMPLES:

```
sage: V = VectorSpace(QQ,3)
sage: W = V.subspace([[1,2,7], [1,1,0]])
sage: W
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1  0 -7]
[ 0  1  7]
sage: C = VectorSpaces(FiniteField(7))
sage: C
Category of vector spaces over Finite Field of size 7
sage: C(W)
Vector space of degree 3 and dimension 2 over Finite Field of size 7
Basis matrix:
[1 0 0]
[0 1 0]

sage: M = ZZ^3
sage: C = VectorSpaces(FiniteField(7))
sage: C(M)
Vector space of dimension 3 over Finite Field of size 7
sage: W = M.submodule([[1,2,7], [8,8,0]])
sage: C(W)
Vector space of degree 3 and dimension 2 over Finite Field of size 7
Basis matrix:
[1 0 0]
[0 1 0]
```

We illustrate the exponent notation for creation of free modules.

```
sage: ZZ^4
Ambient free module of rank 4 over the principal ideal domain Integer Ring
sage: QQ^2
Vector space of dimension 2 over Rational Field
sage: RR^3
Vector space of dimension 3 over Real Field with 53 bits of precision
```

Base ring:

```
sage: R.<x,y> = QQ[]
sage: M = FreeModule(R,2)
sage: M.base_ring()
Multivariate Polynomial Ring in x, y over Rational Field
```

```
sage: VectorSpace(QQ, 10).base_ring()
Rational Field
```

TESTS: We intersect a zero-dimensional vector space with a 1-dimension submodule.

```
sage: V = (QQ^1).span([])
sage: W = ZZ^1
sage: V.intersection(W)
Free module of degree 1 and rank 0 over Integer Ring
Echelon basis matrix:
[]
```

We construct subspaces of real and complex double vector spaces and verify that the element types are correct:

```
sage: V = FreeModule(RDF, 3); V
Vector space of dimension 3 over Real Double Field
sage: V.0
(1.0, 0.0, 0.0)
sage: type(V.0)
<type 'sage.modules.vector_real_double_dense.Vector_real_double_dense'>
sage: W = V.span([V.0]); W
Vector space of degree 3 and dimension 1 over Real Double Field
Basis matrix:
[1.0 0.0 0.0]
sage: type(W.0)
<type 'sage.modules.vector_real_double_dense.Vector_real_double_dense'>
sage: V = FreeModule(CDF, 3); V
Vector space of dimension 3 over Complex Double Field
sage: type(V.0)
<type 'sage.modules.vector_complex_double_dense.Vector_complex_double_dense'>
sage: W = V.span_of_basis([CDF.0 * V.1]); W
Vector space of degree 3 and dimension 1 over Complex Double Field
User basis matrix:
[    0 1.0*I     0]
sage: type(W.0)
<type 'sage.modules.vector_complex_double_dense.Vector_complex_double_dense'>
```

Basis vectors are immutable:

```
sage: A = span([[1,2,3], [4,5,6]], ZZ)
sage: A.0
(1, 2, 3)
sage: A.0[0] = 5
...
ValueError: vector is immutable; please change a copy instead (use self.copy())
```

We can save and load submodules and elements:

```
sage: M = ZZ^3
sage: M == loads(M.dumps())
True
sage: W = M.span_of_basis([[1,2,3],[4,5,19]])
sage: W == loads(W.dumps())
True
sage: v = W.0 + W.1
```

```
sage: v == loads(v.dumps())
True
```

AUTHORS:

- William Stein (2005, 2007)
- David Kohel (2007, 2008)

class ComplexDoubleVectorSpace_class(*n*)

coordinates(*v*)

class FreeModuleFactory()

Create the free module over the given commutative ring of the given rank.

INPUT:

- `base_ring` - a commutative ring
- `rank` - a nonnegative integer
- `sparse` - bool; (default False)
- `inner_product_matrix` - the inner product matrix (default None)

OUTPUT: a free module

Note: In Sage it is the case that there is only one dense and one sparse free ambient module of rank n over R.

EXAMPLES:

First we illustrate creating free modules over various base fields. The base field affects the free module that is created. For example, free modules over a field are vector spaces, and free modules over a principal ideal domain are special in that more functionality is available for them than for completely general free modules.

```
sage: FreeModule(Integers(8),10)
Ambient free module of rank 10 over Ring of integers modulo 8
sage: FreeModule(QQ,10)
Vector space of dimension 10 over Rational Field
sage: FreeModule(ZZ,10)
Ambient free module of rank 10 over the principal ideal domain Integer Ring
sage: FreeModule(FiniteField(5),10)
Vector space of dimension 10 over Finite Field of size 5
sage: FreeModule(Integers(7),10)
Vector space of dimension 10 over Ring of integers modulo 7
sage: FreeModule(PolynomialRing(QQ,'x'),5)
Ambient free module of rank 5 over the principal ideal domain Univariate Polynomial Ring in x ov
sage: FreeModule(PolynomialRing(ZZ,'x'),5)
Ambient free module of rank 5 over the integral domain Univariate Polynomial Ring in x over Inte
```

Of course we can make rank 0 free modules:

```
sage: FreeModule(RealField(100),0)
Vector space of dimension 0 over Real Field with 100 bits of precision
```

Next we create a free module with sparse representation of elements. Functionality with sparse modules is *identical* to dense modules, but they may use less memory and arithmetic may be faster (or slower!).

```
sage: M = FreeModule(ZZ,200,sparse=True)
sage: M.is_sparse()
True
sage: type(M.0)
<type 'sage.modules.free_module_element.FreeModuleElement_generic_sparse'>
```

The default is dense.

```
sage: M = ZZ^200
sage: type(M.0)
<type 'sage.modules.vector_integer_dense.Vector_integer_dense'>
```

Note that matrices associated in some way to sparse free modules are sparse by default:

```
sage: M = FreeModule(Integers(8), 2)
sage: A = M.basis_matrix()
sage: A.is_sparse()
False
sage: Ms = FreeModule(Integers(8), 2, sparse=True)
sage: M == Ms  # as mathematical objects they are equal
True
sage: Ms.basis_matrix().is_sparse()
True
```

We can also specify an inner product matrix, which is used when computing inner products of elements.

```
sage: A = MatrixSpace(ZZ,2)([[1,0],[0,-1]])
sage: M = FreeModule(ZZ,2,inner_product_matrix=A)
sage: v, w = M.gens()
sage: v.inner_product(w)
0
sage: v.inner_product(v)
1
sage: w.inner_product(w)
-1
sage: (v+2*w).inner_product(w)
-2
```

You can also specify the inner product matrix by giving anything that coerces to an appropriate matrix. This is only useful if the inner product matrix takes values in the base ring.

```
sage: FreeModule(ZZ,2,inner_product_matrix=1).inner_product_matrix()
[1 0]
[0 1]
sage: FreeModule(ZZ,2,inner_product_matrix=[1,2,3,4]).inner_product_matrix()
[1 2]
[3 4]
sage: FreeModule(ZZ,2,inner_product_matrix=[[1,2],[3,4]]).inner_product_matrix()
[1 2]
[3 4]
```

create_key(*base_ring, rank, sparse=False, inner_product_matrix=None*)

TESTS:

```
sage: loads(dumps(ZZ^6)) is ZZ^6
True
sage: loads(dumps(RDF^3)) is RDF^3
True
```

create_object(*version, key*)

class FreeModule_ambient(*base_ring, rank, sparse=False*)

Ambient free module over a commutative ring.

ambient_module()

Return self, since self is ambient.

EXAMPLES:

```
sage: A = QQ^5; A.ambient_module()
Vector space of dimension 5 over Rational Field
sage: A = ZZ^5; A.ambient_module()
Ambient free module of rank 5 over the principal ideal domain Integer Ring
```

basis()

Return a basis for this ambient free module.

OUTPUT:

- Sequence - an immutable sequence with universe this ambient free module

EXAMPLES:

```
sage: A = ZZ^3; B = A.basis(); B
[
(1, 0, 0),
(0, 1, 0),
(0, 0, 1)
]
sage: B.universe()
Ambient free module of rank 3 over the principal ideal domain Integer Ring
```

change_ring(*R*)

Return the ambient free module over R of the same rank as self.

EXAMPLES:

```
sage: A = ZZ^3; A.change_ring(QQ)
Vector space of dimension 3 over Rational Field
sage: A = ZZ^3; A.change_ring(GF(5))
Vector space of dimension 3 over Finite Field of size 5
```

For ambient modules any change of rings is defined.

```
sage: A = GF(5)**3; A.change_ring(QQ)
Vector space of dimension 3 over Rational Field
```

coordinate_vector(*v, check=True*)

Write v in terms of the standard basis for self and return the resulting coefficients in a vector over the fraction field of the base ring.

Returns a vector c such that if B is the basis for self, then

$$\sum c_i B_i = v.$$

If v is not in self, raises an ArithmeticError exception.

EXAMPLES:

```
sage: V = Integers(16)^3
sage: v = V.coordinate_vector([1,5,9]); v
(1, 5, 9)
sage: v.parent()
Ambient free module of rank 3 over Ring of integers modulo 16
```

echelon_coordinate_vector(*v, check=True*)

Same as `self.coordinate_vector(v)`, since self is an ambient free module.

INPUT:

- `v` - vector
- `check` - bool (default: True); if True, also verify that v is really in self.

OUTPUT: list

EXAMPLES:

```
sage: V = QQ^4
sage: v = V([-1/2,1/2,-1/2,1/2])
sage: v
(-1/2, 1/2, -1/2, 1/2)
sage: V.coordinate_vector(v)
(-1/2, 1/2, -1/2, 1/2)
sage: V.echelon_coordinate_vector(v)
(-1/2, 1/2, -1/2, 1/2)
sage: W = V.submodule_with_basis([[1/2,1/2,1/2,1/2],[1,0,1,0]])
sage: W.coordinate_vector(v)
(1, -1)
sage: W.echelon_coordinate_vector(v)
(-1/2, 1/2)
```

echelon_coordinates(*v, check=True*)

Returns the coordinate vector of v in terms of the echelon basis for self.

EXAMPLES:

```
sage: U = VectorSpace(QQ,3)
sage: [ U.coordinates(v) for v in U.basis() ]
[[1, 0, 0], [0, 1, 0], [0, 0, 1]]
sage: [ U.echelon_coordinates(v) for v in U.basis() ]
[[1, 0, 0], [0, 1, 0], [0, 0, 1]]
sage: V = U.submodule([[1,1,0],[0,1,1]])
sage: V
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1  0 -1]
[ 0  1  1]
sage: [ V.coordinates(v) for v in V.basis() ]
[[1, 0], [0, 1]]
sage: [ V.echelon_coordinates(v) for v in V.basis() ]
[[1, 0], [0, 1]]
sage: W = U.submodule_with_basis([[1,1,0],[0,1,1]])
sage: W
Vector space of degree 3 and dimension 2 over Rational Field
User basis matrix:
[1 1 0]
[0 1 1]
sage: [ W.coordinates(v) for v in W.basis() ]
[[1, 0], [0, 1]]
sage: [ W.echelon_coordinates(v) for v in W.basis() ]
[[1, 1], [0, 1]]
```

echelonized_basis()

Return a basis for this ambient free module in echelon form.

EXAMPLES:

```
sage: A = ZZ^3; A.echelonized_basis()
[
(1, 0, 0),
(0, 1, 0),
(0, 0, 1)
]
```

echelonized_basis_matrix()

The echelonized basis matrix of self.

EXAMPLES:

```
sage: V = ZZ^4
sage: W = V.submodule([ V.gen(i)-V.gen(0) for i in range(1,4) ])
sage: W.basis_matrix()
[ 1  0  0 -1]
[ 0  1  0 -1]
[ 0  0  1 -1]
sage: W.echelonized_basis_matrix()
[ 1  0  0 -1]
[ 0  1  0 -1]
[ 0  0  1 -1]
sage: U = V.submodule_with_basis([ V.gen(i)-V.gen(0) for i in range(1,4) ])
sage: U.basis_matrix()
[-1  1  0  0]
[-1  0  1  0]
[-1  0  0  1]
sage: U.echelonized_basis_matrix()
[ 1  0  0 -1]
[ 0  1  0 -1]
[ 0  0  1 -1]
```

is_ambient()

Return `True` since this module is an ambient module.

EXAMPLES:

```
sage: A = QQ^5; A.is_ambient()
True
sage: A = (QQ^5).span([[1,2,3,4,5]]); A.is_ambient()
False
```

linear_combination_of_basis(*v*)

Return the linear combination of the basis for self obtained from the elements of the list v.

EXAMPLES:

```
sage: V = span([[1,2,3], [4,5,6]], ZZ)
sage: V
Free module of degree 3 and rank 2 over Integer Ring
Echelon basis matrix:
[1 2 3]
[0 3 6]
sage: V.linear_combination_of_basis([1,1])
(1, 5, 9)
```

random_element(*prob=1.0, **kwds*)

Returns a random element of self.

INPUT:

- `prob` - float; probability that given coefficient is nonzero.
- `**kwds` - passed on to random_element function of base ring.

EXAMPLES:

```
sage: M = FreeModule(ZZ, 3)
sage: M.random_element()
(-1, 2, 1)
sage: M.random_element()
(-95, -1, -2)
sage: M.random_element()
(-12, 0, 0)

sage: M = FreeModule(ZZ, 16)
sage: M.random_element()
(1, -1, 1, -1, -2, -1, 4, -4, -6, 5, 0, 0, -2, 0, 1, -4)
sage: M.random_element(prob=0.3)
(0, 0, 0, 0, 0, 0, 0, -6, 1, -1, 1, 0, 1, 0, 0, 0)
```

class FreeModule_ambient_domain(*base_ring, rank, sparse=False*)

Ambient free module over an integral domain.

ambient_vector_space()

Returns the ambient vector space, which is this free module tensored with its fraction field.

EXAMPLES:

```
sage: M = ZZ^3;
sage: V = M.ambient_vector_space(); V
Vector space of dimension 3 over Rational Field
```

If an inner product on the module is specified, then this is preserved on the ambient vector space.

```
sage: N = FreeModule(ZZ,4,inner_product_matrix=1)
sage: U = N.ambient_vector_space()
sage: U
Ambient quadratic space of dimension 4 over Rational Field
Inner product matrix:
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: P = N.submodule_with_basis([[1,-1,0,0],[0,1,-1,0],[0,0,1,-1]])
sage: P.gram_matrix()
[ 2 -1  0]
[-1  2 -1]
[ 0 -1  2]
sage: U == N.ambient_vector_space()
True
sage: U == V
False
```

base_field()

Return the fraction field of the base ring of self.

EXAMPLES:

```
sage: M = ZZ^3;  M.base_field()
Rational Field
sage: M = PolynomialRing(GF(5),'x')^3;  M.base_field()
Fraction Field of Univariate Polynomial Ring in x over Finite Field of size 5
```

coordinate_vector(*v, check=True*)

Write v in terms of the standard basis for self and return the resulting coefficients in a vector over the fraction field of the base ring.

INPUT:

- v - vector
- check - bool (default: True); if True, also verify that v is really in self.

OUTPUT: list

Returns a vector c such that if B is the basis for self, then

$$\sum c_i B_i = v.$$

If v is not in self, raises an ArithmeticError exception.

EXAMPLES:

```
sage: V = ZZ^3
sage: v = V.coordinate_vector([1,5,9]); v
(1, 5, 9)
sage: v.parent()
Vector space of dimension 3 over Rational Field
```

vector_space(*base_field=None*)

Returns the vector space obtained from self by tensoring with the fraction field of the base ring and extending to the field.

EXAMPLES:

```
sage: M = ZZ^3;  M.vector_space()
Vector space of dimension 3 over Rational Field
```

class FreeModule_ambient_field(*base_field, dimension, sparse=False*)

ambient_vector_space()

Returns self as the ambient vector space.

EXAMPLES:

```
sage: M = QQ^3
sage: M.ambient_vector_space()
Vector space of dimension 3 over Rational Field
```

base_field()

Returns the base field of this vector space.

EXAMPLES:

```
sage: M = QQ^3
sage: M.base_field()
Rational Field
```

class FreeModule_ambient_pid(*base_ring, rank, sparse=False*)

Ambient free module over a principal ideal domain.

class FreeModule_generic(*base_ring, rank, degree, sparse=False*)

Base class for all free modules.

ambient_module()

Return the ambient module associated to this module.

EXAMPLES:

```
sage: R.<x,y> = QQ[]
sage: M = FreeModule(R,2)
sage: M.ambient_module()
Ambient free module of rank 2 over the integral domain Multivariate Polynomial Ring in x, y
```

```
sage: V = FreeModule(QQ, 4).span([[1,2,3,4], [1,0,0,0]]); V
Vector space of degree 4 and dimension 2 over Rational Field
Basis matrix:
[  1   0   0   0]
[  0   1 3/2   2]
sage: V.ambient_module()
Vector space of dimension 4 over Rational Field
```

base_extend(*R*)

Return the base extension of self to R. This is the same as `self.change_ring(R)` except that a TypeError is raised if there is no canonical coerce map from the base ring of self to R.

INPUT:

- R - ring

EXAMPLES:

```
sage: V = ZZ^7
sage: V.base_extend(QQ)
Vector space of dimension 7 over Rational Field
```

basis()

Return the basis of this module.

EXAMPLES:

```
sage: FreeModule(Integers(12),3).basis()
[
(1, 0, 0),
(0, 1, 0),
(0, 0, 1)
]
```

basis_matrix()

Return the matrix whose rows are the basis for this free module.

EXAMPLES:

```
sage: FreeModule(Integers(12),3).basis_matrix()
[1 0 0]
[0 1 0]
[0 0 1]

sage: M = FreeModule(GF(7),3).span([[2,3,4],[1,1,1]]); M
Vector space of degree 3 and dimension 2 over Finite Field of size 7
Basis matrix:
[1 0 6]
[0 1 2]
sage: M.basis_matrix()
[1 0 6]
[0 1 2]

sage: M = FreeModule(GF(7),3).span_of_basis([[2,3,4],[1,1,1]]);
sage: M.basis_matrix()
[2 3 4]
[1 1 1]
```

category()

Return the category to which this free module belongs. This is the category of all free modules over the base ring.

EXAMPLES:

```
sage: FreeModule(GF(7),3).category()
Category of vector spaces over Finite Field of size 7
```

construction()

The construction functor and base ring for self.

EXAMPLES:

```
sage: R = PolynomialRing(QQ,3,'x')
sage: V = R^5
sage: V.construction()
(VectorFunctor, Multivariate Polynomial Ring in x0, x1, x2 over Rational Field)
```

coordinate_module(V)

Suppose V is a submodule of self (or a module comeasurable with self), and that self is a free module over R of rank n. Let ϕ be the map from self to R^n that sends the basis vectors of self in order to the standard basis of R^n. This function returns the image $\phi(V)$.

Warning: If there is no integer d such that dV is a submodule of self, then this function will give total nonsense.

EXAMPLES:

We illustrate this function with some $\mathbf{Z}$-submodules of $\mathbf{Q}^3$.

```
sage: V = (ZZ^3).span([[1/2,3,5], [0,1,-3]])
sage: W = (ZZ^3).span([[1/2,4,2]])
sage: V.coordinate_module(W)
Free module of degree 2 and rank 1 over Integer Ring
Echelon basis matrix:
[1 4]
sage: V.0 + 4*V.1
(1/2, 4, 2)
```

In this example, the coordinate module isn't even in $\mathbf{Z}^3$.

```
sage: W = (ZZ^3).span([[1/4,2,1]])
sage: V.coordinate_module(W)
Free module of degree 2 and rank 1 over Integer Ring
Echelon basis matrix:
[1/2   2]
```

The following more elaborate example illustrates using this function to write a submodule in terms of integral cuspidal modular symbols:

```
sage: M = ModularSymbols(54)
sage: S = M.cuspidal_subspace()
sage: K = S.integral_structure(); K
Free module of degree 19 and rank 8 over Integer Ring
Echelon basis matrix:
[ 0  1  0  0 -1  0  0  0  0  0  0  0  0  0  0  0  0  0]
...
sage: L = M[0].integral_structure(); L
Free module of degree 19 and rank 2 over Integer Ring
Echelon basis matrix:
[ 0  1  1  0 -2  1 -1  1 -1 -2  2  0  0  0  0  0  0  0  0]
[ 0  0  3  0 -3  2 -1  2 -1 -4  2 -1 -2  1  2  0  0 -1  1]
sage: K.coordinate_module(L)
Free module of degree 8 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1  1  1 -1  1 -1  0  0]
```

```
[ 0  3  2 -1  2 -1 -1 -2]
sage: K.coordinate_module(L).basis_matrix() * K.basis_matrix()
[ 0  1  1  0 -2  1 -1  1 -1 -2  2  0  0  0  0  0  0  0]
[ 0  0  3  0 -3  2 -1  2 -1 -4  2 -1 -2  1  2  0  0 -1  1]
```

coordinate_vector(*v, check=True*)

Return the vector whose coefficients give v as a linear combination of the basis for self.

INPUT:

- v - vector
- check - bool (default: True); if True, also verify that v is really in self.

OUTPUT: list

EXAMPLES:

```
sage: M = FreeModule(ZZ, 2); M0,M1=M.gens()
sage: W = M.submodule([M0 + M1, M0 - 2*M1])
sage: W.coordinate_vector(2*M0 - M1)
(2, -1)
```

coordinates(*v, check=True*)

Write v in terms of the basis for self.

INPUT:

- v - vector
- check - bool (default: True); if True, also verify that v is really in self.

OUTPUT: list

Returns a list c such that if B is the basis for self, then

$$\sum c_i B_i = v.$$

If v is not in self, raises an ArithmeticError exception.

EXAMPLES:

```
sage: M = FreeModule(ZZ, 2); M0,M1=M.gens()
sage: W = M.submodule([M0 + M1, M0 - 2*M1])
sage: W.coordinates(2*M0-M1)
[2, -1]
```

degree()

Return the degree of this free module. This is the dimension of the ambient vector space in which it is embedded.

EXAMPLES:

```
sage: M = FreeModule(ZZ, 10)
sage: W = M.submodule([M.gen(0), 2*M.gen(3) - M.gen(0), M.gen(0) + M.gen(3)])
sage: W.degree()
10
sage: W.rank()
2
```

dense_module()

Return corresponding dense module.

EXAMPLES:

We first illustrate conversion with ambient spaces:

```
sage: M = FreeModule(QQ,3)
sage: S = FreeModule(QQ,3, sparse=True)
```

```
sage: M.sparse_module()
Sparse vector space of dimension 3 over Rational Field
sage: S.dense_module()
Vector space of dimension 3 over Rational Field
sage: M.sparse_module() == S
True
sage: S.dense_module() == M
True
sage: M.dense_module() == M
True
sage: S.sparse_module() == S
True
```

Next we create a subspace:

```
sage: M = FreeModule(QQ,3, sparse=True)
sage: V = M.span([ [1,2,3] ] ); V
Sparse vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[1 2 3]
sage: V.sparse_module()
Sparse vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[1 2 3]
```

dimension()

Return the dimension of this free module.

EXAMPLES:

```
sage: M = FreeModule(FiniteField(19), 100)
sage: W = M.submodule([M.gen(50)])
sage: W.dimension()
1
```

direct_sum(*other*)

Return the direct sum of self and other as a free module.

EXAMPLES:

```
sage: V = (ZZ^3).span([[1/2,3,5], [0,1,-3]]); V
Free module of degree 3 and rank 2 over Integer Ring
Echelon basis matrix:
[1/2   0  14]
[  0   1  -3]
sage: W = (ZZ^3).span([[1/2,4,2]]); W
Free module of degree 3 and rank 1 over Integer Ring
Echelon basis matrix:
[1/2   4   2]
sage: V.direct_sum(W)
Free module of degree 6 and rank 3 over Integer Ring
Echelon basis matrix:
[1/2   0  14   0   0   0]
[  0   1  -3   0   0   0]
[  0   0   0 1/2   4   2]
```

discriminant()

Return the discriminant of this free module.

EXAMPLES:

```
sage: M = FreeModule(ZZ, 3)
sage: M.discriminant()
1
sage: W = M.span([[1,2,3]])
sage: W.discriminant()
14
sage: W2 = M.span([[1,2,3], [1,1,1]])
sage: W2.discriminant()
6
```

echelonized_basis_matrix()

The echelonized basis matrix (not implemented for this module).

This example works because M is an ambient module. Submodule creation should exist for generic modules.

EXAMPLES:

```
sage: R = IntegerModRing(12)
sage: S.<x,y> = R[]
sage: M = FreeModule(S,3)
sage: M.echelonized_basis_matrix()
[1 0 0]
[0 1 0]
[0 0 1]
```

TESTS:

```
sage: from sage.modules.free_module import FreeModule_generic
sage: FreeModule_generic.echelonized_basis_matrix(M)
...
NotImplementedError
```

element_class()

The class of elements for this free module.

EXAMPLES:

```
sage: M = FreeModule(ZZ,20,sparse=False)
sage: x = M.random_element()
sage: type(x)
<type 'sage.modules.vector_integer_dense.Vector_integer_dense'>
sage: M.element_class()
<type 'sage.modules.vector_integer_dense.Vector_integer_dense'>
sage: N = FreeModule(ZZ,20,sparse=True)
sage: y = N.random_element()
sage: type(y)
<type 'sage.modules.free_module_element.FreeModuleElement_generic_sparse'>
sage: N.element_class()
<type 'sage.modules.free_module_element.FreeModuleElement_generic_sparse'>
```

free_module()

Return this free module. (This is used by the `FreeModule` functor, and simply returns self.)

EXAMPLES:

```
sage: M = FreeModule(ZZ, 3)
sage: M.free_module()
Ambient free module of rank 3 over the principal ideal domain Integer Ring
```

gen(*i=0*)

Return ith generator for self, where i is between 0 and rank-1, inclusive.

INPUT:

- i - an integer

OUTPUT: i-th basis vector for self.

EXAMPLES:

```
sage: n = 5
sage: V = QQ^n
sage: B = [ V.gen(i) for i in range(n) ]
sage: B
[(1, 0, 0, 0, 0),
(0, 1, 0, 0, 0),
(0, 0, 1, 0, 0),
(0, 0, 0, 1, 0),
(0, 0, 0, 0, 1)]
sage: V.gens() == tuple(B)
True
```

TESTS:

```
sage: (QQ^3).gen(4/3)
...
TypeError: rational is not an integer
```

gram_matrix()

Return the gram matrix associated to this free module, defined to be G = B*A*B.transpose(), where A is the inner product matrix (induced from the ambient space), and B the basis matrix.

EXAMPLES:

```
sage: V = VectorSpace(QQ,4)
sage: u = V([1/2,1/2,1/2,1/2])
sage: v = V([0,1,1,0])
sage: w = V([0,0,1,1])
sage: M = span([u,v,w], ZZ)
sage: M.inner_product_matrix() == V.inner_product_matrix()
True
sage: L = M.submodule_with_basis([u,v,w])
sage: L.inner_product_matrix() == M.inner_product_matrix()
True
sage: L.gram_matrix()
[1 1 1]
[1 2 1]
[1 1 2]
```

has_user_basis()

Return True if the basis of this free module is specified by the user, as opposed to being the default echelon form.

EXAMPLES:

```
sage: V = QQ^3
sage: W = V.subspace([[2,'1/2', 1]])
sage: W.has_user_basis()
False
sage: W = V.subspace_with_basis([[2,'1/2',1]])
sage: W.has_user_basis()
True
```

inner_product_matrix()

Return the default identity inner product matrix associated to this module.

By definition this is the inner product matrix of the ambient space, hence may be of degree greater than the rank of the module.

TODO: Differentiate the image ring of the inner product from the base ring of the module and/or ambient space. E.g. On an integral module over ZZ the inner product pairing could naturally take values in ZZ, QQ, RR, or CC.

EXAMPLES:

```
sage: M = FreeModule(ZZ, 3)
sage: M.inner_product_matrix()
[1 0 0]
[0 1 0]
[0 0 1]
```

is_ambient()

Returns False since this is not an ambient free module.

EXAMPLES:

```
sage: M = FreeModule(ZZ, 3).span([[1,2,3]]); M
Free module of degree 3 and rank 1 over Integer Ring
Echelon basis matrix:
[1 2 3]
sage: M.is_ambient()
False
sage: M = (ZZ^2).span([[1,0], [0,1]])
sage: M
Free module of degree 2 and rank 2 over Integer Ring
Echelon basis matrix:
[1 0]
[0 1]
sage: M.is_ambient()
False
sage: M == M.ambient_module()
True
```

is_dense()

Return `True` if the underlying representation of this module uses dense vectors, and False otherwise.

EXAMPLES:

```
sage: FreeModule(ZZ, 2).is_dense()
True
sage: FreeModule(ZZ, 2, sparse=True).is_dense()
False
```

is_finite()

Returns True if the underlying set of this free module is finite.

EXAMPLES:

```
sage: FreeModule(ZZ, 2).is_finite()
False
sage: FreeModule(Integers(8), 2).is_finite()
True
sage: FreeModule(ZZ, 0).is_finite()
True
```

is_full()

Return `True` if the rank of this module equals its degree.

EXAMPLES:

```
sage: FreeModule(ZZ, 2).is_full()
True
sage: M = FreeModule(ZZ, 2).span([[1,2]])
```

```
sage: M.is_full()
False
```

is_sparse()

Return `True` if the underlying representation of this module uses sparse vectors, and False otherwise.

EXAMPLES:

```
sage: FreeModule(ZZ, 2).is_sparse()
False
sage: FreeModule(ZZ, 2, sparse=True).is_sparse()
True
```

is_submodule(*other*)

Return True if self is a submodule of other.

EXAMPLES:

```
sage: M = FreeModule(ZZ,3)
sage: V = M.ambient_vector_space()
sage: X = V.span([[1/2,1/2,0],[1/2,0,1/2]], ZZ)
sage: Y = V.span([[1,1,1]], ZZ)
sage: N = X + Y
sage: M.is_submodule(X)
False
sage: M.is_submodule(Y)
False
sage: Y.is_submodule(M)
True
sage: N.is_submodule(M)
False
sage: M.is_submodule(N)
True
```

Since basis() is not implemented in general, submodule testing does not work for all PID's. However, trivial cases are already used (and useful) for coercion, e.g.

```
sage: QQ(1/2) * vector(ZZ['x']['y'],[1,2,3,4])
(1/2, 1, 3/2, 2)
sage: vector(ZZ['x']['y'],[1,2,3,4]) * QQ(1/2)
(1/2, 1, 3/2, 2)
```

matrix()

Return the basis matrix of this module, which is the matrix whose rows are a basis for this module.

EXAMPLES:

```
sage: M = FreeModule(ZZ, 2)
sage: M.matrix()
[1 0]
[0 1]
sage: M.submodule([M.gen(0) + M.gen(1), M.gen(0) - 2*M.gen(1)]).matrix()
[1 1]
[0 3]
```

ngens()

Returns the number of basis elements of this free module.

EXAMPLES:

```
sage: FreeModule(ZZ, 2).ngens()
2
sage: FreeModule(ZZ, 0).ngens()
0
```

```
sage: FreeModule(ZZ, 2).span([[1,1]]).ngens()
1
```

nonembedded_free_module()

Returns an ambient free module that is isomorphic to this free module.

Thus if this free module is of rank n over a ring R, then this function returns R^n, as an ambient free module.

EXAMPLES:

```
sage: FreeModule(ZZ, 2).span([[1,1]]).nonembedded_free_module()
Ambient free module of rank 1 over the principal ideal domain Integer Ring
```

random_element(*prob=1.0, **kwds*)

Returns a random element of self.

INPUT:

- `prob` - float; probability that given coefficient is nonzero.
- `**kwds` - passed on to random_element function of base ring.

EXAMPLES:

```
sage: M = FreeModule(ZZ, 2).span([[1,1]])
sage: M.random_element()
(-1, -1)
sage: M.random_element()
(2, 2)
sage: M.random_element()
(1, 1)
```

rank()

Return the rank of this free module.

EXAMPLES:

```
sage: FreeModule(Integers(6), 10000000).rank()
10000000
sage: FreeModule(ZZ, 2).span([[1,1], [2,2], [3,4]]).rank()
2
```

sparse_module()

Return the corresponding sparse module with the same defining data.

EXAMPLES:

We first illustrate conversion with ambient spaces:

```
sage: M = FreeModule(Integers(8),3)
sage: S = FreeModule(Integers(8),3, sparse=True)
sage: M.sparse_module()
Ambient sparse free module of rank 3 over Ring of integers modulo 8
sage: S.dense_module()
Ambient free module of rank 3 over Ring of integers modulo 8
sage: M.sparse_module() is S
True
sage: S.dense_module() is M
True
sage: M.dense_module() is M
True
sage: S.sparse_module() is S
True
```

Next we convert a subspace:

```
sage: M = FreeModule(QQ,3)
sage: V = M.span([ [1,2,3] ] ); V
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[1 2 3]
sage: V.sparse_module()
Sparse vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[1 2 3]
```

uses_ambient_inner_product()

Return `True` if the inner product on this module is the one induced by the ambient inner product.

EXAMPLES:

```
sage: M = FreeModule(ZZ, 2)
sage: W = M.submodule([[1,2]])
sage: W.uses_ambient_inner_product()
True
sage: W.inner_product_matrix()
[1 0]
[0 1]

sage: W.gram_matrix()
[5]
```

zero_vector()

Returns the zero vector in this free module.

EXAMPLES:

```
sage: M = FreeModule(ZZ, 2)
sage: M.zero_vector()
(0, 0)
sage: M(0)
(0, 0)
sage: M.span([[1,1]]).zero_vector()
(0, 0)
sage: M.zero_submodule().zero_vector()
(0, 0)
```

class **FreeModule_generic_field**(*base_field, dimension, degree, sparse=False*)

Base class for all free modules over fields.

category()

Return the category to which this vector space belongs.

EXAMPLES:

```
sage: V = QQ^4; V.category()
Category of vector spaces over Rational Field
sage: V = GF(5)**20; V.category()
Category of vector spaces over Finite Field of size 5
```

echelonized_basis_matrix()

Return basis matrix for self in row echelon form.

EXAMPLES:

```
sage: V = FreeModule(QQ, 3).span_of_basis([[1,2,3],[4,5,6]])
sage: V.basis_matrix()
[1 2 3]
[4 5 6]
```

```
sage: V.echelonized_basis_matrix()
[ 1  0 -1]
[ 0  1  2]
```

intersection(*other*)

Return the intersection of self and other, which must be R-submodules of a common ambient vector space.

EXAMPLES:

```
sage: V  = VectorSpace(QQ,3)
sage: W1 = V.submodule([V.gen(0), V.gen(0) + V.gen(1)])
sage: W2 = V.submodule([V.gen(1), V.gen(2)])
sage: W1.intersection(W2)
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[0 1 0]
sage: W2.intersection(W1)
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[0 1 0]
sage: V.intersection(W1)
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[1 0 0]
[0 1 0]
sage: W1.intersection(V)
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[1 0 0]
[0 1 0]
sage: Z = V.submodule([])
sage: W1.intersection(Z)
Vector space of degree 3 and dimension 0 over Rational Field
Basis matrix:
[]
```

is_subspace(*other*)

True if this vector space is a subspace of other.

EXAMPLES:

```
sage: V = VectorSpace(QQ,3)
sage: W = V.subspace([V.gen(0), V.gen(0) + V.gen(1)])
sage: W2 = V.subspace([V.gen(1)])
sage: W.is_subspace(V)
True
sage: W2.is_subspace(V)
True
sage: W.is_subspace(W2)
False
sage: W2.is_subspace(W)
True
```

quotient(*sub, check=True*)

Return the quotient of self by the given subspace sub.

INPUT:

- `sub` - a submodule of self, or something that can be turned into one via self.submodule(sub).
- `check` - (default: True) whether or not to check that sub is a submodule.

EXAMPLES:

```
sage: A = QQ^3; V = A.span([[1,2,3], [4,5,6]])
sage: Q = V.quotient( [V.0 + V.1] ); Q
Vector space quotient V/W of dimension 1 over Rational Field where
V: Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1  0 -1]
[ 0  1  2]
W: Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[1 1 1]
sage: Q(V.0 + V.1)
(0)
```

quotient_abstract(*sub, check=True*)

Returns an ambient free module isomorphic to the quotient space of self modulo sub, together with maps from self to the quotient, and a lifting map in the other direction.

Use `self.quotient(sub)` to obtain the quotient module as an object equipped with natural maps in both directions, and a canonical coercion.

INPUT:

- `sub` - a submodule of self, or something that can be turned into one via self.submodule(sub).
- `check` - (default: True) whether or not to check that sub is a submodule.

OUTPUT:

- `U` - the quotient as an abstract *ambient* free module
- `pi` - projection map to the quotient
- `lift` - lifting map back from quotient

EXAMPLES:

```
sage: V = GF(19)^3
sage: W = V.span_of_basis([ [1,2,3], [1,0,1] ])
sage: U,pi,lift = V.quotient_abstract(W)
sage: pi(V.2)
(18)
sage: pi(V.0)
(1)
sage: pi(V.0 + V.2)
(0)
```

Another example involving a quotient of one subspace by another.

```
sage: A = matrix(QQ,4,4,[0,1,0,0, 0,0,1,0, 0,0,0,1, 0,0,0,0])
sage: V = (A^3).kernel()
sage: W = A.kernel()
sage: U, pi, lift = V.quotient_abstract(W)
sage: [pi(v) == 0 for v in W.gens()]
[True]
sage: [pi(lift(b)) == b for b in U.basis()]
[True, True]
```

scale(*other*)

Return the product of self by the number other, which is the module spanned by other times each basis vector. Since self is a vector space this product equals self if other is nonzero, and is the zero vector space if other is 0.

EXAMPLES:

```
sage: V = QQ^4
sage: V.scale(5)
```

```
Vector space of dimension 4 over Rational Field
sage: V.scale(0)
Vector space of degree 4 and dimension 0 over Rational Field
Basis matrix:
[]

sage: W = V.span([[1,1,1,1]])
sage: W.scale(2)
Vector space of degree 4 and dimension 1 over Rational Field
Basis matrix:
[1 1 1 1]
sage: W.scale(0)
Vector space of degree 4 and dimension 0 over Rational Field
Basis matrix:
[]

sage: V = QQ^4; V
Vector space of dimension 4 over Rational Field
sage: V.scale(3)
Vector space of dimension 4 over Rational Field
sage: V.scale(0)
Vector space of degree 4 and dimension 0 over Rational Field
Basis matrix:
[]
```

span(*gens, base_ring=None, check=True, already_echelonized=False*)

Return the K-span of the given list of gens, where K is the base field of self or the user-specified base_ring. Note that this span is a subspace of the ambient vector space, but need not be a subspace of self.

INPUT:

- `gens` - list of vectors
- `check` - bool (default: True): whether or not to coerce entries of gens into base field
- `already_echelonized` - bool (default: False): set this if you know the gens are already in echelon form

EXAMPLES:

```
sage: V = VectorSpace(GF(7), 3)
sage: W = V.subspace([[2,3,4]]); W
Vector space of degree 3 and dimension 1 over Finite Field of size 7
Basis matrix:
[1 5 2]
sage: W.span([[1,1,1]])
Vector space of degree 3 and dimension 1 over Finite Field of size 7
Basis matrix:
[1 1 1]
```

TESTS:

```
sage: V = FreeModule(RDF,3)
sage: W = V.submodule([V.gen(0)])
sage: W.span([V.gen(1)], base_ring=GF(7))
Vector space of degree 3 and dimension 1 over Finite Field of size 7
Basis matrix:
[0 1 0]
sage: v = V((1, pi, e)); v
(1.0, 3.14159265359, 2.71828182846)
sage: W.span([v], base_ring=GF(7))
...
```

```
ValueError: Argument gens (= [(1.0, 3.14159265359, 2.71828182846)]) is not compatible with b
sage: W = V.submodule([v])
sage: W.span([V.gen(2)], base_ring=GF(7))
Vector space of degree 3 and dimension 1 over Finite Field of size 7
Basis matrix:
[0 0 1]
```

span_of_basis(*basis, base_ring=None, check=True, already_echelonized=False*)

Return the free K-module with the given basis, where K is the base field of self or user specified base_ring.

Note that this span is a subspace of the ambient vector space, but need not be a suspace of self.

INPUT:

- `basis` - list of vectors
- `check` - bool (default: True): whether or not to coerce entries of gens into base field
- `already_echelonized` - bool (default: False): set this if you know the gens are already in echelon form

EXAMPLES:

```
sage: V = VectorSpace(GF(7), 3)
sage: W = V.subspace([[2,3,4]]); W
Vector space of degree 3 and dimension 1 over Finite Field of size 7
Basis matrix:
[1 5 2]
sage: W.span_of_basis([[2,2,2], [3,3,0]])
Vector space of degree 3 and dimension 2 over Finite Field of size 7
User basis matrix:
[2 2 2]
[3 3 0]
```

The basis vectors must be linearly independent or an ArithmeticError exception is raised.

```
sage: W.span_of_basis([[2,2,2], [3,3,3]])
...
ValueError: The given basis vectors must be linearly independent.
```

subspace(*gens, check=True, already_echelonized=False*)

Return the subspace of self spanned by the elements of gens.

INPUT:

- `gens` - list of vectors
- `check` - bool (default: True) verify that gens are all in self.
- `already_echelonized` - bool (default: False) set to True if you know the gens are in Echelon form.

EXAMPLES:

First we create a 1-dimensional vector subspace of an ambient 3-dimensional space over the finite field of order 7.

```
sage: V = VectorSpace(GF(7), 3)
sage: W = V.subspace([[2,3,4]]); W
Vector space of degree 3 and dimension 1 over Finite Field of size 7
Basis matrix:
[1 5 2]
```

Next we create an invalid subspace, but it's allowed since `check=False`. This is just equivalent to computing the span of the element.

```
sage: W.subspace([[1,1,0]], check=False)
Vector space of degree 3 and dimension 1 over Finite Field of size 7
```

```
Basis matrix:
[1 1 0]
```

With `check=True` (the default) the mistake is correctly detected and reported with an `ArithmeticError` exception.

```
sage: W.subspace([[1,1,0]], check=True)
...
ArithmeticError: Argument gens (= [[1, 1, 0]]) does not generate a submodule of self.
```

subspace_with_basis(*gens, check=True, already_echelonized=False*)

Same as `self.submodule_with_basis(...)`.

EXAMPLES:

We create a subspace with a user-defined basis.

```
sage: V = VectorSpace(GF(7), 3)
sage: W = V.subspace_with_basis([[2,2,2], [1,2,3]]); W
Vector space of degree 3 and dimension 2 over Finite Field of size 7
User basis matrix:
[2 2 2]
[1 2 3]
```

We then create a subspace of the subspace with user-defined basis.

```
sage: W1 = W.subspace_with_basis([[3,4,5]]); W1
Vector space of degree 3 and dimension 1 over Finite Field of size 7
User basis matrix:
[3 4 5]
```

Notice how the basis for the same subspace is different if we merely use the `subspace` command.

```
sage: W2 = W.subspace([[3,4,5]]); W2
Vector space of degree 3 and dimension 1 over Finite Field of size 7
Basis matrix:
[1 6 4]
```

Nonetheless the two subspaces are equal (as mathematical objects):

```
sage: W1 == W2
True
```

subspaces(*dim*)

Iterate over all subspaces of dimension dim.

INPUT:

- `dim` - int, dimension of subspaces to be generated

EXAMPLE:

```
sage: V = VectorSpace(GF(3), 5)
sage: len(list(V.subspaces(0)))
1
sage: len(list(V.subspaces(1)))
121
sage: len(list(V.subspaces(2)))
1210
sage: len(list(V.subspaces(3)))
1210
sage: len(list(V.subspaces(4)))
121
sage: len(list(V.subspaces(5)))
1
```

```
sage: V = VectorSpace(GF(3), 5)
sage: V = V.subspace([V([1,1,0,0,0]),V([0,0,1,1,0])])
sage: list(V.subspaces(1))
[Vector space of degree 5 and dimension 1 over Finite Field of size 3
Basis matrix:
[1 1 0 0 0],
 Vector space of degree 5 and dimension 1 over Finite Field of size 3
Basis matrix:
[1 1 1 1 0],
 Vector space of degree 5 and dimension 1 over Finite Field of size 3
Basis matrix:
[1 1 2 2 0],
 Vector space of degree 5 and dimension 1 over Finite Field of size 3
Basis matrix:
[0 0 1 1 0]]
```

vector_space(*base_field=None*)

Return the vector space associated to self. Since self is a vector space this function simply returns self, unless the base field is different.

EXAMPLES:

```
sage: V = span([[1,2,3]],QQ); V
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[1 2 3]
sage: V.vector_space()
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[1 2 3]
```

zero_submodule()

Return the zero submodule of self.

EXAMPLES:

```
sage: (QQ^4).zero_submodule()
Vector space of degree 4 and dimension 0 over Rational Field
Basis matrix:
[]
```

zero_subspace()

Return the zero subspace of self.

EXAMPLES:

```
sage: (QQ^4).zero_subspace()
Vector space of degree 4 and dimension 0 over Rational Field
Basis matrix:
[]
```

class **FreeModule_generic_pid**(*base_ring, rank, degree, sparse=False*)

Base class for all free modules over a PID.

base_field()

Return the base field, which is the fraction field of the base ring of this module.

EXAMPLES:

```
sage: FreeModule(GF(3), 2).base_field()
Finite Field of size 3
sage: FreeModule(ZZ, 2).base_field()
Rational Field
```

```
sage: FreeModule(PolynomialRing(GF(7),'x'), 2).base_field()
Fraction Field of Univariate Polynomial Ring in x over Finite Field of size 7
```

basis_matrix()

Return the matrix whose rows are the basis for this free module.

EXAMPLES:

```
sage: M = FreeModule(QQ,2).span_of_basis([[1,-1],[1,0]]); M
Vector space of degree 2 and dimension 2 over Rational Field
User basis matrix:
[ 1 -1]
[ 1  0]
sage: M.basis_matrix()
[ 1 -1]
[ 1  0]
```

See #3699: sage: K = FreeModule(ZZ, 2000) sage: I = K.basis_matrix()

denominator()

The denominator of the basis matrix of self (i.e. the LCM of the coordinate entries with respect to the basis of the ambient space).

EXAMPLES:

```
sage: V = QQ^3
sage: L = V.span([[1,1/2,1/3], [-1/5,2/3,3]],ZZ)
sage: L
Free module of degree 3 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1/5 19/6 37/3]
[   0 23/6 46/3]
sage: L.denominator()
30
```

index_in(*other*)

Return the lattice index [other:self] of self in other, as an element of the base field. When self is contained in other, the lattice index is the usual index. If the index is infinite, then this function returns infinity.

EXAMPLES:

```
sage: L1 = span([[1,2]], ZZ)
sage: L2 = span([[3,6]], ZZ)
sage: L2.index_in(L1)
3
```

Note that the free modules being compared need not be integral.

```
sage: L1 = span([['1/2','1/3'], [4,5]], ZZ)
sage: L2 = span([[1,2], [3,4]], ZZ)
sage: L2.index_in(L1)
12/7
sage: L1.index_in(L2)
7/12
sage: L1.discriminant() / L2.discriminant()
49/144
```

The index of a lattice of infinite index is infinite.

```
sage: L1 = FreeModule(ZZ, 2)
sage: L2 = span([[1,2]], ZZ)
sage: L2.index_in(L1)
+Infinity
```

index_in_saturation()

Return the index of this module in its saturation, i.e., its intersection with R^n.

EXAMPLES:

```
sage: W = span([[2,4,6]], ZZ)
sage: W.index_in_saturation()
2
sage: W = span([[1/2,1/3]], ZZ)
sage: W.index_in_saturation()
1/6
```

intersection(*other*)

Return the intersection of self and other.

EXAMPLES:

We intersect two submodules one of which is clearly contained in the other.

```
sage: A = ZZ^2
sage: M1 = A.span([[1,1]])
sage: M2 = A.span([[3,3]])
sage: M1.intersection(M2)
Free module of degree 2 and rank 1 over Integer Ring
Echelon basis matrix:
[3 3]
```

We intersection two submodules of $\mathbf{Z}^3$ of rank 2, whose intersection has rank 1.

```
sage: A = ZZ^3
sage: M1 = A.span([[1,1,1], [1,2,3]])
sage: M2 = A.span([[2,2,2], [1,0,0]])
sage: M1.intersection(M2)
Free module of degree 3 and rank 1 over Integer Ring
Echelon basis matrix:
[2 2 2]
```

We compute an intersection of two $\mathbf{Z}$-modules that are not submodules of $\mathbf{Z}^2$.

```
sage: A = ZZ^2
sage: M1 = A.span([[1,2]]).scale(1/6)
sage: M2 = A.span([[1,2]]).scale(1/15)
sage: M1.intersection(M2)
Free module of degree 2 and rank 1 over Integer Ring
Echelon basis matrix:
[1/3 2/3]
```

We intersect a $\mathbf{Z}$-module with a $\mathbf{Q}$-vector space.

```
sage: A = ZZ^3
sage: L = ZZ^3
sage: V = QQ^3
sage: W = L.span([[1/2,0,1/2]])
sage: K = V.span([[1,0,1], [0,0,1]])
sage: W.intersection(K)
Free module of degree 3 and rank 1 over Integer Ring
Echelon basis matrix:
[1/2   0 1/2]
sage: K.intersection(W)
Free module of degree 3 and rank 1 over Integer Ring
Echelon basis matrix:
[1/2   0 1/2]
```

is_submodule(*other*)

True if this module is a submodule of other.

EXAMPLES:

```
sage: M = FreeModule(ZZ,2)
sage: M.is_submodule(M)
True
sage: N = M.scale(2)
sage: N.is_submodule(M)
True
sage: M.is_submodule(N)
False
sage: N = M.scale(1/2)
sage: N.is_submodule(M)
False
sage: M.is_submodule(N)
True
```

saturation()

Return the saturated submodule of R^n that spans the same vector space as self.

EXAMPLES:

We create a 1-dimensional lattice that is obviously not saturated and saturate it.

```
sage: L = span([[9,9,6]], ZZ); L
Free module of degree 3 and rank 1 over Integer Ring
Echelon basis matrix:
[9 9 6]
sage: L.saturation()
Free module of degree 3 and rank 1 over Integer Ring
Echelon basis matrix:
[3 3 2]
```

We create a lattice spanned by two vectors, and saturate. Computation of discriminants shows that the index of lattice in its saturation is 3, which is a prime of congruence between the two generating vectors.

```
sage: L = span([[1,2,3], [4,5,6]], ZZ)
sage: L.saturation()
Free module of degree 3 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1  0 -1]
[ 0  1  2]
sage: L.discriminant()
54
sage: L.saturation().discriminant()
6
```

Notice that the saturation of a non-integral lattice L is defined, but the result is integral hence does not contain L:

```
sage: L = span([['1/2',1,3]], ZZ)
sage: L.saturation()
Free module of degree 3 and rank 1 over Integer Ring
Echelon basis matrix:
[1 2 6]
```

scale(*other*)

Return the product of this module by the number other, which is the module spanned by other times each basis vector.

EXAMPLES:

```
sage: M = FreeModule(ZZ, 3)
sage: M.scale(2)
Free module of degree 3 and rank 3 over Integer Ring
Echelon basis matrix:
[2 0 0]
[0 2 0]
[0 0 2]

sage: a = QQ('1/3')
sage: M.scale(a)
Free module of degree 3 and rank 3 over Integer Ring
Echelon basis matrix:
[1/3   0   0]
[  0 1/3   0]
[  0   0 1/3]
```

span(*gens, base_ring=None, check=True, already_echelonized=False*)

Return the R-span of the given list of gens, where R = base_ring. The default R is the base ring of self. Note that this span need not be a submodule of self, nor even of the ambient space. It must, however, be contained in the ambient vector space, i.e., the ambient space tensored with the fraction field of R.

EXAMPLES:

```
sage: V = FreeModule(ZZ,3)
sage: W = V.submodule([V.gen(0)])
sage: W.span([V.gen(1)])
Free module of degree 3 and rank 1 over Integer Ring
Echelon basis matrix:
[0 1 0]
sage: W.submodule([V.gen(1)])
...
ArithmeticError: Argument gens (= [(0, 1, 0)]) does not generate a submodule of self.
```

span_of_basis(*basis, base_ring=None, check=True, already_echelonized=False*)

Return the free R-module with the given basis, where R is the base ring of self or user specified base_ring.

Note that this R-module need not be a submodule of self, nor even of the ambient space. It must, however, be contained in the ambient vector space, i.e., the ambient space tensored with the fraction field of R.

EXAMPLES:

```
sage: M = FreeModule(ZZ,3)
sage: W = M.span_of_basis([M([1,2,3])])
```

Next we create two free $\mathbf{Z}$-modules, neither of which is a submodule of W.

```
sage: W.span_of_basis([M([2,4,0])])
Free module of degree 3 and rank 1 over Integer Ring
User basis matrix:
[2 4 0]
```

The following module isn't in the ambient module $\mathbf{Z}^3$ but is contained in the ambient vector space $\mathbf{Q}^3$:

```
sage: V = M.ambient_vector_space()
sage: W.span_of_basis([ V([1/5,2/5,0]), V([1/7,1/7,0]) ])
Free module of degree 3 and rank 2 over Integer Ring
User basis matrix:
[1/5 2/5   0]
[1/7 1/7   0]
```

Of course the input basis vectors must be linearly independent.

```
sage: W.span_of_basis([ [1,2,0], [2,4,0] ])
...
ValueError: The given basis vectors must be linearly independent.
```

submodule(*gens, check=True, already_echelonized=False*)

Create the R-submodule of the ambient vector space with given generators, where R is the base ring of self.

INPUT:

- `gens` - a list of free module elements or a free module
- `check` - (default: True) whether or not to verify that the gens are in self.

OUTPUT:

- `FreeModule` - the submodule spanned by the vectors in the list gens. The basis for the subspace is always put in reduced row echelon form.

EXAMPLES:

We create a submodule of $\mathbf{Z}^3$:

```
sage: M = FreeModule(ZZ, 3)
sage: B = M.basis()
sage: W = M.submodule([B[0]+B[1], 2*B[1]-B[2]])
sage: W
Free module of degree 3 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1  1  0]
[ 0  2 -1]
```

We create a submodule of a submodule.

```
sage: W.submodule([3*B[0] + 3*B[1]])
Free module of degree 3 and rank 1 over Integer Ring
Echelon basis matrix:
[3 3 0]
```

We try to create a submodule that isn't really a submodule, which results in an ArithmeticError exception:

```
sage: W.submodule([B[0] - B[1]])
...
ArithmeticError: Argument gens (= [(1, -1, 0)]) does not generate a submodule of self.
```

Next we try to create a submodule of a free module over the principal ideal domain $\mathbf{Q}[x]$ (general HNF needed):

```
sage: R = PolynomialRing(QQ, 'x'); x = R.gen()
sage: M = FreeModule(R, 3)
sage: B = M.basis()
sage: W = M.submodule([x*B[0], 2*B[1]- x*B[2]])
...
NotImplementedError: echelon form over Univariate Polynomial Ring in x over Rational Field r
```

submodule_with_basis(*basis, check=True, already_echelonized=False*)

Create the R-submodule of the ambient vector space with given basis, where R is the base ring of self.

INPUT:

- `basis` - a list of linearly independent vectors
- `check` - whether or not to verify that each gen is in the ambient vector space

OUTPUT:

- `FreeModule` - the R-submodule with given basis

EXAMPLES:

First we create a submodule of $\mathbf{Z}^3$:

```
sage: M = FreeModule(ZZ, 3)
sage: B = M.basis()
sage: N = M.submodule_with_basis([B[0]+B[1], 2*B[1]-B[2]])
sage: N
Free module of degree 3 and rank 2 over Integer Ring
User basis matrix:
[ 1  1  0]
[ 0  2 -1]
```

A list of vectors in the ambient vector space may fail to generate a submodule.

```
sage: V = M.ambient_vector_space()
sage: X = M.submodule_with_basis([ V(B[0]+B[1])/2, V(B[1]-B[2])/2])
...
ArithmeticError: The given basis does not generate a submodule of self.
```

However, we can still determine the R-span of vectors in the ambient space, or over-ride the submodule check by setting check to False.

```
sage: X = V.span([ V(B[0]+B[1])/2, V(B[1]-B[2])/2 ], ZZ)
sage: X
Free module of degree 3 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1/2    0   1/2]
[   0  1/2  -1/2]
sage: Y = M.submodule([ V(B[0]+B[1])/2, V(B[1]-B[2])/2 ], check=False)
sage: X == Y
True
```

Next we try to create a submodule of a free module over the principal ideal domain $\mathbf{Q}[x]$ (general HNF needed):

```
sage: R = PolynomialRing(QQ, 'x'); x = R.gen()
sage: M = FreeModule(R, 3)
sage: B = M.basis()
sage: W = M.submodule_with_basis([x*B[0], 2*B[1]- x*B[2]])
...
NotImplementedError: echelon form over Univariate Polynomial Ring in x over Rational Field r
```

vector_space_span(*gens, check=True*)

Create the vector subspace of the ambient vector space with given generators.

INPUT:

- `gens` - a list of vector in self
- `check` - whether or not to verify that each gen is in the ambient vector space

OUTPUT: a vector subspace

EXAMPLES:

We create a 2-dimensional subspace of $\mathbf{Q}^3$.

```
sage: V = VectorSpace(QQ, 3)
sage: B = V.basis()
sage: W = V.vector_space_span([B[0]+B[1], 2*B[1]-B[2]])
sage: W
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[   1    0  1/2]
[   0    1 -1/2]
```

We create a subspace of a vector space over $\mathbf{Q}(i)$.

```
sage: R.<x> = QQ[]
sage: K = NumberField(x^2 + 1, 'a'); a = K.gen()
sage: V = VectorSpace(K, 3)
sage: V.vector_space_span([2*V.gen(0) + 3*V.gen(2)])
Vector space of degree 3 and dimension 1 over Number Field in a with defining polynomial x^2
Basis matrix:
[  1   0 3/2]
```

We use the `vector_space_span` command to create a vector subspace of the ambient vector space of a submodule of $\mathbf{Z}^3$.

```
sage: M = FreeModule(ZZ,3)
sage: W = M.submodule([M([1,2,3])])
sage: W.vector_space_span([M([2,3,4])])
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[  1 3/2   2]
```

vector_space_span_of_basis(*basis, check=True*)

Create the vector subspace of the ambient vector space with given basis.

INPUT:

- `basis` - a list of linearly independent vectors
- `check` - whether or not to verify that each gen is in the ambient vector space

OUTPUT: a vector subspace with user-specified basis

EXAMPLES:

```
sage: V = VectorSpace(QQ, 3)
sage: B = V.basis()
sage: W = V.vector_space_span_of_basis([B[0]+B[1], 2*B[1]-B[2]])
sage: W
Vector space of degree 3 and dimension 2 over Rational Field
User basis matrix:
[ 1  1  0]
[ 0  2 -1]
```

zero_submodule()

Return the zero submodule of this module.

EXAMPLES:

```
sage: V = FreeModule(ZZ,2)
sage: V.zero_submodule()
Free module of degree 2 and rank 0 over Integer Ring
Echelon basis matrix:
[]
```

class **FreeModule_submodule_field**(*ambient, gens, check=True, already_echelonized=False*)

An embedded vector subspace with echelonized basis.

EXAMPLES:

Since this is an embedded vector subspace with echelonized basis, the echelon_coordinates() and user coordinates() agree:

```
sage: V = QQ^3
sage: W = V.span([[1,2,3],[4,5,6]])
sage: W
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
```

```
[ 1  0 -1]
[ 0  1  2]

sage: v = V([1,5,9])
sage: W.echelon_coordinates(v)
[1, 5]
sage: vector(QQ, W.echelon_coordinates(v)) * W.basis_matrix()
(1, 5, 9)
sage: v = V([1,5,9])
sage: W.coordinates(v)
[1, 5]
sage: vector(QQ, W.coordinates(v)) * W.basis_matrix()
(1, 5, 9)
```

coordinate_vector(*v, check=True*)

Write v in terms of the user basis for self.

INPUT:

- v - vector
- check - bool (default: True); if True, also verify that v is really in self.

OUTPUT: list

Returns a list c such that if B is the basis for self, then

$$\sum c_i B_i = v.$$

If v is not in self, raises an ArithmeticError exception.

EXAMPLES:

```
sage: V = QQ^3
sage: W = V.span([[1,2,3],[4,5,6]]); W
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1  0 -1]
[ 0  1  2]
sage: v = V([1,5,9])
sage: W.coordinate_vector(v)
(1, 5)
sage: W.coordinates(v)
[1, 5]
sage: vector(QQ, W.coordinates(v)) * W.basis_matrix()
(1, 5, 9)

sage: V = VectorSpace(QQ,5, sparse=True)
sage: W = V.subspace([[0,1,2,0,0], [0,-1,0,0,-1/2]])
sage: W.coordinate_vector([0,0,2,0,-1/2])
(0, 2)
```

echelon_coordinates(*v, check=True*)

Write v in terms of the echelonized basis of self.

INPUT:

- v - vector
- check - bool (default: True); if True, also verify that v is really in self.

OUTPUT: list

Returns a list c such that if B is the basis for self, then

$$\sum c_i B_i = v.$$

If v is not in self, raises an `ArithmeticError` exception.

EXAMPLES:

```
sage: V = QQ^3
sage: W = V.span([[1,2,3],[4,5,6]])
sage: W
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1  0 -1]
[ 0  1  2]

sage: v = V([1,5,9])
sage: W.echelon_coordinates(v)
[1, 5]
sage: vector(QQ, W.echelon_coordinates(v)) * W.basis_matrix()
(1, 5, 9)
```

has_user_basis()

Return `True` if the basis of this free module is specified by the user, as opposed to being the default echelon form.

EXAMPLES:

```
sage: V = QQ^3
sage: W = V.subspace([[2,'1/2', 1]])
sage: W.has_user_basis()
False
sage: W = V.subspace_with_basis([[2,'1/2',1]])
sage: W.has_user_basis()
True
```

class **FreeModule_submodule_pid**(*ambient, gens, check=True, already_echelonized=False*)

An R-submodule of K^n where K is the fraction field of a principal ideal domain R.

EXAMPLES:

```
sage: M = ZZ^3
sage: W = M.span_of_basis([[1,2,3],[4,5,19]]); W
Free module of degree 3 and rank 2 over Integer Ring
User basis matrix:
[ 1  2  3]
[ 4  5 19]
```

We can save and load submodules and elements.

```
sage: loads(W.dumps()) == W
True
sage: v = W.0 + W.1
sage: loads(v.dumps()) == v
True
```

coordinate_vector(*v, check=True*)

Write v in terms of the user basis for self.

INPUT:

- `v` - vector
- `check` - bool (default: True); if True, also verify that v is really in self.

OUTPUT: list

Returns a list c such that if B is the basis for self, then

$$\sum c_i B_i = v.$$

If v is not in self, raises an `ArithmeticError` exception.

EXAMPLES:

```
sage: V = ZZ^3
sage: W = V.span_of_basis([[1,2,3],[4,5,6]])
sage: W.coordinate_vector([1,5,9])
(5, -1)
```

has_user_basis()

Return `True` if the basis of this free module is specified by the user, as opposed to being the default echelon form.

EXAMPLES:

```
sage: A = ZZ^3; A
Ambient free module of rank 3 over the principal ideal domain Integer Ring
sage: A.has_user_basis()
False
sage: W = A.span_of_basis([[2,'1/2',1]])
sage: W.has_user_basis()
True
sage: W = A.span([[2,'1/2',1]])
sage: W.has_user_basis()
False
```

class FreeModule_submodule_with_basis_field(*ambient, basis, check=True, echelonize=False, echelonized_basis=None, already_echelonized=False*)

An embedded vector subspace with a distinguished user basis.

EXAMPLES:

```
sage: M = QQ^3; W = M.submodule_with_basis([[1,2,3], [4,5,19]]); W
Vector space of degree 3 and dimension 2 over Rational Field
User basis matrix:
[ 1  2  3]
[ 4  5 19]
```

Since this is an embedded vector subspace with a distinguished user basis possibly different than the echelonized basis, the echelon_coordinates() and user coordinates() do not agree:

```
sage: V = QQ^3

sage: W = V.submodule_with_basis([[1,2,3], [4,5,6]])
sage: W
Vector space of degree 3 and dimension 2 over Rational Field
User basis matrix:
[1 2 3]
[4 5 6]

sage: v = V([1,5,9])
sage: W.echelon_coordinates(v)
[1, 5]
sage: vector(QQ, W.echelon_coordinates(v)) * W.echelonized_basis_matrix()
(1, 5, 9)

sage: v = V([1,5,9])
sage: W.coordinates(v)
[5, -1]
```

```
sage: vector(QQ, W.coordinates(v)) * W.basis_matrix()
(1, 5, 9)
```

We can load and save submodules:

```
sage: loads(W.dumps()) == W
True
```

```
sage: K.<x> = FractionField(PolynomialRing(QQ,'x'))
sage: M = K^3; W = M.span_of_basis([[1,1,x]])
sage: loads(W.dumps()) == W
True
```

is_ambient()

Return False since this is not an ambient module.

EXAMPLES:

```
sage: V = QQ^3
sage: V.is_ambient()
True
sage: W = V.span_of_basis([[1,2,3],[4,5,6]])
sage: W.is_ambient()
False
```

class **FreeModule_submodule_with_basis_pid**(*ambient, basis, check=True, echelonize=False, echelonized_basis=None, already_echelonized=False*)

An R-submodule of K^n with distinguished basis, where K is the fraction field of a principal ideal domain R.

ambient_module()

Return the ambient module related to the R-module self, which was used when creating this module, and is of the form R^n. Note that self need not be contained in the ambient module, though self will be contained in the ambient vector space.

EXAMPLES:

```
sage: A = ZZ^3
sage: M = A.span_of_basis([[1,2,'3/7'],[4,5,6]])
sage: M
Free module of degree 3 and rank 2 over Integer Ring
User basis matrix:
[  1   2 3/7]
[  4   5   6]
sage: M.ambient_module()
Ambient free module of rank 3 over the principal ideal domain Integer Ring
sage: M.is_submodule(M.ambient_module())
False
```

ambient_vector_space()

Return the ambient vector space in which this free module is embedded.

EXAMPLES:

```
sage: M = ZZ^3;  M.ambient_vector_space()
Vector space of dimension 3 over Rational Field
```

```
sage: N = M.span_of_basis([[1,2,'1/5']])
sage: N
Free module of degree 3 and rank 1 over Integer Ring
User basis matrix:
[  1   2 1/5]
```

```
sage: M.ambient_vector_space()
Vector space of dimension 3 over Rational Field
sage: M.ambient_vector_space() is N.ambient_vector_space()
True
```

If an inner product on the module is specified, then this is preserved on the ambient vector space.

```
sage: M = FreeModule(ZZ,4,inner_product_matrix=1)
sage: V = M.ambient_vector_space()
sage: V
Ambient quadratic space of dimension 4 over Rational Field
Inner product matrix:
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: N = M.submodule([[1,-1,0,0],[0,1,-1,0],[0,0,1,-1]])
sage: N.gram_matrix()
[2 1 1]
[1 2 1]
[1 1 2]
sage: V == N.ambient_vector_space()
True
```

basis()

Return the user basis for this free module.

EXAMPLES:

```
sage: V = ZZ^3
sage: V.basis()
[
(1, 0, 0),
(0, 1, 0),
(0, 0, 1)
]
sage: M = V.span_of_basis([['1/8',2,1]])
sage: M.basis()
[
(1/8, 2, 1)
]
```

change_ring(*R*)

Return the free module over R obtained by coercing each element of self into a vector over the fraction field of R, then taking the resulting R-module. Raises a TypeError if coercion is not possible.

INPUT:

- R - a principal ideal domain

EXAMPLES:

```
sage: V = QQ^3
sage: W = V.subspace([[2,'1/2', 1]])
sage: W.change_ring(GF(7))
Vector space of degree 3 and dimension 1 over Finite Field of size 7
Basis matrix:
[1 2 4]
```

construction()

Returns the functorial construction of self, namely, the subspace of the ambient module spanned by the given basis.

EXAMPLE:

```
sage: M = ZZ^3
sage: W = M.span_of_basis([[1,2,3],[4,5,6]]); W
Free module of degree 3 and rank 2 over Integer Ring
User basis matrix:
[1 2 3]
[4 5 6]
sage: c, V = W.construction()
sage: c(V) == W
True
```

coordinate_vector(*v, check=True*)

Write v in terms of the user basis for self.

INPUT:

- v - vector
- check - bool (default: True); if True, also verify that v is really in self.

OUTPUT: list

Returns a vector c such that if B is the basis for self, then

If v is not in self, raises an ArithmeticError exception.

EXAMPLES:

```
sage: V = ZZ^3
sage: M = V.span_of_basis([['1/8',2,1]])
sage: M.coordinate_vector([1,16,8])
(8)
```

echelon_coordinate_vector(*v, check=True*)

Write v in terms of the user basis for self.

INPUT:

- v - vector
- check - bool (default: True); if True, also verify that v is really in self.

Returns a list c such that if B is the echelonized basis for self, then

$$\sum c_i B_i = v.$$

If v is not in self, raises an ArithmeticError exception.

EXAMPLES:

```
sage: V = ZZ^3
sage: M = V.span_of_basis([['1/2',3,1], [0,'1/6',0]])
sage: B = M.echelonized_basis(); B
[
(1/2, 0, 1),
(0, 1/6, 0)
]
sage: M.echelon_coordinate_vector(['1/2', 3, 1])
(1, 18)
```

echelon_coordinates(*v, check=True*)

Write v in terms of the echelonized basis for self.

INPUT:

- v - vector
- check - bool (default: True); if True, also verify that v is really in self.

OUTPUT: list

Returns a list c such that if B is the basis for self, then

$$\sum c_i B_i = v.$$

If v is not in self, raises an `ArithmeticError` exception.

EXAMPLES:

```
sage: A = ZZ^3
sage: M = A.span_of_basis([[1,2,'3/7'],[4,5,6]])
sage: M.coordinates([8,10,12])
[0, 2]
sage: M.echelon_coordinates([8,10,12])
[8, -2]
sage: B = M.echelonized_basis(); B
[
(1, 2, 3/7),
(0, 3, -30/7)
]
sage: 8*B[0] - 2*B[1]
(8, 10, 12)
```

We do an example with a sparse vector space:

```
sage: V = VectorSpace(QQ,5, sparse=True)
sage: W = V.subspace_with_basis([[0,1,2,0,0], [0,-1,0,0,-1/2]])
sage: W.echelonized_basis()
[
(0, 1, 0, 0, 1/2),
(0, 0, 1, 0, -1/4)
]
sage: W.echelon_coordinates([0,0,2,0,-1/2])
[0, 2]
```

echelon_to_user_matrix()

Return matrix that transforms the echelon basis to the user basis of self. This is a matrix A such that if v is a vector written with respect to the echelon basis for self then vA is that vector written with respect to the user basis of self.

EXAMPLES:

```
sage: V = QQ^3
sage: W = V.span_of_basis([[1,2,3],[4,5,6]])
sage: W.echelonized_basis()
[
(1, 0, -1),
(0, 1, 2)
]
sage: A = W.echelon_to_user_matrix(); A
[-5/3  2/3]
[ 4/3 -1/3]
```

The vector $(1, 1, 1)$ has coordinates $v = (1, 1)$ with respect to the echelonized basis for self. Multiplying vA we find the coordinates of this vector with respect to the user basis.

```
sage: v = vector(QQ, [1,1]); v
(1, 1)
sage: v * A
(-1/3, 1/3)
sage: u0, u1 = W.basis()
```

```
sage: (-u0 + u1)/3
(1, 1, 1)
```

echelonized_basis()

Return the basis for self in echelon form.

EXAMPLES:

```
sage: V = ZZ^3
sage: M = V.span_of_basis([['1/2',3,1], [0,'1/6',0]])
sage: M.basis()
[
(1/2, 3, 1),
(0, 1/6, 0)
]
sage: B = M.echelonized_basis(); B
[
(1/2, 0, 1),
(0, 1/6, 0)
]
sage: V.span(B) == M
True
```

echelonized_basis_matrix()

Return basis matrix for self in row echelon form.

EXAMPLES:

```
sage: V = FreeModule(ZZ, 3).span_of_basis([[1,2,3],[4,5,6]])
sage: V.basis_matrix()
[1 2 3]
[4 5 6]
sage: V.echelonized_basis_matrix()
[1 2 3]
[0 3 6]
```

has_user_basis()

Return `True` if the basis of this free module is specified by the user, as opposed to being the default echelon form.

EXAMPLES:

```
sage: V = ZZ^3; V.has_user_basis()
False
sage: M = V.span_of_basis([[1,3,1]]); M.has_user_basis()
True
sage: M = V.span([[1,3,1]]); M.has_user_basis()
False
```

linear_combination_of_basis(*v*)

Return the linear combination of the basis for self obtained from the coordinates of v.

EXAMPLES:

```
sage: V = span([[1,2,3], [4,5,6]], ZZ); V
Free module of degree 3 and rank 2 over Integer Ring
Echelon basis matrix:
[1 2 3]
[0 3 6]
sage: V.linear_combination_of_basis([1,1])
(1, 5, 9)
```

user_to_echelon_matrix()

Return matrix that transforms a vector written with respect to the user basis of self to one written with respect to the echelon basis. The matrix acts from the right, as is usual in Sage.

EXAMPLES:

```
sage: A = ZZ^3
sage: M = A.span_of_basis([[1,2,3],[4,5,6]])
sage: M.echelonized_basis()
[
(1, 2, 3),
(0, 3, 6)
]
sage: M.user_to_echelon_matrix()
[ 1  0]
[ 4 -1]
```

The vector $v = (5, 7, 9)$ in M is $(1, 1)$ with respect to the user basis. Multiplying the above matrix on the right by this vector yields $(5, -1)$, which has components the coordinates of v with respect to the echelon basis.

```
sage: v0,v1 = M.basis(); v = v0+v1
sage: e0,e1 = M.echelonized_basis()
sage: v
(5, 7, 9)
sage: 5*e0 + (-1)*e1
(5, 7, 9)
```

vector_space(*base_field=None*)

Return the vector space associated to this free module via tensor product with the fraction field of the base ring.

EXAMPLES:

```
sage: A = ZZ^3; A
Ambient free module of rank 3 over the principal ideal domain Integer Ring
sage: A.vector_space()
Vector space of dimension 3 over Rational Field
sage: M = A.span_of_basis([['1/3',2,'3/7'],[4,5,6]]); M
Free module of degree 3 and rank 2 over Integer Ring
User basis matrix:
[1/3   2 3/7]
[  4   5   6]
sage: M.vector_space()
Vector space of degree 3 and dimension 2 over Rational Field
User basis matrix:
[1/3   2 3/7]
[  4   5   6]
```

class RealDoubleVectorSpace_class(*n*)

coordinates(*v*)

VectorSpace(*K, dimension, sparse=False, inner_product_matrix=None*)

EXAMPLES:

The base can be complicated, as long as it is a field.

```
sage: V = VectorSpace(FractionField(PolynomialRing(ZZ,'x')),3)
sage: V
Vector space of dimension 3 over Fraction Field of Univariate Polynomial Ring in x over Integer
sage: V.basis()
[
```

```
(1, 0, 0),
(0, 1, 0),
(0, 0, 1)
]
```

The base must be a field or a `TypeError` is raised.

```
sage: VectorSpace(ZZ,5)
...
TypeError: Argument K (= Integer Ring) must be a field.
```

basis_seq(*V, vecs*)

This converts a list vecs of vectors in V to an Sequence of immutable vectors.

Should it? I.e. in most other parts of the system the return type of basis or generators is a tuple.

EXAMPLES:

```
sage: V = VectorSpace(QQ,2)
sage: B = V.gens()
sage: B
((1, 0), (0, 1))
sage: v = B[0]
sage: v[0] = 0 # immutable
...
ValueError: vector is immutable; please change a copy instead (use self.copy())
sage: sage.modules.free_module.basis_seq(V, V.gens())
[
(1, 0),
(0, 1)
]
```

element_class(*R, is_sparse*)

The class of the vectors (elements of a free module) with base ring R and boolean is_sparse.

EXAMPLES:

```
sage: FF = FiniteField(2)
sage: P = PolynomialRing(FF,'x')
sage: sage.modules.free_module.element_class(QQ, is_sparse=True)
<type 'sage.modules.free_module_element.FreeModuleElement_generic_sparse'>
sage: sage.modules.free_module.element_class(QQ, is_sparse=False)
<type 'sage.modules.vector_rational_dense.Vector_rational_dense'>
sage: sage.modules.free_module.element_class(ZZ, is_sparse=True)
<type 'sage.modules.free_module_element.FreeModuleElement_generic_sparse'>
sage: sage.modules.free_module.element_class(ZZ, is_sparse=False)
<type 'sage.modules.vector_integer_dense.Vector_integer_dense'>
sage: sage.modules.free_module.element_class(FF, is_sparse=True)
<type 'sage.modules.free_module_element.FreeModuleElement_generic_sparse'>
sage: sage.modules.free_module.element_class(FF, is_sparse=False)
<type 'sage.modules.vector_modn_dense.Vector_modn_dense'>
sage: sage.modules.free_module.element_class(P, is_sparse=True)
<type 'sage.modules.free_module_element.FreeModuleElement_generic_sparse'>
sage: sage.modules.free_module.element_class(P, is_sparse=False)
<type 'sage.modules.free_module_element.FreeModuleElement_generic_dense'>
```

is_FreeModule(*M*)

Return True if M inherits from from FreeModule_generic.

EXAMPLES:

```
sage: from sage.modules.free_module import is_FreeModule
sage: V = ZZ^3
sage: is_FreeModule(V)
True
sage: W = V.span([ V.random_element() for i in range(2) ])
sage: is_FreeModule(W)
True
```

span(*gens, base_ring=None, check=True, already_echelonized=False*)

Return the R-span of gens (a list of vectors) where R = base_ring.

EXAMPLES:

```
sage: V = span([[1,2,5], [2,2,2]], QQ); V
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1  0 -3]
[ 0  1  4]
sage: span([V.gen(0)], QuadraticField(-7,'a'))
Vector space of degree 3 and dimension 1 over Number Field in a with defining polynomial x^2 + 7
Basis matrix:
[ 1  0 -3]
sage: span([[1,2,3], [2,2,2], [1,2,5]], GF(2))
Vector space of degree 3 and dimension 1 over Finite Field of size 2
Basis matrix:
[1 0 1]
```

TESTS:

```
sage: span([[1,2,3], [2,2,2], [1,2/3,5]], ZZ)
Free module of degree 3 and rank 3 over Integer Ring
Echelon basis matrix:
[  1   0  13]
[  0 2/3   6]
[  0   0  14]
sage: span([[1,2,3], [2,2,2], [1,2,QQ['x'].gen()]], ZZ)
...
ValueError: The elements of gens (= [[1, 2, 3], [2, 2, 2], [1, 2, x]]) must be defined over base
```

For backwards compatibility one can also give the base ring as the first argument:

```
sage: span(QQ,[[1,2],[3,4]])
Vector space of degree 2 and dimension 2 over Rational Field
Basis matrix:
[1 0]
[0 1]
```

Fix trac 5575:

```
sage: V = QQ^3
sage: span([V.0, V.1])
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[1 0 0]
[0 1 0]
```

33.3 Elements of free modules

AUTHORS:

- William Stein
- Josh Kantor

TODO: Change to use a get_unsafe / set_unsafe, etc., structure exactly like with matrices, since we'll have to define a bunch of special purpose implementations of vectors easily and systematically.

EXAMPLES: We create a vector space over $\mathbf{Q}$ and a subspace of this space.

```
sage: V = QQ^5
sage: W = V.span([V.1, V.2])
```

Arithmetic operations always return something in the ambient space, since there is a canonical map from W to V but not from V to W.

```
sage: parent(W.0 + V.1)
Vector space of dimension 5 over Rational Field
sage: parent(V.1 + W.0)
Vector space of dimension 5 over Rational Field
sage: W.0 + V.1
(0, 2, 0, 0, 0)
sage: W.0 - V.0
(-1, 1, 0, 0, 0)
```

Next we define modules over $\mathbf{Z}$ and a finite field.

```
sage: K = ZZ^5
sage: M = GF(7)^5
```

Arithmetic between the $\mathbf{Q}$ and $\mathbf{Z}$ modules is defined, and the result is always over $\mathbf{Q}$, since there is a canonical coercion map to $\mathbf{Q}$.

```
sage: K.0 + V.1
(1, 1, 0, 0, 0)
sage: parent(K.0 + V.1)
Vector space of dimension 5 over Rational Field
```

Since there is no canonical coercion map to the finite field from $\mathbf{Q}$ the following arithmetic is not defined:

```
sage: V.0 + M.0
...
TypeError: unsupported operand parent(s) for '+': 'Vector space of dimension 5 over Rational Field' a
```

However, there is a map from $\mathbf{Z}$ to the finite field, so the following is defined, and the result is in the finite field.

```
sage: w = K.0 + M.0; w
(2, 0, 0, 0, 0)
sage: parent(w)
Vector space of dimension 5 over Finite Field of size 7
sage: parent(M.0 + K.0)
Vector space of dimension 5 over Finite Field of size 7
```

Matrix vector multiply:

```
sage: MS = MatrixSpace(QQ,3)
sage: A = MS([0,1,0,1,0,0,0,0,1])
sage: V = QQ^3
sage: v = V([1,2,3])
sage: v * A
(2, 1, 3)
```

TESTS:

```
sage: D = 46341
sage: u = 7
sage: R = Integers(D)
sage: p = matrix(R,[[84, 97, 55, 58, 51]])
sage: 2*p.row(0)
(168, 194, 110, 116, 102)
```

class FreeModuleElement()

An element of a generic free module.

Mod()

EXAMPLES:

```
sage: V = vector(ZZ, [5, 9, 13, 15])
sage: V.Mod(7)
(5, 2, 6, 1)
sage: parent(V.Mod(7))
Vector space of dimension 4 over Ring of integers modulo 7
```

additive_order()

Return the additive order of self.

EXAMPLES:

```
sage: v = vector(Integers(4), [1,2])
sage: v.additive_order()
4

sage: v = vector([1,2,3])
sage: v.additive_order()
+Infinity

sage: v = vector(Integers(30), [6, 15]); v
(6, 15)
sage: v.additive_order()
10
sage: 10*v
(0, 0)
```

apply_map()

Apply the given map phi (an arbitrary Python function or callable object) to this free module element. If R is not given, automatically determine the base ring of the resulting element.

INPUT: **sparse – True or False will control whether the result** is sparse. By default, the result is sparse iff self is sparse.

- `phi` - arbitrary Python function or callable object
- `R` - (optional) ring

OUTPUT: a free module element over R
EXAMPLES:

```
sage: m = vector([1,x,sin(x+1)])
sage: m.apply_map(lambda x: x^2)
(1, x^2, sin(x + 1)^2)
sage: m.apply_map(sin)
(sin(1), sin(x), sin(sin(x + 1)))

sage: m = vector(ZZ, 9, range(9))
sage: k.<a> = GF(9)
sage: m.apply_map(k)
(0, 1, 2, 0, 1, 2, 0, 1, 2)
```

In this example, we explicitly specify the codomain.

```
sage: s = GF(3)
sage: f = lambda x: s(x)
sage: n = m.apply_map(f, k); n
(0, 1, 2, 0, 1, 2, 0, 1, 2)
sage: n.parent()
Vector space of dimension 9 over Finite Field in a of size 3^2
```

If your map sends 0 to a non-zero value, then your resulting vector is not mathematically sparse:

```
sage: v = vector([0] * 6 + [1], sparse=True); v
(0, 0, 0, 0, 0, 0, 1)
sage: v2 = v.apply_map(lambda x: x+1); v2
(1, 1, 1, 1, 1, 1, 2)
```

but it's still represented with a sparse data type:

```
sage: parent(v2)
Ambient sparse free module of rank 7 over the principal ideal domain Integer Ring
```

This data type is inefficient for dense vectors, so you may want to specify sparse=False:

```
sage: v2 = v.apply_map(lambda x: x+1, sparse=False); v2
(1, 1, 1, 1, 1, 1, 2)
sage: parent(v2)
Ambient free module of rank 7 over the principal ideal domain Integer Ring
```

Or if you have a map that will result in mostly zeroes, you may want to specify sparse=True:

```
sage: v = vector(srange(10))
sage: v2 = v.apply_map(lambda x: 0 if x else 1, sparse=True); v2
(1, 0, 0, 0, 0, 0, 0, 0, 0, 0)
sage: parent(v2)
Ambient sparse free module of rank 10 over the principal ideal domain Integer Ring
```

TESTS:

```
sage: m = vector(SR,[])
sage: m.apply_map(lambda x: x*x) == m
True
```

Check that we don't unnecessarily apply phi to 0 in the sparse case:

```
sage: m = vector(ZZ, range(1, 4), sparse=True)
sage: m.apply_map(lambda x: 1/x)
(1, 1/2, 1/3)

sage: parent(vector(RDF, (), sparse=True).apply_map(lambda x: x, sparse=True))
Sparse vector space of dimension 0 over Real Double Field
```

```
sage: parent(vector(RDF, (), sparse=True).apply_map(lambda x: x, sparse=False))
Vector space of dimension 0 over Real Double Field
sage: parent(vector(RDF, (), sparse=False).apply_map(lambda x: x, sparse=True))
Sparse vector space of dimension 0 over Real Double Field
sage: parent(vector(RDF, (), sparse=False).apply_map(lambda x: x, sparse=False))
Vector space of dimension 0 over Real Double Field
```

change_ring()

Change the base ring of this vector, by coercing each element of this vector into R.

EXAMPLES:

```
sage: v = vector(QQ['x,y'], [1..5]); v.change_ring(GF(3))
(1, 2, 0, 1, 2)
```

copy()

Make a copy of this vector.

EXAMPLES:

```
sage: v = vector([1..5]); v
(1, 2, 3, 4, 5)
sage: w = v.copy()
sage: v == w
True
sage: v is w
False

sage: v = vector([1..5], sparse=True); v
(1, 2, 3, 4, 5)
sage: v.copy()
(1, 2, 3, 4, 5)
```

cross_product()

Return the cross product of self and right, which is only defined for vectors of length 3.

This product is performed under the assumption that the basis vectors are orthonormal.

EXAMPLES:

```
sage: v = vector([1,2,3]); w = vector([0,5,-9])
sage: v.cross_product(v)
(0, 0, 0)
sage: u = v.cross_product(w); u
(-33, 9, 5)
sage: u.dot_product(v)
0
sage: u.dot_product(w)
0
```

degree()

denominator()

dense_vector()

derivative()

Derivative with respect to variables supplied in args.

Multiple variables and iteration counts may be supplied; see documentation for the global derivative() function for more details.

EXAMPLES:

```
sage: v = vector([1,x,x^2])
sage: v.derivative(x)
```

```
(0, 1, 2*x)
sage: type(v.derivative(x)) == type(v)
True
sage: v = vector([1,x,x^2], sparse=True)
sage: v.derivative(x)
(0, 1, 2*x)
sage: type(v.derivative(x)) == type(v)
True
sage: v.derivative(x,x)
(0, 0, 2)
```

dict()

dot_product()

Return the dot product of self and right, which is the sum of the product of the corresponding entries.

INPUT:

- `right` - vector of the same degree as self. It need not be in the same vector space as self, as long as the coefficients can be multiplied.

EXAMPLES:

```
sage: V = FreeModule(ZZ, 3)
sage: v = V([1,2,3])
sage: w = V([4,5,6])
sage: v.dot_product(w)
32

sage: W = VectorSpace(GF(3),3)
sage: w = W([0,1,2])
sage: w.dot_product(v)
2
sage: w.dot_product(v).parent()
Finite Field of size 3
```

Implicit coercion is well defined (regardless of order), so we get 2 even if we do the dot product in the other order.

```
sage: v.dot_product(w)
2
```

element()

get()

get is meant to be more efficient than getitem, because it does not do any error checking.

inner_product()

Returns the inner product of self and other, with respect to the inner product defined on the parent of self.

EXAMPLES:

```
sage: I = matrix(ZZ,3,[2,0,-1,0,2,0,-1,0,6])
sage: M = FreeModule(ZZ, 3, inner_product_matrix = I)
sage: (M.0).inner_product(M.0)
2
sage: K = M.span_of_basis([[0/2,-1/2,-1/2], [0,1/2,-1/2],[2,0,0]])
sage: (K.0).inner_product(K.0)
2
```

is_dense()

is_immutable()

Return True if this vector is immutable, i.e., the entries cannot be changed.

EXAMPLES:

```
sage: v = vector(QQ['x,y'], [1..5]); v.is_immutable()
False
sage: v.set_immutable()
sage: v.is_immutable()
True
```

is_mutable()

Return True if this vector is mutable, i.e., the entries can be changed.

EXAMPLES:

```
sage: v = vector(QQ['x,y'], [1..5]); v.is_mutable()
True
sage: v.set_immutable()
sage: v.is_mutable()
False
```

is_sparse()

is_vector()

iteritems()

lift()

EXAMPLES:

```
sage: V = vector(Integers(7), [5, 9, 13, 15]) ; V
(5, 2, 6, 1)
sage: V.lift()
(5, 2, 6, 1)
sage: parent(V.lift())
Ambient free module of rank 4 over the principal ideal domain Integer Ring
```

list()

list_from_positions()

nonzero_positions()

Return the sorted list of integers i such that self[i] != 0.

norm()

Return the p-norm of this vector, where p can be a real number ≥ 1, Infinity, or a symbolic expression. If $p = 2$ (default), this is the usual Euclidean norm; if p=Infinity, this is the maximum norm; if $p = 1$, this is the taxicab (Manhattan) norm.

EXAMPLES:

```
sage: v = vector([1,2,-3])
sage: v.norm(5)
276^(1/5)
```

The default is the usual Euclidean norm:

```
sage: v.norm()
sqrt(14)
sage: v.norm(2)
sqrt(14)
```

The infinity norm is the maximum size of any entry:

```
sage: v.norm(Infinity)
3
```

Any real or symbolic value works:

```
sage: v=vector(RDF,[1,2,3])
sage: v.norm(5)
3.07738488539
sage: v.norm(pi/2)
4.2165958647
sage: _=var('a b c d p'); v=vector([a, b, c, d])
sage: v.norm(p)
(abs(a)^p + abs(b)^p + abs(c)^p + abs(d)^p)^(1/p)
```

normalize()

Return this vector divided through by the first nonzero entry of this vector.

EXAMPLES:

```
sage: v = vector(QQ,[0,4/3,5,1,2])
sage: v.normalize()
(0, 1, 15/4, 3/4, 3/2)
```

pairwise_product()

Return the pairwise product of self and right, which is a vector of the products of the corresponding entries.

INPUT:

- `right` - vector of the same degree as self. It need not be in the same vector space as self, as long as the coefficients can be multiplied.

EXAMPLES:

```
sage: V = FreeModule(ZZ, 3)
sage: v = V([1,2,3])
sage: w = V([4,5,6])
sage: v.pairwise_product(w)
(4, 10, 18)
sage: sum(v.pairwise_product(w)) == v.dot_product(w)
True

sage: W = VectorSpace(GF(3),3)
sage: w = W([0,1,2])
sage: w.pairwise_product(v)
(0, 2, 0)
sage: w.pairwise_product(v).parent()
Vector space of dimension 3 over Finite Field of size 3
```

Implicit coercion is well defined (regardless of order), so we get 2 even if we do the dot product in the other order.

```
sage: v.pairwise_product(w).parent()
Vector space of dimension 3 over Finite Field of size 3
```

TESTS:

```
sage: x, y = var('x, y')

sage: parent(vector(ZZ,[1,2]).pairwise_product(vector(ZZ,[1,2])))
Ambient free module of rank 2 over the principal ideal domain Integer Ring
sage: parent(vector(ZZ,[1,2]).pairwise_product(vector(QQ,[1,2])))
Vector space of dimension 2 over Rational Field
sage: parent(vector(QQ,[1,2]).pairwise_product(vector(ZZ,[1,2])))
Vector space of dimension 2 over Rational Field
sage: parent(vector(QQ,[1,2]).pairwise_product(vector(QQ,[1,2])))
Vector space of dimension 2 over Rational Field
```

```
sage: parent(vector(QQ,[1,2,3,4]).pairwise_product(vector(ZZ[x],[1,2,3,4])))
Ambient free module of rank 4 over the principal ideal domain Univariate Polynomial Ring in
sage: parent(vector(ZZ[x],[1,2,3,4]).pairwise_product(vector(QQ,[1,2,3,4])))
Ambient free module of rank 4 over the principal ideal domain Univariate Polynomial Ring in

sage: parent(vector(QQ,[1,2,3,4]).pairwise_product(vector(ZZ[x][y],[1,2,3,4])))
Ambient free module of rank 4 over the integral domain Univariate Polynomial Ring in y over
sage: parent(vector(ZZ[x][y],[1,2,3,4]).pairwise_product(vector(QQ,[1,2,3,4])))
Ambient free module of rank 4 over the integral domain Univariate Polynomial Ring in y over

sage: parent(vector(QQ[x],[1,2,3,4]).pairwise_product(vector(ZZ[x][y],[1,2,3,4])))
Ambient free module of rank 4 over the integral domain Univariate Polynomial Ring in y over
sage: parent(vector(ZZ[x][y],[1,2,3,4]).pairwise_product(vector(QQ[x],[1,2,3,4])))
Ambient free module of rank 4 over the integral domain Univariate Polynomial Ring in y over

sage: parent(vector(QQ[y],[1,2,3,4]).pairwise_product(vector(ZZ[x][y],[1,2,3,4])))
Ambient free module of rank 4 over the integral domain Univariate Polynomial Ring in y over
sage: parent(vector(ZZ[x][y],[1,2,3,4]).pairwise_product(vector(QQ[y],[1,2,3,4])))
Ambient free module of rank 4 over the integral domain Univariate Polynomial Ring in y over

sage: parent(vector(ZZ[x],[1,2,3,4]).pairwise_product(vector(ZZ[y],[1,2,3,4])))
...
TypeError: no common canonical parent for objects with parents: 'Ambient free module of rank
sage: parent(vector(ZZ[x],[1,2,3,4]).pairwise_product(vector(QQ[y],[1,2,3,4])))
...
TypeError: no common canonical parent for objects with parents: 'Ambient free module of rank
sage: parent(vector(QQ[x],[1,2,3,4]).pairwise_product(vector(ZZ[y],[1,2,3,4])))
...
TypeError: no common canonical parent for objects with parents: 'Ambient free module of rank
sage: parent(vector(QQ[x],[1,2,3,4]).pairwise_product(vector(QQ[y],[1,2,3,4])))
...
TypeError: no common canonical parent for objects with parents: 'Ambient free module of rank
sage: v = vector({1: 1, 3: 2})  # test sparse vectors
sage: w = vector({0: 6, 3: -4})
sage: v.pairwise_product(w)
(0, 0, 0, -8)
sage: w.pairwise_product(v) == v.pairwise_product(w)
True
```

plot()

INPUT:

- **plot_type - (default: 'arrow' if v has 3 or fewer components,** otherwise 'step') type of plot. Options are:
  - 'arrow' to draw an arrow
  - 'point' to draw a point at the coordinates specified by the vector
  - 'step' to draw a step function representing the coordinates of the vector.

  Both 'arrow' and 'point' raise exceptions if the vector has more than 3 dimensions.

EXAMPLES:

```
sage: v = vector(RDF, (1,2))
sage: eps = 0.1
sage: plot(v, plot_type='arrow')
sage: plot(v, plot_type='point')
sage: plot(v, plot_type='step') # calls v.plot_step()
sage: plot(v, plot_type='step', eps=eps, xmax=5, hue=0)
sage: v = vector(RDF, (1,2,1))
```

```
sage: plot(v) # defaults to an arrow plot
sage: plot(v, plot_type='arrow')
sage: from sage.plot.plot3d.shapes2 import frame3d
sage: plot(v, plot_type='point')+frame3d((0,0,0), v.list())
sage: plot(v, plot_type='step') # calls v.plot_step()
sage: plot(v, plot_type='step', eps=eps, xmax=5, hue=0)
sage: v = vector(RDF, (1,2,3,4))
sage: plot(v) # defaults to a step plot
```

plot_step()

INPUT:

- xmin - (default: 0) start x position to start plotting
- xmax - (default: 1) stop x position to stop plotting
- eps - (default: determined by xmax) we view this vector as defining a function at the points xmin, xmin + eps, xmin + 2*eps, ...,
- res - (default: all points) total number of points to include in the graph
- connect - (default: True) if True draws a line; otherwise draw a list of points.

EXAMPLES:

```
sage: eps=0.1
sage: v = vector(RDF, [sin(n*eps) for n in range(100)])
sage: v.plot_step(eps=eps, xmax=5, hue=0)
```

set()

set is meant to be more efficient than setitem, because it does not do any error checking or coercion. Use with care.

set_immutable()

Make this vector immutable. This operation can't be undone.

EXAMPLES:

```
sage: v = vector([1..5]); v
(1, 2, 3, 4, 5)
sage: v[1] = 10
sage: v.set_immutable()
sage: v[1] = 10
...
ValueError: vector is immutable; please change a copy instead (use self.copy())
```

sparse_vector()

support()

Return the integers i such that self[i] != 0. This is the same as the nonzero_positions function.

transpose()

EXAMPLES:

```
sage: v = vector(ZZ, [2, 12, 22])
sage: transpose(vector(v))
[ 2]
[12]
[22]

sage: transpose(vector(GF(7), v))
[2]
[5]
[1]
```

```
sage: transpose(vector(v, ZZ['x', 'y']))
[ 2]
[12]
[22]
```

class FreeModuleElement_generic_dense()

A generic dense element of a free module.

list()

n()

Returns a numerical approximation of self by calling the n() method on all of its entries.

EXAMPLES:

```
sage: v = vector(RealField(212), [1,2,3])
sage: v.n()
(1.00000000000000, 2.00000000000000, 3.00000000000000)
sage: _.parent()
Vector space of dimension 3 over Real Field with 53 bits of precision
sage: v.n(prec=75)
(1.000000000000000000000, 2.000000000000000000000, 3.000000000000000000000)
sage: _.parent()
Vector space of dimension 3 over Real Field with 75 bits of precision
```

class FreeModuleElement_generic_sparse()

A generic sparse free module element is a dictionary with keys ints i and entries in the base ring.

EXAMPLES:

Pickling works:

```
sage: v = FreeModule(ZZ, 3, sparse=True).0
sage: loads(dumps(v)) == v
True
sage: v = FreeModule(Integers(8)['x,y'], 5, sparse=True).1
sage: loads(dumps(v)) - v
(0, 0, 0, 0, 0)
```

```
sage: a = vector([-1,0,1/1],sparse=True); b = vector([-1/1,0,0],sparse=True)
sage: a.parent()
Sparse vector space of dimension 3 over Rational Field
sage: b - a
(0, 0, -1)
sage: (b-a).dict()
{2: -1}
```

denominator()

dict()

get()

Like __getitem__ but with no type or bounds checking. Returns 0 if access is out of bounds.

iteritems()

list()

n()

Returns a numerical approximation of self by calling the n() method on all of its entries.

EXAMPLES:

```
sage: v = vector(RealField(200), [1,2,3], sparse=True)
sage: v.n()
(1.00000000000000, 2.00000000000000, 3.00000000000000)
sage: _.parent()
Sparse vector space of dimension 3 over Real Field with 53 bits of precision
sage: v.n(prec=75)
(1.000000000000000000000, 2.000000000000000000000, 3.000000000000000000000)
sage: _.parent()
Sparse vector space of dimension 3 over Real Field with 75 bits of precision
```

nonzero_positions()
Returns the list of numbers i such that self[i] != 0.
EXAMPLES:

```
sage: v = vector({1: 1, 3: -2})
sage: w = vector({1: 4, 3: 2})
sage: v+w
(0, 5, 0, 0)
sage: (v+w).nonzero_positions()
[1]
```

set()
Like __setitem__ but with no type or bounds checking.

free_module_element()
Return a vector over R with given entries.
CALL FORMATS:

1.vector(object)
2.vector(ring, object)
3.vector(object, ring)
4.vector(numpy_array)

In each case, give `sparse=True` or `sparse=False` as an option.
INPUT:

- `elts` - entries of a vector (either a list or dict).
- `R` - ring
- `sparse` - optional

OUTPUT: An element of the free module over R of rank len(elts).
EXAMPLES:

```
sage: v = vector([1,2,3]); v
(1, 2, 3)
sage: v.parent()
Ambient free module of rank 3 over the principal ideal domain Integer Ring
sage: v = vector([1,2,3/5]); v
(1, 2, 3/5)
sage: v.parent()
Vector space of dimension 3 over Rational Field
```

All entries must *canonically* coerce to some common ring:

```
sage: v = vector([17, GF(11)(5), 19/3]); v
...
TypeError: unable to find a common ring for all elements
```

```
sage: v = vector([17, GF(11)(5), 19]); v
(6, 5, 8)
sage: v.parent()
Vector space of dimension 3 over Finite Field of size 11
sage: v = vector([17, GF(11)(5), 19], QQ); v
(17, 5, 19)
sage: v.parent()
Vector space of dimension 3 over Rational Field
sage: v = vector((1,2,3), QQ); v
(1, 2, 3)
sage: v.parent()
Vector space of dimension 3 over Rational Field
sage: v = vector(QQ, (1,2,3)); v
(1, 2, 3)
sage: v.parent()
Vector space of dimension 3 over Rational Field
sage: v = vector(vector([1,2,3])); v
(1, 2, 3)
sage: v.parent()
Ambient free module of rank 3 over the principal ideal domain Integer Ring
```

You can also use `free_module_element`, which is the same as `vector`.

```
sage: free_module_element([1/3, -4/5])
(1/3, -4/5)
```

Make a vector mod 3 out of a vector over **Z**:

```
sage: vector(vector([1,2,3]), GF(3))
(1, 2, 0)
```

Here we illustrate the creation of sparse vectors by using a dictionary:

```
sage: vector({1:1.1, 3:3.14})
(0.000000000000000, 1.10000000000000, 0.000000000000000, 3.14000000000000)
```

Any 1 dimensional numpy array of type float or complex may be passed to vector. The result will be a vector in the appropriate dimensional vector space over the real double field or the complex double field. The data in the array must be contiguous so columnwise slices of numpy matrices will raise an exception.

```
sage: import numpy
sage: x=numpy.random.randn(10)
sage: y=vector(x)
sage: v=numpy.random.randn(10)*numpy.complex(0,1)
sage: w=vector(v)
```

If any of the arguments to vector have Python type int, long, real, or complex, they will first be coerced to the appropriate Sage objects. This fixes trac #3847:

```
sage: v = vector([int(0)]); v
(0)
sage: v[0].parent()
Integer Ring
sage: v = vector(range(10)); v
(0, 1, 2, 3, 4, 5, 6, 7, 8, 9)
sage: v[3].parent()
Integer Ring
sage: v = vector([float(23.4), int(2), complex(2+7*I), long(1)]); v
```

```
(23.4, 2.0, 2.0 + 7.0*I, 1.0)
sage: v[1].parent()
Complex Double Field
```

is_FreeModuleElement()

make_FreeModuleElement_generic_dense()

make_FreeModuleElement_generic_dense_v1()

make_FreeModuleElement_generic_sparse()

make_FreeModuleElement_generic_sparse_v1()

prepare()

prepare_dict()

EXAMPLES:

```
sage: from sage.modules.free_module_element import prepare_dict
sage: prepare_dict({3:1 , 5:3}, QQ)
([0, 0, 0, 1, 0, 3], Rational Field)
sage: prepare_dict({},QQ)
([], Rational Field)
```

vector()

Return a vector over R with given entries.

CALL FORMATS:

1.vector(object)

2.vector(ring, object)

3.vector(object, ring)

4.vector(numpy_array)

In each case, give `sparse=True` or `sparse=False` as an option.

INPUT:

- `elts` - entries of a vector (either a list or dict).
- `R` - ring
- `sparse` - optional

OUTPUT: An element of the free module over R of rank len(elts).

EXAMPLES:

```
sage: v = vector([1,2,3]); v
(1, 2, 3)
sage: v.parent()
Ambient free module of rank 3 over the principal ideal domain Integer Ring
sage: v = vector([1,2,3/5]); v
(1, 2, 3/5)
sage: v.parent()
Vector space of dimension 3 over Rational Field
```

All entries must *canonically* coerce to some common ring:

```
sage: v = vector([17, GF(11)(5), 19/3]); v
...
TypeError: unable to find a common ring for all elements
```

```
sage: v = vector([17, GF(11)(5), 19]); v
(6, 5, 8)
sage: v.parent()
Vector space of dimension 3 over Finite Field of size 11
sage: v = vector([17, GF(11)(5), 19], QQ); v
(17, 5, 19)
sage: v.parent()
Vector space of dimension 3 over Rational Field
sage: v = vector((1,2,3), QQ); v
(1, 2, 3)
sage: v.parent()
Vector space of dimension 3 over Rational Field
sage: v = vector(QQ, (1,2,3)); v
(1, 2, 3)
sage: v.parent()
Vector space of dimension 3 over Rational Field
sage: v = vector(vector([1,2,3])); v
(1, 2, 3)
sage: v.parent()
Ambient free module of rank 3 over the principal ideal domain Integer Ring
```

You can also use `free_module_element`, which is the same as `vector`.

```
sage: free_module_element([1/3, -4/5])
(1/3, -4/5)
```

Make a vector mod 3 out of a vector over **Z**:

```
sage: vector(vector([1,2,3]), GF(3))
(1, 2, 0)
```

Here we illustrate the creation of sparse vectors by using a dictionary:

```
sage: vector({1:1.1, 3:3.14})
(0.000000000000000, 1.10000000000000, 0.000000000000000, 3.14000000000000)
```

Any 1 dimensional numpy array of type float or complex may be passed to vector. The result will be a vector in the appropriate dimensional vector space over the real double field or the complex double field. The data in the array must be contiguous so columnwise slices of numpy matrices will raise an exception.

```
sage: import numpy
sage: x=numpy.random.randn(10)
sage: y=vector(x)
sage: v=numpy.random.randn(10)*numpy.complex(0,1)
sage: w=vector(v)
```

If any of the arguments to vector have Python type int, long, real, or complex, they will first be coerced to the appropriate Sage objects. This fixes trac #3847:

```
sage: v = vector([int(0)]); v
(0)
sage: v[0].parent()
Integer Ring
sage: v = vector(range(10)); v
(0, 1, 2, 3, 4, 5, 6, 7, 8, 9)
sage: v[3].parent()
Integer Ring
sage: v = vector([float(23.4), int(2), complex(2+7*I), long(1)]); v
```

```
(23.4, 2.0, 2.0 + 7.0*I, 1.0)
sage: v[1].parent()
Complex Double Field
```

33.4 Pickling for the old CDF vector class.

AUTHORS:

- Jason Grout

TESTS:

```
sage: v = vector(CDF,[(1,-1), (2,pi), (3,5)])
sage: v
(1.0 - 1.0*I, 2.0 + 3.14159265359*I, 3.0 + 5.0*I)
sage: loads(dumps(v)) == v
True
```

33.5 Pickling for the old RDF vector class.

AUTHORS:

- Jason Grout

TESTS:

```
sage: v = vector(RDF, [1,2,3,4])
sage: loads(dumps(v)) == v
True
```

33.6 Homspaces between free modules

EXAMPLES: We create $\mathrm{End}(\mathbf{Z}^2)$ and compute a basis.

```
sage: M = FreeModule(IntegerRing(),2)
sage: E = End(M)
sage: B = E.basis()
sage: len(B)
4
sage: B[0]
Free module morphism defined by the matrix
[1 0]
[0 0]
Domain: Ambient free module of rank 2 over the principal ideal domain ...
Codomain: Ambient free module of rank 2 over the principal ideal domain ...
```

We create $\mathrm{Hom}(\mathbf{Q}^3, \mathbf{Q}^2)$ and compute a basis.

```
sage: V3 = VectorSpace(RationalField(),3)
sage: V2 = VectorSpace(RationalField(),2)
sage: H = Hom(V3,V2)
sage: H
Set of Morphisms from Vector space of dimension 3 over Rational Field
to Vector space of dimension 2 over Rational Field in Category of
vector spaces over Rational Field
sage: B = H.basis()
sage: len(B)
6
sage: B[0]
Free module morphism defined by the matrix
[1 0]
[0 0]
[0 0]...
```

TESTS:

```
sage: H = Hom(QQ^2, QQ^1)
sage: loads(dumps(H)) == H
True
```

See trac 5886:

```
sage: V = (QQ^2).span_of_basis([[1,2],[3,4]])
sage: V.hom([V.0, V.1])
Free module morphism defined by the matrix
[1 0]
[0 1]...
```

class FreeModuleHomspace(*X, Y, cat=None, check=True, base=None*)

basis()

Return a basis for this space of free module homomorphisms.

OUTPUT: • tuple

EXAMPLES:

```
sage: H = Hom(QQ^2, QQ^1)
sage: H.basis()
(Free module morphism defined by the matrix
[1]
[0]
Domain: Vector space of dimension 2 over Rational Field
Codomain: Vector space of dimension 1 over Rational Field,
 Free module morphism defined by the matrix
[0]
[1]
Domain: Vector space of dimension 2 over Rational Field
Codomain: Vector space of dimension 1 over Rational Field)
```

identity()

Return identity morphism in an endomorphism ring.

EXAMPLE:

```
sage: V=VectorSpace(QQ,5)
sage: H=V.Hom(V)
sage: H.identity()
Free module morphism defined by the matrix
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
Domain: Vector space of dimension 5 over Rational Field
Codomain: Vector space of dimension 5 over Rational Field
```

is_FreeModuleHomspace(*x*)

Return True if x is a Free module homspace.

EXAMPLES:

```
sage: H = Hom(QQ^3, QQ^2)
sage: sage.modules.free_module_homspace.is_FreeModuleHomspace(H)
True
sage: sage.modules.free_module_homspace.is_FreeModuleHomspace(2)
False
```

33.7 Morphisms of free modules

class FreeModuleMorphism(*parent, A*)

is_FreeModuleMorphism(*x*)

33.8 Morphisms defined by a matrix.

A matrix morphism is a morphism that is defined by multiplication by a matrix. Elements of domain must either have a method `vector()` that returns a vector that the defining matrix can hit from the left, or be coercible into vector space of appropriate dimension.

EXAMPLES:

```
sage: from sage.modules.matrix_morphism import MatrixMorphism, is_MatrixMorphism
sage: V = QQ^3
sage: T = End(V)
sage: M = MatrixSpace(QQ,3)
sage: I = M.identity_matrix()
sage: m = MatrixMorphism(T, I); m
Morphism defined by the matrix
[1 0 0]
[0 1 0]
[0 0 1]
sage: is_MatrixMorphism(m)
True
sage: m.charpoly('x')
x^3 - 3*x^2 + 3*x - 1
sage: m.base_ring()
Rational Field
sage: m.det()
```

```
1
sage: m.fcp('x')
(x - 1)^3
sage: m.matrix()
[1 0 0]
[0 1 0]
[0 0 1]
sage: m.rank()
3
sage: m.trace()
3
```

AUTHOR:

- William Stein: initial versions
- David Joyner (2005-12-17): added examples
- William Stein (2005-01-07): added __reduce__
- Craig Citro (2008-03-18): refactored MatrixMorphism class

class **MatrixMorphism**(*parent, A*)

A morphism defined by a matrix.

matrix()

Return matrix that defines this morphism.

EXAMPLES:

```
sage: V = ZZ^2; phi = V.hom([3*V.0, 2*V.1])
sage: phi.matrix()
[3 0]
[0 2]
```

class **MatrixMorphism_abstract**(*parent*)

base_ring()

Return the base ring of self, that is, the ring over which self is given by a matrix.

EXAMPLES:

```
sage: sage.modules.matrix_morphism.MatrixMorphism((ZZ**2).endomorphism_ring(), Matrix(ZZ,2,[
Integer Ring
```

charpoly(*var='x'*)

Return the characteristic polynomial of this endomorphism.

INPUT: • var – variable

EXAMPLES:

```
sage: V = ZZ^2; phi = V.hom([V.0+V.1, 2*V.1])
sage: phi.charpoly()
x^2 - 3*x + 2
sage: phi.matrix().charpoly()
x^2 - 3*x + 2
sage: phi.charpoly('T')
T^2 - 3*T + 2
```

decomposition(**args, **kwds*)

Return decomposition of this endomorphism, i.e., sequence of subspaces obtained by finding invariant subspaces of self.

See the documentation for self.matrix().decomposition for more details. All inputs to this function are passed onto the matrix one.

EXAMPLES:

```
sage: V = ZZ^2; phi = V.hom([V.0+V.1, 2*V.1])
sage: phi.decomposition()
[
Free module of degree 2 and rank 1 over Integer Ring
Echelon basis matrix:
[0 1],
Free module of degree 2 and rank 1 over Integer Ring
Echelon basis matrix:
[ 1 -1]
]
```

det()

Return the determinant of this endomorphism.

EXAMPLES:

```
sage: V = ZZ^2; phi = V.hom([V.0+V.1, 2*V.1])
sage: phi.det()
2
```

fcp(*var='x'*)

Return the factorization of the characteristic polynomial.

EXAMPLES:

```
sage: V = ZZ^2; phi = V.hom([V.0+V.1, 2*V.1])
sage: phi.fcp()
(x - 2) * (x - 1)
sage: phi.fcp('T')
(T - 2) * (T - 1)
```

image()

Compute the image of this morphism.

EXAMPLES:

```
sage: V = VectorSpace(QQ,3)
sage: phi = V.Hom(V)(range(9))
sage: phi.image()
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1  0 -1]
[ 0  1  2]
sage: hom(GF(7)^3, GF(7)^2, 0).image()
Vector space of degree 2 and dimension 0 over Finite Field of size 7
Basis matrix:
[]
```

Compute the image of the identity map on a ZZ-submodule:

```
sage: V = (ZZ^2).span([[1,2],[3,4]])
sage: phi = V.Hom(V)(identity_matrix(ZZ,2))
sage: phi(V.0) == V.0
True
sage: phi(V.1) == V.1
```

```
True
sage: phi.image()
Free module of degree 2 and rank 2 over Integer Ring
Echelon basis matrix:
[1 0]
[0 2]
sage: phi.image() == V
True
```

kernel()

Compute the kernel of this morphism.

EXAMPLES:

```
sage: V = VectorSpace(QQ,3)
sage: id = V.Hom(V)(identity_matrix(QQ,3))
sage: null = V.Hom(V)(0*identity_matrix(QQ,3))
sage: id.kernel()
Vector space of degree 3 and dimension 0 over Rational Field
Basis matrix:
[]
sage: phi = V.Hom(V)(matrix(QQ,3,range(9)))
sage: phi.kernel()
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2  1]
sage: hom(CC^2, CC^2, 1).kernel()
Vector space of degree 2 and dimension 0 over Complex Field with 53 bits of precision
Basis matrix:
[]
```

matrix()

EXAMPLES:

```
sage: V = ZZ^2; phi = V.hom(V.basis())
sage: phi.matrix()
[1 0]
[0 1]
sage: sage.modules.matrix_morphism.MatrixMorphism_abstract.matrix(phi)
...
NotImplementedError: this method must be overridden in the extension class
```

rank()

EXAMPLES:

```
sage: V = ZZ^2; phi = V.hom(V.basis())
sage: phi.rank()
2
sage: V = ZZ^2; phi = V.hom([V.0, V.0])
sage: phi.rank()
1
```

restrict(*sub*)

Restrict this matrix morphism to a subspace sub of the domain.

The codomain and domain of the resulting matrix are both sub.

EXAMPLES:

```
sage: V = ZZ^2; phi = V.hom([3*V.0, 2*V.1])
sage: phi.restrict(V.span([V.0]))
Free module morphism defined by the matrix
```

```
[3]
Domain: Free module of degree 2 and rank 1 over Integer Ring
Echelon ...
Codomain: Free module of degree 2 and rank 1 over Integer Ring
Echelon ...
```

restrict_codomain(*sub*)

Restrict this matrix morphism to a subspace sub of the codomain.

The resulting morphism has the same domain as before, but a new codomain.

EXAMPLES:

```
sage: V = ZZ^2; phi = V.hom([4*(V.0+V.1),0])
sage: W = V.span([2*(V.0+V.1)])
sage: phi
Free module morphism defined by the matrix
[4 4]
[0 0]
Domain: Ambient free module of rank 2 over the principal ideal domain ...
Codomain: Ambient free module of rank 2 over the principal ideal domain ...
sage: psi = phi.restrict_codomain(W); psi
Free module morphism defined by the matrix
[2]
[0]
Domain: Ambient free module of rank 2 over the principal ideal domain ...
Codomain: Free module of degree 2 and rank 1 over Integer Ring
Echelon ...
```

restrict_domain(*sub*)

Restrict this matrix morphism to a subspace sub of the domain. The subspace sub should have a basis() method and elements of the basis should be coercible into domain.

The resulting morphism has the same codomain as before, but a new domain.

EXAMPLES:

```
sage: V = ZZ^2; phi = V.hom([3*V.0, 2*V.1])
sage: phi.restrict_domain(V.span([V.0]))
Free module morphism defined by the matrix
[3 0]
Domain: Free module of degree 2 and rank 1 over Integer Ring
Echelon ...
Codomain: Ambient free module of rank 2 over the principal ideal domain ...
sage: phi.restrict_domain(V.span([V.1]))
Free module morphism defined by the matrix
[0 2]...
```

trace()

EXAMPLES:

```
sage: V = ZZ^2; phi = V.hom([V.0+V.1, 2*V.1])
sage: phi.trace()
3
```

is_MatrixMorphism(*x*)

Return True if x is a Matrix morphism of free modules.

EXAMPLES:

```
sage: V = ZZ^2; phi = V.hom([3*V.0, 2*V.1])
sage: sage.modules.matrix_morphism.is_MatrixMorphism(phi)
True
```

```
sage: sage.modules.matrix_morphism.is_MatrixMorphism(3)
False
```

CHAPTER

THIRTYFOUR

COMBINATORIAL GEOMETRY

Sage includes support for computing with lattice and reflexive polytopes and Groebner fans. It also has optional support for computing with general polytopes via the polymake program.

34.1 Lattice and reflexive polytopes

This module provides tools for work with lattice and reflexive polytopes. A *convex polytope* is the convex hull of finitely many points in $\mathbf{R}^n$. The dimension n of a polytope is the smallest n such that the polytope can be embedded in $\mathbf{R}^n$.

A *lattice polytope* is a polytope whose vertices all have integer coordinates.

If L is a lattice polytope, the dual polytope of L is

$$\{y \in \mathbf{Z}^n : x \cdot y \geq -1 \text{ all } x \in L\}$$

A *reflexive polytope* is a lattice polytope, such that its polar is also a lattice polytope, i.e. has vertices with integer coordinates.

This Sage module uses Package for Analyzing Lattice Polytopes (PALP), which is a program written in C by Maximilian Kreuzer and Harald Skarke, which is freely available under the GNU licence terms at http://tph16.tuwien.ac.at/~kreuzer/CY/. Moreover, PALP is included standard with Sage.

PALP is described in the paper math.SC/0204356. Its distribution also contains the application nef.x, which was created by Erwin Riegler and computes nef partitions and Hodge data for toric complete intersections.

ACKNOWLEDGMENT: polytope.py module written by William Stein was used as an example of organizing an interface between an external program and Sage. William Stein also helped Andrey Novoseltsev with debugging and tuning of this module.

Robert Bradshaw helped Andrey Novoseltsev to realize plot3d function.

Note: IMPORTANT: PALP requires some parameters to be determined during compilation time, i.e., the maximum dimension of polytopes, the maximum number of points, etc. These limitations may lead to errors during calls to different functions of these module. Currently, a ValueError exception will be raised if the output of poly.x or nef.x is empty or contains the exclamation mark. The error message will contain the exact command that caused an error, the description and vertices of the polytope, and the obtained output.

Data obtained from PALP and some other data is cached and most returned values are immutable. In particular, you cannot change the vertices of the polytope or their order after creation of the polytope.

If you are going to work with large sets of data, take a look at `all_*` functions in this module. They precompute different data for sequences of polynomials with a few runs of external programs. This can significantly affect the time of future computations. You can also use dump/load, but not all data will be stored (currently only faces and the number of their internal and boundary points are stored, in addition to polytope vertices and its polar).

AUTHORS:

- Andrey Novoseltsev (2007-01-11): initial version of this module
- Andrey Novoseltsev (2007-01-15): `all_*` functions
- Andrey Novoseltsev (2008-04-01): second version, including:
  - dual NEF-partitions and necessary convex_hull and minkowski_sum
  - built-in sequences of 2- and 3-dimensional reflexive polytopes
  - plot3d, skeleton_show
- Maximilian Kreuzer and Harald Skarke: authors of PALP (which was also used to obtain the list of 3-dimensional reflexive polytopes)
- Erwin Riegler: the author of nef.x

LatticePolytope(*data, desc=None, compute_vertices=True, copy_vertices=True, n=0*)

Construct a lattice polytope.

LatticePolytope(data, [desc], [compute_vertices], [copy_vertices], [n])

INPUT:

- `data` - matrix whose columns are vertices of the polytope (unless `compute_vertices` is True); a file with matrix data, open for reading; or a filename of such a file. See `read_palp_matrix` for the file format. Points of the given matrix must span the space.
- `desc` - (default: "A lattice polytope") description of the polytope.
- `compute_vertices` - (default: True) if True, the convex hull of the given points will be computed for determining vertices. Otherwise, the given points are vertices.
- `copy_vertices` - (default: True) if False, and compute_vertices is False, and `data` is a matrix of vertices, it will be made immutable.
- `n` - (default: 0) if `data` is a name of a file, that contains data blocks for several polytopes, the n-th block will be used. *NUMERATION STARTS WITH ZERO*.

OUTPUT: a lattice polytope

EXAMPLES: Here we construct a polytope from a matrix whose columns are vertices in 3-dimensional space. In the first case a copy of the given matrix is made during construction, in the second one the matrix is made immutable and used as a matrix of vertices.

```
sage: m = matrix(ZZ, [[1, 0, 0, -1,  0,  0],
...                   [0, 1, 0,  0, -1,  0],
...                   [0, 0, 1,  0,  0, -1]])
...
sage: p = LatticePolytope(m)
sage: p
A lattice polytope: 3-dimensional, 6 vertices.
sage: m.is_mutable()
True
sage: m is p.vertices()
False
sage: p = LatticePolytope(m, compute_vertices=False, copy_vertices=False)
sage: m.is_mutable()
False
sage: m is p.vertices()
True
```

We draw a pretty picture of the polytype in 3-dimensional space:

```
sage: p.plot3d().show()
```

Now we add an extra point, which is in the interiour of the polytope...

```
sage: m = matrix(ZZ, [[1, 0, 0, -1,  0,  0, 0],
...                   [0, 1, 0,  0, -1,  0, 0],
...                   [0, 0, 1,  0,  0, -1, 0]])
...
sage: p = LatticePolytope(m, "A lattice polytope constructed from 7 points")
sage: p
A lattice polytope constructed from 7 points: 3-dimensional, 6 vertices.
```

You can suppress vertex computation for speed but this can lead to mistakes:

```
sage: p = LatticePolytope(m, "A lattice polytope with WRONG vertices",
...                          compute_vertices=False)
...
sage: p
A lattice polytope with WRONG vertices: 3-dimensional, 7 vertices.
```

Points of the given matrix must always span the space, this conditions will be checked unless you specify `compute_vertices=False` option:

```
sage: m = matrix(ZZ, [[1, 0, -1,  0],
...                   [0, 1,  0, -1],
...                   [0, 0,  0,  0]])
...
sage: p = LatticePolytope(m)
...
ValueError: Points must span the space!
Given:
[ 1  0 -1  0]
[ 0  1  0 -1]
[ 0  0  0  0]
```

class **LatticePolytopeClass**(*data, desc, compute_vertices, copy_vertices=True, n=0*)

Class of lattice/reflexive polytopes.

Use `LatticePolytope` for constructing a polytope.

dim()

Return the dimension of this polytope.

EXAMPLES: We create a 3-dimensional octahedron and check its dimension:

```
sage: o = lattice_polytope.octahedron(3)
sage: o.dim()
3
```

distances(*point=None*)

Return the matrix of distances for this polytope or distances for the given point.

The matrix of distances m gives distances m[i,j] between the i-th facet (which is also the i-th vertex of the polar polytope in the reflexive case) and j-th point of this polytope.

If point is specified, integral distances from the point to all facets of this polytope will be computed.

EXAMPLES: The matrix of distances for a 3-dimensional octahedron:

```
sage: o = lattice_polytope.octahedron(3)
sage: o.distances()
[0 0 2 2 2 0 1]
[2 0 2 0 2 0 1]
[0 2 2 2 0 0 1]
[2 2 2 0 0 0 1]
[0 0 0 2 2 2 1]
[2 0 0 0 2 2 1]
[0 2 0 2 0 2 1]
[2 2 0 0 0 2 1]
```

Distances from facets to the point (1,2,3):

```
sage: o.distances([1,2,3])
(1, 3, 5, 7, -5, -3, -1, 1)
```

It is OK to use RATIONAL coordinates:

```
sage: o.distances([1,2,3/2])
(-1/2, 3/2, 7/2, 11/2, -7/2, -3/2, 1/2, 5/2)
sage: o.distances([1,2,sqrt(2)])
...
TypeError: unable to convert sqrt(2) to a rational
```

edges()

Return the sequence of edges of this polytope (i.e. faces of dimension 1).

EXAMPLES: The octahedron has 12 edges:

```
sage: o = lattice_polytope.octahedron(3)
sage: len(o.edges())
12
sage: o.edges()
[[1, 5], [0, 5], [0, 1], [3, 5], [1, 3], [4, 5], [0, 4], [3, 4], [1, 2], [0, 2], [2, 3], [2,
```

faces(*dim=None, codim=None*)

Return the sequence of faces of this polytope.

If `dim` or `codim` are specified, returns a sequence of faces of the corresponding dimension or codimension. Otherwise returns the sequence of such sequences for all dimensions.

EXAMPLES: All faces of the 3-dimensional octahedron:

```
sage: o = lattice_polytope.octahedron(3)
sage: o.faces()
[
[[0], [1], [2], [3], [4], [5]],
[[1, 5], [0, 5], [0, 1], [3, 5], [1, 3], [4, 5], [0, 4], [3, 4], [1, 2], [0, 2], [2, 3], [2,
[[0, 1, 5], [1, 3, 5], [0, 4, 5], [3, 4, 5], [0, 1, 2], [1, 2, 3], [0, 2, 4], [2, 3, 4]]
]
```

Its faces of dimension one (i.e., edges):

```
sage: o.faces(dim=1)
[[1, 5], [0, 5], [0, 1], [3, 5], [1, 3], [4, 5], [0, 4], [3, 4], [1, 2], [0, 2], [2, 3], [2,
```

Its faces of codimension two (also edges):

```
sage: o.faces(codim=2)
[[1, 5], [0, 5], [0, 1], [3, 5], [1, 3], [4, 5], [0, 4], [3, 4], [1, 2], [0, 2], [2, 3], [2,
```

It is an error to specify both dimension and codimension at the same time, even if they do agree:

```
sage: o.faces(dim=1, codim=2)
...
ValueError: Both dim and codim are given!
```

facets()

Return the sequence of facets of this polytope (i.e. faces of codimension 1).

EXAMPLES: All facets of the 3-dimensional octahedron:

```
sage: o = lattice_polytope.octahedron(3)
sage: o.facets()
[[0, 1, 5], [1, 3, 5], [0, 4, 5], [3, 4, 5], [0, 1, 2], [1, 2, 3], [0, 2, 4], [2, 3, 4]]
```

Facets are the same as faces of codimension one:

```
sage: o.facets() is o.faces(codim=1)
True
```

index()

Return the index of this polytope in the internal database of 2- or 3-dimensional reflexive polytopes. Databases are stored in the directory of the package.

Note: The first call to this function for each dimension can take a second or so while the dictionary of all polytopes is loaded, but after that it is cached and fast.

EXAMPLES: We check what is the index of the "diamond" in the database:

```
sage: o = lattice_polytope.octahedron(2)
sage: o.index()
3
```

Note that polytopes with the same index are not necessarily the same:

```
sage: o.vertices()
[ 1  0 -1  0]
[ 0  1  0 -1]
sage: lattice_polytope.ReflexivePolytope(2,3).vertices()
[ 1  0  0 -1]
[ 0  1 -1  0]
```

But they are in the same $GL(Z^n)$ orbit and have the same normal form:

```
sage: o.normal_form()
[ 1  0  0 -1]
[ 0  1 -1  0]
sage: lattice_polytope.ReflexivePolytope(2,3).normal_form()
[ 1  0  0 -1]
[ 0  1 -1  0]
```

is_reflexive()

Return True if this polytope is reflexive.

EXAMPLES: The 3-dimensional octahedron is reflexive (and 4318 other 3-polytopes):

```
sage: o = lattice_polytope.octahedron(3)
sage: o.is_reflexive()
True
```

But not all polytopes are reflexive:

```
sage: m = matrix(ZZ, [[1, 0, 0, -1,  0,  0],
...                   [0, 1, 0,  0, -1,  0],
...                   [0, 0, 0,  0,  0, -1]])
...
sage: p = LatticePolytope(m)
```

```
sage: p.is_reflexive()
False
```

mif (*partition*)

Return all vectors $m_{i,f}$, grouped into matrices.

INPUT:

- `partition` - NEF-partition (instance of class NEFPartition)

OUTPUT: A sequence of matrices, one for each facet f of this polytope. Each row of each matrix corresponds to a part of the NEF-partition.

EXAMPLES: We compute $m_{i,f}$ matrices for one of the nef-partitions of the 3-dimensional octahedron:

```
sage: o = lattice_polytope.octahedron(3)
sage: nefp = o.nef_partitions()[0]
sage: o.mif(nefp)
[
[ 0  0  1]
[-1 -1  0],
[ 0  0  1]
[ 1 -1  0],
[ 0  1  1]
[-1  0  0],
[0 1 1]
[1 0 0],
[ 0  0 -1]
[-1 -1  0],
[ 0  0 -1]
[ 1 -1  0],
[ 0  1 -1]
[-1  0  0],
[ 0  1 -1]
[ 1  0  0]
]
```

nef_partitions (*keep_symmetric=False, keep_products=True, keep_projections=True, hodge_numbers=False*)

Return the sequence of NEF-partitions for this polytope.

INPUT:

- `keep_symmetric` - (default: False) if True, "-s" option will be passed to nef.x in order to keep symmetric partitions;
- `keep_products` - (default: True) if True, "-D" option will be passed to nef.x in order to keep product partitions;
- `keep_projections` - (default: True) if True, "-P" option will be passed to nef.x in order to keep projection partitions;
- `hodge_numbers` - (default: False) if False, "-p" option will be passed to nef.x in order to skip Hodge numbers computation, which takes a lot of time.

EXAMPLES: NEF-partitions of the 4-dimensional octahedron:

```
sage: o = lattice_polytope.octahedron(4)
sage: o.nef_partitions()
[
[1, 1, 0, 0, 1, 1, 0, 0] (direct product),
[1, 1, 1, 0, 1, 0, 0, 0],
[1, 1, 1, 0, 1, 1, 0, 0],
[1, 1, 1, 0, 1, 1, 1, 0] (direct product),
[1, 1, 1, 1, 0, 0, 0, 0],
[1, 1, 1, 1, 1, 0, 0, 0],
```

```
[1, 1, 1, 1, 1, 1, 0, 0],
[1, 1, 1, 1, 1, 1, 1, 0] (projection)
]
```

Now we omit projections:

```
sage: o.nef_partitions(keep_projections=False)
[
[1, 1, 0, 0, 1, 1, 0, 0] (direct product),
[1, 1, 1, 0, 1, 0, 0, 0],
[1, 1, 1, 0, 1, 1, 0, 0],
[1, 1, 1, 0, 1, 1, 1, 0] (direct product),
[1, 1, 1, 1, 0, 0, 0, 0],
[1, 1, 1, 1, 1, 0, 0, 0],
[1, 1, 1, 1, 1, 1, 0, 0]
]
```

At present, Hodge numbers cannot be computed for a given NEF-partition:

```
sage: o.nef_partitions()[1].hodge_numbers()
...
NotImplementedError: use nef_partitions(hodge_numbers=True)!
```

But they can be obtained from nef.x for all partitions at once. Partitions will be exactly the same:

```
sage: o.nef_partitions(hodge_numbers=True)
[
[1, 1, 0, 0, 1, 1, 0, 0] (direct product),
[1, 1, 1, 0, 1, 0, 0, 0],
[1, 1, 1, 0, 1, 1, 0, 0],
[1, 1, 1, 0, 1, 1, 1, 0] (direct product),
[1, 1, 1, 1, 0, 0, 0, 0],
[1, 1, 1, 1, 1, 0, 0, 0],
[1, 1, 1, 1, 1, 1, 0, 0],
[1, 1, 1, 1, 1, 1, 1, 0] (projection)
]
```

Now it is possible to get Hodge numbers:

```
sage: o.nef_partitions(hodge_numbers=True)[1].hodge_numbers()
[20]
```

Since NEF-partitions are cached, Hodge numbers are accessible after the first request, even if you do not specify hodge_numbers anymore:

```
sage: o.nef_partitions()[1].hodge_numbers()
[20]
```

We illustrate removal of symmetric partitions on a diamond:

```
sage: o = lattice_polytope.octahedron(2)
sage: o.nef_partitions()
[
[1, 0, 1, 0] (direct product),
[1, 1, 0, 0],
[1, 1, 1, 0] (projection)
]
sage: o.nef_partitions(keep_symmetric=True)
[
[1, 1, 0, 1] (projection),
[1, 0, 1, 1] (projection),
[1, 0, 0, 1],
```

```
[0, 1, 1, 1] (projection),
[0, 1, 0, 1] (direct product),
[0, 0, 1, 1],
[1, 1, 1, 0] (projection)
]
```

NEF-partitions can be computed only for reflexive polytopes:

```
sage: m = matrix(ZZ, [[1, 0, 0, -1,  0,  0],
...                   [0, 1, 0,  0, -1,  0],
...                   [0, 0, 2,  0,  0, -1]])
...
sage: p = LatticePolytope(m)
sage: p.nef_partitions()
...
ValueError: The given polytope is not reflexive!
Polytope: A lattice polytope: 3-dimensional, 6 vertices.
```

nef_x(*keys*)

Run nef.x wilth given `keys` on vertices of this polytope.

INPUT:

- `keys` - a string of options passed to nef.x. The key "-f" is added automatically.

OUTPUT: the output of nef.x as a string.

EXAMPLES: This call is used internally for computing NEF-partitions:

```
sage: o = lattice_polytope.octahedron(3)
sage: s = o.nef_x("-N -V -p")
sage: s                        # output contains random time
M:27 8 N:7 6  codim=2 #part=5
3 6  Vertices of P:
    1    0    0   -1    0    0
    0    1    0    0   -1    0
    0    0    1    0    0   -1
 P:0 V:2 4 5       0sec  0cpu
 P:2 V:3 4 5       0sec  0cpu
 P:3 V:4 5       0sec  0cpu
np=3 d:1 p:1    0sec     0cpu
```

nfacets()

Return the number of facets of this polytope.

EXAMPLES: The number of facets of the 3-dimensional octahedron:

```
sage: o = lattice_polytope.octahedron(3)
sage: o.nfacets()
8
```

normal_form()

Return the normal form of vertices of the polytope. Two lattice polytopes are in the same GL(Z)-orbit if and only if their normal forms are the same.

EXAMPLES: We compute the normal form of the "diamond":

```
sage: o = lattice_polytope.octahedron(2)
sage: o.vertices()
[ 1  0 -1  0]
[ 0  1  0 -1]
sage: o.normal_form()
[ 1  0  0 -1]
[ 0  1 -1  0]
```

The diamond is the 3rd polytope in the internal database...

```
sage: o.index()
3
sage: lattice_polytope.ReflexivePolytope(2,3).vertices()
[ 1  0  0 -1]
[ 0  1 -1  0]
```

npoints()

Return the number of lattice points of this polytope.

EXAMPLES: The number of lattice points of the 3-dimensional octahedron and its polar cube:

```
sage: o = lattice_polytope.octahedron(3)
sage: o.npoints()
7
sage: cube = o.polar()
sage: cube.npoints()
27
```

nvertices()

Return the number of vertices of this polytope.

EXAMPLES: The number of vertices of the 3-dimensional octahedron and its polar cube:

```
sage: o = lattice_polytope.octahedron(3)
sage: o.nvertices()
6
sage: cube = o.polar()
sage: cube.nvertices()
8
```

parent()

Return the set of all lattice polytopes.

EXAMPLES:

```
sage: o = lattice_polytope.octahedron(3)
sage: o.parent()
Set of all Lattice Polytopes
```

plot3d(*show_facets=True, facet_opacity=0.5, facet_color=(0, 1, 0), show_edges=True, edge_thickness=3, edge_color=(0.5, 0.5, 0.5), show_vertices=True, vertex_size=10, vertex_color=(1, 0, 0), show_points=True, point_size=10, point_color=(0, 0, 1), show_vindices=None, vindex_color=(0, 0, 0), show_pindices=None, pindex_color=(0, 0, 0), index_shift=1.1000000000000001*)

Return a 3d-plot of a 3-dimensional polytope.

By default, everything is shown with more or less pretty combination of size and color parameters.

INPUT: Most of the parameters are self-explanatory:

- `show_facets` - (default:True)
- `facet_opacity` - (default:0.5)
- `facet_color` - (default:(0,1,0))
- `show_edges` - (default:True) whether to draw edges as lines
- `edge_thickness` - (default:3)
- `edge_color` - (default:(0.5,0.5,0.5))
- `show_vertices` - (default:True) whether to draw vertices as balls
- `vertex_size` - (default:10)
- `vertex_color` - (default:(1,0,0))
- `show_points` - (default:True) whether to draw other poits as balls
- `point_size` - (default:10)

- point_color - (default:(0,0,1))
- show_vindices - (default:same as show_vertices) whether to show indices of vertices
- vindex_color - (default:(0,0,0)) color for vertex labels
- show_pindices - (default:same as show_points) whether to show indices of other points
- pindex_color - (default:(0,0,0)) color for point labels
- index_shift - (default:1.1)) if 1, labels are placed exactly at the corresponding points. Otherwise the label position is computed as a multiple of the point position vector.

EXAMPLES: The default plot of a cube:

```
sage: c = lattice_polytope.octahedron(3).polar()
sage: c.plot3d()
```

Plot without facets and points, shown without the frame:

```
sage: c.plot3d(show_facets=false,show_points=false).show(frame=False)
```

TESTS:

```
sage: m = matrix([[0,0,0],[0,1,1],[1,0,1],[1,1,0]]).transpose()
sage: p = LatticePolytope(m, compute_vertices=True)
sage: p.plot3d()
```

point(*i*)

Return the i-th point of this polytope, i.e. the i-th column of the matrix returned by points().

EXAMPLES: First few points are actually vertices:

```
sage: o = lattice_polytope.octahedron(3)
sage: o.vertices()
[ 1  0  0 -1  0  0]
[ 0  1  0  0 -1  0]
[ 0  0  1  0  0 -1]
sage: o.point(1)
(0, 1, 0)
```

The only other point in the octahedron is the origin:

```
sage: o.point(6)
(0, 0, 0)
sage: o.points()
[ 1  0  0 -1  0  0  0]
[ 0  1  0  0 -1  0  0]
[ 0  0  1  0  0 -1  0]
```

points()

Return all lattice points of this polytope as columns of a matrix.

EXAMPLES: The lattice points of the 3-dimensional octahedron and its polar cube:

```
sage: o = lattice_polytope.octahedron(3)
sage: o.points()
[ 1  0  0 -1  0  0  0]
[ 0  1  0  0 -1  0  0]
[ 0  0  1  0  0 -1  0]
sage: cube = o.polar()
sage: cube.points()
[-1  1 -1  1 -1  1 -1  1 -1 -1 -1 -1 -1  0  0  0  0  0  0  0  0  1  1  1  1  1]
[-1 -1  1  1 -1 -1  1  1 -1  0  0  0  1 -1 -1 -1  0  0  0  1  1  1 -1  0  0  0  1]
[ 1  1  1  1 -1 -1 -1 -1  0 -1  0  1  0 -1  0  1 -1  0  1 -1  0  1  0 -1  0  1  0]
```

polar()

Return the polar polytope, if this polytope is reflexive.

EXAMPLES: The polar polytope to the 3-dimensional octahedron:

```
sage: o = lattice_polytope.octahedron(3)
sage: cube = o.polar()
sage: cube
A polytope polar to An octahedron: 3-dimensional, 8 vertices.
```

The polar polytope "remembers" the original one:

```
sage: cube.polar()
An octahedron: 3-dimensional, 6 vertices.
sage: cube.polar().polar() is cube
True
```

Only reflexive polytopes have polars:

```
sage: m = matrix(ZZ, [[1, 0, 0, -1,  0,  0],
...                   [0, 1, 0,  0, -1,  0],
...                   [0, 0, 2,  0,  0, -1]])
...
sage: p = LatticePolytope(m)
sage: p.polar()
...
ValueError: The given polytope is not reflexive!
Polytope: A lattice polytope: 3-dimensional, 6 vertices.
```

poly_x(*keys*)

Run poly.x with given `keys` on vertices of this polytope.

INPUT:

- `keys` - a string of options passed to poly.x. The key "f" is added automatically.

OUTPUT: the output of poly.x as a string.

EXAMPLES: This call is used for determining if a polytope is reflexive or not:

```
sage: o = lattice_polytope.octahedron(3)
sage: print o.poly_x("e")
8 3  Vertices of P-dual <-> Equations of P
  -1  -1   1
   1  -1   1
  -1   1   1
   1   1   1
  -1  -1  -1
   1  -1  -1
  -1   1  -1
   1   1  -1
```

Since PALP has limits on different parameters determined during compilation, the following code is likely to fail, unless you change default settings of PALP:

```
sage: BIGO = lattice_polytope.octahedron(7)
sage: BIGO
An octahedron: 7-dimensional, 14 vertices.
sage: BIGO.poly_x("e")      # possibly different output depending on your system
...
ValueError: Error executing "poly.x -fe" for the given polytope!
Polytope: An octahedron: 7-dimensional, 14 vertices.
Vertices:
[ 1  0  0  0  0  0  0 -1  0  0  0  0  0  0]
[ 0  1  0  0  0  0  0  0 -1  0  0  0  0  0]
[ 0  0  1  0  0  0  0  0  0 -1  0  0  0  0]
[ 0  0  0  1  0  0  0  0  0  0 -1  0  0  0]
```

```
[ 0  0  0  0  1  0  0  0  0  0  0 -1  0  0]
[ 0  0  0  0  0  1  0  0  0  0  0  0 -1  0]
[ 0  0  0  0  0  0  1  0  0  0  0  0  0 -1]
Output:
increase POLY_Dmax!
```

show3d()

Show a 3d picture of the polytope with default settings and without axes or frame.

See self.plot3d? for more details.

EXAMPLES:

```
sage: o = lattice_polytope.octahedron(3)
sage: o.show3d()
```

skeleton()

Return the graph of the one-skeleton of this polytope.

EXAMPLES: We construct the one-skeleton graph for the "diamond":

```
sage: o = lattice_polytope.octahedron(2)
sage: g = o.skeleton()
sage: g
Graph on 4 vertices
sage: g.edges()
[(0, 1, None), (0, 3, None), (1, 2, None), (2, 3, None)]
```

skeleton_points(*k=1*)

Return the increasing list of indices of lattice points in k-skeleton of the polytope (k is 1 by default).

EXAMPLES: We compute all skeleton points for the cube:

```
sage: o = lattice_polytope.octahedron(3)
sage: c = o.polar()
sage: c.skeleton_points()
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 12, 13, 15, 19, 21, 22, 23, 25, 26]
```

The default was 1-skeleton:

```
sage: c.skeleton_points(k=1)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 12, 13, 15, 19, 21, 22, 23, 25, 26]
```

0-skeleton just lists all vertices:

```
sage: c.skeleton_points(k=0)
[0, 1, 2, 3, 4, 5, 6, 7]
```

2-skeleton lists all points except for the origin (point #17):

```
sage: c.skeleton_points(k=2)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 18, 19, 20, 21, 22, 23, 24, 25, 2
```

3-skeleton includes all points:

```
sage: c.skeleton_points(k=3)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 2
```

It is OK to compute higher dimensional skeletons - you will get the list of all points:

```
sage: c.skeleton_points(k=100)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 2
```

skeleton_show(*normal=None*)

Show the graph of one-skeleton of this polytope. Works only for 3-dimensional polytopes.

INPUT:

- `normal` - a 3-dimensional vector (can be given as a list), which should be perpendicular to the screen. If not given, will be selected randomly (new each time and it may be far from "nice").

EXAMPLES: Show a pretty picture of the octahedron:

```
sage: o = lattice_polytope.octahedron(3)
sage: o.skeleton_show([1,2,4])
```

vertex(*i*)

Return the i-th vertex of this polytope, i.e. the i-th column of the matrix returned by vertices().

EXAMPLES: Note that numeration starts with zero:

```
sage: o = lattice_polytope.octahedron(3)
sage: o.vertices()
[ 1  0  0 -1  0  0]
[ 0  1  0  0 -1  0]
[ 0  0  1  0  0 -1]
sage: o.vertex(3)
(-1, 0, 0)
```

vertices()

Return vertices of this polytope as columns of a matrix.

EXAMPLES: The lattice points of the 3-dimensional octahedron and its polar cube:

```
sage: o = lattice_polytope.octahedron(3)
sage: o.vertices()
[ 1  0  0 -1  0  0]
[ 0  1  0  0 -1  0]
[ 0  0  1  0  0 -1]
sage: cube = o.polar()
sage: cube.vertices()
[-1  1 -1  1 -1  1 -1  1]
[-1 -1  1  1 -1 -1  1  1]
[ 1  1  1  1 -1 -1 -1 -1]
```

class NEFPartition(*data, polytope=None*)

Construct a NEF-partition from the given list. If the second argument is given, it must be the polytope of the NEF-partition.

A NEF-partition with k parts, $V = V_0 \cap V_1 \cap \cdots \cap V_{k-1}$, is represented by a single list of lenght $n = \#V$, in which the i-th entry is the part number of the i-th vertex of a polytope.

EXAMPLES: All elements of the list will be coerced to integers, so it is OK to use either a list of numbers or a list of strings:

```
sage: lattice_polytope.NEFPartition([1, 1, 0, 0, 0, 1])
[1, 1, 0, 0, 0, 1]
sage: lattice_polytope.NEFPartition(['1', '1', '0', '0', '0', '1'])
[1, 1, 0, 0, 0, 1]
```

dual()

Compute dual nef-partition.

Computation follows the article "Combinatorial aspects of mirror symmetry" by V.Batyrev and B.Nill, initial polytope corresponds to Nabla*, output to Delta*.

EXAMPLES: We compute the dual nef-partition for the first nef-partition of the octahedron:

```
sage: o = lattice_polytope.octahedron(3)
sage: np = o.nef_partitions()[0]
sage: np
[1, 1, 0, 1, 0, 0]
```

```
sage: npd = np.dual()
sage: npd
[1, 0, 1, 0, 0, 1, 0, 1]
sage: npd.polytope().vertices()
[ 1  0  1  0  0 -1  0 -1]
[-1  1  0  0  0 -1  1  0]
[ 0  1  0  1 -1  0 -1  0]
```

hodge_numbers()

Return Hodge numbers corresponding to the given nef-partition.

Note: In order to use this function you must use `nef_partitions(hodge_numbers=True)` for computing nef-partitions.

EXAMPLE: Currently, you need to request hodge_numbers when you compute nef-partitions. (The following weird construction ensures that there are no cached numbers.)

```
sage: o = LatticePolytope(lattice_polytope.octahedron(4).vertices())
sage: np = o.nef_partitions()[0]
sage: np.hodge_numbers()
...
NotImplementedError: use nef_partitions(hodge_numbers=True)!
sage: np = o.nef_partitions(hodge_numbers=True)[0]
sage: np.hodge_numbers()
[4]
```

nparts()

Return the number of parts of this partitions.

EXAMPLES:

```
sage: nefp = lattice_polytope.NEFPartition([1, 1, 0, 0, 0, 1])
sage: nefp.nparts()
2
```

part(*i*)

Return the `i`-th part of the partition.

NUMERATON OF PARTS STARTS WITH ZERO.

EXAMPLES:

```
sage: nefp = lattice_polytope.NEFPartition([1, 1, 0, 0, 0, 1])
sage: nefp.part(0)
[2, 3, 4]
sage: nefp.part(1)
[0, 1, 5]
```

part_of_vertex(*i*)

Return the index of the part containing the `i`-vertex.

EXAMPLES: `nefp.part_of_vertex(i)` is equivalent to `nefp[i]`.

```
sage: nefp = lattice_polytope.NEFPartition([1, 1, 0, 0, 0, 1])
sage: nefp.part_of_vertex(3)
0
sage: nefp.part_of_vertex(5)
1
sage: nefp[3]
0
sage: nefp[5]
1
```

You cannot change a NEF-partition once it is constructed:

```
sage: nefp[3] = 1
...
ValueError: object is immutable; please change a copy instead.
```

polytope()

Return the polytope of this NEF-partition.

EXAMPLE:

```
sage: o = lattice_polytope.octahedron(3)
sage: np = o.nef_partitions()[0]
sage: np.polytope() == o
True
```

ReflexivePolytope(*dim, n*)

Return n-th reflexive polytope from the database of 2- or 3-dimensional reflexive polytopes.

Note:

1. Numeration starts with zero: `0=n=15` for `dim=2` and `0=n=4318` for `dim=3`.
2. During the first call, all reflexive polytopes of requested dimension are loaded and cached for future use, so the first call for 3-dimensional polytopes can take several seconds, but all consecutive calls are fast.
3. Equivalent to `ReflexivePolytopes(dim)[n]` but checks bounds first.

EXAMPLES: The 3rd 2-dimensional polytope is "the diamond:"

```
sage: ReflexivePolytope(2,3)
Reflexive polygon  3: 2-dimensional, 4 vertices.
sage: lattice_polytope.ReflexivePolytope(2,3).vertices()
[ 1  0  0 -1]
[ 0  1 -1  0]
```

There are 16 reflexive polygons and numeration starts with 0:

```
sage: ReflexivePolytope(2,16)
...
ValueError: there are only 16 reflexive polygons!
```

It is not possible to load a 4-dimensional polytope in this way:

```
sage: ReflexivePolytope(4,16)
...
NotImplementedError: only 2- and 3-dimensional reflexive polytopes are available!
```

ReflexivePolytopes(*dim*)

Return the sequence of all 2- or 3-dimensional reflexive polytopes.

Note: During the first call the database is loaded and cached for future use, so repetitive calls will return the same object in memory.

TODO: load a database with precomputed faces. Requires better pickling, otherwise takes forever!

EXAMPLES: There are 16 reflexive polygons:

```
sage: len(ReflexivePolytopes(2))
16
```

It is not possible to load 4-dimensional polytopes in this way:

```
sage: ReflexivePolytopes(4)
...
NotImplementedError: only 2- and 3-dimensional reflexive polytopes are available!
```

class SetOfAllLatticePolytopesClass()

all_cached_data(*polytopes*)

Compute all cached data for all given `polytopes` and their polars.

This functions does it MUCH faster than member functions of `LatticePolytope` during the first run. So it is recommended to use this functions if you work with big sets of data. None of the polytopes in the given sequence should be constructed as the polar polytope to another one.

INPUT: a sequence of lattice polytopes.

EXAMPLES: This function has no output, it is just a fast way to work with long sequences of polytopes. Of course, you can use short sequences as well:

```
sage: o = lattice_polytope.octahedron(3)
sage: lattice_polytope.all_cached_data([o])
sage: o.faces()
[
[[0], [1], [2], [3], [4], [5]],
[[1, 5], [0, 5], [0, 1], [3, 5], [1, 3], [4, 5], [0, 4], [3, 4], [1, 2], [0, 2], [2, 3], [2, 4]]
[[0, 1, 5], [1, 3, 5], [0, 4, 5], [3, 4, 5], [0, 1, 2], [1, 2, 3], [0, 2, 4], [2, 3, 4]]
]
```

However, you cannot use it for polytopes that are constructed as polar polytopes of others:

```
sage: lattice_polytope.all_cached_data([o.polar()])
...
ValueError: Cannot read face structure for a polytope constructed as polar, use _compute_faces!
```

all_faces(*polytopes*)

Compute faces for all given `polytopes`.

This functions does it MUCH faster than member functions of `LatticePolytope` during the first run. So it is recommended to use this functions if you work with big sets of data.

INPUT: a sequence of lattice polytopes.

EXAMPLES: This function has no output, it is just a fast way to work with long sequences of polytopes. Of course, you can use short sequences as well:

```
sage: o = lattice_polytope.octahedron(3)
sage: lattice_polytope.all_faces([o])
sage: o.faces()
[
[[0], [1], [2], [3], [4], [5]],
[[1, 5], [0, 5], [0, 1], [3, 5], [1, 3], [4, 5], [0, 4], [3, 4], [1, 2], [0, 2], [2, 3], [2, 4]]
[[0, 1, 5], [1, 3, 5], [0, 4, 5], [3, 4, 5], [0, 1, 2], [1, 2, 3], [0, 2, 4], [2, 3, 4]]
]
```

However, you cannot use it for polytopes that are constructed as polar polytopes of others:

```
sage: lattice_polytope.all_faces([o.polar()])
...
ValueError: Cannot read face structure for a polytope constructed as polar, use _compute_faces!
```

all_nef_partitions (*polytopes, keep_symmetric=False*)

Compute NEF-partitions for all given `polytopes`.

This functions does it MUCH faster than member functions of `LatticePolytope` during the first run. So it is recommended to use this functions if you work with big sets of data.

Note: member function `is_reflexive` will be called separately for each polytope. It is strictly recommended to call `all_polars` on the sequence of `polytopes` before using this function.

INPUT: a sequence of lattice polytopes.

EXAMPLES: This function has no output, it is just a fast way to work with long sequences of polytopes. Of course, you can use short sequences as well:

```
sage: o = lattice_polytope.octahedron(3)
sage: lattice_polytope.all_nef_partitions([o])
sage: o.nef_partitions()
[
[1, 1, 0, 1, 0, 0],
[1, 1, 1, 0, 0, 0],
[1, 1, 1, 1, 0, 0]
]
```

You cannot use this function for non-reflexive polytopes:

```
sage: m = matrix(ZZ, [[1, 0, 0, -1,  0,  0],
...                   [0, 1, 0,  0, -1,  0],
...                   [0, 0, 2,  0,  0, -1]])
...
sage: p = LatticePolytope(m)
sage: lattice_polytope.all_nef_partitions([o, p])
...
ValueError: The given polytope is not reflexive!
Polytope: A lattice polytope: 3-dimensional, 6 vertices.
```

all_points (*polytopes*)

Compute lattice points for all given `polytopes`.

This functions does it MUCH faster than member functions of `LatticePolytope` during the first run. So it is recommended to use this functions if you work with big sets of data.

INPUT: a sequence of lattice polytopes.

EXAMPLES: This function has no output, it is just a fast way to work with long sequences of polytopes. Of course, you can use short sequences as well:

```
sage: o = lattice_polytope.octahedron(3)
sage: lattice_polytope.all_points([o])
sage: o.points()
[ 1  0  0 -1  0  0  0]
[ 0  1  0  0 -1  0  0]
[ 0  0  1  0  0 -1  0]
```

all_polars (*polytopes*)

Compute polar polytopes for all reflexive and equations of facets for all non-reflexive `polytopes`.

This functions does it MUCH faster than member functions of `LatticePolytope` during the first run. So it is recommended to use this functions if you work with big sets of data.

INPUT: a sequence of lattice polytopes.

EXAMPLES: This function has no output, it is just a fast way to work with long sequences of polytopes. Of course, you can use short sequences as well:

```
sage: o = lattice_polytope.octahedron(3)
sage: lattice_polytope.all_polars([o])
sage: o.polar()
A polytope polar to An octahedron: 3-dimensional, 8 vertices.
```

convex_hull (*points*)

Compute the convex hull of the given points.

Note: `points` might not span the space. Also, it fails for large numbers of vertices in dimensions 4 or greater

INPUT:

- `points` - a list that can be converted into vectors of the same dimension over ZZ.

OUTPUT: list of vertices of the convex hull of the given points (as vectors).

EXAMPLES: Let's compute the convex hull of several points on a line in the plane:

```
sage: lattice_polytope.convex_hull([[1,2],[3,4],[5,6],[7,8]])
[(1, 2), (7, 8)]
```

filter_polytopes (*f, polytopes, subseq=None, print_numbers=False*)

Use the function `f` to filter polytopes in a list.

INPUT:

- `f` - filtering function, it must take one argument, a lattice polytope, and return True or False.
- `polytopes` - list of polytopes.
- `subseq` - (default: None) list of integers. If it is specified, only polytopes with these numbers will be considered.
- `print_numbers` - (default: False) if True, the number of the current polytope will be printed on the screen before calling `f`.

OUTPUT: a list of integers – numbers of polytopes in the given list, that satisfy the given condition (i.e. function `f` returns True) and are elements of subseq, if it is given.

EXAMPLES: Consider a sequence of octahedrons:

```
sage: polytopes = Sequence([lattice_polytope.octahedron(n) for n in range(2, 7)], cr=True)
sage: polytopes
[
An octahedron: 2-dimensional, 4 vertices.,
An octahedron: 3-dimensional, 6 vertices.,
An octahedron: 4-dimensional, 8 vertices.,
An octahedron: 5-dimensional, 10 vertices.,
An octahedron: 6-dimensional, 12 vertices.
]
```

This filters octahedrons of dimension at least 4:

```
sage: lattice_polytope.filter_polytopes(lambda p: p.dim() >= 4, polytopes)
[2, 3, 4]
```

For long tests you can see the current progress:

```
sage: lattice_polytope.filter_polytopes(lambda p: p.nvertices() >= 10, polytopes, print_numbers=
0
1
2
```

```
3
4
[3, 4]
```

Here we consider only some of the polytopes:

```
sage: lattice_polytope.filter_polytopes(lambda p: p.nvertices() >= 10, polytopes, [2, 3, 4], pri
2
3
4
[3, 4]
```

minkowski_sum(*points1, points2*)

Compute the Minkowski sum of two convex polytopes.

Note: Polytopes might not be of maximal dimension.

INPUT:

- `points1, points2` - lists of objects that can be converted into vectors of the same dimension, treated as vertices of two polytopes.

OUTPUT: list of vertices of the Minkowski sum, given as vectors.

EXAMPLES: Let's compute the Minkovski sum of two line segments:

```
sage: lattice_polytope.minkowski_sum([[1,0],[-1,0]],[[0,1],[0,-1]])
[(1, 1), (1, -1), (-1, 1), (-1, -1)]
```

octahedron(*dim*)

Return an octahedron of the given dimension.

EXAMPLES: Here are 3- and 4-dimensional octahedrons:

```
sage: o = lattice_polytope.octahedron(3)
sage: o
An octahedron: 3-dimensional, 6 vertices.
sage: o.vertices()
[ 1  0  0 -1  0  0]
[ 0  1  0  0 -1  0]
[ 0  0  1  0  0 -1]
sage: o = lattice_polytope.octahedron(4)
sage: o
An octahedron: 4-dimensional, 8 vertices.
sage: o.vertices()
[ 1  0  0  0 -1  0  0  0]
[ 0  1  0  0  0 -1  0  0]
[ 0  0  1  0  0  0 -1  0]
[ 0  0  0  1  0  0  0 -1]
```

There exists only one octahedron of each dimension:

```
sage: o is lattice_polytope.octahedron(4)
True
```

positive_integer_relations(*points*)

Return relations between given points.

INPUT:

- `points` - lattice points given as columns of a matrix

OUTPUT: matrix of relations between given points with non-negative integer coefficients

EXAMPLES: This is a 3-dimensional reflexive polytope:

```
sage: m = matrix(ZZ,[[1, 0, -1, 0, -1],
...                  [0, 1, -1, 0,  0],
...                  [0, 0,  0, 1, -1]])
...
sage: p = LatticePolytope(m)
sage: p.points()
[ 1  0 -1  0 -1  0]
[ 0  1 -1  0  0  0]
[ 0  0  0  1 -1  0]
```

We can compute linear relations between its points in the following way:

```
sage: p.points().transpose().kernel().echelonized_basis_matrix()
[ 1  0  0  1  1  0]
[ 0  1  1 -1 -1  0]
[ 0  0  0  0  0  1]
```

However, the above relations may contain negative and rational numbers. This function transforms them in such a way, that all coefficients are non-negative integers:

```
sage: lattice_polytope.positive_integer_relations(p.points())
[1 0 0 1 1 0]
[1 1 1 0 0 0]
[0 0 0 0 0 1]
```

projective_space(*dim*)

Return a simplex of the given dimension, corresponding to P_{dim}.

EXAMPLES: We construct 3- and 4-dimensional simplexes:

```
sage: p = lattice_polytope.projective_space(3)
sage: p
A simplex: 3-dimensional, 4 vertices.
sage: p.vertices()
[ 1  0  0 -1]
[ 0  1  0 -1]
[ 0  0  1 -1]
sage: p = lattice_polytope.projective_space(4)
sage: p
A simplex: 4-dimensional, 5 vertices.
sage: p.vertices()
[ 1  0  0  0 -1]
[ 0  1  0  0 -1]
[ 0  0  1  0 -1]
[ 0  0  0  1 -1]
```

read_all_polytopes(*file_name, desc=None*)

Read all polytopes from the given file.

INPUT:

- `file_name` - the name of a file with VERTICES of polytopes
- `desc` - a string, that will be used for creating polytope descriptions. By default it will be set to 'A lattice polytope #%d from "filename"' + and will be used as `desc % n` where `n` is the number of the polytope in the file (*STARTING WITH ZERO*).

OUTPUT: a sequence of polytopes

EXAMPLES: We use poly.x to compute polar polytopes of 2- and 3-octahedrons and read them:

```
sage: o2 = lattice_polytope.octahedron(2)
sage: o3 = lattice_polytope.octahedron(3)
sage: result_name = lattice_polytope._palp("poly.x -fe", [o2, o3])
sage: f = open(result_name)
sage: f.readlines()
['4 2  Vertices of P-dual <-> Equations of P\n', '  -1   1\n', '   1   1\n', '  -1  -1\n', '   1
sage: f.close()
sage: lattice_polytope.read_all_polytopes(result_name, desc="Polytope from file %d")
[
Polytope from file 0: 2-dimensional, 4 vertices.,
Polytope from file 1: 3-dimensional, 8 vertices.
]
sage: os.remove(result_name)
```

read_palp_matrix(*data*)

Read and return an integer matrix from a string or an opened file.

First input line must start with two integers m and n, the number of rows and columns of the matrix. The rest of the first line is ignored. The next m lines must contain n numbers each.

If m>n, returns the transposed matrix. If the string is empty or EOF is reached, returns the empty matrix, constructed by `matrix()`.

EXAMPLES:

```
sage: lattice_polytope.read_palp_matrix("2 3 comment \n 1 2 3 \n 4 5 6")
[1 2 3]
[4 5 6]
sage: lattice_polytope.read_palp_matrix("3 2 Will be transposed \n 1 2 \n 3 4 \n 5 6")
[1 3 5]
[2 4 6]
```

sage_matrix_to_maxima(*m*)

Convert a Sage matrix to the string representation of Maxima.

EXAMPLE:

```
sage: m = matrix(ZZ,2)
sage: lattice_polytope.sage_matrix_to_maxima(m)
matrix([0,0],[0,0])
```

skip_palp_matrix(*data, n=1*)

Skip matrix data in a file.

INPUT:

- `data` - opened file with blocks of matrix data in the following format: A block consisting of m+1 lines has the number m as the first element of its first line.
- `n` - (default: 1) integer, specifies how many blocks should be skipped

If EOF is reached during the process, raises ValueError exception.

EXAMPLE: We create a file with vertices of the square and the cube, but read only the second set:

```
sage: o2 = lattice_polytope.octahedron(2)
sage: o3 = lattice_polytope.octahedron(3)
sage: result_name = lattice_polytope._palp("poly.x -fe", [o2, o3])
sage: f = open(result_name)
```

```
sage: f.readlines()
['4 2  Vertices of P-dual <-> Equations of P\n', '  -1   1\n', '   1   1\n', '  -1  -1\n', '   1
sage: f.close()
sage: f = open(result_name)
sage: lattice_polytope.skip_palp_matrix(f)
sage: lattice_polytope.read_palp_matrix(f)
[-1  1 -1  1 -1  1 -1  1]
[-1 -1  1  1 -1 -1  1  1]
[ 1  1  1  1 -1 -1 -1 -1]
sage: f.close()
sage: os.remove(result_name)
```

write_palp_matrix(*m, ofile=None, comment='', format=None*)

Write a matrix into a file.

INPUT:

- `m` - a matrix over integers.
- `ofile` - a file opened for writing (default: stdout)
- `comment` - a string (default: empty) see output description
- `format` - a format string used to print matrix entries. By default, "

OUTPUT: First line: number_of_rows number_of_columns comment Next number_of_rows lines: rows of the matrix.

EXAMPLES: This functions is used for writing polytope vertices in PALP format:

```
sage: o = lattice_polytope.octahedron(3)
sage: lattice_polytope.write_palp_matrix(o.vertices(), comment="3D Octahedron")
3 6 3D Octahedron
 1  0  0 -1  0  0
 0  1  0  0 -1  0
 0  0  1  0  0 -1
sage: lattice_polytope.write_palp_matrix(o.vertices(), format="%4d")
3 6
   1    0    0   -1    0    0
   0    1    0    0   -1    0
   0    0    1    0    0   -1
```

34.2 Groebner Fans

Sage provides much of the functionality of gfan, which is a software package whose main function is to enumerate all reduced Groebner bases of a polynomial ideal. The reduced Groebner bases yield the maximal cones in the Groebner fan of the ideal. Several subcomputations can be issued and additional tools are included. Among these the highlights are:

- Commands for computing tropical varieties.
- Interactive walks in the Groebner fan of an ideal.
- Commands for graphical renderings of Groebner fans and monomial ideals.

AUTHORS:

- Anders Nedergaard Jensen: Wrote the gfan C++ program, which implements algorithms many of which were invented by Jensen, Komei Fukuda, and Rekha Thomas. All the underlying hard work of the Groebner fans functionality of Sage depends on this C++ program.
- William Stein (2006-04-20): Wrote first version of the Sage code for working with Groebner fans.
- Tristram Bogart: the design of the Sage interface to gfan is joint work with Tristram Bogart, who also supplied numerous examples.
- Marshall Hampton (2008-03-25): Rewrote various functions to use gfan-0.3. This is still a work in progress, comments are appreciated on sage-devel@googlegroups.com (or personally at hamptonio@gmail.com).

EXAMPLES:

```
sage: x,y = QQ['x,y'].gens()
sage: i = ideal(x^2 - y^2 + 1)
sage: g = i.groebner_fan()
sage: g.reduced_groebner_bases()
[[x^2 - y^2 + 1], [-x^2 + y^2 - 1]]
```

TESTS:

```
sage: x,y = QQ['x,y'].gens()
sage: i = ideal(x^2 - y^2 + 1)
sage: g = i.groebner_fan()
sage: g == loads(dumps(g))
True
```

REFERENCES:

- Anders N. Jensen; Gfan, a software system for Groebner fans; available at http://www.math.tu-berlin.de/~jensen/software/gfan/gfan.html

class GroebnerFan(*I, is_groebner_basis=False, symmetry=None, verbose=False*)

buchberger()

Computes and returns a lexicographic reduced Groebner basis for the ideal.

EXAMPLES:

```
sage: R.<x,y,z> = PolynomialRing(QQ,3)
sage: G = R.ideal([x - z^3, y^2 - x + x^2 - z^3*x]).groebner_fan()
sage: G.buchberger()
[-z^3 + y^2, -z^3 + x]
```

characteristic()

Return the characteristic of the base ring.

EXAMPLES:

```
sage: R.<x,y,z> = PolynomialRing(QQ,3)
sage: i1 = ideal(x*z + 6*y*z - z^2, x*y + 6*x*z + y*z - z^2, y^2 + x*z + y*z)
sage: gf = i1.groebner_fan()
sage: gf.characteristic()
0
```

dimension_of_homogeneity_space()

Return the dimension of the homogeneity space.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: G = R.ideal([y^3 - x^2, y^2 - 13*x]).groebner_fan()
sage: G.dimension_of_homogeneity_space()
0
```

gfan(*cmd=”, I=None, format=True*)

Returns the gfan output as a string given an input cmd; the default is to produce the list of reduced Groebner bases in gfan format.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: gf = R.ideal([x^3-y,y^3-x-1]).groebner_fan()
sage: gf.gfan()
'Q[x,y]\n{{\ny^9-1-y+3*y^3-3*y^6,\nx+1-y^3}\n,\n{\ny^3-1-x,\nx^3-y}\n,\n{\ny-x^3,\nx^9-1-x}\
```

homogeneity_space()

Return the homogeneity space of a the list of polynomials that define this Groebner fan.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: G = R.ideal([y^3 - x^2, y^2 - 13*x]).groebner_fan()
sage: H = G.homogeneity_space()
```

ideal()

Return the ideal the was used to define this Groebner fan.

EXAMPLES:

```
sage: R.<x1,x2> = PolynomialRing(QQ,2)
sage: gf = R.ideal([x1^3-x2,x2^3-2*x1-2]).groebner_fan()
sage: gf.ideal()
Ideal (x1^3 - x2, x2^3 - 2*x1 - 2) of Multivariate Polynomial Ring in x1, x2 over Rational F
```

interactive(**args, **kwds*)

See the documentation for self[0].interactive(). This does not work with the notebook.

EXAMPLES:

```
sage: print "This is not easily doc-testable; please write a good one!"
This is not easily doc-testable; please write a good one!
```

maximal_total_degree_of_a_groebner_basis()

Return the maximal total degree of any Groebner basis.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: G = R.ideal([y^3 - x^2, y^2 - 13*x]).groebner_fan()
sage: G.maximal_total_degree_of_a_groebner_basis()
4
```

minimal_total_degree_of_a_groebner_basis()

Return the minimal total degree of any Groebner basis.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: G = R.ideal([y^3 - x^2, y^2 - 13*x]).groebner_fan()
sage: G.minimal_total_degree_of_a_groebner_basis()
2
```

number_of_reduced_groebner_bases()

Return the number of reduced Groebner bases.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: G = R.ideal([y^3 - x^2, y^2 - 13*x]).groebner_fan()
sage: G.number_of_reduced_groebner_bases()
3
```

number_of_variables()

Return the number of variables.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: G = R.ideal([y^3 - x^2, y^2 - 13*x]).groebner_fan()
sage: G.number_of_variables()
2

sage: R = PolynomialRing(QQ,'x',10)
sage: R.inject_variables(globals())
Defining x0, x1, x2, x3, x4, x5, x6, x7, x8, x9
sage: G = ideal([x0 - x9, sum(R.gens())]).groebner_fan()
sage: G.number_of_variables()
10
```

polyhedralfan()

Returns a polyhedral fan object corresponding to the reduced Groebner bases.

EXAMPLES:

```
sage: R3.<x,y,z> = PolynomialRing(QQ,3)
sage: gf = R3.ideal([x^8-y^4,y^4-z^2,z^2-1]).groebner_fan()
sage: pf = gf.polyhedralfan()
sage: pf.rays()
[[1, 0, 0], [0, 1, 0], [0, 0, 1]]
```

reduced_groebner_bases()

EXAMPLES:

```
sage: R.<x,y,z> = PolynomialRing(QQ, 3, order='lex')
sage: G = R.ideal([x^2*y - z, y^2*z - x, z^2*x - y]).groebner_fan()
sage: X = G.reduced_groebner_bases()
sage: len(X)
33
sage: X[0]
[z^15 - z, y - z^11, x - z^9]
sage: X[0].ideal()
Ideal (z^15 - z, y - z^11, x - z^9) of Multivariate Polynomial Ring in x, y, z over Rational
sage: X[:5]
[[z^15 - z, y - z^11, x - z^9],
[-y + z^11, y*z^4 - z, y^2 - z^8, x - z^9],
[-y^2 + z^8, y*z^4 - z, y^2*z^3 - y, y^3 - z^5, x - y^2*z],
[-y^3 + z^5, y*z^4 - z, y^2*z^3 - y, y^4 - z^2, x - y^2*z],
[-y^4 + z^2, y^6*z - y, y^9 - z, x - y^2*z]]
sage: R3.<x,y,z> = PolynomialRing(GF(2477),3)
sage: gf = R3.ideal([300*x^3-y,y^2-z,z^2-12]).groebner_fan()
sage: gf.reduced_groebner_bases()
[[z^2 - 12, y^2 - z, x^3 + 933*y],
[-y^2 + z, y^4 - 12, x^3 + 933*y],
[z^2 - 12, -300*x^3 + y, x^6 - 1062*z],
[-828*x^6 + z, -300*x^3 + y, x^12 + 200]]
```

render(*file=None, larger=False, shift=0, rgbcolor=(0, 0, 0), polyfill=<function max_degree at 0x8fdcde8>, scale_colors=True*)

Render a Groebner fan as sage graphics or save as an xfig file.

More precisely, the output is a drawing of the Groebner fan intersected with a triangle. The corners of the triangle are (1,0,0) to the right, (0,1,0) to the left and (0,0,1) at the top. If there are more than three variables in the ring we extend these coordinates with zeros.

INPUT:

- `file` - a filename if you prefer the output saved to a file. This will be in xfig format.
- `shift` - shift the positions of the variables in the drawing. For example, with shift=1, the corners will be b (right), c (left), and d (top). The shifting is done modulo the number of variables in the polynomial ring. The default is 0.
- `larger` - bool (default: False); if True, make the triangle larger so that the shape of of the Groebner region appears. Affects the xfig file but probably not the sage graphics (?)
- `rgbcolor` - This will not affect the saved xfig file, only the sage graphics produced.
- `polyfill` - Whether or not to fill the cones with a color determined by the highest degree in each reduced Groebner basis for that cone.
- `scale_colors` - if True, this will normalize color values to try to maximize the range

EXAMPLES:

```
sage: R.<x,y,z> = PolynomialRing(QQ,3)
sage: G = R.ideal([y^3 - x^2, y^2 - 13*x,z]).groebner_fan()
sage: test_render = G.render()

sage: R.<x,y,z> = PolynomialRing(QQ,3)
sage: G = R.ideal([x^2*y - z, y^2*z - x, z^2*x - y]).groebner_fan()
sage: test_render = G.render(larger=True)
```

TESTS:

Testing the case where the number of generators is < 3. Currently, this should raise a `NotImplementedError` error.

```
sage: R.<x,y> = PolynomialRing(QQ, 2)
sage: R.ideal([y^3 - x^2, y^2 - 13*x]).groebner_fan().render()
...
NotImplementedError
```

render3d(*verbose=False*)

For a Groebner fan of an ideal in a ring with four variables, this function intersects the fan with the standard simplex perpendicular to (1,1,1,1), creating a 3d polytope, which is then projected into 3 dimensions. The edges of this projected polytope are returned as lines.

EXAMPLES:

```
sage: R4.<w,x,y,z> = PolynomialRing(QQ,4)
sage: gf = R4.ideal([w^2-x,x^2-y,y^2-z,z^2-x]).groebner_fan()
sage: three_d = gf.render3d()
```

TESTS:

Now test the case where the number of generators is not 4. Currently, this should raise a `NotImplementedError` error.

```
sage: P.<a,b,c> = PolynomialRing(QQ, 3, order="lex")
sage: sage.rings.ideal.Katsura(P, 3).groebner_fan().render3d()
...
NotImplementedError
```

ring()

Return the multivariate polynomial ring.

EXAMPLES:

```
sage: R.<x1,x2> = PolynomialRing(QQ,2)
sage: gf = R.ideal([x1^3-x2,x2^3-x1-2]).groebner_fan()
sage: gf.ring()
Multivariate Polynomial Ring in x1, x2 over Rational Field
```

tropical_basis(*check=True, verbose=False*)

Return a tropical basis for the tropical curve associated to this ideal.

INPUT:

- `check` - bool (default: True); if True raises a ValueError exception if this ideal does not define a tropical curve (i.e., the condition that R/I has dimension equal to 1 + the dimension of the homogeneity space is not satisfied).

EXAMPLES:

```
sage: R.<x,y,z> = PolynomialRing(QQ,3, order='lex')
sage: G = R.ideal([y^3-3*x^2, z^3-x-y-2*y^3+2*x^2]).groebner_fan()
sage: G
Groebner fan of the ideal:
Ideal (-3*x^2 + y^3, 2*x^2 - x - 2*y^3 - y + z^3) of Multivariate Polynomial Ring in x, y, z
sage: G.tropical_basis()
[-3*x^2 + y^3, 2*x^2 - x - 2*y^3 - y + z^3, 3/4*x + y^3 + 3/4*y - 3/4*z^3]
```

tropical_intersection(*ideal_arg=False, *args, **kwds*)

Returns information about the tropical intersection of the polynomials defining the ideal.

EXAMPLES:

```
sage: R.<x,y,z> = PolynomialRing(QQ,3)
sage: i1 = ideal(x*z + 6*y*z - z^2, x*y + 6*x*z + y*z - z^2, y^2 + x*z + y*z)
sage: gf = i1.groebner_fan()
sage: pf = gf.tropical_intersection()
sage: pf.rays()
[[-1, 0, 0]]
```

weight_vectors()

Returns the weight vectors corresponding to the reduced Groebner bases.

EXAMPLES:

```
sage: r3.<x,y,z> = PolynomialRing(QQ,3)
sage: g = r3.ideal([x^3+y,y^3-z,z^2-x]).groebner_fan()
sage: g.weight_vectors()
[(3, 7, 1), (5, 1, 2), (7, 1, 4), (1, 1, 4), (1, 1, 1), (1, 4, 1), (1, 4, 10)]
sage: r4.<x,y,z,w> = PolynomialRing(QQ,4)
sage: g4 = r4.ideal([x^3+y,y^3-z,z^2-x,z^3 - w]).groebner_fan()
sage: len(g4.weight_vectors())
23
```

class **PolyhedralCone**(*gfan_polyhedral_cone, ring=Rational Field*)

ambient_dim()

Returns the ambient dimension of the Groebner cone.

EXAMPLES:

```
sage: R3.<x,y,z> = PolynomialRing(QQ,3)
sage: gf = R3.ideal([x^8-y^4,y^4-z^2,z^2-2]).groebner_fan()
sage: a = gf[0].groebner_cone()
sage: a.ambient_dim()
3
```

dim()
Returns the dimension of the Groebner cone.
EXAMPLES:

```
sage: R3.<x,y,z> = PolynomialRing(QQ,3)
sage: gf = R3.ideal([x^8-y^4,y^4-z^2,z^2-2]).groebner_fan()
sage: a = gf[0].groebner_cone()
sage: a.dim()
3
```

facets()
Returns the inward facet normals of the Groebner cone.
EXAMPLES:

```
sage: R3.<x,y,z> = PolynomialRing(QQ,3)
sage: gf = R3.ideal([x^8-y^4,y^4-z^2,z^2-2]).groebner_fan()
sage: a = gf[0].groebner_cone()
sage: a.facets()
[[0, 0, 1], [0, 1, 0], [1, 0, 0]]
```

lineality_dim()
Returns the lineality dimension of the Groebner cone. This is just the difference between the ambient dimension and the dimension of the cone.
EXAMPLES:

```
sage: R3.<x,y,z> = PolynomialRing(QQ,3)
sage: gf = R3.ideal([x^8-y^4,y^4-z^2,z^2-2]).groebner_fan()
sage: a = gf[0].groebner_cone()
sage: a.lineality_dim()
0
```

relative_interior_point()
Returns a point in the relative interior of the Groebner cone.
EXAMPLES:

```
sage: R3.<x,y,z> = PolynomialRing(QQ,3)
sage: gf = R3.ideal([x^8-y^4,y^4-z^2,z^2-2]).groebner_fan()
sage: a = gf[0].groebner_cone()
sage: a.relative_interior_point()
[1, 1, 1]
```

class **PolyhedralFan**(*gfan_polyhedral_fan*)

ambient_dim()
Returns the ambient dimension of the Groebner fan.
EXAMPLES:

```
sage: R3.<x,y,z> = PolynomialRing(QQ,3)
sage: gf = R3.ideal([x^8-y^4,y^4-z^2,z^2-2]).groebner_fan()
sage: a = gf.polyhedralfan()
sage: a.ambient_dim()
3
```

dim()
Returns the dimension of the Groebner fan.
EXAMPLES:

```
sage: R3.<x,y,z> = PolynomialRing(QQ,3)
sage: gf = R3.ideal([x^8-y^4,y^4-z^2,z^2-2]).groebner_fan()
```

```
sage: a = gf.polyhedralfan()
sage: a.dim()
3
```

lineality_dim()

Returns the lineality dimension of the Groebner fan. This is just the difference between the ambient dimension and the dimension of the cone.

EXAMPLES:

```
sage: R3.<x,y,z> = PolynomialRing(QQ,3)
sage: gf = R3.ideal([x^8-y^4,y^4-z^2,z^2-2]).groebner_fan()
sage: a = gf.polyhedralfan()
sage: a.lineality_dim()
0
```

rays()

Returns a list of rays of the polyhedral fan.

EXAMPLES:

```
sage: R.<x,y,z> = PolynomialRing(QQ,3)
sage: i2 = ideal(x*z + 6*y*z - z^2, x*y + 6*x*z + y*z - z^2, y^2 + x*z + y*z)
sage: gf2 = i2.groebner_fan(verbose = False)
sage: pf = gf2.polyhedralfan()
sage: pf.rays()
[[1, 0, 0], [-2, -1, 0], [1, 1, 0], [0, -1, 0], [-1, 1, 0]]
```

class **ReducedGroebnerBasis**(*groebner_fan, gens, gfan_gens*)

groebner_cone(*restrict=False*)

Return defining inequalities for the full-dimensional Groebner cone associated to this marked minimal reduced Groebner basis.

INPUT:

- `restrict` - bool (default: False); if True, add an inequality for each coordinate, so that the cone is restricted to the positive orthant.

OUTPUT: tuple of integer vectors

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: G = R.ideal([y^3 - x^2, y^2 - 13*x]).groebner_fan()
sage: poly_cone = G[1].groebner_cone()
sage: poly_cone.facets()
[[-1, 2], [1, -1]]
sage: [g.groebner_cone().facets() for g in G]
[[[0, 1], [1, -2]], [[-1, 2], [1, -1]], [[-1, 1], [1, 0]]]
sage: G[1].groebner_cone(restrict=True).facets()
[[-1, 2], [1, -1]]
```

ideal()

Return the ideal generated by this basis.

EXAMPLES:

```
sage: R.<x,y,z> = PolynomialRing(QQ,3)
sage: G = R.ideal([x - z^3, y^2 - 13*x]).groebner_fan()
sage: G[0].ideal()
Ideal (-13*z^3 + y^2, -z^3 + x) of Multivariate Polynomial Ring in x, y, z over Rational Fie
```

interactive(*latex=False, flippable=False, wall=False, inequalities=False, weight=False*)

Do an interactive walk of the Groebner fan starting at this reduced Groebner basis.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: G = R.ideal([y^3 - x^2, y^2 - 13*x]).groebner_fan()
sage: G[0].interactive()      # not tested
Initializing gfan interactive mode
*******************************************
*     Press control-C to return to Sage     *
*******************************************
....
```

max_degree(*list_of_polys*)

Computes the maximum degree of a list of polynomials

EXAMPLES:

```
sage: from sage.rings.polynomial.groebner_fan import max_degree
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: p_list = [x^2-y,x*y^10-x]
sage: max_degree(p_list)
11.0
```

prefix_check(*str_list*)

Checks if any strings in a list are prefixes of another string in the list.

EXAMPLES:

```
sage: from sage.rings.polynomial.groebner_fan import prefix_check
sage: prefix_check(['z1','z1z1'])
False
sage: prefix_check(['z1','zz1'])
True
```

34.3 Polytopes

This module provides access to polymake, which 'has been developed since 1997 in the Discrete Geometry group at the Institute of Mathematics of Technische Universitat Berlin. Since 2004 the development is shared with Fachbereich Mathematik, Technische Universitat Darmstadt. The system offers access to a wide variety of algorithms and packages within a common framework. polymake is flexible and continuously expanding. The software supplies C++ and perl interfaces which make it highly adaptable to individual needs.'

Note: If you have trouble with this module do:

```
sage:  !polymake --reconfigure   # not tested
```

at the command line.

AUTHORS:

- Ewgenij Gawrilow, Michael Joswig: main authors of polymake
- William Stein: Sage interface

class Polymake()

associahedron(*dimension*)

birkhoff(*n*)

cell24()
EXAMPLES:

```
sage: polymake.cell24()            # optional: needs polymake
The 24-cell
```

convex_hull(*points=, []*)
EXAMPLES:

```
sage: R.<x,y,z> = PolynomialRing(QQ,3)
sage: f = x^3 + y^3 + z^3 + x*y*z
sage: e = f.exponents()
sage: a = [[1] + list(v) for v in e]
sage: a
[[1, 3, 0, 0], [1, 0, 3, 0], [1, 1, 1, 1], [1, 0, 0, 3]]
sage: n = polymake.convex_hull(a)       # optional: needs polymake
sage: n                                 # optional
Convex hull of points [[1, 0, 0, 3], [1, 0, 3, 0], [1, 1, 1, 1], [1, 3, 0, 0]]
sage: n.facets()                        # optional
[(0, 1, 0, 0), (3, -1, -1, 0), (0, 0, 1, 0)]
sage: n.is_simple()                     # optional
True
sage: n.graph()                         # optional
'GRAPH\n{1 2}\n{0 2}\n{0 1}\n\n'
```

cube(*dimension, scale=0*)

from_data(*data*)

rand01(*d, n, seed=None*)

reconfigure()
Reconfigure polymake.

Remember to run polymake.reconfigure() as soon as you have changed the customization file and/or installed missing software!

class **Polytope**(*datafile, desc*)
Create a polytope.

EXAMPLES:

```
sage: P = polymake.convex_hull([[1,0,0,0], [1,0,0,1], [1,0,1,0], [1,0,1,1],  [1,1,0,0], [1,1,0,1
```

Note: If you have trouble with this module do:

```
sage:  !polymake --reconfigure   # not tested
```

at the command line.

cmd(*cmd*)

data()

facets()
EXAMPLES:

```
sage: P = polymake.convex_hull([[1,0,0,0], [1,0,0,1], [1,0,1,0], [1,0,1,1],  [1,1,0,0], [1,1
sage: P.facets()                          # optional
[(0, 0, 0, 1), (0, 1, 0, 0), (0, 0, 1, 0), (1, 0, 0, -1), (1, 0, -1, 0), (1, -1, 0, 0)]
```

graph()

is_simple()
Return True if this polytope is simple.

A polytope is *simple* if the degree of each vertex equals the dimension of the polytope.

EXAMPLES:

```
sage: P = polymake.convex_hull([[1,0,0,0], [1,0,0,1], [1,0,1,0], [1,0,1,1],  [1,1,0,0], [1,1
sage: P.is_simple()                              # optional
True
```

AUTHORS:

- Edwin O'Shea (2006-05-02): Definition of simple.

n_facets()
EXAMPLES:

```
sage: P = polymake.convex_hull([[1,0,0,0], [1,0,0,1], [1,0,1,0], [1,0,1,1],  [1,1,0,0], [1,1
sage: P.n_facets()                               # optional
6
```

vertices()
EXAMPLES:

```
sage: P = polymake.convex_hull([[1,0,0,0], [1,0,0,1], [1,0,1,0], [1,0,1,1],  [1,1,0,0], [1,1
sage: P.vertices()                               # optional
[(1, 0, 0, 0), (1, 0, 0, 1), (1, 0, 1, 0), (1, 0, 1, 1), (1, 1, 0, 0), (1, 1, 0, 1), (1, 1,
```

CHAPTER

THIRTYFIVE

HOMOLOGY OF SIMPLICIAL COMPLEXES

Sage includes support for constructing simplicial complexes and computing their homology.

35.1 Finite simplicial complexes

AUTHORS:

- John H. Palmieri (2009-04)

This module implements the basic structure of finite simplicial complexes. Given a set V of "vertices", a simplicial complex on V is a collection K of subsets of V satisfying the condition that if S is one of the subsets in K, then so is every subset of S. The subsets S are called the 'simplices' of K.

A simplicial complex K can be viewed as a purely combinatorial object, as described above, but it also gives rise to a topological space $|K|$ (its *geometric realization*) as follows: first, the points of V should be in general position in euclidean space. Next, if $\{v\}$ is in K, then the vertex v is in $|K|$. If $\{v, w\}$ is in K, then the line segment from v to w is in $|K|$ If $\{u, v, w\}$ is in K, then the triangle with vertices u, v, and w is in $|K|$. In general, $|K|$ is the union of the convex hulls of simplices of K. Frequently, one abuses notation and uses K to denote both the simplicial complex and the associated topological space.

For any simplicial complex K and any commutative ring R there is an associated chain complex, with differential of degree -1. The n^{th} term is the free R-module with basis given by the n-simplices of K. The differential is determined by its value on any simplex: on the n-simplex with vertices $(v_0, v_1, ..., v_n)$, the differential is the alternating sum with i^{th} summand $(-1)^i$ multiplied by the $(n-1)$-simplex obtained by omitting vertex v_i.

In the implementation here, the vertex set must be finite. To define a simplicial complex, specify its vertex set: this should be a list, tuple, or set, or it can be a non-negative integer n, in which case the vertex set is $(0, ..., n)$. Also specify the facets: the maximal faces.

Note: The elements of the vertex set are not automatically contained in the simplicial complex: each one is only included if and only if it is a vertex of at least one of the specified facets.

EXAMPLES:

```
sage: SimplicialComplex([1, 3, 7], [[1], [3, 7]])
Simplicial complex with vertex set (1, 3, 7) and facets {(3, 7), (1,)}
sage: SimplicialComplex(2)    # the empty simplicial complex
Simplicial complex with vertex set (0, 1, 2) and facets {()}
sage: X = SimplicialComplex(3, [[0,1], [1,2], [2,3], [3,0]])
sage: X
```

```
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(1, 2), (2, 3), (0, 3), (0, 1)}
sage: X.stanley_reisner_ring()
Quotient of Multivariate Polynomial Ring in x0, x1, x2, x3 over Integer Ring by the ideal (x1*x3, x0*
sage: X.is_pure()
True
```

Sage can perform a number of operations on simplicial complexes, such as the join and the product, and it can also compute homology:

```
sage: S = SimplicialComplex(3, [[0,1], [1,2], [0,2]]) # circle
sage: T = S.product(S)  # torus
sage: T
Simplicial complex with 16 vertices and 18 facets
sage: T.homology()   # this computes reduced homology
{0: 0, 1: Z x Z, 2: Z}
sage: T.euler_characteristic()
0
```

Sage knows about some basic combinatorial data associated to a simplicial complex:

```
sage: X = SimplicialComplex(3, [[0,1], [1,2], [2,3], [0,3]])
sage: X.f_vector()
[1, 4, 4]
sage: X.face_poset()
Finite poset containing 8 elements
sage: X.stanley_reisner_ring()
Quotient of Multivariate Polynomial Ring in x0, x1, x2, x3 over Integer Ring by the ideal (x1*x3, x0*
```

class **Simplex**(*X*)

Define a simplex.

Topologically, a simplex is the convex hull of a collection of vertices in general position. Combinatorially, it is defined just by specifying a set of vertices. It is represented in Sage by the tuple of the vertices.

INPUT:

- X - set of vertices

OUTPUT: simplex with those vertices

X may be a non-negative integer n, in which case the simplicial complex will have $n+1$ vertices $(0, 1, ..., n)$, or it may be anything which may be converted to a tuple, in which case the vertices will be that tuple.

Warning: The vertices should be distinct, and no error checking is done to make sure this is the case.

EXAMPLES:

```
sage: from sage.homology.simplicial_complex import Simplex
sage: Simplex(4)
(0, 1, 2, 3, 4)
sage: Simplex([3, 4, 1])
(3, 4, 1)
sage: X = Simplex((3, 'a', 'vertex')); X
(3, 'a', 'vertex')
sage: X == loads(dumps(X))
True
```

dimension()

The dimension of this simplex: the number of vertices minus 1.

EXAMPLES:

```
sage: from sage.homology.simplicial_complex import Simplex
sage: Simplex(5).dimension() == 5
True
sage: Simplex(5).face(1).dimension()
4
```

face(*n*)

The nth face of this simplex.

INPUT:

- n - an integer between 0 and the dimension of this simplex

OUTPUT: the simplex obtained by removing the nth vertex from this simplex

EXAMPLES:

```
sage: from sage.homology.simplicial_complex import Simplex
sage: S = Simplex(4)
sage: S.face(0)
(1, 2, 3, 4)
sage: S.face(3)
(0, 1, 2, 4)
```

faces()

The list of faces (of codimension 1) of this simplex.

EXAMPLES:

```
sage: from sage.homology.simplicial_complex import Simplex
sage: S = Simplex(4)
sage: S.faces()
[(1, 2, 3, 4), (0, 2, 3, 4), (0, 1, 3, 4), (0, 1, 2, 4), (0, 1, 2, 3)]
sage: len(Simplex(10).faces())
11
```

is_empty()

Return True iff this simplex is the empty simplex.

EXAMPLES:

```
sage: from sage.homology.simplicial_complex import Simplex
sage: [Simplex(n).is_empty() for n in range(-1,4)]
[True, False, False, False, False]
```

is_face(*other*)

Return True iff this simplex is a face of other.

EXAMPLES:

```
sage: from sage.homology.simplicial_complex import Simplex
sage: Simplex(3).is_face(Simplex(5))
True
sage: Simplex(5).is_face(Simplex(2))
False
sage: Simplex(['a', 'b', 'c']).is_face(Simplex(8))
False
```

join(*right, rename_vertices=True*)

The join of this simplex with another one.

The join of two simplices $[v_0, ..., v_k]$ and $[w_0, ..., w_n]$ is the simplex $[v_0, ..., v_k, w_0, ..., w_n]$.

INPUT:

- `right` - the other simplex (the right-hand factor)
- `rename_vertices` – boolean (optional, default True). If this is True, the vertices in the join will be renamed by this formula: vertex "v" in the left-hand factor –> vertex "Lv" in the join, vertex "w" in the right-hand factor –> vertex "Rw" in the join. If this is false, this tries to construct the join without renaming the vertices; this may cause problems if the two factors have any vertices with names in common.

EXAMPLES:

```
sage: from sage.homology.simplicial_complex import Simplex
sage: Simplex(2).join(Simplex(3))
('L0', 'L1', 'L2', 'R0', 'R1', 'R2', 'R3')
sage: Simplex(['a', 'b']).join(Simplex(['x', 'y', 'z']))
('La', 'Lb', 'Rx', 'Ry', 'Rz')
sage: Simplex(['a', 'b']).join(Simplex(['x', 'y', 'z']), rename_vertices=False)
('a', 'b', 'x', 'y', 'z')
```

product (*other, rename_vertices=False*)

The product of this simplex with another one, as a list of simplices.

INPUT:

- `other` - the other simplex
- **`rename_vertices` – boolean (optional, default True). If** this is False, then the vertices in the product are the set of ordered pairs (v, w) where v is a vertex in the left-hand factor (`self`) and w is a vertex in the right-hand factor (`other`). If this is True, then the vertices are renamed as "LvRw" (e.g., the vertex (1,2) would become "L1R2"). This is useful if you want to define the Stanley-Reisner ring of the complex: vertex names like (0,1) are not suitable for that, while vertex names like "L0R1" are.

Algorithm: see Hatcher, p. 277-278 (who in turn refers to Eilenberg-Steenrod, p. 68): given `Simplex(m)` and `Simplex(n)`, then `Simplex(m)` x `Simplex(n)` can be triangulated as follows: for each path f from $(0, 0)$ to (m, n) along the integer grid in the plane, going up or right at each lattice point, associate an $(m + n)$-simplex with vertices v_0, v_1, ..., where v_k is the k^{th} vertex in the path f.

Note that there are $m+n$ choose n such paths. Note also that each vertex in the product is a pair of vertices (v, w) where v is a vertex in the left-hand factor and w is a vertex in the right-hand factor.

Note: This produces a list of simplices – not a `Simplex`, not a `SimplicialComplex`.

EXAMPLES:

```
sage: from sage.homology.simplicial_complex import Simplex
sage: len(Simplex(2).product(Simplex(2)))
6
sage: Simplex(1).product(Simplex(1))
[((0, 0), (0, 1), (1, 1)), ((0, 0), (1, 0), (1, 1))]
```

REFERENCES:

- A. Hatcher, "Algebraic Topology", Cambridge University Press (2002).

set ()

The frozenset attached to this simplex.

EXAMPLES:

```
sage: from sage.homology.simplicial_complex import Simplex
sage: Simplex(3).set()
frozenset([0, 1, 2, 3])
```

tuple ()

The tuple attached to this simplex.

EXAMPLES:

```
sage: from sage.homology.simplicial_complex import Simplex
sage: Simplex(3).tuple()
(0, 1, 2, 3)
```

Although simplices are printed as if they were tuples, they are not the same type:

```
sage: type(Simplex(3).tuple())
<type 'tuple'>
sage: type(Simplex(3))
<class 'sage.homology.simplicial_complex.Simplex'>
```

class SimplicialComplex(*vertex_set=, [], maximal_faces=, [], **kwds*)

Define a simplicial complex.

INPUT:

- `vertex_set` - set of vertices
- `maximal_faces` - set of maximal faces
- `vertex_check` - boolean (optional, default True)
- `maximality_check` - boolean (optional, default True)
- `sort_facets` - boolean (optional, default True)
- `name_check` - boolean (optional, default False)

OUTPUT: a simplicial complex

`vertex_set` may be a non-negative integer n (in which case the simplicial complex will have $n+1$ vertices $\{0, 1, ..., n\}$), or it may be anything which may be converted to a tuple. Call the elements of this 'vertices'.

`maximal_faces` should be a list or tuple or set (indeed, anything which may be converted to a set) whose elements are lists (or tuples, etc.) of vertices.

If `vertex_check` is True, check to see that each given maximal face is a subset of the vertex set. Raise an error for any bad face.

If `maximality_check` is True, check that each maximal face is, in fact, maximal. In this case, when producing the internal representation of the simplicial complex, omit those that are not. It is highly recommended that this be True; various methods for this class may fail if faces which are claimed to be maximal are in fact not.

If `sort_facets` is True, sort the vertices in each facet. If the vertices in different facets are not ordered compatibly (e.g., if you have facets (1, 3, 5) and (5, 3, 8)), then homology calculations may have unpredictable results.

If `name_check` is True, check the names of the vertices to see if they can be easily converted to generators of a polynomial ring – use this if you plan to use the Stanley-Reisner ring for the simplicial complex.

Note: The elements of `vertex_set` are not automatically in the simplicial complex: each one is only included if it is a vertex of at least one of the specified facets.

EXAMPLES:

```
sage: SimplicialComplex(4, [[1,2], [1,4]])
Simplicial complex with vertex set (0, 1, 2, 3, 4) and facets {(1, 2), (1, 4)}
sage: SimplicialComplex(3, [[0,2], [0,3], [0]])
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(0, 2), (0, 3)}
sage: SimplicialComplex(3, [[0,2], [0,3], [0]], maximality_check=False)
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(0, 2), (0, 3), (0,)}
sage: S = SimplicialComplex(['a', 'b', 'c'], (('a', 'b'), ('a', 'c'), ('b', 'c')))
sage: S
Simplicial complex with vertex set ('a', 'b', 'c') and facets {('b', 'c'), ('a', 'c'), ('a', 'b'
sage: S == loads(dumps(S))
True
```

add_face(*face*)

Add a face to this simplicial complex

INPUT:

- face - a subset of the vertex set

This changes the simplicial complex, adding a new face and all of its subfaces.

EXAMPLES:

```
sage: X = SimplicialComplex(2, [[0,1], [0,2]])
sage: X.add_face([0,1,2,]); X
Simplicial complex with vertex set (0, 1, 2) and facets {(0, 1, 2)}
sage: Y = SimplicialComplex(3); Y
Simplicial complex with vertex set (0, 1, 2, 3) and facets {()}
sage: Y.add_face([0,1])
sage: Y.add_face([1,2,3])
sage: Y
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(1, 2, 3), (0, 1)}
```

If you add a face which is already present, there is no effect:

```
sage: Y.add_face([1,3]); Y
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(1, 2, 3), (0, 1)}
```

alexander_dual()

The Alexander dual of this simplicial complex: according to the Macaulay2 documentation, this is the simplicial complex whose faces are the complements of its nonfaces.

Thus find the minimal nonfaces and take their complements to find the facets in the Alexander dual.

EXAMPLES:

```
sage: Y = SimplicialComplex(4); Y
Simplicial complex with vertex set (0, 1, 2, 3, 4) and facets {()}
sage: Y.alexander_dual()
Simplicial complex with vertex set (0, 1, 2, 3, 4) and 5 facets
sage: X = SimplicialComplex(3, [[0,1], [1,2], [2,3], [3,0]])
sage: X.alexander_dual()
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(1, 3), (0, 2)}
```

barycentric_subdivision()

The barycentric subdivision of this simplicial complex.

See http://en.wikipedia.org/wiki/Barycentric_subdivision for a definition.

EXAMPLES:

```
sage: triangle = SimplicialComplex(2, [[0,1], [1,2], [0, 2]])
sage: hexagon = triangle.barycentric_subdivision()
sage: hexagon
Simplicial complex with 6 vertices and 6 facets
sage: hexagon.homology(1) == triangle.homology(1)
True
```

Barycentric subdivisions can get quite large, since each n-dimensional facet in the original complex produces $(n+1)!$ facets in the subdivision:

```
sage: S4 = simplicial_complexes.Sphere(4)
sage: S4
Simplicial complex with vertex set (0, 1, 2, 3, 4, 5) and 6 facets
sage: S4.barycentric_subdivision()
Simplicial complex with 62 vertices and 720 facets
```

betti(*dim=None, subcomplex=None*)

The Betti numbers of this simplicial complex as a dictionary (or a single Betti number, if only one dimension is given).

INPUT:

- `dim` - integer or list of integers or None (optional, default None). If None, then return every Betti number, as a dictionary with keys the non-negative integers. If `dim` is an integer or list, return the Betti number for each given dimension. (Actually, if `dim` is a list, return the Betti numbers, as a dictionary, in the range from `min(dim)` to `max(dim)`. If `dim` is a number, return the Betti number in that dimension.)
- `subcomplex` - a subcomplex of this simplicial complex (optional, default None). Compute the Betti numbers of the homology relative to this subcomplex.

EXAMPLES: Build the two-sphere as a three-fold join of a two-point space with itself:

```
sage: S = SimplicialComplex(1, [[0], [1]])
sage: (S*S*S).betti()
{0: 0, 1: 0, 2: 1}
sage: (S*S*S).betti([1,2])
{1: 0, 2: 1}
sage: (S*S*S).betti(2)
1
```

category()

Return the category to which this chain complex belongs: the category of all simplicial complexes.

EXAMPLES:

```
sage: SimplicialComplex(5, [[0,1], [1,2,3,4,5]]).category()
Category of simplicial complexes
```

chain_complex(*dimensions=None, base_ring=Integer Ring, subcomplex=None, augmented=False, cochain=False, verbose=False, check_diffs=False*)

The chain complex associated to this simplicial complex.

INPUT:

- `dimensions` - if None, compute the chain complex in all dimensions. If a list or tuple of integers, compute the chain complex in those dimensions, setting the chain groups in all other dimensions to zero.
- `base_ring` - commutative ring (optional, default ZZ)
- `subcomplex` - a subcomplex of this simplicial complex (optional, default empty). Compute the chain complex relative to this subcomplex.
- `augmented` - boolean (optional, default False). If True, return the augmented chain complex (that is, include a class in dimension -1 corresponding to the empty cell). This is ignored if `dimensions` is specified.
- `cochain` - boolean (optional, default False). If True, return the cochain complex (that is, the dual of the chain complex).
- `verbose` - boolean (optional, default False). If True, print some messages as the chain complex is computed.
- `check_diffs` - boolean (optional, default False). If True, make sure that the chain complex is actually a chain complex: the differentials are composable and their product is zero.

Note: If subcomplex is nonempty, then the argument `augmented` has no effect: the chain complex relative to a nonempty subcomplex is zero in dimension -1.

EXAMPLES:

```
sage: circle = SimplicialComplex(2, [[0,1], [1,2], [0, 2]])
sage: circle.chain_complex()
Chain complex with at most 2 nonzero terms over Integer Ring.
sage: circle.chain_complex()._latex_()
'\Bold{Z}^{3} \xrightarrow{d_{1}} \Bold{Z}^{3}'
sage: circle.chain_complex(base_ring=QQ, augmented=True)
Chain complex with at most 3 nonzero terms over Rational Field.
```

cohomology(*dim=None, base_ring=Integer Ring, subcomplex=None, enlarge=True, algorithm='auto', verbose=False*)

The reduced cohomology of this simplicial complex.

INPUT:

- `dim` - integer or list of integers or None (optional, default None). If None, then return the cohomology in every dimension. If `dim` is an integer or list, return the cohomology in the given dimensions. (Actually, if `dim` is a list, return the cohomology in the range from `min(dim)` to `max(dim)`.)
- `base_ring` - commutative ring (optional, default ZZ). Must be ZZ or a field.
- `subcomplex` - a subcomplex of this simplicial complex (optional, default empty). Compute cohomology relative to this subcomplex.
- `enlarge` - boolean (optional, default True). If True, find a new subcomplex homotopy equivalent to, and probably larger than, the given one.
- `algorithm` - string (optional, default 'auto'). This only has an effect if working over the integers. If 'dhsw', then preprocess each boundary matrix using the Dumas, Heckenbach, Saunders, and Welker elimination algorithm. If 'pari', then compute elementary divisors using Pari. If 'linbox', then use LinBox. If 'auto', then use 'dhsw' for large matrices and Pari for small ones.
- `verbose` - boolean (optional, default False). If True, print some messages as the cohomology is computed.

EXAMPLES:

```
sage: circle = SimplicialComplex(2, [[0,1], [1,2], [0, 2]])
sage: circle.cohomology()
{0: 0, 1: Z}
sage: P2 = SimplicialComplex(5, [[0,1,2], [0,2,3], [0,1,5], [0,4,5], [0,3,4], [1,2,4], [1,3,
sage: P2.cohomology()
{0: 0, 1: 0, 2: C2}
sage: P2.cohomology(base_ring=GF(2))
{0: Vector space of dimension 0 over Finite Field of size 2,
1: Vector space of dimension 1 over Finite Field of size 2,
2: Vector space of dimension 1 over Finite Field of size 2}
sage: P2.cohomology(base_ring=GF(3))
{0: Vector space of dimension 0 over Finite Field of size 3,
1: Vector space of dimension 0 over Finite Field of size 3,
2: Vector space of dimension 0 over Finite Field of size 3}
```

Relative cohomology:

```
sage: T = SimplicialComplex(1, [[0,1]])
sage: U = SimplicialComplex(1, [[0], [1]])
sage: T.cohomology(subcomplex=U)
{0: 0, 1: Z}
```

cone()

The cone on this simplicial complex.

The cone is the simplicial complex formed by adding a new vertex C and simplices of the form $[C, v_0, ..., v_k]$ for every simplex $[v_0, ..., v_k]$ in the original simplicial complex. That is, the cone is the join of the original complex with a one-point simplicial complex.

EXAMPLES:

```
sage: S = SimplicialComplex(1, [[0], [1]])
sage: S.cone()
Simplicial complex with vertex set ('L0', 'L1', 'R0') and facets {('L0', 'R0'), ('L1', 'R0')
```

dimension()

The dimension of this simplicial complex: the maximum dimension of its faces.

EXAMPLES:

```
sage: U = SimplicialComplex(5, [[1,2], [1, 3, 4]])
sage: U.dimension()
2
sage: X = SimplicialComplex(3, [[0,1], [0,2], [1,2]])
sage: X.dimension()
1
```

euler_characteristic()

The Euler characteristic of this simplicial complex: the alternating sum over $n \geq 0$ of the number of n-simplices.

EXAMPLES:

```
sage: Y = SimplicialComplex(5, [[1,2], [1,4]])
sage: Y.euler_characteristic()
1
sage: X = SimplicialComplex(3, [[0,1], [0,2], [1,2]])
sage: X.euler_characteristic()
0
```

f_vector()

The f-vector of this simplicial complex: a list whose n^{th} item is the number of $(n-1)$-faces. Note that, like all lists in Sage, this is indexed starting at 0: the 0th element in this list is the number of -1 faces.

EXAMPLES:

```
sage: S = Set(range(1,5))
sage: Z = SimplicialComplex(S, S.subsets()); Z
Simplicial complex with vertex set (1, 2, 3, 4) and facets {(1, 2, 3, 4)}
sage: Z.f_vector()
[1, 4, 6, 4, 1]
sage: Y = SimplicialComplex(5, [[1,2], [1,4]])
sage: Y.f_vector()[2]
2
```

face_poset()

The face poset of this simplicial complex, the poset of nonempty faces, ordered by inclusion.

EXAMPLES:

```
sage: P = SimplicialComplex(3, [[0, 1], [1,2], [2,3]]).face_poset(); P
Finite poset containing 7 elements
sage: P.list()
[(3,), (2,), (2, 3), (1,), (0,), (0, 1), (1, 2)]
```

faces(*subcomplex=None*)

The faces of this simplicial complex, in the form of a dictionary of sets keyed by dimension. If the optional argument `subcomplex` is present, then return only the faces which are *not* in the subcomplex.

INPUT:

- `subcomplex` - a subcomplex of this simplicial complex (optional, default None). Return faces which are not in this subcomplex.

EXAMPLES:

```
sage: Y = SimplicialComplex(5, [[1,2], [1,4]])
sage: Y.faces()
{0: set([(4,), (2,), (1,)]), 1: set([(1, 2), (1, 4)]), -1: set([()])}
sage: L = SimplicialComplex(5, [[1,2]])
sage: Y.faces(subcomplex=L)
{0: set([(4,)]), 1: set([(1, 4)]), -1: set([])}
```

facets()

The maximal faces (a.k.a. facets) of this simplicial complex.

This just returns the set of facets used in defining the simplicial complex, so if the simplicial complex was defined with no maximality checking, none is done here, either.

EXAMPLES:

```
sage: Y = SimplicialComplex(5, [[0,2], [1,4]])
sage: Y.maximal_faces()
{(1, 4), (0, 2)}
```

`facets` is a synonym for `maximal_faces`:

```
sage: S = SimplicialComplex(2, [[0,1], [0,1,2]])
sage: S.facets()
{(0, 1, 2)}
```

graph()

The 1-skeleton of this simplicial complex, as a graph.

EXAMPLES:

```
sage: S = SimplicialComplex(3, [[0,1,2,3]])
sage: G = S.graph(); G
Graph on 4 vertices
sage: G.edges()
[(0, 1, None), (0, 2, None), (0, 3, None), (1, 2, None), (1, 3, None), (2, 3, None)]
```

homology(*dim=None, base_ring=Integer Ring, subcomplex=None, cohomology=False, enlarge=True, algorithm='auto', verbose=False*)

The reduced homology of this simplicial complex.

INPUT:

- `dim` - integer or list of integers or None (optional, default None). If None, then return the homology in every dimension. If `dim` is an integer or list, return the homology in the given dimensions. (Actually, if `dim` is a list, return the homology in the range from `min(dim)` to `max(dim)`.)
- `base_ring` - commutative ring (optional, default ZZ). Must be ZZ or a field.
- `subcomplex` - a subcomplex of this simplicial complex (optional, default None). Compute homology relative to this subcomplex.
- `cohomology` - boolean (optional, default False). If True, compute cohomology rather than homology.
- `enlarge` - boolean (optional, default True). If True, find a new subcomplex homotopy equivalent to, and probably larger than, the given one.
- `algorithm` - string (optional, default 'auto'). This only has an effect if working over the integers. If 'dhsw', then preprocess each boundary matrix using the Dumas, Heckenbach, Saunders, and Welker elimination algorithm. If 'pari', then compute elementary divisors using Pari. If 'linbox', then use LinBox. If 'auto', then use 'dhsw' for large matrices and Pari for small ones.
- `verbose` - boolean (optional, default False). If True, print some messages as the homology is computed.

Algorithm: if `subcomplex` is None, replace it with a facet – a contractible subcomplex of the original complex. Then no matter what `subcomplex` is, replace it with a subcomplex L which is homotopy equivalent and as large as possible. Compute the homology of the original complex relative to L: if L is large, then the relative chain complex will be small enough to speed up computations considerably.

EXAMPLES:

```
sage: circle = SimplicialComplex(2, [[0,1], [1,2], [0, 2]])
sage: circle.homology()
{0: 0, 1: Z}
sage: sphere = SimplicialComplex(3, [[0,1,2,3]])
sage: sphere.remove_face([0,1,2,3])
sage: sphere
```

```
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(0, 2, 3), (0, 1, 2), (1, 2, 3),
sage: sphere.homology()
{0: 0, 1: 0, 2: Z}
```

Another way to get a two-sphere: take a two-point space and take its three-fold join with itself:

```
sage: S = SimplicialComplex(1, [[0], [1]])
sage: (S*S*S).homology(dim=2, cohomology=True)
Z
```

Relative homology:

```
sage: T = SimplicialComplex(2, [[0,1,2]])
sage: U = SimplicialComplex(2, [[0,1], [1,2], [0,2]])
sage: T.homology(subcomplex=U)
{0: 0, 1: 0, 2: Z}
```

is_pure()

True iff this simplicial complex is pure: a simplicial complex is pure iff all of its maximal faces have the same dimension.

Warning: This may give the wrong answer if the simplicial complex was constructed with `maximality_check` set to False.

EXAMPLES:

```
sage: U = SimplicialComplex(5, [[1,2], [1, 3, 4]])
sage: U.is_pure()
False
sage: X = SimplicialComplex(3, [[0,1], [0,2], [1,2]])
sage: X.is_pure()
True
```

join(*right, rename_vertices=True*)

The join of this simplicial complex with another one.

The join of two simplicial complexes S and T is the simplicial complex $S * T$ with simplices of the form $[v_0, ..., v_k, w_0, ..., w_n]$ for all simplices $[v_0, ..., v_k]$ in S and $[w_0, ..., w_n]$ in T.

INPUT:

- `right` - the other simplicial complex (the right-hand factor)
- `rename_vertices` – boolean (optional, default True). If this is True, the vertices in the join will be renamed by the formula: vertex "v" in the left-hand factor –> vertex "Lv" in the join, vertex "w" in the right-hand factor –> vertex "Rw" in the join. If this is false, this tries to construct the join without renaming the vertices; this will cause problems if the two factors have any vertices with names in common.

EXAMPLES:

```
sage: S = SimplicialComplex(1, [[0], [1]])
sage: T = SimplicialComplex([2, 3], [[2], [3]])
sage: S.join(T)
Simplicial complex with vertex set ('L0', 'L1', 'R2', 'R3') and 4 facets
sage: S.join(T, rename_vertices=False)
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(1, 3), (1, 2), (0, 2), (0, 3)}
```

The notation '*' may be used, as well:

```
sage: S * S
Simplicial complex with vertex set ('L0', 'L1', 'R0', 'R1') and 4 facets
sage: S * S * S * S * S * S * S * S * S
Simplicial complex with 16 vertices and 256 facets
```

link(*simplex*)

The link of a simplex in this simplicial complex.

The link of a simplex F is the simplicial complex formed by all simplices G which are disjoint from F but for which $F \cup G$ is a simplex.

INPUT:

- `simplex` - a simplex in this simplicial complex.

EXAMPLES:

```
sage: X = SimplicialComplex(4, [[0,1,2], [1,2,3]])
sage: from sage.homology.simplicial_complex import Simplex
sage: X.link(Simplex([0]))
Simplicial complex with vertex set (0, 1, 2, 3, 4) and facets {(1, 2)}
sage: X.link([1,2])
Simplicial complex with vertex set (0, 1, 2, 3, 4) and facets {(3,), (0,)}
sage: Y = SimplicialComplex(3, [[0,1,2,3]])
sage: Y.link([1])
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(0, 2, 3)}
```

maximal_faces()

The maximal faces (a.k.a. facets) of this simplicial complex.

This just returns the set of facets used in defining the simplicial complex, so if the simplicial complex was defined with no maximality checking, none is done here, either.

EXAMPLES:

```
sage: Y = SimplicialComplex(5, [[0,2], [1,4]])
sage: Y.maximal_faces()
{(1, 4), (0, 2)}
```

`facets` is a synonym for `maximal_faces`:

```
sage: S = SimplicialComplex(2, [[0,1], [0,1,2]])
sage: S.facets()
{(0, 1, 2)}
```

minimal_nonfaces()

Set consisting of the minimal subsets of the vertex set of this simplicial complex which do not form faces.

Algorithm: first take the complement (within the vertex set) of each facet, obtaining a set $(f_1, f_2, ...)$ of simplices. Now form the set of all simplices of the form $(v_1, v_2, ...)$ where vertex v_i is in face f_i. This set will contain the minimal nonfaces and may contain some non-minimal nonfaces also, so loop through the set to find the minimal ones. (The last two steps are taken care of by the `_transpose_simplices` routine.)

This is used in computing the Stanley-Reisner ring and the Alexander dual.

EXAMPLES:

```
sage: X = SimplicialComplex(4)
sage: X.minimal_nonfaces()
{(4,), (2,), (3,), (0,), (1,)}
sage: X.add_face([1,2])
sage: X.add_face([1,3])
sage: X.minimal_nonfaces()
{(4,), (2, 3), (0,)}
sage: Y = SimplicialComplex(3, [[0,1], [1,2], [2,3], [3,0]])
sage: Y.minimal_nonfaces()
{(1, 3), (0, 2)}
```

n_faces(*n, subcomplex=None*)

The set of faces of dimension n of this simplicial complex. If the optional argument `subcomplex` is present, then return the `n`-dimensional faces which are *not* in the subcomplex.

INPUT:

- n - non-negative integer
- subcomplex - a subcomplex of this simplicial complex (optional, default None). Return n-dimensional faces which are not in this subcomplex.

EXAMPLES:

```
sage: S = Set(range(1,5))
sage: Z = SimplicialComplex(S, S.subsets())
sage: Z
Simplicial complex with vertex set (1, 2, 3, 4) and facets {(1, 2, 3, 4)}
sage: Z.n_faces(2)
set([(1, 3, 4), (1, 2, 3), (2, 3, 4), (1, 2, 4)])
sage: K = SimplicialComplex(S, [[1,2,3], [2,3,4]])
sage: Z.n_faces(2, subcomplex=K)
set([(1, 3, 4), (1, 2, 4)])
```

n_skeleton(*n*)

The n-skeleton of this simplicial complex: the simplicial complex obtained by discarding all of the simplices in dimensions larger than n.

INPUT:

- n - non-negative integer

EXAMPLES:

```
sage: X = SimplicialComplex(3, [[0,1], [1,2,3], [0,2,3]])
sage: X.n_skeleton(1)
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(2, 3), (0, 2), (1, 3), (1, 2),
sage: X.n_skeleton(2)
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(0, 2, 3), (1, 2, 3), (0, 1)}
```

product(*right, rename_vertices=True*)

The product of this simplicial complex with another one.

INPUT:

- right - the other simplicial complex (the right-hand factor)
- **rename_vertices – boolean (optional, default True). If** this is False, then the vertices in the product are the set of ordered pairs (v, w) where v is a vertex in self and w is a vertex in right. If this is True, then the vertices are renamed as "LvRw" (e.g., the vertex (1,2) would become "L1R2"). This is useful if you want to define the Stanley-Reisner ring of the complex: vertex names like (0,1) are not suitable for that, while vertex names like "L0R1" are.

The vertices in the product will be the set of ordered pairs (v, w) where v is a vertex in self and w is a vertex in right.

Warning: If X and Y are simplicial complexes, then X*Y returns their join, not their product.

EXAMPLES:

```
sage: S = SimplicialComplex(3, [[0,1], [1,2], [0,2]]) # circle
sage: K = SimplicialComplex(1, [[0,1]])   # edge
sage: S.product(K).vertices()  # cylinder
('L0R0', 'L0R1', 'L1R0', 'L1R1', 'L2R0', 'L2R1', 'L3R0', 'L3R1')
sage: S.product(K, rename_vertices=False).vertices()
((0, 0), (0, 1), (1, 0), (1, 1), (2, 0), (2, 1), (3, 0), (3, 1))
sage: T = S.product(S)  # torus
sage: T
Simplicial complex with 16 vertices and 18 facets
sage: T.homology()
{0: 0, 1: Z x Z, 2: Z}
```

These can get large pretty quickly:

```
sage: T = simplicial_complexes.Torus(); T
Simplicial complex with vertex set (0, 1, 2, 3, 4, 5, 6) and 14 facets
sage: K = simplicial_complexes.KleinBottle(); K
Simplicial complex with 9 vertices and 18 facets
sage: T.product(K)      # long time: 5 or 6 seconds
Simplicial complex with 63 vertices and 1512 facets
```

remove_face (*face*)

Remove a face from this simplicial complex

INPUT:

- `face` - a face of the simplicial complex

This changes the simplicial complex, removing the given face any face which contains it.

Algorithm: take the Alexander dual, add the complement of `face`, and then take the Alexander dual again.

EXAMPLES:

```
sage: S = range(1,5)
sage: Z = SimplicialComplex(S, [S]); Z
Simplicial complex with vertex set (1, 2, 3, 4) and facets {(1, 2, 3, 4)}
sage: Z.remove_face([1,2])
sage: Z
Simplicial complex with vertex set (1, 2, 3, 4) and facets {(1, 3, 4), (2, 3, 4)}
```

stanley_reisner_ring (*base_ring=Integer Ring*)

The Stanley-Reisner ring of this simplicial complex.

INPUT:

- `base_ring` - a commutative ring (optional, default ZZ)

OUTPUT:

- a quotient of a polynomial algebra with coefficients in `base_ring`, with one generator for each vertex in the simplicial complex, by the ideal generated by the products of those vertices which do not form faces in it.

Thus the ideal is generated by the products corresponding to the minimal nonfaces of the simplicial complex.

> **Warning:** This may be quite slow!
> Also, this may behave badly if the vertices have the 'wrong' names. To avoid this, define the simplicial complex at the start with the flag `name_check` set to True.
> More precisely, this is a quotient of a polynomial ring with one generator for each vertex. If the name of a vertex is a non-negative integer, then the corresponding polynomial generator is named 'x' followed by that integer (e.g., 'x2', 'x3', 'x5', ...). Otherwise, the polynomial generators are given the same names as the vertices. Thus if the vertex set is (2, 'x2'), there will be problems.

EXAMPLES:

```
sage: X = SimplicialComplex(3, [[0,1], [1,2], [2,3], [0,3]])
sage: X.stanley_reisner_ring()
Quotient of Multivariate Polynomial Ring in x0, x1, x2, x3 over Integer Ring by the ideal (x
sage: Y = SimplicialComplex(4); Y
Simplicial complex with vertex set (0, 1, 2, 3, 4) and facets {()}
sage: Y.stanley_reisner_ring()
Quotient of Multivariate Polynomial Ring in x0, x1, x2, x3, x4 over Integer Ring by the idea
sage: Y.add_face([0,1,2,3,4])
sage: Y.stanley_reisner_ring(base_ring=QQ)
Quotient of Multivariate Polynomial Ring in x0, x1, x2, x3, x4 over Rational Field by the id
```

suspension(*n=1*)

The suspension of this simplicial complex.

INPUT:

- n - positive integer (optional, default 1): suspend this many times.

The suspension is the simplicial complex formed by adding two new vertices S_0 and S_1 and simplices of the form $[S_0, v_0, ..., v_k]$ and $[S_1, v_0, ..., v_k]$ for every simplex $[v_0, ..., v_k]$ in the original simplicial complex. That is, the cone is the join of the original complex with a two-point simplicial complex.

EXAMPLES:

```
sage: S = SimplicialComplex(1, [[0], [1]])
sage: S.suspension()
Simplicial complex with vertex set ('L0', 'L1', 'R0', 'R1') and 4 facets
sage: S3 = S.suspension(3)  # the 3-sphere
sage: S3.homology()
{0: 0, 1: 0, 2: 0, 3: Z}
```

vertices()

The vertex set of this simplicial complex.

EXAMPLES:

```
sage: S = SimplicialComplex(15, [[0,1], [1,2]])
sage: S
Simplicial complex with 16 vertices and facets {(1, 2), (0, 1)}
sage: S.vertices()
(0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15)
```

Note that this actually returns a simplex:

```
sage: type(S.vertices())
<class 'sage.homology.simplicial_complex.Simplex'>
```

lattice_paths(*t1, t2*)

Given lists (or tuples or ...) t1 and t2, think of them as labelings for vertices: t1 labeling points on the x-axis, t2 labeling points on the y-axis, both increasing. Return the list of rectilinear paths along the grid defined by these points in the plane, starting from (t1[0], t2[0]), ending at (t1[last], t2[last]), and at each grid point, going either right or up. See the examples.

INPUT:

- t1, t2 - tuples, lists, other iterables.

OUTPUT: list of lists of vertices making up the paths as described above

This is used when triangulating the product of simplices.

EXAMPLES:

```
sage: from sage.homology.simplicial_complex import lattice_paths
sage: lattice_paths([0,1,2], [0,1,2])
[[(0, 0), (0, 1), (0, 2), (1, 2), (2, 2)],
 [(0, 0), (0, 1), (1, 1), (1, 2), (2, 2)],
 [(0, 0), (1, 0), (1, 1), (1, 2), (2, 2)],
 [(0, 0), (0, 1), (1, 1), (2, 1), (2, 2)],
 [(0, 0), (1, 0), (1, 1), (2, 1), (2, 2)],
 [(0, 0), (1, 0), (2, 0), (2, 1), (2, 2)]]
sage: lattice_paths(('a', 'b', 'c'), (0, 3, 5))
[[('a', 0), ('a', 3), ('a', 5), ('b', 5), ('c', 5)],
 [('a', 0), ('a', 3), ('b', 3), ('b', 5), ('c', 5)],
 [('a', 0), ('b', 0), ('b', 3), ('b', 5), ('c', 5)],
 [('a', 0), ('a', 3), ('b', 3), ('c', 3), ('c', 5)],
```

```
[('a', 0), ('b', 0), ('b', 3), ('c', 3), ('c', 5)],
[('a', 0), ('b', 0), ('c', 0), ('c', 3), ('c', 5)]]
```

35.2 Chain complexes

AUTHORS:

- John H. Palmieri (2009-04)

This module implements chain complexes of free R-modules, for any commutative ring R (although the interesting things, like homology, only work if R is the integers or a field).

Fix a ring R. A chain complex over R is a collection of R-modules $\{C_n\}$ indexed by the integers, with R-module maps $d_n : C_n \to C_{n+1}$ such that $d_{n+1} \circ d_n = 0$ for all n. The maps d_n are called *differentials*.

One can vary this somewhat: the differentials may decrease degree by one instead of increasing it: sometimes a chain complex is defined with $d_n : C_n \to C_{n-1}$ for each n. Indeed, the differentials may change dimension by any fixed integer.

Also, the modules may be indexed over an abelian group other than the integers, e.g., $\mathbf{Z}^m$ for some integer $m \geq 1$, in which case the differentials may change the grading by any element of that grading group.

In this implementation, the ring R must be commutative and the modules C_n must be free R-modules. As noted above, homology calculations will only work if the ring R is either $\mathbf{Z}$ or a field. The modules may be indexed by any free abelian group. The differentials may increase degree by 1 or decrease it, or indeed change it by any fixed amount: this is controlled by the `degree` parameter used in defining the chain complex.

class `ChainComplex` (*data=None, base_ring=None, grading_group=Integer Ring, degree=1, check_products=True*)

Define a chain complex.

INPUT:

- `data` - the data defining the chain complex; see below for more details.
- `base_ring` - a commutative ring (optional), the ring over which the chain complex is defined. If this is not specified, it is determined by the data defining the chain complex.
- `grading_group` - a free abelian group (optional, default ZZ), the group over which the chain complex is indexed.
- `degree` - element of grading_group (optional, default 1), the degree of the differential.
- `check_products` - boolean (optional, default True). If True, check that each consecutive pair of differentials are composable and have composite equal to zero.

OUTPUT: a chain complex

Warning: Right now, homology calculations will only work if the base ring is either ZZ or a field, so please take this into account when defining a chain complex.

Use data to define the chain complex. This may be in any of the following forms.

1. a dictionary with integers (or more generally, elements of grading_group) for keys, and with data[n] a matrix representing (via left multiplication) the differential coming from degree n. (Note that the shape of the matrix then determines the rank of the free modules C_n and C_{n+d}.)
2. a list or tuple of the form $[C_0, d_0, C_1, d_1, C_2, d_2, ...]$, where each C_i is a free module and each d_i is a matrix, as above. This only makes sense if `grading_group` is $\mathbf{Z}$ and `degree` is 1.

3. a list or tuple of the form $[r_0, d_0, r_1, d_1, r_2, d_2, ...]$, where r_i is the rank of the free module C_i and each d_i is a matrix, as above. This only makes sense if `grading_group` is **Z** and `degree` is 1.
4. a list or tuple of the form $[d_0, d_1, d_2, ...]$ where each d_i is a matrix, as above. This only makes sense if `grading_group` is **Z** and `degree` is 1.

Note: In fact, the free modules C_i in case 2 and the ranks r_i in case 3 are ignored: only the matrices are kept, and from their shapes, the ranks of the modules are determined. (Indeed, if `data` is a list or tuple, then any element which is not a matrix is discarded; thus the list may have any number of different things in it, and all of the non-matrices will be ignored.) No error checking is done to make sure, for instance, that the given modules have the appropriate ranks for the given matrices. However, as long as `check_products` is True, the code checks to see if the matrices are composable and that each appropriate composite is zero.

If the base ring is not specified, then the matrices are examined to determine a ring over which they are all naturally defined, and this becomes the base ring for the complex. If no such ring can be found, an error is raised. If the base ring is specified, then the matrices are converted automatically to this ring when defining the chain complex. If some matrix cannot be converted, then an error is raised.

EXAMPLES:

```
sage: ChainComplex()
Chain complex with at most 0 nonzero terms over Integer Ring.
sage: C = ChainComplex({0: matrix(ZZ, 2, 3, [3, 0, 0, 0, 0, 0])})
sage: C
Chain complex with at most 2 nonzero terms over Integer Ring.
sage: D = ChainComplex([matrix(ZZ, 2, 2, [0, 1, 0, 0]), matrix(ZZ, 2, 2, [0, 1, 0, 0])], base_ri
Chain complex with at most 3 nonzero terms over Finite Field of size 2.
sage: D == loads(dumps(D))
True
```

Note that when a chain complex is defined in Sage, new differentials may be created: every nonzero module in the chain complex must have a differential coming from it, even if that differential is zero:

```
sage: IZ = ChainComplex({0: identity_matrix(ZZ, 1)})
sage: IZ.differential()  # the differentials in the chain complex
{0: [1], 1: []}
sage: IZ.differential(1).parent()
Full MatrixSpace of 0 by 1 dense matrices over Integer Ring
```

Defining the base ring implicitly:

```
sage: ChainComplex([matrix(QQ, 3, 1), matrix(ZZ, 4, 3)])
Chain complex with at most 2 nonzero terms over Rational Field.
sage: ChainComplex([matrix(GF(125, 'a'), 3, 1), matrix(ZZ, 4, 3)])
Chain complex with at most 2 nonzero terms over Finite Field in a of size 5^3.
```

If the matrices are defined over incompatible rings, an error results:

```
sage: ChainComplex([matrix(GF(125, 'a'), 3, 1), matrix(QQ, 4, 3)])
...
TypeError: unable to find a common ring for all elements
```

If the base ring is given explicitly but is not compatible with the matrices, an error results:

```
sage: ChainComplex([matrix(GF(125, 'a'), 3, 1)], base_ring=QQ)
...
TypeError: Unable to coerce 0 (<type 'sage.rings.finite_field_givaro.FiniteField_givaroElement'>
```

base_ring()

The base ring for this simplicial complex.

EXAMPLES:

```
sage: ChainComplex().base_ring()
Integer Ring
```

betti(*dim=None, base_ring=None*)

The Betti number of the homology of the chain complex in this dimension.

That is, write the homology in this dimension as a direct sum of a free module and a torsion module; the Betti number is the rank of the free summand.

INPUT:

- dim - an element of the grading group for the chain complex or None (optional, default None). If None, then return every Betti number, as a dictionary indexed by degree. If an element of the grading group, then return the Betti number in that dimension.
- base_ring - a commutative ring (optional, default is the base ring for the chain complex). Compute homology with these coefficients. Must be either the integers or a field.

OUTPUT: the Betti number in dimension dim - the rank of the free part of the homology module in this dimension.

EXAMPLES:

```
sage: C = ChainComplex({0: matrix(ZZ, 2, 3, [3, 0, 0, 0, 0, 0])})
sage: C.betti(0)
2
sage: [C.betti(n) for n in range(5)]
[2, 1, 0, 0, 0]
sage: C.betti()
{0: 2, 1: 1}
```

category()

Return the category to which this chain complex belongs: the category of all chain complexes over the base ring.

EXAMPLES:

```
sage: C = ChainComplex({0: matrix(ZZ, 2, 3, [3, 0, 0, 0, 0, 0])}, base_ring=GF(7))
sage: C.category()
Category of chain complexes over Finite Field of size 7
```

differential(*dim=None*)

The differentials which make up the chain complex.

INPUT:

- dim - element of the grading group (optional, default None). If this is None, return a dictionary of all of the differentials. If this is a single element, return the differential starting in that dimension.

OUTPUT: either a dictionary of all of the differentials or a single differential (i.e., a matrix)

EXAMPLES:

```
sage: D = ChainComplex({0: matrix(ZZ, 2, 2, [1,0,0,2])})
sage: D.differential()
{0: [1 0]
[0 2], 1: []}
sage: D.differential(0)
[1 0]
[0 2]
sage: C = ChainComplex({0: identity_matrix(ZZ, 40)})
sage: C.differential()
{0: 40 x 40 dense matrix over Integer Ring, 1: []}
```

free_module()

The free module underlying this chain complex.

EXAMPLES:

```
sage: C = ChainComplex({0: matrix(ZZ, 2, 3, [3, 0, 0, 0, 0, 0]), 1: matrix(ZZ, 0, 2)})
sage: C.free_module()
Ambient free module of rank 5 over the principal ideal domain Integer Ring
```

This defines the forgetful functor from the category of chain complexes to the category of free modules:

```
sage: FreeModules(ZZ)(C)
Ambient free module of rank 5 over the principal ideal domain Integer Ring
```

homology(*dim=None, base_ring=None, verbose=False, algorithm='auto'*)

The homology of the chain complex in the given dimension.

INPUT:

- `dim` - an element of the grading group for the chain complex (optional, default None): the degree in which to compute homology. If this is None, return the homology in every dimension in which the chain complex is possibly nonzero.
- `base_ring` - a commutative ring (optional, default is the base ring for the chain complex). Must be either the integers **Z** or a field.
- `verbose` - boolean (optional, default False). If True, print some messages as the homology is computed.
- `algorithm` - string (optional, default 'auto'). This only has an effect if working over the integers. If 'dhsw', then preprocess each boundary matrix using the Dumas, Heckenbach, Saunders, and Welker elimination algorithm, and then compute elementary divisors using Pari. If 'pari', then just compute elementary divisors using Pari. If 'linbox', then use LinBox if available (likely it's not). If 'auto', then use 'dhsw' for large matrices and 'pari' for small ones.

OUTPUT: if dim is specified, the homology in dimension dim. Otherwise, the homology in every dimension as a dictionary indexed by dimension.

Warning: This only works if the base ring is the integers or a field. Other values will return an error.

EXAMPLES:

```
sage: C = ChainComplex({0: matrix(ZZ, 2, 3, [3, 0, 0, 0, 0, 0])})
sage: C.homology()
{0: Z x Z, 1: Z x C3}
sage: C.homology(dim=1, base_ring = GF(3))
Vector space of dimension 2 over Finite Field of size 3
sage: D = ChainComplex({0: identity_matrix(ZZ, 4), 4: identity_matrix(ZZ, 30)})
sage: D.homology()
{0: 0, 1: 0, 4: 0, 5: 0}
```

torsion_list(*max_prime, min_prime=2*)

Look for torsion in this chain complex by computing its mod p homology for a range of primes p.

INPUT:

- `max_prime` - prime number: search for torsion mod p for all p strictly less than this number.
- `min_prime` - prime (optional, default 2): search for torsion mod p for primes at least as big as this.

Return a list of pairs (p, `dims`) where p is a prime at which there is torsion and `dims` is a list of dimensions in which this torsion occurs.

The base ring for the chain complex must be the integers; if not, an error is raised.

Algorithm: let C denote the chain complex. Let P equal `max_prime`. Compute the mod P homology of C, and use this as the base-line computation: the assumption is that this is isomorphic to the integral

homology tensored with $\mathbf{F}_P$. Then compute the mod p homology for a range of primes p, and record whenever the answer differs from the base-line answer.

EXAMPLES:

```
sage: C = ChainComplex({0: matrix(ZZ, 2, 3, [3, 0, 0, 0, 0, 0])})
sage: C.homology()
{0: Z x Z, 1: Z x C3}
sage: C.torsion_list(11)
[(3, [1])]
sage: C = ChainComplex([matrix(ZZ, 1, 1, [2]), matrix(ZZ, 1, 1), matrix(1, 1, [3])])
sage: C.homology()
{0: 0, 1: C2, 2: 0, 3: C3}
sage: C.torsion_list(5)
[(2, [1]), (3, [3])]
```

HomologyGroup(*n, invfac=None*)

Abelian group on n generators. This class inherits from `AbelianGroup`; see that for more documentation. The main difference between the classes is in the print representation; also, this class does not accept a `names` argument.

EXAMPLES:

```
sage: from sage.homology.chain_complex import HomologyGroup
sage: G = AbelianGroup(5,[5,5,7,8,9]); G
Multiplicative Abelian Group isomorphic to C5 x C5 x C7 x C8 x C9
sage: H = HomologyGroup(5,[5,5,7,8,9]); H
C5 x C5 x C7 x C8 x C9
sage: AbelianGroup(4)
Multiplicative Abelian Group isomorphic to Z x Z x Z x Z
sage: HomologyGroup(4)
Z x Z x Z x Z
sage: HomologyGroup(100)
Z^100
```

class **HomologyGroup_class**(*n, invfac*)

Abelian group on n generators. This class inherits from `AbelianGroup`; see that for more documentation. The main difference between the classes is in the print representation; also, this class does not accept a `names` argument.

EXAMPLES:

```
sage: from sage.homology.chain_complex import HomologyGroup
sage: G = AbelianGroup(5,[5,5,7,8,9]); G
Multiplicative Abelian Group isomorphic to C5 x C5 x C7 x C8 x C9
sage: H = HomologyGroup(5,[5,5,7,8,9]); H
C5 x C5 x C7 x C8 x C9
sage: G == loads(dumps(G))
True
sage: AbelianGroup(4)
Multiplicative Abelian Group isomorphic to Z x Z x Z x Z
sage: HomologyGroup(4)
Z x Z x Z x Z
sage: HomologyGroup(100)
Z^100
```

dhsw_snf(*mat, verbose=False*)

Preprocess a matrix using the "Elimination algorithm" described by Dumas et al., and then call `elementary_divisors` on the resulting (smaller) matrix.

'dhsw' stands for 'Dumas, Heckenbach, Saunders, Welker,' and 'snf' stands for 'Smith Normal Form.'

INPUT:

- `mat` - an integer matrix, either sparse or dense.

(They use the transpose of the matrix considered here, so they use rows instead of columns.)

Algorithm: go through `mat` one column at a time. For each column, add multiples of previous columns to it until either

- it's zero, in which case it should be deleted.
- its first nonzero entry is 1 or -1, in which case it should be kept.
- its first nonzero entry is something else, in which case it is deferred until the second pass.

Then do a second pass on the deferred columns.

At this point, the columns with 1 or -1 in the first entry contribute to the rank of the matrix, and these can be counted and then deleted (after using the 1 or -1 entry to clear out its row). Suppose that there were N of these.

The resulting matrix should be much smaller; we then feed it to Sage's `elementary_divisors` function, and prepend N 1's to account for the rows deleted in the previous step.

EXAMPLES:

```
sage: from sage.homology.chain_complex import dhsw_snf
sage: mat = matrix(ZZ, 3, 4, range(12))
sage: dhsw_snf(mat)
[1, 4, 0]
sage: mat = random_matrix(ZZ, 20, 20, x=-1, y=2)
sage: mat.elementary_divisors() == dhsw_snf(mat)
True
```

35.3 Examples of simplicial complexes

AUTHORS:

- John H. Palmieri (2009-04)

This file constructs some examples of simplicial complexes. There are two main types: surfaces and examples related to graph theory.

For surfaces, this file introduces a class, SimplicialSurface, which is based on SimplicialComplex but also includes a `connected_sum` method. It also has routines for defining the 2-sphere, the n-sphere for any n, the torus, the real projective plane, the Klein bottle, and surfaces of arbitrary genus, all as simplicial complexes.

Aside from surfaces, this file also provides some functions for constructing some other simplicial complexes: the simplicial complex of not-i-connected graphs on n vertices, the matching complex on n vertices, and the chessboard complex for an n by i chessboard. These provide examples of large simplicial complexes; for example, not_i_connected_graphs(7,2) has over a million simplices.

All of these examples are accessible by typing "simplicial_complexes.NAME", where "NAME" is the name of the example; you can get a list by typing "simplicial_complexes." and hitting the TAB key:

```
Sphere
Simplex
Torus
ProjectivePlane
KleinBottle
SurfaceOfGenus
MooreSpace
NotIConnectedGraphs
MatchingComplex
ChessboardComplex
RandomComplex
```

See the documentation for `simplicial_complexes` and for each particular type of example for full details.

class SimplicialComplexExamples()

Some examples of simplicial complexes.

Here are the available examples; you can also type "simplicial_complexes." and hit tab to get a list:

```
Sphere
Simplex
Torus
ProjectivePlane
KleinBottle
SurfaceOfGenus
MooreSpace
NotIConnectedGraphs
MatchingComplex
ChessboardComplex
RandomComplex
```

EXAMPLES:

```
sage: S = simplicial_complexes.Sphere(2) # the 2-sphere
sage: S.homology()
{0: 0, 1: 0, 2: Z}
sage: simplicial_complexes.SurfaceOfGenus(3)
Simplicial complex with 15 vertices and 38 facets
sage: M4 = simplicial_complexes.MooreSpace(4)
sage: M4.homology()
{0: 0, 1: C4, 2: 0}
sage: simplicial_complexes.MatchingComplex(6).homology()
{0: 0, 1: Z^16, 2: 0}
```

ChessboardComplex(*n, i*)

The chessboard complex for an n by i chessboard.

Fix integers $n, i > 0$ and consider sets V of n vertices and W of i vertices. A 'partial matching' between V and W is a graph formed by edges (v, w) with $v \in V$ and $w \in W$ so that each vertex is in at most one edge. If G is a partial matching, then so is any graph obtained by deleting edges from G. Thus the set of all partial matchings on V and W, viewed as a set of subsets of the $n + i$ choose 2 possible edges, is closed under taking subsets, and thus forms a simplicial complex called the 'chessboard complex'. This function produces that simplicial complex. (It is called the chessboard complex because such graphs also correspond to ways of placing rooks on an n by i chessboard so that none of them are attacking each other.)

INPUT:

- `n, i` - positive integers.

See Dumas et al. for information on computing its homology by computer, and see Wachs for an expository article about the theory.

EXAMPLES:

```
sage: C = simplicial_complexes.ChessboardComplex(5,5)
sage: C.f_vector()
[1, 25, 200, 600, 600, 120]
sage: simplicial_complexes.ChessboardComplex(3,3).homology()
{0: 0, 1: Z x Z x Z x Z, 2: 0}
```

REFERENCES:

- Dumas, Heckenbach, Saunders, Welker, "Computing simplicial homology based on efficient Smith normal form algorithms," in "Algebra, geometry, and software systems" (2003), 177-206.
- Wachs, "Topology of Matching, Chessboard and General Bounded Degree Graph Complexes" (Algebra Universalis Special Issue in Memory of Gian-Carlo Rota, Algebra Universalis, 49 (2003) 345-385)

KleinBottle()

A triangulation of the Klein bottle, formed by taking the connected sum of a projective plane with itself. (This is not a minimal triangulation.)

EXAMPLES:

```
sage: simplicial_complexes.KleinBottle()
Simplicial complex with 9 vertices and 18 facets
```

MatchingComplex(n)

The matching complex of graphs on n vertices.

Fix an integer $n > 0$ and consider a set V of n vertices. A 'partial matching' on V is a graph formed by edges so that each vertex is in at most one edge. If G is a partial matching, then so is any graph obtained by deleting edges from G. Thus the set of all partial matchings on n vertices, viewed as a set of subsets of the n choose 2 possible edges, is closed under taking subsets, and thus forms a simplicial complex called the 'matching complex'. This function produces that simplicial complex.

INPUT:

- n - positive integer.

See Dumas et al. for information on computing its homology by computer, and see Wachs for an expository article about the theory. For example, the homology of these complexes seems to have only mod 3 torsion, and this has been proved for the bottom non-vanishing homology group for the matching complex M_n.

EXAMPLES:

```
sage: M = simplicial_complexes.MatchingComplex(7)
sage: H = M.homology()
sage: H
{0: 0, 1: C3, 2: Z^20}
sage: H[2].ngens()
20
sage: simplicial_complexes.MatchingComplex(8).homology(2)  # long time (a few seconds)
Z^132
```

- Wachs, "Topology of Matching, Chessboard and General Bounded Degree Graph Complexes" (Algebra Universalis Special Issue in Memory of Gian-Carlo Rota, Algebra Universalis, 49 (2003) 345-385)

MooreSpace(q)

Triangulation of the mod q Moore space.

INPUT:

- q - integer, at least 2

This is a simplicial complex with simplices of dimension 0, 1, and 2, such that its reduced homology is isomorphic to $\mathbf{Z}/q\mathbf{Z}$ in dimension 1, zero otherwise.

If $q = 2$, this is the projective plane. If $q > 2$, then construct it as follows: start with a triangle with vertices 1, 2, 3. We take a $3q$-gon forming a q-fold cover of the triangle, and we form the resulting complex as an identification space of the $3q$-gon. To triangulate this identification space, put q vertices A_0, ..., A_{q-1}, in the interior, each of which is connected to 1, 2, 3 (two facets each: $[1, 2, A_i]$, $[2, 3, A_i]$). Put q more vertices in the interior: B_0, ..., B_{q-1}, with facets $[3, 1, B_i]$, $[3, B_i, A_i]$, $[1, B_i, A_{i+1}]$, $[B_i, A_i, A_{i+1}]$. Then triangulate the interior polygon with vertices A_0, A_1, ..., A_{q-1}.

EXAMPLES:

```
sage: simplicial_complexes.MooreSpace(3).homology()
{0: 0, 1: C3, 2: 0}
sage: simplicial_complexes.MooreSpace(4).suspension().homology()
{0: 0, 1: 0, 2: C4, 3: 0}
sage: simplicial_complexes.MooreSpace(8)
Simplicial complex with 19 vertices and 54 facets
```

NotIConnectedGraphs(*n, i*)

The simplicial complex of all graphs on n vertices which are not i-connected.

Fix an integer $n > 0$ and consider the set of graphs on n vertices. View each graph as its set of edges, so it is a subset of a set of size n choose 2. A graph is i-connected if, for any $j < i$, if any j vertices are removed along with the edges emanating from them, then the graph remains connected. Now fix i: it is clear that if G is not i-connected, then the same is true for any graph obtained from G by deleting edges. Thus the set of all graphs which are not i-connected, viewed as a set of subsets of the n choose 2 possible edges, is closed under taking subsets, and thus forms a simplicial complex. This function produces that simplicial complex.

INPUT:

- `n`, `i` - non-negative integers with i at most n

See Dumas et al. for information on computing its homology by computer, and see Babson et al. for theory. For example, Babson et al. show that when $i = 2$, the reduced homology of this complex is nonzero only in dimension $2n - 5$, where it is free abelian of rank $(n - 2)!$.

EXAMPLES:

```
sage: simplicial_complexes.NotIConnectedGraphs(5,2).f_vector()
[1, 10, 45, 120, 210, 240, 140, 20]
sage: simplicial_complexes.NotIConnectedGraphs(5,2).homology(5).ngens()
6
```

REFERENCES:

- Babson, Bjorner, Linusson, Shareshian, and Welker, "Complexes of not i-connected graphs," Topology 38 (1999), 271-299
- Dumas, Heckenbach, Saunders, Welker, "Computing simplicial homology based on efficient Smith normal form algorithms," in "Algebra, geometry, and software systems" (2003), 177-206.

ProjectivePlane()

A minimal triangulation of the real projective plane.

EXAMPLES:

```
sage: P = simplicial_complexes.ProjectivePlane()
sage: P.cohomology()
{0: 0, 1: 0, 2: C2}
sage: P.cohomology(base_ring=GF(2))
{0: Vector space of dimension 0 over Finite Field of size 2,
1: Vector space of dimension 1 over Finite Field of size 2,
2: Vector space of dimension 1 over Finite Field of size 2}
```

RandomComplex(*n, d, p=0.5*)

A random d-dimensional simplicial complex on n vertices.

INPUT:

- n - number of vertices
- d - dimension of the complex
- p - floating point number between 0 and 1 (optional, default 0.5)

A random d-dimensional simplicial complex on n vertices, as defined for example by Meshulam and Wallach, is constructed as follows: take n vertices and include all of the simplices of dimension strictly less than d, and then for each possible simplex of dimension d, include it with probability p.

EXAMPLES:

```
sage: simplicial_complexes.RandomComplex(6, 2)
Simplicial complex with vertex set (0, 1, 2, 3, 4, 5, 6) and 15 facets
```

If d is too large (if $d > n + 1$, so that there are no d-dimensional simplices), then return the simplicial complex with a single $(n + 1)$-dimensional simplex:

```
sage: simplicial_complexes.RandomComplex(6,12)
Simplicial complex with vertex set (0, 1, 2, 3, 4, 5, 6, 7) and facets {(0, 1, 2, 3, 4, 5, 6
```

REFERENCES:

- Meshulam and Wallach, "Homological connectivity of random k-dimensional complexes", preprint, math.CO/0609773.

Simplex(*n*)

An n-dimensional simplex, as a simplicial complex.

INPUT:

- n - a non-negative integer

OUTPUT: the simplicial complex consisting of the n-simplex on vertices $(0, 1, ..., n)$ and all of its faces.

EXAMPLES:

```
sage: simplicial_complexes.Simplex(3)
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(0, 1, 2, 3)}
sage: simplicial_complexes.Simplex(5).euler_characteristic()
1
```

Sphere(*n*)

A minimal triangulation of the n-dimensional sphere.

INPUT:

- n - positive integer

EXAMPLES:

```
sage: simplicial_complexes.Sphere(2)
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(0, 2, 3), (0, 1, 2), (1, 2, 3),
sage: simplicial_complexes.Sphere(5).homology()
{0: 0, 1: 0, 2: 0, 3: 0, 4: 0, 5: Z}
sage: [simplicial_complexes.Sphere(n).euler_characteristic() for n in range(6)]
[2, 0, 2, 0, 2, 0]
sage: [simplicial_complexes.Sphere(n).f_vector() for n in range(6)]
[[1, 2],
 [1, 3, 3],
 [1, 4, 6, 4],
 [1, 5, 10, 10, 5],
 [1, 6, 15, 20, 15, 6],
 [1, 7, 21, 35, 35, 21, 7]]
```

SurfaceOfGenus(*g, orientable=True*)

A surface of genus g.

INPUT:

- `g` - a non-negative integer. The desired genus
- `orientable` - boolean (optional, default True). If True, return an orientable surface, and if False, return a non-orientable surface.

In the orientable case, return a sphere if g is zero, and otherwise return a g-fold connected sum of a torus with itself.

In the non-orientable case, raise an error if g is zero. If g is positive, return a g-fold connected sum of a projective plane with itself.

EXAMPLES:

```
sage: simplicial_complexes.SurfaceOfGenus(2)
Simplicial complex with 11 vertices and 26 facets
sage: simplicial_complexes.SurfaceOfGenus(1, orientable=False)
Simplicial complex with vertex set (0, 1, 2, 3, 4, 5) and 10 facets
```

Torus()

A minimal triangulation of the torus.

EXAMPLES:

```
sage: simplicial_complexes.Torus().homology(1)
Z x Z
```

class **SimplicialSurface**(*complex, faces=, []*)

A simplicial surface is a simplicial complex structure on a surface without boundary. (The only difference between this and a SimplicialComplex is that there is a connected sum operation defined for these surfaces.)

This can either take one argument, a simplicial complex, or two arguments, the usual arguments to define a simplicial complex. It does almost no error checking to see whether the resulting complex actually represents a surface.

INPUT:

- `complex` - either a SimplicialComplex or a vertex set suitable for defining a simplicial complex.
- **faces - (optional, default []). If the argument complex is** a simplicial complex, then the faces argument is ignored. If complex is a vertex set, then faces is treated as the list of maximal faces to define the simplicial complex.

OUTPUT: a simplicial complex representing a surface.

EXAMPLES:

```
sage: from sage.homology.examples import SimplicialSurface
sage: sphere = SimplicialSurface(3, [[1,2,3], [0,2,3], [0,1,3], [0,1,2]])
sage: sphere
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(0, 2, 3), (0, 1, 2), (1, 2, 3), (0,
sage: sphere == loads(dumps(sphere))
True
```

connected_sum(*other*)

The connected sum of this simplicial surface with another one.

The connected sum of two surfaces is defined as follows: remove a 2-simplex from each, producing a boundary for each surface consisting of three edges, and then glue the two surfaces together along this triangular boundary.

INPUT:

- `other` - the other simplicial surface.

OUTPUT: the connected sum (self # other) as a simplicial surface

Algorithm: a facet is chosen from each surface, and removed. The vertices of these two facets are relabeled to (0,1,2). Of the remaining vertices, the ones from the left-hand factor are renamed by prepending an "L", and similarly the remaining vertices in the right-hand factor are renamed by prepending an "R".

EXAMPLES:

```
sage: from sage.homology.examples import SimplicialSurface
sage: S = SimplicialSurface(3, [[1,2,3], [0,2,3], [0,1,3], [0,1,2]])
sage: S     # S is the sphere
Simplicial complex with vertex set (0, 1, 2, 3) and facets {(0, 2, 3), (0, 1, 2), (1, 2, 3),
sage: S.connected_sum(S)
Simplicial complex with vertex set (0, 1, 2, 'L0', 'R0') and 6 facets
sage: P = SimplicialSurface(5, [[0,1,2], [0,2,3], [0,1,5], [0,4,5], [0,3,4], [1,2,4], [1,3,4
sage: P     # P is the projective plane
Simplicial complex with vertex set (0, 1, 2, 3, 4, 5) and 10 facets
sage: P.connected_sum(P)    # the Klein bottle
Simplicial complex with 9 vertices and 18 facets
```

The notation '+' may be used for connected sum, also:

```
sage: P + P    # the Klein bottle
Simplicial complex with 9 vertices and 18 facets
sage: (P + P).homology()
{0: 0, 1: Z x C2, 2: 0}
```

matching(*A, B*)

List of maximal matchings between the sets A and B: a matching is a set of pairs (a,b) in A x B where each a, b appears in at most one pair. A maximal matching is one which is maximal with respect to inclusion of subsets of A x B.

INPUT:

- `A, B` - list, tuple, or indeed anything which can be converted to a set.

EXAMPLES:

```
sage: from sage.homology.examples import matching
sage: matching([1,2], [3,4])
[set([(1, 3), (2, 4)]), set([(2, 3), (1, 4)])]
sage: matching([0,2], [0])
[set([(0, 0)]), set([(2, 0)])]
```

rename_vertex(*n, keep, left=True*)

Rename a vertex: the three vertices from the list 'keep' get relabeled 0, 1, 2, in order. Any other vertex (e.g. 4) gets renamed to by prepending an 'L' or an 'R' (thus to either 'L4' or 'R4'), depending on whether the argument left is True or False.

INPUT:

- `n` - a 'vertex': either an integer or a string
- `keep` - a list of three vertices
- `left` - boolean (optional, default True)

This is used by the `connected_sum` method for simplicial surfaces.

EXAMPLES:

```
sage: from sage.homology.examples import rename_vertex
sage: rename_vertex(6, [5, 6, 7])
1
```

```
sage: rename_vertex(3, [5, 6, 7])
'L3'
sage: rename_vertex(3, [5, 6, 7], left=False)
'R3'
```

CHAPTER

THIRTYSIX

L-FUNCTIONS

Sage includes several standard open source packages for computing with L-functions.

36.1 Rubinstein's L-function Calculator

This a standard part of Sage. This interface provides complete access to Rubinstein's lcalc calculator with extra PARI functionality compiled in.

Note: Each call to `lcalc` runs a complete `lcalc` process. On a typical Linux system, this entails about 0.3 seconds overhead.

AUTHORS:

- Michael Rubinstein (2005): released under GPL the C++ program lcalc
- William Stein (2006-03-05): wrote Sage interface to lcalc

class `LCalc`()

Rubinstein's L-functions Calculator

Type `lcalc.[tab]` for a list of useful commands that are implemented using the command line interface, but return objects that make sense in Sage. For each command the possible inputs for the L-function are:

- `"` - (default) the Riemann zeta function
- `'tau'` - the L function of the Ramanujan delta function
- elliptic curve E - where E is an elliptic curve over $\mathbb{Q}$; defines $L(E, s)$

You can also use the complete command-line interface of Rubinstein's L-functions calculations program via this class. Type `lcalc.help()` for a list of commands and how to call them.

`analytic_rank`(*L=''*)

Return the analytic rank of the L-function at the central critical point.

INPUT:

- `L` - defines L-function (default: Riemann zeta function)

OUTPUT: integer

Note: Of course this is not provably correct in general, since it is an open problem to compute analytic ranks provably correctly in general.

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: lcalc.analytic_rank(E)
1
```

help()

twist_values(*s, dmin, dmax, L=''*)

Return values of $L(s, \chi_k)$ for each quadratic character χ_k whose discriminant d satisfies $d_{\min} \leq d \leq d_{\max}$.

INPUT:

- `s` - complex numbers
- `dmin` - integer
- `dmax` - integer
- `L` - defines L-function (default: Riemann zeta function)

OUTPUT:

- `list` - list of pairs (d, L(s,chi_d))

EXAMPLES:

```
sage: lcalc.twist_values(0.5, -10, 10)
[(-8, 1.10042141), (-7, 1.14658567), (-4, 0.667691457), (-3, 0.480867558), (5, 0.231750947),
```

twist_zeros(*n, dmin, dmax, L=''*)

Return first n real parts of nontrivial zeros for each quadratic character χ_k whose discriminant d satisfies $d_{\min} \leq d \leq d_{\max}$.

INPUT:

- `n` - integer
- `dmin` - integer
- `dmax` - integer
- `L` - defines L-function (default: Riemann zeta function)

OUTPUT:

- `dict` - keys are the discriminants d, and values are list of corresponding zeros.

EXAMPLES:

```
sage: lcalc.twist_zeros(3, -3, 6)
{-3: [8.03973716, 11.2492062, 15.7046192], 5: [6.64845335, 9.83144443, 11.9588456]}
```

value(*s, L=''*)

Return $L(s)$ for s a complex number.

INPUT:

- `s` - complex number
- `L` - defines L-function (default: Riemann zeta function)

EXAMPLES:

```
sage: I = CC.0
sage: lcalc.value(0.5 + 100*I)
2.69261989 - 0.0203860296*I
```

Note, Sage can also compute zeta at complex numbers (using the PARI C library):

```
sage: (0.5 + 100*I).zeta()
2.69261988568132 - 0.0203860296025982*I
```

values_along_line(*s0, s1, number_samples, L=''*)

Return values of $L(s)$ at `number_samples` equally-spaced sample points along the line from s_0 to s_1 in the complex plane.

INPUT:

- `s0, s1` - complex numbers
- `number_samples` - integer

- L - defines L-function (default: Riemann zeta function)

OUTPUT:

- list - list of pairs (s, zeta(s)), where the s are equally spaced sampled points on the line from s0 to s1.

EXAMPLES:

```
sage: I = CC.0
sage: lcalc.values_along_line(0.5, 0.5+20*I, 5)
[(0.500000000, -1.46035451), (0.500000000 + 4.00000000*I, 0.606783764 + 0.0911121400*I), (0.
```

Sometimes warnings are printed (by lcalc) when this command is run:

```
sage: E = EllipticCurve('389a')
sage: E.lseries().values_along_line(0.5, 3, 5)
[(0, 0.209951303),
 (0.500000000, -...e-16),
 (1.00000000, 0.133768433),
 (1.50000000, 0.360092864),
 (2.00000000, 0.552975867)]
```

zeros (*n, L=''*)

Return the imaginary parts of the first n nontrivial zeros of the L-function in the upper half plane, as 32-bit reals.

INPUT:

- n - integer
- L - defines L-function (default: Riemann zeta function)

This function also checks the Riemann Hypothesis and makes sure no zeros are missed. This means it looks for several dozen zeros to make sure none have been missed before outputting any zeros at all, so takes longer than `self.zeros_of_zeta_in_interval(...)`.

EXAMPLES:

```
sage: lcalc.zeros(4)                          # long
[14.1347251, 21.0220396, 25.0108576, 30.4248761]
sage: lcalc.zeros(5, L='--tau')               # long
[9.22237940, 13.9075499, 17.4427770, 19.6565131, 22.3361036]
sage: lcalc.zeros(3, EllipticCurve('37a'))    # long
[0.000000000, 5.00317001, 6.87039122]
```

zeros_in_interval (*x, y, stepsize, L=''*)

Return the imaginary parts of (most of) the nontrivial zeros of the L-function on the line $\Re(s) = 1/2$ with positive imaginary part between x and y, along with a technical quantity for each.

INPUT:

- x, y, stepsize - positive floating point numbers
- L - defines L-function (default: Riemann zeta function)

OUTPUT: list of pairs (zero, S(T)).

Rubinstein writes: The first column outputs the imaginary part of the zero, the second column a quantity related to $S(T)$ (it increases roughly by 2 whenever a sign change, i.e. pair of zeros, is missed). Higher up the critical strip you should use a smaller stepsize so as not to miss zeros.

EXAMPLES:

```
sage: lcalc.zeros_in_interval(10, 30, 0.1)
[(14.1347251, 0.184672916), (21.0220396, -0.0677893290), (25.0108576, -0.0555872781)]
```

36.2 Watkins Symmetric Power L-function Calculator

SYMPOW is a package to compute special values of symmetric power elliptic curve L-functions. It can compute up to about 64 digits of precision. This interface provides complete access to sympow, which is a standard part of Sage (and includes the extra data files).

Note: Each call to `sympow` runs a complete `sympow` process. This incurs about 0.2 seconds overhead.

AUTHORS:

- Mark Watkins (2005-2006): wrote and released sympow
- William Stein (2006-03-05): wrote Sage interface

ACKNOWLEDGEMENT (from sympow readme):

- The quad-double package was modified from David Bailey's package: http://crd.lbl.gov/~dhbailey/mpdist/
- The `squfof` implementation was modified from Allan Steel's version of Arjen Lenstra's original LIP-based code.
- The `ec_ap` code was originally written for the kernel of MAGMA, but was modified to use small integers when possible.
- SYMPOW was originally developed using PARI, but due to licensing difficulties, this was eliminated. SYMPOW also does not use the standard math libraries unless Configure is run with the -lm option. SYMPOW still uses GP to compute the meshes of inverse Mellin transforms (this is done when a new symmetric power is added to datafiles).

class **Sympow**()

Watkins Symmetric Power L-function Calculator

Type `sympow.[tab]` for a list of useful commands that are implemented using the command line interface, but return objects that make sense in Sage.

You can also use the complete command-line interface of sympow via this class. Type `sympow.help()` for a list of commands and how to call them.

L(*E, n, prec*)

Return $L(\mathrm{Sym}^{(n)}(E, \text{edge}))$ to prec digits of precision, where edge is the *right* edge. Here n must be even.

INPUT:

- `E` - elliptic curve
- `n` - even integer
- `prec` - integer

OUTPUT:

- `string` - real number to prec digits of precision as a string.

Note: Before using this function for the first time for a given n, you may have to type `sympow('-new_data n')`, where `n` is replaced by your value of n.

If you would like to see the extensive output sympow prints when running this function, just type `set_verbose(2)`.

EXAMPLES:

```
sage: a = sympow.L(EllipticCurve('11a'), 2, 16); a   # optional
'1.057599244590958E+00'
sage: RR(a)                    # optional -- requires precomputations
1.05759924459096
```

Lderivs(*E, n, prec, d*)

Return 0^{th} to d^{th} derivatives of $L(\mathrm{Sym}^{(n)}(E,s)$ to prec digits of precision, where s is the right edge if n is even and the center if n is odd.

INPUT:

- `E` - elliptic curve
- `n` - integer (even or odd)
- `prec` - integer
- `d` - integer

OUTPUT: a string, exactly as output by sympow

Note: To use this function you may have to run a few commands like `sympow('-new_data 1d2')`, each which takes a few minutes. If this function fails it will indicate what commands have to be run.

EXAMPLES:

```
sage: print sympow.Lderivs(EllipticCurve('11a'), 1, 16, 2)  # not tested
...
 1n0: 2.538418608559107E-01
 1w0: 2.538418608559108E-01
 1n1: 1.032321840884568E-01
 1w1: 1.059251499158892E-01
 1n2: 3.238743180659171E-02
 1w2: 3.414818600982502E-02
```

analytic_rank(*E*)

Return the analytic rank and leading L-value of the elliptic curve E.

INPUT:

- `E` - elliptic curve over Q

OUTPUT:

- `integer` - analytic rank
- `string` - leading coefficient (as string)

Note: The analytic rank is *not* computed provably correctly in general.

Note: In computing the analytic rank we consider $L^{(r)}(E,1)$ to be 0 if $L^{(r)}(E,1)/\Omega_E > 0.0001$.

EXAMPLES: We compute the analytic ranks of the lowest known conductor curves of the first few ranks:

```
sage: sympow.analytic_rank(EllipticCurve('11a'))
(0, '2.53842e-01')
sage: sympow.analytic_rank(EllipticCurve('37a'))
(1, '3.06000e-01')
sage: sympow.analytic_rank(EllipticCurve('389a'))
(2, '7.59317e-01')
sage: sympow.analytic_rank(EllipticCurve('5077a'))
(3, '1.73185e+00')
sage: sympow.analytic_rank(EllipticCurve([1, -1, 0, -79, 289]))
(4, '8.94385e+00')
sage: sympow.analytic_rank(EllipticCurve([0, 0, 1, -79, 342]))  # long
(5, '3.02857e+01')
sage: sympow.analytic_rank(EllipticCurve([1, 1, 0, -2582, 48720]))  # long
(6, '3.20781e+02')
sage: sympow.analytic_rank(EllipticCurve([0, 0, 0, -10012, 346900]))  # long
(7, '1.32517e+03')
```

help()

modular_degree(*E*)

Return the modular degree of the elliptic curve E, assuming the Stevens conjecture.

INPUT:

- `E` - elliptic curve over Q

OUTPUT:

- `integer` - modular degree

EXAMPLES: We compute the modular degrees of the lowest known conductor curves of the first few ranks:

```
sage: sympow.modular_degree(EllipticCurve('11a'))
1
sage: sympow.modular_degree(EllipticCurve('37a'))
2
sage: sympow.modular_degree(EllipticCurve('389a'))
40
sage: sympow.modular_degree(EllipticCurve('5077a'))
1984
sage: sympow.modular_degree(EllipticCurve([1, -1, 0, -79, 289]))
334976
```

new_data(*n*)

Pre-compute data files needed for computation of n-th symmetric powers.

36.3 Dokchitser's L-functions Calculator

AUTHORS:

- Tim Dokchitser (2002): original PARI code and algorithm (and the documentation below is based on Dokchitser's docs).
- William Stein (2006-03-08): Sage interface

TODO:

- add more examples from data/extcode/pari/dokchitser that illustrate use with Eisenstein series, number fields, etc.
- plug this code into number fields and modular forms code (elliptic curves are done).

class Dokchitser(*conductor, gammaV, weight, eps, poles=, [], residues='automatic', prec=53, init=None*)

Dokchitser's L-functions Calculator

Create a Dokchitser L-series with

Dokchitser(conductor, gammaV, weight, eps, poles, residues, init, prec)

where

- `conductor` - integer, the conductor
- `gammaV` - list of Gamma-factor parameters, e.g. [0] for Riemann zeta, [0,1] for ell.curves, (see examples).
- `weight` - positive real number, usually an integer e.g. 1 for Riemann zeta, 2 for H^1 of curves/$\mathbf{Q}$
- `eps` - complex number; sign in functional equation
- `poles` - (default: []) list of points where $L^*(s)$ has (simple) poles; only poles with $Re(s) > weight/2$ should be included
- `residues` - vector of residues of $L^*(s)$ in those poles or set residues='automatic' (default value)
- `prec` - integer (default: 53) number of *bits* of precision

RIEMANN ZETA FUNCTION:

We compute with the Riemann Zeta function.

```
sage: L = Dokchitser(conductor=1, gammaV=[0], weight=1, eps=1, poles=[1], residues=[-1], init='1
sage: L
Dokchitser L-series of conductor 1 and weight 1
sage: L(1)
...
ArithmeticError:   ###   user error: L*(s) has a pole at s=1.000000000000000000
sage: L(2)
1.64493406684823
sage: L(2, 1.1)
1.64493406684823
sage: L.derivative(2)
-0.937548254315844
sage: h = RR('0.0000000000001')
sage: (zeta(2+h) - zeta(2))/h
-0.937028232783632
sage: L.taylor_series(2, k=5)
1.64493406684823 - 0.937548254315844*z + 0.994640117149451*z^2 - 1.00002430047384*z^3 + 1.000061
```

RANK 1 ELLIPTIC CURVE:

We compute with the L-series of a rank 1 curve.

```
sage: E = EllipticCurve('37a')
sage: L = E.lseries().dokchitser(); L
Dokchitser L-function associated to Elliptic Curve defined by y^2 + y = x^3 - x over Rational Fi
sage: L(1)
0
sage: L.derivative(1)
0.305999773834052
sage: L.derivative(1,2)
0.373095594536324
sage: L.num_coeffs()
48
sage: L.taylor_series(1,4)
0.305999773834052*z + 0.186547797268162*z^2 - 0.136791463097188*z^3 + O(z^4)
sage: L.check_functional_equation()
6.11218974800000e-18                          # 32-bit
6.04442711160669e-18                          # 64-bit
```

RANK 2 ELLIPTIC CURVE:

We compute the leading coefficient and Taylor expansion of the L-series of a rank 2 curve.

```
sage: E = EllipticCurve('389a')
sage: L = E.lseries().dokchitser()
sage: L.num_coeffs ()
156
sage: L.derivative(1,E.rank())
1.51863300057685
sage: L.taylor_series(1,4)
-1.28158145691931e-23 + (7.26268290635587e-24)*z + 0.759316500288427*z^2 - 0.430302337583362*z^3
-2.69129566562797e-23 + (1.52514901968783e-23)*z + 0.759316500288427*z^2 - 0.430302337583362*z^3
```

RAMANUJAN DELTA L-FUNCTION:

The coefficients are given by Ramanujan's tau function:

```
sage: L = Dokchitser(conductor=1, gammaV=[0,1], weight=12, eps=1)
sage: pari_precode = 'tau(n)=(5*sigma(n,3)+7*sigma(n,5))*n/12 - 35*sum(k=1,n-1,(6*k-4*(n-k))*sig
sage: L.init_coeffs('tau(k)', pari_precode=pari_precode)
```

We redefine the default bound on the coefficients: Deligne's estimate on tau(n) is better than the default coefgrow(n)='(4n)^{11/2}' (by a factor 1024), so re-defining coefgrow() improves efficiency (slightly faster).

```
sage: L.num_coeffs()
12
sage: L.set_coeff_growth('2*n^(11/2)')
sage: L.num_coeffs()
11
```

Now we're ready to evaluate, etc.

```
sage: L(1)
0.0374412812685155
sage: L(1, 1.1)
0.0374412812685155
sage: L.taylor_series(1,3)
0.0374412812685155 + 0.0709221123619322*z + 0.0380744761270520*z^2 + O(z^3)
```

check_functional_equation(*T=1.2*)

Verifies how well numerically the functional equation is satisfied, and also determines the residues if `self.poles != []` and residues='automatic'.

More specifically: for $T > 1$ (default 1.2), `self.check_functional_equation(T)` should ideally return 0 (to the current precision).

- if what this function returns does not look like 0 at all, probably the functional equation is wrong (i.e. some of the parameters gammaV, conductor etc., or the coefficients are wrong),
- if checkfeq(T) is to be used, more coefficients have to be generated (approximately T times more), e.g. call cflength(1.3), initLdata("a(k)",1.3), checkfeq(1.3)
- T=1 always (!) returns 0, so T has to be away from 1
- default value $T = 1.2$ seems to give a reasonable balance
- if you don't have to verify the functional equation or the L-values, call num_coeffs(1) and initLdata("a(k)",1), you need slightly less coefficients.

EXAMPLES:

```
sage: L = Dokchitser(conductor=1, gammaV=[0], weight=1, eps=1, poles=[1], residues=[-1], ini
sage: L.check_functional_equation ()
-2.71050543200000e-20                          # 32-bit
-2.71050543121376e-20                          # 64-bit
```

If we choose the sign in functional equation for the ζ function incorrectly, the functional equation doesn't check out.

```
sage: L = Dokchitser(conductor=1, gammaV=[0], weight=1, eps=-11, poles=[1], residues=[-1], i
sage: L.check_functional_equation ()
-9.73967861488124
```

derivative(*s, k=1*)

Return the k-th derivative of the L-series at s.

Warning: If k is greater than the order of vanishing of L at s you may get nonsense.

EXAMPLES:

```
sage: E = EllipticCurve('389a')
sage: L = E.lseries().dokchitser()
sage: L.derivative(1,E.rank())
1.51863300057685
```

gp()

Return the gp interpreter that is used to implement this Dokchitser L-function.

EXAMPLES:

```
sage: E = EllipticCurve('11a')
sage: L = E.lseries().dokchitser()
sage: L(2)
0.546048036215014
sage: L.gp()
GP/PARI interpreter
```

init_coeffs(*v, cutoff=1, w=None, pari_precode='', max_imaginary_part=0, max_asymp_coeffs=40*)

Set the coefficients a_n of the L-series. If $L(s)$ is not equal to its dual, pass the coefficients of the dual as the second optional argument.

INPUT:

- `v` - list of complex numbers or string (pari function of k)
- `cutoff` - real number = 1 (default: 1)
- `w` - list of complex numbers or string (pari function of k)
- `pari_precode` - some code to execute in pari before calling initLdata
- `max_imaginary_part` - (default: 0): redefine if you want to compute L(s) for s having large imaginary part,
- `max_asymp_coeffs` - (default: 40): at most this many terms are generated in asymptotic series for phi(t) and G(s,t).

EXAMPLES:

```
sage: L = Dokchitser(conductor=1, gammaV=[0,1], weight=12, eps=1)
sage: pari_precode = 'tau(n)=(5*sigma(n,3)+7*sigma(n,5))*n/12 - 35*sum(k=1,n-1,(6*k-4*(n-k))
sage: L.init_coeffs('tau(k)', pari_precode=pari_precode)
```

num_coeffs(*T=1*)

Return number of coefficients a_n that are needed in order to perform most relevant L-function computations to the desired precision.

EXAMPLES:

```
sage: E = EllipticCurve('11a')
sage: L = E.lseries().dokchitser()
sage: L.num_coeffs()
26
sage: E = EllipticCurve('5077a')
sage: L = E.lseries().dokchitser()
sage: L.num_coeffs()
568
sage: L = Dokchitser(conductor=1, gammaV=[0], weight=1, eps=1, poles=[1], residues=[-1], ini
sage: L.num_coeffs()
4
```

set_coeff_growth(*coefgrow*)

You might have to redefine the coefficient growth function if the a_n of the L-series are not given by the following PARI function:

```
coefgrow(n) = if(length(Lpoles),
                 1.5*n^(vecmax(real(Lpoles))-1),
                 sqrt(4*n)^(weight-1));
```

INPUT:

- `coefgrow` - string that evaluates to a PARI function of n that defines a coefgrow function.

EXAMPLE:

```
sage: L = Dokchitser(conductor=1, gammaV=[0,1], weight=12, eps=1)
sage: pari_precode = 'tau(n)=(5*sigma(n,3)+7*sigma(n,5))*n/12 - 35*sum(k=1,n-1,(6*k-4*(n-k))
sage: L.init_coeffs('tau(k)', pari_precode=pari_precode)
sage: L.set_coeff_growth('2*n^(11/2)')
sage: L(1)
0.0374412812685155
```

taylor_series(*a=0, k=6, var='z'*)

Return the first k terms of the Taylor series expansion of the L-series about a.

This is returned as a series in `var`, where you should view `var` as equal to $s - a$. Thus this function returns the formal power series whose coefficients are $L^{(n)}(a)/n!$.

INPUT:

- `a` - complex number (default: 0); point about which to expand
- `k` - integer (default: 6), series is $O(\text{“}var\text{“}^k)$
- `var` - string (default: 'z'), variable of power series

EXAMPLES:

```
sage: L = Dokchitser(conductor=1, gammaV=[0], weight=1, eps=1, poles=[1], residues=[-1], ini
sage: L.taylor_series(2, 3)
1.64493406684823 - 0.937548254315844*z + 0.994640117149451*z^2 + O(z^3)
sage: E = EllipticCurve('37a')
sage: L = E.lseries().dokchitser()
sage: L.taylor_series(1)
0.305999773834052*z + 0.186547797268162*z^2 - 0.136791463097188*z^3 + 0.0161066468496401*z^4
```

We compute a Taylor series where each coefficient is to high precision.

```
sage: E = EllipticCurve('389a')
sage: L = E.lseries().dokchitser(200)
sage: L.taylor_series(1,3)
6.2239725530250970363983975962696997888173850098274602272589e-73 + (-3.527106203544994604921

```

reduce_load_dokchitser(*D*)

CHAPTER

THIRTYSEVEN

SCHEMES

37.1 Scheme implementation overview

Various parts of schemes were implemented by David Kohel, David Joyner, and William Stein.

AUTHORS:

- David Kohel (2006-01-03): initial version
- William Stein (2006-01-05)
- William Stein (2006-01-20)

- **Scheme:** A scheme whose datatype might be not be defined in terms of algebraic equations: e.g. the Jacobian of a curve may be represented by means of a Scheme.
- **AlgebraicScheme:** A scheme defined by means of polynomial equations, which may be reducible or defined over a ring other than a field. In particular, the defining ideal need not be a radical ideal, and an algebraic scheme may be defined over Spec(R).
- **AmbientSpaces:** Most effective models of algebraic scheme will be defined, not by generic gluings, but by embeddings in some fixed ambient space.
- **AffineSpace:** Affine spaces, and their affine subschemes form the most important universal objects from which algebraic schemes are built. The affine spaces form universal objects in the sense that a morphism is uniquely determined by the images of its coordinate functions and any such images determine a well-defined morphism.

  By default affine spaces will embed in some ordinary projective space, unless it is created as an affine patch of another object.
- **ProjectiveSpace:** The projective spaces are the most natural ambient spaces for most projective objects. They are locally universal objects.
- **ProjectiveSpace_ordinary (not implemented)** The ordinary projective spaces have the standard weights $[1, .., 1]$ on their coefficients.
- **ProjectiveSpace_weighted (not implemented):** A special subtype for non-standard weights.
- **ToricSpace (not implemented):** This defines a projective toric variety, which defines a space equipped with a toral action and certain defining data. These generalise projective spaces, but it is not envisioned that the latter should inherit from the `ToricSpace` type.
- **AlgebraicScheme_subscheme_affine:** An algebraic scheme defined by means of an embedding in a fixed ambient affine space.

- **AlgebraicScheme_subscheme_projective:** An algebraic scheme defined by means of an embedding in a fixed ambient projective space.
- **QuasiAffineScheme (not yet implemented):** An open subset $U = X \setminus Z$ of a closed subset X of affine space; note that this is mathematically a quasi-projective scheme, but its ambient space is an affine space and its points are represented by affine rather than projective points.

  Note: AlgebraicScheme_quasi is implemented, as a base class for this.
- **QuasiProjectiveScheme (not yet implemented):** An open subset of a closed subset of projective space; this datatype stores the defining polynomial, polynomials, or ideal defining the projective closure X plus the closed subscheme Z of X whose complement $U = X \setminus Z$ is the quasi-projective scheme.

  Note: the quasi-affine and quasi-projective datatype lets one create schemes like the multiplicative group scheme $\mathbb{G}_m = \mathbb{A}^1 \setminus \{(0)\}$ and the non-affine scheme $\mathbb{A}^2 \setminus \{(0,0)\}$. The latter is not affine and is not of the form $\mathrm{Spec}(R)$.

37.1.1 TODO List

- **PointSets and points over a ring:** For algebraic schemes X/S and T/S over S, one can form the point set $X(T)$ of morphisms from $T \to X$ over S.

  ```
  sage: PP.<X,Y,Z> = ProjectiveSpace(2, QQ)
  sage: PP
  Projective Space of dimension 2 over Rational Field
  ```

  The last line is an abuse of language – returning the generators of the coordinate ring by `gens()`.

  A projective space object in the category of schemes is a locally free object – the images of the generator functions *locally* determine a point. Over a field, one can choose one of the standard affine patches by the condition that a coordinate function $X_i \neq 0$

  ```
  sage: PP(QQ)
  Set of Rational Points of Projective Space of dimension 2 over Rational Field
  sage: PP(QQ)([-2,3,5])
  (-2/5 : 3/5 : 1)
  ```

  Over a ring, this is not true, e.g. even over an integral domain which is not a PID, there may be no *single* affine patch which covers a point.

  ```
  sage: R.<x> = ZZ[]
  sage: S.<t> = R.quo(x^2+5)
  sage: P.<X,Y,Z> = ProjectiveSpace(2, S)
  sage: P(S)
  Set of Rational Points of Projective Space of dimension 2 over
  Univariate Quotient Polynomial Ring in t over Integer Ring with
  modulus x^2 + 5
  ```

  In order to represent the projective point $(2 : 1+t) = (1-t : 3)$ we note that the first representative is not well-defined at the prime $pp = (2, 1+t)$ and the second element is not well-defined at the prime $qq = (1-t, 3)$, but that $pp + qq = (1)$, so globally the pair of coordinate representatives is well-defined.

  ```
  sage: P( [2, 1+t] )
  ...
  NotImplementedError
  ```

  In fact, we need a test `R.ideal([2,1+t]) == R.ideal([1])` in order to make this meaningful.

37.2 Schemes

AUTHORS:

- William Stein, David Kohel, Kiran Kedlaya (2008): added zeta_series

class AffineScheme(*X*)

An abstract affine scheme.

hom(*x*, *Y=None*)

Return the scheme morphism from self to Y defined by x.

If Y is not given, try to determine from context.

EXAMPLES: We construct the inclusion from $\mathrm{Spec}(\mathbf{Q})$ into $\mathrm{Spec}(\mathbf{Z})$ induced by the inclusion from $\mathbf{Z}$ into $\mathbf{Q}$.

```
sage: X = Spec(QQ)
sage: X.hom(ZZ.hom(QQ))
Affine Scheme morphism:
  From: Spectrum of Rational Field
  To:   Spectrum of Integer Ring
  Defn: Ring Coercion morphism:
          From: Integer Ring
          To:   Rational Field
```

class Scheme(*X*)

base_extend(*Y*)

Y is either a scheme in the same category as self or a ring.

EXAMPLES:

```
sage: X = Spec(QQ)
sage: X.base_scheme()
Spectrum of Integer Ring
sage: X.base_extend(QQ)
...
NotImplementedError
```

base_morphism()

Return the structure morphism from the scheme self to its base scheme.

EXAMPLES:

```
sage: A = AffineSpace(4, QQ)
sage: A.base_morphism()
Scheme morphism:
  From: Affine Space of dimension 4 over Rational Field
  To:   Spectrum of Rational Field
  Defn: Structure map

sage: X = Spec(QQ)
sage: X.base_morphism()
Scheme morphism:
  From: Spectrum of Rational Field
  To:   Spectrum of Integer Ring
  Defn: Structure map
```

base_ring()

Return the base ring of the scheme self.

EXAMPLES:

```
sage: A = AffineSpace(4, QQ)
sage: A.base_ring()
Rational Field

sage: X = Spec(QQ)
sage: X.base_ring()
Integer Ring
```

base_scheme()

Return the base scheme of the scheme self.

EXAMPLES:

```
sage: A = AffineSpace(4, QQ)
sage: A.base_scheme()
Spectrum of Rational Field

sage: X = Spec(QQ)
sage: X.base_scheme()
Spectrum of Integer Ring
```

category()

Return the category to which this scheme belongs. This is the category of all schemes over the base scheme of self.

EXAMPLES:

```
sage: ProjectiveSpace(4, QQ).category()
Category of schemes over Spectrum of Rational Field
```

coordinate_ring()

Return the coordinate ring of this scheme, if defined. Otherwise raise a ValueError.

EXAMPLES:

```
sage: R.<x, y> = QQ[]
sage: I = (x^2 - y^2)*R
sage: X = Spec(R.quotient(I))
sage: X.coordinate_ring()
Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the ideal (x^2 - y^2
```

count_points(n)

Count points over $\mathbf{F}_q, \ldots, \mathbf{F}_{q^n}$ on a scheme over a finite field $\mathbf{F}_q$.

Note: This is currently only implemented for schemes over prime order finite fields.

EXAMPLES:

```
sage: P.<x> = PolynomialRing(GF(3))
sage: C = HyperellipticCurve(x^3+x^2+1)
sage: C.count_points(4)
[6, 12, 18, 96]
sage: C.base_extend(GF(9,'a')).count_points(2)
...
NotImplementedError: Point counting only implemented for schemes over prime fields
```

dimension()

Return the absolute dimension of this scheme.

EXAMPLES:

```
sage: R.<x, y> = QQ[]
sage: I = (x^2 - y^2)*R
sage: X = Spec(R.quotient(I))
```

```
sage: X.dimension_absolute()
...
NotImplementedError
sage: X.dimension()
...
NotImplementedError
```

dimension_absolute()

Return the absolute dimension of this scheme.

EXAMPLES:

```
sage: R.<x, y> = QQ[]
sage: I = (x^2 - y^2)*R
sage: X = Spec(R.quotient(I))
sage: X.dimension_absolute()
...
NotImplementedError
sage: X.dimension()
...
NotImplementedError
```

dimension_relative()

Return the relative dimension of this scheme over its base.

EXAMPLES:

```
sage: R.<x, y> = QQ[]
sage: I = (x^2 - y^2)*R
sage: X = Spec(R.quotient(I))
sage: X.dimension_relative()
...
NotImplementedError
```

hom(*x, Y=None*)

Return the scheme morphism from self to Y defined by x. If x is a scheme, try to determine a natural map to x.

If Y is not given, try to determine Y from context.

EXAMPLES:

```
sage: P = ProjectiveSpace(ZZ, 3)
sage: P.hom(Spec(ZZ))
Scheme morphism:
  From: Projective Space of dimension 3 over Integer Ring
  To:   Spectrum of Integer Ring
  Defn: Structure map
```

identity_morphism()

Return the identity morphism of the scheme self.

EXAMPLES:

```
sage: X = Spec(QQ)
sage: X.identity_morphism()
Scheme endomorphism of Spectrum of Rational Field
  Defn: Identity map
```

point(*v, check=True*)

point_homset(*S=None*)

Return the set of S-valued points of this scheme.

EXAMPLES:

```
sage: P = ProjectiveSpace(ZZ, 3)
sage: P.point_homset(ZZ)
Set of Rational Points of Projective Space of dimension 3 over Integer Ring
sage: P.point_homset(QQ)
Set of Rational Points of Projective Space of dimension 3 over Rational Field
sage: P.point_homset(GF(11))
Set of Rational Points of Projective Space of dimension 3 over Finite Field of size 11
```

point_set(*S=None*)

Return the set of S-valued points of this scheme.

EXAMPLES:

```
sage: P = ProjectiveSpace(ZZ, 3)
sage: P.point_homset(ZZ)
Set of Rational Points of Projective Space of dimension 3 over Integer Ring
sage: P.point_homset(QQ)
Set of Rational Points of Projective Space of dimension 3 over Rational Field
sage: P.point_homset(GF(11))
Set of Rational Points of Projective Space of dimension 3 over Finite Field of size 11
```

structure_morphism()

Return the structure morphism from the scheme self to its base scheme.

EXAMPLES:

```
sage: A = AffineSpace(4, QQ)
sage: A.base_morphism()
Scheme morphism:
  From: Affine Space of dimension 4 over Rational Field
  To:   Spectrum of Rational Field
  Defn: Structure map

sage: X = Spec(QQ)
sage: X.base_morphism()
Scheme morphism:
  From: Spectrum of Rational Field
  To:   Spectrum of Integer Ring
  Defn: Structure map
```

union(*X*)

Return the disjoint union of the schemes self and X.

EXAMPLES:

```
sage: S = Spec(QQ)
sage: X = AffineSpace(1, QQ)
sage: S.union(X)
...
NotImplementedError
```

zeta_series(*n, t*)

Compute a power series approximation to the zeta function of a scheme over a finite field.

INPUT:

- `n` - the number of terms of the power series to compute
- `t` - the variable which the series should be returned

OUTPUT: A power series approximating the zeta function of self

EXAMPLES:

```
sage: P.<x> = PolynomialRing(GF(3))
sage: C = HyperellipticCurve(x^3+x^2+1)
sage: R.<t> = PowerSeriesRing(Integers())
sage: C.zeta_series(4,t)
1 + 6*t + 24*t^2 + 78*t^3 + 240*t^4 + O(t^5)
sage: (1+2*t+3*t^2)/(1-t)/(1-3*t) + O(t^5)
1 + 6*t + 24*t^2 + 78*t^3 + 240*t^4 + O(t^5)
```

Note that this function depends on count_points, which is only defined for prime order fields:

```
sage: C.base_extend(GF(9,'a')).zeta_series(4,t)
...
NotImplementedError: Point counting only implemented for schemes over prime fields
```

is_AffineScheme(*x*)

Return True if x is an affine scheme.

EXAMPLES:

```
sage: from sage.schemes.generic.scheme import is_AffineScheme
sage: is_AffineScheme(5)
False
sage: E = Spec(QQ)
sage: is_AffineScheme(E)
True
```

is_Scheme(*x*)

Return True if x is a scheme.

EXAMPLES:

```
sage: from sage.schemes.generic.scheme import is_Scheme
sage: is_Scheme(5)
False
sage: X = Spec(QQ)
sage: is_Scheme(X)
True
```

37.3 Spec of a ring

class Spec(*R, S=None, check=True*)

The spectrum of a commutative ring, as a scheme.

Note: Calling `Spec(R)` twice produces two distinct (but equal) schemes, which is important for gluing to construct more general schemes.

EXAMPLES:

```
sage: Spec(QQ)
Spectrum of Rational Field
sage: Spec(PolynomialRing(QQ, 'x'))
Spectrum of Univariate Polynomial Ring in x over Rational Field
sage: Spec(PolynomialRing(QQ, 'x', 3))
Spectrum of Multivariate Polynomial Ring in x0, x1, x2 over Rational Field
sage: X = Spec(PolynomialRing(GF(49,'a'), 3, 'x')); X
Spectrum of Multivariate Polynomial Ring in x0, x1, x2 over Finite Field in a of size 7^2
sage: loads(X.dumps()) == X
True
```

```
sage: A = Spec(ZZ); B = Spec(ZZ)
sage: A is B
False
sage: A == B
True
```

A TypeError is raised if the input is not a CommutativeRing.

```
sage: Spec(5)
...
TypeError: R (=5) must be a commutative ring
sage: Spec(FreeAlgebra(QQ,2, 'x'))
...
TypeError: R (=Free Algebra on 2 generators (x0, x1) over Rational Field) must be a commutative
```

EXAMPLES:

```
sage: X = Spec(ZZ)
sage: X
Spectrum of Integer Ring
sage: X.base_scheme()
Spectrum of Integer Ring
sage: X.base_ring()
Integer Ring
sage: X.dimension()
1
```

coordinate_ring()

Return the underlying ring of this scheme.

EXAMPLES:

```
sage: Spec(QQ).coordinate_ring()
Rational Field
sage: Spec(PolynomialRing(QQ, 3, 'x')).coordinate_ring()
Multivariate Polynomial Ring in x0, x1, x2 over Rational Field
```

dimension()

Return the absolute dimension of this scheme.

EXAMPLES:

```
sage: S = Spec(ZZ)
sage: S.dimension_absolute()
1
sage: S.dimension()
1
```

dimension_absolute()

Return the absolute dimension of this scheme.

EXAMPLES:

```
sage: S = Spec(ZZ)
sage: S.dimension_absolute()
1
sage: S.dimension()
1
```

dimension_relative()

Return the relative dimension of this scheme over its base.

EXAMPLES:

```
sage: S = Spec(ZZ)
sage: S.dimension_relative()
0
```

is_noetherian()
Return True if this scheme is Noetherian.
EXAMPLES:

```
sage: Spec(ZZ).is_noetherian()
True
```

is_Spec(*X*)
EXAMPLES:

```
sage: from sage.schemes.generic.spec import is_Spec
sage: is_Spec(QQ^3)
False
sage: X = Spec(QQ); X
Spectrum of Rational Field
sage: is_Spec(X)
True
```

37.4 Scheme obtained by glueing two other schemes

class GluedScheme(*f, g, check=True*)
INPUT:

- f - open immersion from a scheme U to a scheme X
- g - open immersion from U to a scheme Y

OUTPUT: The scheme obtained by gluing X and Y along the open set U.

Note: Checking that f and g are open immersions is not implemented.

gluing_maps()

37.5 Points on schemes

class SchemePoint(*S*)
Base class for points on a scheme, either topological or defined by a morphism.

scheme()
Return the scheme on which self is a point.
EXAMPLES:

```
sage: from sage.schemes.generic.point import SchemePoint
sage: S = Spec(ZZ)
sage: P = SchemePoint(S)
sage: P.scheme()
Spectrum of Integer Ring
```

class SchemeRationalPoint(*f*)

morphism()

class SchemeTopologicalPoint(*S*)

class SchemeTopologicalPoint_affine_open(*u, x*)

affine_open()
Return the affine open subset U.

embedding_of_affine_open()
Return the embedding from the affine open subset U into this scheme.

point_on_affine()
Return the scheme point on the affine open U.

class SchemeTopologicalPoint_prime_ideal(*S, P, check=False*)

prime_ideal()
Return the prime ideal that defines this scheme point.
EXAMPLES:

```
sage: from sage.schemes.generic.point import SchemeTopologicalPoint_prime_ideal
sage: P2.<x, y, z> = ProjectiveSpace(2, QQ)
sage: pt = SchemeTopologicalPoint_prime_ideal(P2, y*z-x^2)
sage: pt.prime_ideal()
Principal ideal (-x^2 + y*z) of Multivariate Polynomial Ring in x, y, z over Rational Field
```

is_SchemeRationalPoint(*x*)

is_SchemeTopologicalPoint(*x*)

37.6 Ambient Spaces

class AmbientSpace(*n, R=Integer Ring*)
Base class for ambient spaces over a ring.
INPUT:

- n - dimension
- R - ring

ambient_space()
Return the ambient space of the scheme self, in this case self itself.
EXAMPLES:

```
sage: P = ProjectiveSpace(4, ZZ)
sage: P.ambient_space() is P
True

sage: A = AffineSpace(2, GF(3))
sage: A.ambient_space()
Affine Space of dimension 2 over Finite Field of size 3
```

base_extend(*S, check=True*)
Return the base change of self to the ring S, via the natural map from the base ring of self to S.
A ValueError is raised if there is no natural map between the two rings.
EXAMPLES:

```
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: PQ = P.base_extend(QQ); PQ
Projective Space of dimension 2 over Rational Field
sage: PQ.base_extend(GF(5))
...
ValueError: No natural map from the base ring (=Rational Field) to S (=Finite Field of size
```

defining_polynomials()

Return the defining polynomials of the scheme self. Since self is an ambient space, this is an empty list.

EXAMPLES:

```
sage: ProjectiveSpace(2, QQ).defining_polynomials()
()
sage: AffineSpace(0, ZZ).defining_polynomials()
()
```

dimension()

Return the absolute dimension of this scheme.

EXAMPLES:

```
sage: A2Q = AffineSpace(2, QQ)
sage: A2Q.dimension_absolute()
2
sage: A2Q.dimension()
2
sage: A2Z = AffineSpace(2, ZZ)
sage: A2Z.dimension_absolute()
3
sage: A2Z.dimension()
3
```

dimension_absolute()

Return the absolute dimension of this scheme.

EXAMPLES:

```
sage: A2Q = AffineSpace(2, QQ)
sage: A2Q.dimension_absolute()
2
sage: A2Q.dimension()
2
sage: A2Z = AffineSpace(2, ZZ)
sage: A2Z.dimension_absolute()
3
sage: A2Z.dimension()
3
```

dimension_relative()

Return the relative dimension of this scheme over its base.

EXAMPLES:

```
sage: A2Q = AffineSpace(2, QQ)
sage: A2Q.dimension_relative()
2
sage: A2Z = AffineSpace(2, ZZ)
sage: A2Z.dimension_relative()
2
```

gen(*n=0*)

Return the n-th generator of the coordinate ring of the scheme self.

EXAMPLES:

```
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: P.gen(1)
y
```

gens()

Return the generators of the coordinate ring of the scheme self.

EXAMPLES:

```
sage: AffineSpace(0, QQ).gens()
()

sage: P.<x, y, z> = ProjectiveSpace(2, GF(5))
sage: P.gens()
(x, y, z)
```

ngens()

Return the number of generators of the coordinate ring of the scheme self.

EXAMPLES:

```
sage: AffineSpace(0, QQ).ngens()
0

sage: ProjectiveSpace(50, ZZ).ngens()
51
```

is_AmbientSpace(x)

Return True if x is an ambient space.

EXAMPLES:

```
sage: from sage.schemes.generic.ambient_space import is_AmbientSpace
sage: is_AmbientSpace(ProjectiveSpace(3, ZZ))
True
sage: is_AmbientSpace(AffineSpace(2, QQ))
True
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: is_AmbientSpace(P.subscheme([x+y+z]))
False
```

37.7 Affine n space over a ring.

AffineSpace(*n, R=None, names='x'*)

Return affine space of dimension n over the ring R.

EXAMPLES: The dimension and ring can be given in either order.

```
sage: AffineSpace(3, QQ, 'x')
Affine Space of dimension 3 over Rational Field
sage: AffineSpace(5, QQ, 'x')
Affine Space of dimension 5 over Rational Field
sage: A = AffineSpace(2, QQ, names='XY'); A
Affine Space of dimension 2 over Rational Field
sage: A.coordinate_ring()
Multivariate Polynomial Ring in X, Y over Rational Field
```

Use the divide operator for base extension.

```
sage: AffineSpace(5, names='x')/GF(17)
Affine Space of dimension 5 over Finite Field of size 17
```

The default base ring is **Z**.

```
sage: AffineSpace(5, names='x')
Affine Space of dimension 5 over Integer Ring
```

There is also an affine space associated to each polynomial ring.

```
sage: R = GF(7)['x,y,z']
sage: A = AffineSpace(R); A
Affine Space of dimension 3 over Finite Field of size 7
sage: A.coordinate_ring() is R
True
```

class **AffineSpace_generic**(*n, R, names*)

Affine space of dimension n over the ring R.

EXAMPLES:

```
sage: X.<x,y,z> = AffineSpace(3, QQ)
sage: X.base_scheme()
Spectrum of Rational Field
sage: X.base_ring()
Rational Field
sage: X.structure_morphism ()
Scheme morphism:
  From: Affine Space of dimension 3 over Rational Field
  To:   Spectrum of Rational Field
  Defn: Structure map
```

Loading and saving:

```
sage: loads(X.dumps()) == X
True
```

We create several other examples of affine spaces.

```
sage: AffineSpace(5, PolynomialRing(QQ, 'z'), 'Z')
Affine Space of dimension 5 over Univariate Polynomial Ring in z over Rational Field
```

```
sage: AffineSpace(RealField(), 3, 'Z')
Affine Space of dimension 3 over Real Field with 53 bits of precision
```

```
sage: AffineSpace(Qp(7), 2, 'x')
Affine Space of dimension 2 over 7-adic Field with capped relative precision 20
```

Even 0-dimensional affine spaces are supported.

```
sage: AffineSpace(0)
Affine Space of dimension 0 over Integer Ring
```

coordinate_ring()

Return the coordinate ring of this scheme, if defined.

EXAMPLES:

```
sage: R = AffineSpace(2, GF(9,'alpha'), 'z').coordinate_ring(); R
Multivariate Polynomial Ring in z0, z1 over Finite Field in alpha of size 3^2
sage: AffineSpace(3, R, 'x').coordinate_ring()
Multivariate Polynomial Ring in x0, x1, x2 over Multivariate Polynomial Ring in z0, z1 over
```

ngens()

Return the number of generators of self, i.e. the number of variables in the coordinate ring of self.

EXAMPLES:

```
sage: AffineSpace(3, QQ).ngens()
3
sage: AffineSpace(7, ZZ).ngens()
7
```

projective_embedding(*i=None, PP=None*)

Returns a morphism from this space into an ambient projective space of the same dimension.

INPUT:

- `i` - integer (default: dimension of self = last coordinate) determines which projective embedding to compute. The embedding is that which has a 1 in the i-th coordinate, numbered from 0.
- `PP` - (default: None) ambient projective space, i.e., codomain of morphism; this is constructed if it is not given.

EXAMPLES:

```
sage: AA = AffineSpace(2, QQ, 'x')
sage: pi = AA.projective_embedding(0); pi
Scheme morphism:
  From: Affine Space of dimension 2 over Rational Field
  To:   Projective Space of dimension 2 over Rational Field
  Defn: Defined on coordinates by sending (x0, x1) to
        (1 : x0 : x1)
sage: z = AA(3,4)
sage: pi(z)
(1/4 : 3/4 : 1)
sage: pi(AA(0,2))
(1/2 : 0 : 1)
sage: pi = AA.projective_embedding(1); pi
Scheme morphism:
  From: Affine Space of dimension 2 over Rational Field
  To:   Projective Space of dimension 2 over Rational Field
  Defn: Defined on coordinates by sending (x0, x1) to
        (x0 : 1 : x1)
sage: pi(z)
(3/4 : 1/4 : 1)
sage: pi = AA.projective_embedding(2)
sage: pi(z)
(3 : 4 : 1)
```

rational_points(*F=None*)

Return the list of F-rational points on the affine space self, where F is a given finite field, or the base ring of self.

EXAMPLES:

```
sage: A = AffineSpace(1, GF(3))
sage: A.rational_points()
[(0), (1), (2)]
sage: A.rational_points(GF(3^2, 'b'))
[(0), (2*b), (b + 1), (b + 2), (2), (b), (2*b + 2), (2*b + 1), (1)]
```

```
sage: AffineSpace(2, ZZ).rational_points(GF(2))
[(0, 0), (1, 0), (0, 1), (1, 1)]
```

TESTS:

```
sage: AffineSpace(2, QQ).rational_points()
...
TypeError: Base ring (= Rational Field) must be a finite field.
sage: AffineSpace(1, GF(3)).rational_points(ZZ)
...
TypeError: Second argument (= Integer Ring) must be a finite field.
```

subscheme(*X*)

Return the closed subscheme defined by X.

INPUT:

•X - a list or tuple of equations

EXAMPLES:

```
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: X = A.subscheme([x, y^2, x*y^2]); X
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
  x
  y^2
  x*y^2

sage: X.defining_polynomials ()
(x, y^2, x*y^2)
sage: I = X.defining_ideal(); I
Ideal (x, y^2, x*y^2) of Multivariate Polynomial Ring in x, y over Rational Field
sage: I.groebner_basis()
[y^2, x]
sage: X.dimension()
0
sage: X.base_ring()
Rational Field
sage: X.base_scheme()
Spectrum of Rational Field
sage: X.structure_morphism()
Scheme morphism:
  From: Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
  x
  y^2
  x*y^2
  To:   Spectrum of Rational Field
  Defn: Structure map
sage: X.dimension()
0
```

is_AffineSpace(*x*)

Returns True if x is an affine space, i.e., an ambient space $\mathbb{A}^n_R$, where R is a ring and $n \geq 0$ is an integer.

EXAMPLES:

```
sage: from sage.schemes.generic.affine_space import is_AffineSpace
sage: is_AffineSpace(AffineSpace(5, names='x'))
True
sage: is_AffineSpace(AffineSpace(5, GF(9,'alpha'), names='x'))
True
```

```
sage: is_AffineSpace(Spec(ZZ))
False
```

37.8 Projective n space over a ring.

EXAMPLES: We construct projective space over various rings of various dimensions.

The simplest projective space:

```
sage: ProjectiveSpace(0)
Projective Space of dimension 0 over Integer Ring
```

A slightly bigger projective space over $\mathbf{Q}$:

```
sage: X = ProjectiveSpace(1000, QQ); X
Projective Space of dimension 1000 over Rational Field
sage: X.dimension()
1000
```

We can use "over" notation to create projective spaces over various base rings.

```
sage: X = ProjectiveSpace(5)/QQ; X
Projective Space of dimension 5 over Rational Field
sage: X/CC
Projective Space of dimension 5 over Complex Field with 53 bits of precision
```

The third argument specifies the printing names of the generators of the homogenous coordinate ring. Using objgens() you can obtain both the space and the generators as ready to use variables.

```
sage: P2, (x,y,z) = ProjectiveSpace(2, QQ, 'xyz').objgens()
sage: P2
Projective Space of dimension 2 over Rational Field
sage: x.parent()
Multivariate Polynomial Ring in x, y, z over Rational Field
```

For example, we use x, y, z to define the intersection of two lines.

```
sage: V = P2.subscheme([x+y+z, x+y-z]); V
Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
 x + y + z
 x + y - z
sage: V.dimension()
0
```

ProjectiveSpace(*n, R=None, names='x'*)

Return projective space of dimension n over the ring R.

EXAMPLES: The dimension and ring can be given in either order.

```
sage: ProjectiveSpace(3, QQ)
Projective Space of dimension 3 over Rational Field
sage: ProjectiveSpace(5, QQ)
Projective Space of dimension 5 over Rational Field
sage: P = ProjectiveSpace(2, QQ, names='XYZ'); P
```

```
Projective Space of dimension 2 over Rational Field
sage: P.coordinate_ring()
Multivariate Polynomial Ring in X, Y, Z over Rational Field
```

The divide operator does base extension.

```
sage: ProjectiveSpace(5)/GF(17)
Projective Space of dimension 5 over Finite Field of size 17
```

The default base ring is $\mathbf{Z}$.

```
sage: ProjectiveSpace(5)
Projective Space of dimension 5 over Integer Ring
```

There is also an projective space associated each polynomial ring.

```
sage: R = GF(7)['x,y,z']
sage: P = ProjectiveSpace(R); P
Projective Space of dimension 2 over Finite Field of size 7
sage: P.coordinate_ring()
Multivariate Polynomial Ring in x, y, z over Finite Field of size 7
sage: P.coordinate_ring() is R
True
```

Projective spaces are not cached, i.e., there can be several with the same base ring and dimension (to facilitate glueing constructions).

class **ProjectiveSpace_field**(*n, R=Integer Ring, names=None*)

class **ProjectiveSpace_finite_field**(*n, R=Integer Ring, names=None*)

rational_points(*F=None*)

Return the list of F-rational points on the affine space self, where F is a given finite field, or the base ring of self.

EXAMPLES:

```
sage: P = ProjectiveSpace(1, GF(3))
sage: P.rational_points()
[(0 : 1), (1 : 1), (2 : 1), (1 : 0)]
sage: P.rational_points(GF(3^2, 'b'))
[(0 : 1), (2*b : 1), (b + 1 : 1), (b + 2 : 1), (2 : 1), (b : 1), (2*b + 2 : 1), (2*b + 1 : 1
```

class **ProjectiveSpace_rational_field**(*n, R=Integer Ring, names=None*)

rational_points(*bound=0*)

Returns the projective points $(x_0 : \cdots : x_n)$ over $\mathbf{Q}$ with $|x_i| \leq$ bound.

INPUT:

- `bound` - integer

EXAMPLES:

```
sage: PP = ProjectiveSpace(0,QQ)
sage: PP.rational_points(1)
[(1)]
sage: PP = ProjectiveSpace(1,QQ)
sage: PP.rational_points(2)
[(-2 : 1), (-1 : 1), (0 : 1), (1 : 1), (2 : 1), (-1/2 : 1), (1/2 : 1), (1 : 0)]
sage: PP = ProjectiveSpace(2,QQ)
```

```
sage: PP.rational_points(2)
[(-2 : -2 : 1), (-1 : -2 : 1), (0 : -2 : 1), (1 : -2 : 1), (2 : -2 : 1),
(-2 : -1 : 1), (-1 : -1 : 1), (0 : -1 : 1), (1 : -1 : 1), (2 : -1 : 1),
(-2 : 0 : 1), (-1 : 0 : 1), (0 : 0 : 1), (1 : 0 : 1), (2 : 0 : 1), (-2 :
1 : 1), (-1 : 1 : 1), (0 : 1 : 1), (1 : 1 : 1), (2 : 1 : 1), (-2 : 2 :
1), (-1 : 2 : 1), (0 : 2 : 1), (1 : 2 : 1), (2 : 2 : 1), (-1/2 : -1 :
1), (1/2 : -1 : 1), (-1 : -1/2 : 1), (-1/2 : -1/2 : 1), (0 : -1/2 : 1),
(1/2 : -1/2 : 1), (1 : -1/2 : 1), (-1/2 : 0 : 1), (1/2 : 0 : 1), (-1 :
1/2 : 1), (-1/2 : 1/2 : 1), (0 : 1/2 : 1), (1/2 : 1/2 : 1), (1 : 1/2 :
1), (-1/2 : 1 : 1), (1/2 : 1 : 1), (-2 : 1 : 0), (-1 : 1 : 0), (0 : 1 :
0), (1 : 1 : 0), (2 : 1 : 0), (-1/2 : 1 : 0), (1/2 : 1 : 0), (1 : 0 :
0)]
```

Note: The very simple algorithm works as follows: every point $(x_0 : \cdots : x_n)$ in projective space has a unique largest index i for which x_i is not zero. The algorithm then iterates downward on this index. We normalize by choosing x_i positive. Then, the points $x_0, \ldots, x_{i-1}$ are the points of affine i-space that are relatively prime to x_i. We access these by using the Tuples method.

AUTHORS:

- Benjamin Antieau (2008-01-12)

class **ProjectiveSpace_ring**(*n, R=Integer Ring, names=None*)

Projective space of dimension n over the ring R.

EXAMPLES:

```
sage: X.<x,y,z,w> = ProjectiveSpace(3, QQ)
sage: X.base_scheme()
Spectrum of Rational Field
sage: X.base_ring()
Rational Field
sage: X.structure_morphism ()
Scheme morphism:
  From: Projective Space of dimension 3 over Rational Field
  To:   Spectrum of Rational Field
  Defn: Structure map
sage: X.coordinate_ring()
Multivariate Polynomial Ring in x, y, z, w over Rational Field
```

Loading and saving:

```
sage: loads(X.dumps()) == X
True
```

affine_patch(*i*)

Return the i^{th} affine patch of this projective space. This is an ambient affine space $\mathbb{A}^n_R$, where R is the base ring of self, whose "projective embedding" map is 1 in the i^{th} factor.

INPUT:

- `i` - integer between 0 and dimension of self, inclusive.

OUTPUT: an ambient affine space with fixed projective_embedding map.

EXAMPLES:

```
sage: PP = ProjectiveSpace(5) / QQ
sage: AA = PP.affine_patch(2)
sage: AA
Affine Space of dimension 5 over Rational Field
sage: AA.projective_embedding()
Scheme morphism:
```

```
    From: Affine Space of dimension 5 over Rational Field
    To:   Projective Space of dimension 5 over Rational Field
    Defn: Defined on coordinates by sending (x0, x1, x2, x3, x4) to
          (x0 : x1 : 1 : x2 : x3 : x4)
sage: AA.projective_embedding(0)
Scheme morphism:
    From: Affine Space of dimension 5 over Rational Field
    To:   Projective Space of dimension 5 over Rational Field
    Defn: Defined on coordinates by sending (x0, x1, x2, x3, x4) to
          (1 : x0 : x1 : x2 : x3 : x4)
```

coordinate_ring()

Return the coordinate ring of this scheme.

EXAMPLES:

```
sage: ProjectiveSpace(3, GF(19^2,'alpha'), 'abcd').coordinate_ring()
Multivariate Polynomial Ring in a, b, c, d over Finite Field in alpha of size 19^2

sage: ProjectiveSpace(3).coordinate_ring()
Multivariate Polynomial Ring in x0, x1, x2, x3 over Integer Ring

sage: ProjectiveSpace(2, QQ, ['alpha', 'beta', 'gamma']).coordinate_ring()
Multivariate Polynomial Ring in alpha, beta, gamma over Rational Field
```

ngens()

Return the number of generators of self, i.e. the number of variables in the coordinate ring of self.

EXAMPLES:

```
sage: ProjectiveSpace(3, QQ).ngens()
4
sage: ProjectiveSpace(7, ZZ).ngens()
8
```

subscheme(*X*)

Return the closed subscheme defined by X.

INPUT:

- X - a list or tuple of equations

EXAMPLES:

```
sage: A.<x,y,z> = ProjectiveSpace(2, QQ)
sage: X = A.subscheme([x*z^2, y^2*z, x*y^2]); X
Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
  x*z^2
  y^2*z
  x*y^2
sage: X.defining_polynomials ()
(x*z^2, y^2*z, x*y^2)
sage: I = X.defining_ideal(); I
Ideal (x*z^2, y^2*z, x*y^2) of Multivariate Polynomial Ring in x, y, z over Rational Field
sage: I.groebner_basis()
[x*y^2, y^2*z,  x*z^2]
sage: X.dimension()
0
sage: X.base_ring()
Rational Field
sage: X.base_scheme()
Spectrum of Rational Field
sage: X.structure_morphism()
```

```
Scheme morphism:
  From: Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
  x*z^2
  y^2*z
  x*y^2
  To:   Spectrum of Rational Field
  Defn: Structure map
```

is_ProjectiveSpace(*x*)

Return True if x is a projective space, i.e., an ambient space $\mathbb{P}^n_R$, where R is a ring and $n \geq 0$ is an integer.

EXAMPLES:

```
sage: from sage.schemes.generic.projective_space import is_ProjectiveSpace
sage: is_ProjectiveSpace(ProjectiveSpace(5, names='x'))
True
sage: is_ProjectiveSpace(ProjectiveSpace(5, GF(9,'alpha'), names='x'))
True
sage: is_ProjectiveSpace(Spec(ZZ))
False
```

37.9 Algebraic schemes

An algebraic scheme must be defined by sets of equations in affine or projective spaces, perhaps by means of gluing relations.

class AlgebraicScheme(*A*)

An algebraic scheme presented as a subscheme in an ambient space.

ambient_space()

Return the ambient space of this algebraic scheme.

EXAMPLES:

```
sage: A.<x, y> = AffineSpace(2, GF(5))
sage: S = A.subscheme([])
sage: S.ambient_space()
Affine Space of dimension 2 over Finite Field of size 5

sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: S = P.subscheme([x-y, x-z])
sage: S.ambient_space() is P
True
```

coordinate_ring()

Return the coordinate ring of this algebraic scheme. The result is cached.

EXAMPLES:

```
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: S = P.subscheme([x-y, x-z])
sage: S.coordinate_ring()
Quotient of Multivariate Polynomial Ring in x, y, z over Integer Ring by the ideal (x - y, x
```

ngens()

Return the number of generators of the ambient space of this algebraic scheme.

EXAMPLES:

```
sage: A.<x, y> = AffineSpace(2, GF(5))
sage: S = A.subscheme([])
sage: S.ngens()
2

sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: S = P.subscheme([x-y, x-z])
sage: P.ngens()
3
```

class AlgebraicScheme_quasi(*X, Y*)

The quasi-affine or quasi-projective scheme $X - Y$, where X and Y are both closed subschemes of a common ambient affine or projective space.

X()

Return the scheme X such that self is represented as $X - Y$.

EXAMPLES:

```
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: S = P.subscheme([])
sage: T = P.subscheme([x-y])
sage: U = T.complement(S)
sage: U.X() is S
True
```

Y()

Return the scheme Y such that self is represented as $X - Y$.

EXAMPLES:

```
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: S = P.subscheme([])
sage: T = P.subscheme([x-y])
sage: U = T.complement(S)
sage: U.Y() is T
True
```

rational_points(*F=None, bound=0*)

Return the set of rational points on this algebraic scheme over the field F.

EXAMPLES:

```
sage: A.<x, y> = AffineSpace(2, GF(7))
sage: S = A.subscheme([x^2-y])
sage: T = A.subscheme([x-y])
sage: U = T.complement(S)
sage: U.rational_points()
[(2, 4), (3, 2), (4, 2), (5, 4), (6, 1)]
sage: U.rational_points(GF(7^2, 'b'))
[(2, 4), (3, 2), (4, 2), (5, 4), (6, 1), (b, b + 4), (b + 1, 3*b + 5), (b + 2, 5*b + 1),
(b + 3, 6), (b + 4, 2*b + 6), (b + 5, 4*b + 1), (b + 6, 6*b + 5), (2*b, 4*b + 2),
(2*b + 1, b + 3), (2*b + 2, 5*b + 6), (2*b + 3, 2*b + 4), (2*b + 4, 6*b + 4),
(2*b + 5, 3*b + 6), (2*b + 6, 3), (3*b, 2*b + 1), (3*b + 1, b + 2), (3*b + 2, 5),
(3*b + 3, 6*b + 3), (3*b + 4, 5*b + 3), (3*b + 5, 4*b + 5), (3*b + 6, 3*b + 2),
(4*b, 2*b + 1), (4*b + 1, 3*b + 2), (4*b + 2, 4*b + 5), (4*b + 3, 5*b + 3),
(4*b + 4, 6*b + 3), (4*b + 5, 5), (4*b + 6, b + 2), (5*b, 4*b + 2), (5*b + 1, 3),
(5*b + 2, 3*b + 6), (5*b + 3, 6*b + 4), (5*b + 4, 2*b + 4), (5*b + 5, 5*b + 6),
(5*b + 6, b + 3), (6*b, b + 4), (6*b + 1, 6*b + 5), (6*b + 2, 4*b + 1), (6*b + 3, 2*b + 6),
(6*b + 4, 6), (6*b + 5, 5*b + 1), (6*b + 6, 3*b + 5)]
```

class AlgebraicScheme_subscheme(*A, polys*)

An algebraic scheme presented as a closed subscheme is defined by explicit polynomial equations. This is as opposed to a general scheme, which could, e.g., be the Neron model of some object, and for which we do not want to give explicit equations.

INPUT:

- `A` - ambient space (affine or projective n-space over a ring)
- `polys` - ideal or tuple of defining polynomials

base_extend(*R*)

Return the base change to the ring R of this scheme.

EXAMPLES:

```
sage: P.<x, y, z> = ProjectiveSpace(2, GF(11))
sage: S = P.subscheme([x^2-y*z])
sage: S.base_extend(GF(11^2, 'b'))
Closed subscheme of Projective Space of dimension 2 over Finite Field in b of size 11^2 defi
  x^2 - y*z
sage: S.base_extend(ZZ)
...
ValueError: No natural map from the base ring (=Finite Field of size 11) to S (=Integer Ring
```

complement(*other=None*)

Return the scheme-theoretic complement other - self, where self and other are both closed algebraic subschemes of the same ambient space.

If other is unspecified, it is taken to be the ambient space of self.

EXAMPLES:

```
sage: A.<x, y, z> = AffineSpace(3, ZZ)
sage: X = A.subscheme([x+y-z])
sage: Y = A.subscheme([x-y+z])
sage: Y.complement(X)
Quasi-affine scheme X - Y, where:
  X: Closed subscheme of Affine Space of dimension 3 over Integer Ring defined by:
  x + y - z
  Y: Closed subscheme of Affine Space of dimension 3 over Integer Ring defined by:
  x - y + z
sage: Y.complement()
Quasi-affine scheme X - Y, where:
  X: Closed subscheme of Affine Space of dimension 3 over Integer Ring defined by:
  (no equations)
  Y: Closed subscheme of Affine Space of dimension 3 over Integer Ring defined by:
  x - y + z

sage: P.<x, y, z> = ProjectiveSpace(2, QQ)
sage: X = P.subscheme([x^2+y^2+z^2])
sage: Y = P.subscheme([x*y+y*z+z*x])
sage: Y.complement(X)
Quasi-projective scheme X - Y, where:
  X: Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
  x^2 + y^2 + z^2
  Y: Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
  x*y + x*z + y*z
sage: Y.complement(P)
Quasi-projective scheme X - Y, where:
  X: Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
  (no equations)
  Y: Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
  x*y + x*z + y*z
```

defining_ideal()

Return the ideal that defines this scheme as a subscheme of its ambient space.

EXAMPLES:

```
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: S = P.subscheme([x^2-y*z, x^3+z^3])
sage: S.defining_ideal()
Ideal (x^2 - y*z, x^3 + z^3) of Multivariate Polynomial Ring in x, y, z over Integer Ring
```

defining_polynomials()

Return the polynomials that define this scheme as a subscheme of its ambient space.

EXAMPLES:

```
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: S = P.subscheme([x^2-y*z, x^3+z^3])
sage: S.defining_polynomials()
(x^2 - y*z, x^3 + z^3)
```

intersection(*other*)

Return the scheme-theoretic intersection of self and other in their common ambient space.

EXAMPLES:

```
sage: A.<x, y> = AffineSpace(2, ZZ)
sage: X = A.subscheme([x^2-y])
sage: Y = A.subscheme([y])
sage: X.intersection(Y)
Closed subscheme of Affine Space of dimension 2 over Integer Ring defined by:
  x^2 - y
  y
```

irreducible_components()

Return the irreducible components of this algebraic scheme, as subschemes of the same ambient space.

OUTPUT: an immutable sequence of irreducible subschemes of the ambient space of this scheme

The components are cached.

EXAMPLES:

We define what is clearly a union of four hypersurfaces in $\P^4_{\mathbf{Q}}$ then find the irreducible components.

```
sage: PP.<x,y,z,w,v> = ProjectiveSpace(4,QQ)
sage: V = PP.subscheme( (x^2 - y^2 - z^2)*(w^5 -  2*v^2*z^3)* w * (v^3 - x^2*z) )
sage: V.irreducible_components()
[
Closed subscheme of Projective Space of dimension 4 over Rational Field defined by:
w,
Closed subscheme of Projective Space of dimension 4 over Rational Field defined by:
x^2 - y^2 - z^2,
Closed subscheme of Projective Space of dimension 4 over Rational Field defined by:
x^2*z - v^3,
Closed subscheme of Projective Space of dimension 4 over Rational Field defined by:
w^5 - 2*z^3*v^2
]
```

rational_points(*F=None, bound=0*)

EXAMPLES:

One can enumerate points up to a given bound on a projective scheme over the rationals.

```
sage: E = EllipticCurve('37a')
sage: E.rational_points(bound=8)
[(0 : 0 : 1),
```

```
 (1 : 0 : 1),
 (-1 : 0 : 1),
 (0 : -1 : 1),
 (1 : -1 : 1),
 (-1 : -1 : 1),
 (2 : 2 : 1),
 (2 : -3 : 1),
 (1/4 : -3/8 : 1),
 (1/4 : -5/8 : 1),
 (0 : 1 : 0)]
```

For a small finite field, the complete set of points can be enumerated.

```
sage: Etilde = E.base_extend(GF(3))
sage: Etilde.rational_points()
[(0 : 0 : 1), (1 : 0 : 1), (2 : 0 : 1), (0 : 2 : 1), (1 : 2 : 1), (2 : 2 : 1), (0 : 1 : 0)]
```

The class of hyperelliptic curves does not (yet) support desingularization of the places at infinity into two points.

```
sage: FF = FiniteField(7)
sage: P.<x> = PolynomialRing(FiniteField(7))
sage: C = HyperellipticCurve(x^8+x+1)
sage: C.rational_points()
[(2 : 0 : 1), (4 : 0 : 1), (0 : 1 : 1), (6 : 1 : 1), (0 : 6 : 1), (6 : 6 : 1), (0 : 1 : 0)]
```

TODO:

1. The above algorithms enumerate all projective points and test whether they lie on the scheme; Implement a more naive sieve at least for covers of the projective line.
2. Implement Stoll's model in weighted projective space to resolve singularities and find two points (1 : 1 : 0) and (-1 : 1 : 0) at infinity.

reduce()

Return the corresponding reduced algebraic space associated to this scheme.

EXAMPLES: First we construct the union of a doubled and triplled line in the affine plane over $\mathbf{Q}$.

```
sage: A.<x,y> = AffineSpace(2, QQ)
sage: X = A.subscheme([(x-1)^2*(x-y)^3]); X
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
  x^5 - 3*x^4*y + 3*x^3*y^2 - x^2*y^3 - 2*x^4 + 6*x^3*y - 6*x^2*y^2 + 2*x*y^3 + x^3 - 3*x^2*
sage: X.dimension()
1
```

Then we compute the corresponding reduced scheme.

```
sage: Y = X.reduce(); Y
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
  x^2 - x*y - x + y
```

Finally, we verify that the reduced scheme Y is the union of those two lines.

```
sage: L1 = A.subscheme([x-1]); L1
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
  x - 1
sage: L2 = A.subscheme([x-y]); L2
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
  x - y
sage: W = L1.union(L2); W             # taken in ambient space
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
  x^2 - x*y - x + y
```

```
sage: Y == W
True
```

union(*other*)

Return the scheme-theoretic union of self and other in their common ambient space.

EXAMPLES: We construct the union of a line and a tripled-point on the line.

```
sage: A.<x,y> = AffineSpace(2, QQ)
sage: I = ideal([x,y])^3
sage: P = A.subscheme(I)
sage: L = A.subscheme([y-1])
sage: S = L.union(P); S
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
y^4 - y^3
x*y^3 - x*y^2
x^2*y^2 - x^2*y
x^3*y - x^3
sage: S.dimension()
1
sage: S.reduce()
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
y^2 - y
x*y - x
```

We can also use the notation "+" for the union:

```
sage: A.subscheme([x]) + A.subscheme([y^2 - (x^3+1)])
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
-x^4 + x*y^2 - x
```

Saving and loading:

```
sage: loads(S.dumps()) == S
True
```

class **AlgebraicScheme_subscheme_affine**(*A*, *polys*)

dimension()

EXAMPLES:

```
sage: A.<x,y> = AffineSpace(2, QQ)
sage: A.subscheme([]).dimension()
2
sage: A.subscheme([x]).dimension()
1
sage: A.subscheme([x^5]).dimension()
1
sage: A.subscheme([x^2 + y^2 - 1]).dimension()
1
sage: A.subscheme([x*(x-1), y*(y-1)]).dimension()
0
```

Something less obvious

```
sage: A.<x,y,z,w> = AffineSpace(4, QQ)
sage: X = A.subscheme([x^2, x^2*y^2 + z^2, z^2 - w^2, 10*x^2 + w^2 - z^2])
sage: X
Closed subscheme of Affine Space of dimension 4 over Rational Field defined by:
x^2
x^2*y^2 + z^2
```

```
z^2 - w^2
10*x^2 - z^2 + w^2
sage: X.dimension()
1
```

projective_embedding(*i=None, X=None*)

Returns a morphism from this affine scheme into an ambient projective space of the same dimension.

INPUT:

- `i` - integer (default: dimension of self = last coordinate) determines which projective embedding to compute. The embedding is that which has a 1 in the i-th coordinate, numbered from 0.
- `X` - (default: None) projective scheme, i.e., codomain of morphism; this is constructed if it is not given.

EXAMPLES:

```
sage: A.<x, y, z> = AffineSpace(3, ZZ)
sage: S = A.subscheme([x*y-z])
sage: S.projective_embedding()
Scheme morphism:
  From: Closed subscheme of Affine Space of dimension 3 over Integer Ring defined by:
  x*y - z
  To:   Closed subscheme of Projective Space of dimension 3 over Integer Ring defined by:
  x0*x1 - x2*x3
  Defn: Defined on coordinates by sending (x, y, z) to
        (x : y : z : 1)
```

class **AlgebraicScheme_subscheme_projective**(*A, polys*)

affine_patch(*i*)

Return the i^{th} affine patch of this projective scheme. This is the intersection with this i^{th} affine patch of its ambient space.

INPUT:

- `i` - integer between 0 and dimension of self, inclusive.

OUTPUT: an affine scheme with fixed projective_embedding map.

EXAMPLES:

```
sage: PP = ProjectiveSpace(2, QQ, names='X,Y,Z')
sage: X,Y,Z = PP.gens()
sage: C = PP.subscheme(X^3*Y + Y^3*Z + Z^3*X)
sage: U = C.affine_patch(0)
sage: U
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
x0^3*x1 + x1^3 + x0
sage: U.projective_embedding()
Scheme morphism:
  From: Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
  x0^3*x1 + x1^3 + x0
  To:   Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
  X^3*Y + Y^3*Z + X*Z^3
  Defn: Defined on coordinates by sending (x0, x1) to
        (1 : x0 : x1)
```

dimension()

EXAMPLES:

```
sage: A.<x,y> = AffineSpace(2, QQ)
sage: A.subscheme([]).dimension()
2
sage: A.subscheme([x]).dimension()
1
sage: A.subscheme([x^5]).dimension()
1
sage: A.subscheme([x^2 + y^2 - 1]).dimension()
1
sage: A.subscheme([x*(x-1), y*(y-1)]).dimension()
0
```

Something less obvious

```
sage: A.<x,y,z,w> = AffineSpace(4, QQ)
sage: X = A.subscheme([x^2, x^2*y^2 + z^2, z^2 - w^2, 10*x^2 + w^2 - z^2])
sage: X
Closed subscheme of Affine Space of dimension 4 over Rational Field defined by:
x^2
x^2*y^2 + z^2
z^2 - w^2
10*x^2 - z^2 + w^2
sage: X.dimension()
1
```

is_AlgebraicScheme(x)

Return True if x is an algebraic scheme, i.e., a subscheme of an ambient space over a ring defined by polynomial equations.

EXAMPLES: Affine space is itself not an algebraic scheme, though the closed subscheme defined by no equations is.

```
sage: from sage.schemes.generic.algebraic_scheme import is_AlgebraicScheme
sage: is_AlgebraicScheme(AffineSpace(10, QQ))
False
sage: V = AffineSpace(10, QQ).subscheme([]); V
Closed subscheme of Affine Space of dimension 10 over
Rational Field defined by:
  (no equations)
sage: is_AlgebraicScheme(V)
True
```

We create a more complicated closed subscheme.

```
sage: A, x = AffineSpace(10, QQ).objgens()
sage: X = A.subscheme([sum(x)]); X
Closed subscheme of Affine Space of dimension 10 over Rational Field defined by:
x0 + x1 + x2 + x3 + x4 + x5 + x6 + x7 + x8 + x9
sage: is_AlgebraicScheme(X)
True

sage: is_AlgebraicScheme(QQ)
False
sage: S = Spec(QQ)
sage: is_AlgebraicScheme(S)
False
```

37.10 Hypersurfaces in affine and projective space

AUTHORS:

- William Stein <wstein@gmail.com> (2005-12-08)
- David Kohel <kohel@maths.usyd.edu.au> (2005-12-08)
- Alex Ghitza <aghitza@alum.mit.edu> (2009-04-17)

class **AffineHypersurface** (*poly, ambient=None*)

The affine hypersurface defined by the given polynomial.

EXAMPLES:

```
sage: A.<x, y, z> = AffineSpace(ZZ, 3)
sage: AffineHypersurface(x*y-z^3, A)
Affine hypersurface defined by -z^3 + x*y in Affine Space of dimension 3 over Integer Ring
```

```
sage: A.<x, y, z> = QQ[]
sage: AffineHypersurface(x*y-z^3)
Affine hypersurface defined by -z^3 + x*y in Affine Space of dimension 3 over Rational Field
```

defining_polynomial ()

Return the polynomial equation that cuts out this affine hypersurface.

EXAMPLES:

```
sage: R.<x, y, z> = ZZ[]
sage: H = AffineHypersurface(x*z+y^2)
sage: H.defining_polynomial()
y^2 + x*z
```

class **ProjectiveHypersurface** (*poly, ambient=None*)

The projective hypersurface defined by the given polynomial.

EXAMPLES:

```
sage: P.<x, y, z> = ProjectiveSpace(ZZ, 2)
sage: ProjectiveHypersurface(x-y, P)
Projective hypersurface defined by x - y in Projective Space of dimension 2 over Integer Ring
```

```
sage: R.<x, y, z> = QQ[]
sage: ProjectiveHypersurface(x-y)
Projective hypersurface defined by x - y in Projective Space of dimension 2 over Rational Field
```

defining_polynomial ()

Return the polynomial equation that cuts out this projective hypersurface.

EXAMPLES:

```
sage: R.<x, y, z> = ZZ[]
sage: H = ProjectiveHypersurface(x*z+y^2)
sage: H.defining_polynomial()
y^2 + x*z
```

is_Hypersurface (*self*)

Return True if self is a hypersurface, i.e. an object of the type ProjectiveHypersurface or AffineHypersurface.

EXAMPLES:

```
sage: from sage.schemes.generic.hypersurface import is_Hypersurface
sage: R.<x, y, z> = ZZ[]
sage: H = ProjectiveHypersurface(x*z+y^2)
sage: is_Hypersurface(H)
True

sage: H = AffineHypersurface(x*z+y^2)
sage: is_Hypersurface(H)
True

sage: H = ProjectiveSpace(QQ, 5)
sage: is_Hypersurface(H)
False
```

37.11 Set of homomorphisms between two schemes

SchemeHomset(*R, S, cat=None, check=True*)

class **SchemeHomsetModule_abelian_variety_coordinates_field**(*X, S, cat=None, check=True*)

base_extend(*R*)

class **SchemeHomset_affine_coordinates**(*X, S*)
Set of points on X defined over the base ring of X, and given by explicit tuples.

points(*B=0*)

class **SchemeHomset_coordinates**(*X, S*)
Set of points on X defined over the base ring of X, and given by explicit tuples.

value_ring()
Returns S for a homset X(T) where T = Spec(S).

class **SchemeHomset_generic**(*X, Y, cat=None, check=True, base=Integer Ring*)

has_coerce_map_from_impl(*S*)

natural_map()

class **SchemeHomset_projective_coordinates_field**(*X, S*)
Set of points on X defined over the base ring of X, and given by explicit tuples.

points(*B=0*)

class **SchemeHomset_projective_coordinates_ring**(*X, S*)
Set of points on X defined over the base ring of X, and given by explicit tuples.

points(*B=0*)

class **SchemeHomset_spec**(*X, Y, cat=None, check=True, base=Integer Ring*)

enum_affine_finite_field(*X*)

enum_affine_rational_field(*X, B*)

enum_projective_finite_field(*X*)

enum_projective_rational_field(*X, B*)

is_SchemeHomset(*H*)

37.12 Scheme morphism

AUTHORS:

- David Kohel, William Stein
- William Stein (2006-02-11): fixed bug where P(0,0,0) was allowed as a projective point.

class PyMorphism(*parent*)

category()

codomain()

domain()

is_endomorphism()

class SchemeMorphism(*parent*)

A scheme morphism

glue_along_domains(*other*)

Assuming that self and other are open immersions with the same domain, return scheme obtained by gluing along the images.

EXAMPLES: We construct a scheme isomorphic to the projective line over $\mathrm{Spec}(\mathbf{Q})$ by gluing two copies of $\mathbb{A}^1$ minus a point.

```
sage: R.<x,y> = PolynomialRing(QQ, 2)
sage: S.<xbar, ybar> = R.quotient(x*y - 1)
sage: Rx = PolynomialRing(QQ, 'x')
sage: i1 = Rx.hom([xbar])
sage: Ry = PolynomialRing(QQ, 'y')
sage: i2 = Ry.hom([ybar])
sage: Sch = Schemes()
sage: f1 = Sch(i1)
sage: f2 = Sch(i2)
```

Now f1 and f2 have the same domain, which is a $\mathbb{A}^1$ minus a point. We glue along the domain:

```
sage: P1 = f1.glue_along_domains(f2)
sage: P1
Scheme obtained by gluing X and Y along U, where
  X: Spectrum of Univariate Polynomial Ring in x over Rational Field
  Y: Spectrum of Univariate Polynomial Ring in y over Rational Field
  U: Spectrum of Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the

sage: a, b = P1.gluing_maps()
sage: a
Affine Scheme morphism:
 From: Spectrum of Quotient of Multivariate Polynomial Ring in x, y over Rational Field by t
  To:   Spectrum of Univariate Polynomial Ring in x over Rational Field
  Defn: Ring morphism:
          From: Univariate Polynomial Ring in x over Rational Field
          To:   Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the
          Defn: x |--> xbar
sage: b
Affine Scheme morphism:
  From: Spectrum of Quotient of Multivariate Polynomial Ring in x, y over Rational Field by
  To:   Spectrum of Univariate Polynomial Ring in y over Rational Field
  Defn: Ring morphism:
```

```
From: Univariate Polynomial Ring in y over Rational Field
To:   Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the
Defn: y |--> ybar
```

class SchemeMorphism_abelian_variety_coordinates_field(*X, v, check=True*)

class SchemeMorphism_affine_coordinates(*X, v, check=True*)

A morphism determined by giving coordinates in a ring.

INPUT:

- X - a subscheme of an ambient affine space over a ring R.
- v - a list or tuple of coordinates in R

EXAMPLES:

```
sage: A = AffineSpace(2, QQ)
sage: A(1,2)
(1, 2)
```

class SchemeMorphism_coordinates(*parent*)

scheme()

class SchemeMorphism_id(*X*)

Return the identity morphism from X to itself.

EXAMPLES:

```
sage: X = Spec(ZZ)
sage: X.identity_morphism()
Scheme endomorphism of Spectrum of Integer Ring
  Defn: Identity map
```

class SchemeMorphism_on_points(*parent*)

A morphism of schemes determined by rational functions that define what the morphism does on points in the ambient space.

EXAMPLES: An example involving the affine plane:

```
sage: R.<x,y> = QQ[]
sage: A2 = AffineSpace(R)
sage: H = A2.Hom(A2)
sage: f = H([x-y, x*y])
sage: f([0,1])
(-1, 0)
```

An example involving the projective line:

```
sage: R.<x,y> = QQ[]
sage: P1 = ProjectiveSpace(R)
sage: H = P1.Hom(P1)
sage: f = H([x^2+y^2,x*y])
sage: f([0,1])
(1 : 0)
```

class SchemeMorphism_on_points_affine_space(*parent, polys, check=True*)

A morphism of schemes determined by rational functions that define what the morphism does on points in the ambient affine space.

defining_polynomials()

class SchemeMorphism_on_points_projective_space(*parent, polys, check=True*)
A morphism of schemes determined by rational functions that define what the morphism does on points in the ambient projective space.

defining_polynomials()

class SchemeMorphism_projective_coordinates_field(*X, v, check=True*)
A morphism determined by giving coordinates in a field.

INPUT:

- X - a subscheme of an ambient projective space over a field K
- v - a list or tuple of coordinates in K

EXAMPLES:

```
sage: P = ProjectiveSpace(3, RR)
sage: P(2,3,4,5)
(0.400000000000000 : 0.600000000000000 : 0.800000000000000 : 1.00000000000000)

sage: P = ProjectiveSpace(3, QQ)
sage: P(0,0,0,0)
...
ValueError: [0, 0, 0, 0] does not define a valid point since all entries are 0
```

class SchemeMorphism_projective_coordinates_ring(*X, v, check=True*)
A morphism determined by giving coordinates in a ring (how?).

class SchemeMorphism_spec(*parent, phi, check=True*)
A morphism of spectrums of rings

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: phi = R.hom([QQ(7)]); phi
Ring morphism:
  From: Univariate Polynomial Ring in x over Rational Field
  To:   Rational Field
  Defn: x |--> 7

sage: X = Spec(QQ); Y = Spec(R)
sage: f = X.hom(phi); f
Affine Scheme morphism:
  From: Spectrum of Rational Field
  To:   Spectrum of Univariate Polynomial Ring in x over Rational Field
  Defn: Ring morphism:
          From: Univariate Polynomial Ring in x over Rational Field
          To:   Rational Field
          Defn: x |--> 7

sage: f.ring_homomorphism()
Ring morphism:
  From: Univariate Polynomial Ring in x over Rational Field
  To:   Rational Field
  Defn: x |--> 7
```

ring_homomorphism()

class SchemeMorphism_structure_map(*parent*)

is_SchemeMorphism(*f*)

37.13 Divisors on schemes

AUTHORS:

- William Stein
- David Kohel
- David Joyner

EXAMPLES:

```
sage: x,y,z = ProjectiveSpace(2, GF(5), names='x,y,z').gens()
sage: C = Curve(y^2*z^7 - x^9 - x*z^8)
sage: pts = C.rational_points(); pts
[(0 : 0 : 1), (0 : 1 : 0), (2 : 2 : 1), (2 : 3 : 1), (3 : 1 : 1), (3 : 4 : 1)]
sage: D1 = C.divisor(pts[0])*3
sage: D2 = C.divisor(pts[1])
sage: D3 = 10*C.divisor(pts[5])
sage: D1.parent() is D2.parent()
True
sage: D = D1 - D2 + D3; D
-(x, z) + 3*(x, y) + 10*(x + 2*z, y + z)
sage: D[1][0]
3
sage: D[1][1]
Ideal (x, y) of Multivariate Polynomial Ring in x, y, z over Finite Field of size 5
sage: C.divisor([(3, pts[0]), (-1, pts[1]), (10,pts[5])])
-(x, z) + 3*(x, y) + 10*(x + 2*z, y + z)
```

CurvePointToIdeal(*C, P*)

class Divisor_curve(*v, check=True, reduce=True, parent=None*)

For any curve C, use `C.divisor(v)` to construct a divisor on C. Here v can be either

- a rational point on C
- a list of rational points
- a list of 2-tuples (c, P), where c is an integer and P is a rational point.

TODO: Divisors shouldn't be restricted to rational points. The problem is that the divisor group is the formal sum of the group of points on the curve, and there's no implemented notion of point on E/K that has coordinates in L. This is what should be implemented, by adding an appropriate class to `schemes/generic/morphism.py`.

EXAMPLES:

```
sage: E = EllipticCurve([0, 0, 1, -1, 0])
sage: P = E(0,0)
sage: 10*P
(161/16 : -2065/64 : 1)
sage: D = E.divisor(P)
sage: D
```

```
(x, y)
sage: 10*D
10*(x, y)
sage: E.divisor([P, P])
2*(x, y)
sage: E.divisor([(3,P), (-4,5*P)])
3*(x, y) - 4*(x - 1/4*z, y + 5/8*z)
```

coeff(*P*)

Return the coefficient of a given point P in this divisor.

EXAMPLES:

```
sage: x,y = AffineSpace(2, GF(5), names='xy').gens()
sage: C = Curve(y^2 - x^9 - x)
sage: pts = C.rational_points(); pts
[(0, 0), (2, 2), (2, 3), (3, 1), (3, 4)]
sage: D = C.divisor(pts[0])
sage: D.coeff(pts[0])
1
sage: D = C.divisor([(3,pts[0]), (-1,pts[1])]); D
3*(x, y) - (x - 2, y - 2)
sage: D.coeff(pts[0])
3
sage: D.coeff(pts[1])
-1
```

support()

Return the support of this divisor, which is the set of points that occur in this divisor with nonzero coefficients.

EXAMPLES:

```
sage: x,y = AffineSpace(2, GF(5), names='xy').gens()
sage: C = Curve(y^2 - x^9 - x)
sage: pts = C.rational_points(); pts
[(0, 0), (2, 2), (2, 3), (3, 1), (3, 4)]
sage: D = C.divisor([(3,pts[0]), (-1, pts[1])]); D
3*(x, y) - (x - 2, y - 2)
sage: D.support()
[(0, 0), (2, 2)]
```

class Divisor_generic(*v, check=True, reduce=True, parent=None*)

scheme()

Return the scheme that this divisor is on.

EXAMPLES:

```
sage: A.<x, y> = AffineSpace(2, GF(5))
sage: C = Curve(y^2 - x^9 - x)
sage: pts = C.rational_points(); pts
[(0, 0), (2, 2), (2, 3), (3, 1), (3, 4)]
sage: D = C.divisor(pts[0])*3 - C.divisor(pts[1]); D
3*(x, y) - (x - 2, y - 2)
sage: D.scheme()
Affine Curve over Finite Field of size 5 defined by -x^9 + y^2 - x
```

is_Divisor(*Div*)

is_DivisorGroup(*Div*)

CHAPTER

THIRTYEIGHT

ELLIPTIC AND PLANE CURVES

38.1 Plane curve constructors

AUTHORS:

- William Stein (2005-11-13)
- David Kohel (2006-01)

Curve(*F*)

Return the plane or space curve defined by F, where F can be either a multivariate polynomial, a list or tuple of polynomials, or an algebraic scheme.

If F is in two variables the curve is affine, and if it is homogenous in 3 variables, then the curve is projective.

EXAMPLE: A projective plane curve

```
sage: x,y,z = QQ['x,y,z'].gens()
sage: C = Curve(x^3 + y^3 + z^3); C
Projective Curve over Rational Field defined by x^3 + y^3 + z^3
sage: C.genus()
1
```

EXAMPLE: Affine plane curves

```
sage: x,y = GF(7)['x,y'].gens()
sage: C = Curve(y^2 + x^3 + x^10); C
Affine Curve over Finite Field of size 7 defined by x^10 + x^3 + y^2
sage: C.genus()
0
sage: x, y = QQ['x,y'].gens()
sage: Curve(x^3 + y^3 + 1)
Affine Curve over Rational Field defined by x^3 + y^3 + 1
```

EXAMPLE: A projective space curve

```
sage: x,y,z,w = QQ['x,y,z,w'].gens()
sage: C = Curve([x^3 + y^3 - z^3 - w^3, x^5 - y*z^4]); C
Projective Space Curve over Rational Field defined by x^3 + y^3 - z^3 - w^3
sage: C.genus()
13
```

EXAMPLE: An affine space curve

```
sage: x,y,z = QQ['x,y,z'].gens()
sage: C = Curve([y^2 + x^3 + x^10 + z^7,  x^2 + y^2]); C
Affine Space Curve over Rational Field defined by x^10 + z^7 + x^3 + y^2
sage: C.genus()
47
```

EXAMPLE: We can also make non-reduced non-irreducible curves.

```
sage: x,y,z = QQ['x,y,z'].gens()
sage: Curve((x-y)*(x+y))
Projective Curve over Rational Field defined by x^2 - y^2
sage: Curve((x-y)^2*(x+y)^2)
Projective Curve over Rational Field defined by x^4 - 2*x^2*y^2 + y^4
```

EXAMPLE: A union of curves is a curve.

```
sage: x,y,z = QQ['x,y,z'].gens()
sage: C = Curve(x^3 + y^3 + z^3)
sage: D = Curve(x^4 + y^4 + z^4)
sage: C.union(D)
Projective Curve over Rational Field defined by
x^7 + x^4*y^3 + x^3*y^4 + y^7 + x^4*z^3 + y^4*z^3 + x^3*z^4 + y^3*z^4 + z^7
```

The intersection is not a curve, though it is a scheme.

```
sage: X = C.intersection(D); X
Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
 x^3 + y^3 + z^3
 x^4 + y^4 + z^4
```

Note that the intersection has dimension 0.

```
sage: X.dimension()
0
sage: I = X.defining_ideal(); I
Ideal (x^3 + y^3 + z^3, x^4 + y^4 + z^4) of Multivariate Polynomial Ring in x, y, z over Rationa
```

EXAMPLE: In three variables, the defining equation must be homogeneous.

If the parent polynomial ring is in three variables, then the defining ideal must be homogeneous.

```
sage: x,y,z = QQ['x,y,z'].gens()
sage: Curve(x^2+y^2)
Projective Curve over Rational Field defined by x^2 + y^2
sage: Curve(x^2+y^2+z)
...
TypeError: The polynomial(s) x^2 + y^2 + z must be homogeneous
```

The defining polynomial must always be nonzero:

```
sage: P1.<x,y> = ProjectiveSpace(1,GF(5))
sage: Curve(0*x)
...
ValueError: defining polynomial of curve must be nonzero
```

38.2 Affine plane curves over a general ring

AUTHORS:

- William Stein (2005-11-13)
- David Joyner (2005-11-13)
- David Kohel (2006-01)

class AffineCurve_finite_field(*A, f*)

rational_points(*algorithm='enum'*)

Return sorted list of all rational points on this curve.

Use *very* naive point enumeration to find all rational points on this curve over a finite field.

EXAMPLE:

```
sage: A, (x,y) = AffineSpace(2,GF(9,'a')).objgens()
sage: C = Curve(x^2 + y^2 - 1)
sage: C
Affine Curve over Finite Field in a of size 3^2 defined by x0^2 + x1^2 - 1
sage: C.rational_points()
[(0, 1), (0, 2), (1, 0), (2, 0), (a + 1, a + 1), (a + 1, 2*a + 2), (2*a + 2, a + 1), (2*a +
```

class AffineCurve_generic(*A, f*)

divisor_of_function(*r*)

Return the divisor of a function on a curve.

INPUT: r is a rational function on X

OUTPUT:

•`list` - The divisor of r represented as a list of coefficients and points. (TODO: This will change to a more structural output in the future.)

EXAMPLES:

```
sage: F = GF(5)
sage: P2 = AffineSpace(2, F, names = 'xy')
sage: R = P2.coordinate_ring()
sage: x, y = R.gens()
sage: f = y^2 - x^9 - x
sage: C = Curve(f)
sage: K = FractionField(R)
sage: r = 1/x
sage: C.divisor_of_function(r)      # todo: not implemented (broken)
      [[-1, (0, 0, 1)]]
sage: r = 1/x^3
sage: C.divisor_of_function(r)      # todo: not implemented (broken)
      [[-3, (0, 0, 1)]]
```

local_coordinates(*pt, n*)

Return local coordinates to precision n at the given point.

Behaviour is flakey - some choices of n are worst that others.

INPUT:

•`pt` - an F-rational point on X which is not a point of ramification for the projection (x,y) - x.

•`n` - the number of terms desired

OUTPUT: x = x0 + t y = y0 + power series in t

EXAMPLES:

```
sage: F = GF(5)
sage: pt = (2,3)
sage: R = PolynomialRing(F,2, names = ['x','y'])
sage: x,y = R.gens()
sage: f = y^2-x^9-x
sage: C = Curve(f)
sage: C.local_coordinates(pt, 9)
[t + 2, -2*t^12 - 2*t^11 + 2*t^9 + t^8 - 2*t^7 - 2*t^6 - 2*t^4 + t^3 - 2*t^2 - 2]
```

plot(**args, **kwds*)

Plot the real points on this affine plane curve.

INPUT:

- `self` - an affine plane curve
- `*args` - optional tuples (variable, minimum, maximum) for plotting dimensions
- `**kwds` - optional keyword arguments passed on to `implicit_plot`

EXAMPLES:

A cuspidal curve:

```
sage: R.<x, y> = QQ[]
sage: C = Curve(x^3 - y^2)
sage: C.plot()
```

A 5-nodal curve of degree 11. This example also illustrates some of the optional arguments:

```
sage: R.<x, y> = ZZ[]
sage: C = Curve(32*x^2 - 2097152*y^11 + 1441792*y^9 - 360448*y^7 + 39424*y^5 - 1760*y^3 + 22
sage: C.plot((x, -1, 1), (y, -1, 1), plot_points=400)
```

A line over $\mathbf{RR}$:

```
sage: R.<x, y> = RR[]
sage: C = Curve(R(y - sqrt(2)*x))
sage: C.plot()
```

class **AffineCurve_prime_finite_field**(*A, f*)

rational_points(*algorithm='enum'*)

Return sorted list of all rational points on this curve.

INPUT:

- `algorithm` - string:
- `'enum'` - straightforward enumeration
- `'bn'` - via Singular's Brill-Noether package.
- `'all'` - use all implemented algorithms and verify that they give the same answer, then return it

Note: The Brill-Noether package does not always work. When it fails a RuntimeError exception is raised.

EXAMPLE:

```
sage: x, y = (GF(5)['x,y']).gens()
sage: f = y^2 - x^9 - x
sage: C = Curve(f); C
Affine Curve over Finite Field of size 5 defined by -x^9 + y^2 - x
sage: C.rational_points(algorithm='bn')
[(0, 0), (2, 2), (2, 3), (3, 1), (3, 4)]
```

```
sage: C = Curve(x - y + 1)
sage: C.rational_points()
[(0, 1), (1, 2), (2, 3), (3, 4), (4, 0)]
```

The following seems to run fine on Linux but *crashes* on OS X intel:

```
sage: x, y = (GF(17)['x,y']).gens()
sage: C = Curve(x^2 + y^5 + x*y - 19)
sage: v = C.rational_points(algorithm='bn')       # not tested
sage: w = C.rational_points(algorithm='enum')     # not tested
sage: len(v)                                      # not tested
20
sage: v == w                                      # not tested
True
```

riemann_roch_basis(*D*)

Interfaces with Singular's BrillNoether command.

INPUT:

- `self` - a plane curve defined by a polynomial eqn f(x,y) = 0 over a prime finite field F = GF(p) in 2 variables x,y representing a curve X: f(x,y) = 0 having n F-rational points (see the Sage function places_on_curve)
- `D` - an n-tuple of integers $(d1, ..., dn)$ representing the divisor $Div = d1 * P1 + ... + dn * Pn$, where $X(F) = \{P1, ..., Pn\}$. *The ordering is that dictated by places_on_curve.*

OUTPUT: basis of L(Div)

EXAMPLE:

```
sage: R = PolynomialRing(GF(5),2,names = ["x","y"])
sage: x, y = R.gens()
sage: f = y^2 - x^9 - x
sage: C = Curve(f)
sage: D = [6,0,0,0,0,0]
sage: C.riemann_roch_basis(D)
[1, (y^2*z^4 - x*z^5)/x^6, (y^2*z^5 - x*z^6)/x^7, (y^2*z^6 - x*z^7)/x^8]
```

class **AffineSpaceCurve_generic**(*A, X*)

38.3 Projective plane curves over a general ring

AUTHORS:

- William Stein (2005-11-13)
- David Joyner (2005-11-13)
- David Kohel (2006-01)

Hasse_bounds(*q, genus=1*)

Return the Hasse-Weil bounds for the cardinality of a nonsingular curve defined over $\mathbf{F}_q$ of given `genus`.

INPUT:

- `q` (int) – a prime power
- `genus` (int, default 1) – a non-negative integer,

OUTPUT:

(tuple) The Hasse bounds (lb,ub) for the cardinality of a curve of genus `genus` defined over $\mathbf{F}_q$.

EXAMPLES:

```
sage: Hasse_bounds(2)
(1, 5)
sage: Hasse_bounds(next_prime(10^30))
(999999999999998000000000000058, 1000000000000002000000000000058)
```

class `ProjectiveCurve_finite_field`(*A, f*)

`rational_points`(*algorithm='enum', sort=True*)

Return the rational points on this curve computed via enumeration.

Note: This is a slow Python-level implementation.

class `ProjectiveCurve_generic`(*A, f*)

`arithmetic_genus`()

Return the arithmetic genus of this curve.

This is the arithmetic genus $g_a(C)$ as defined in Hartshorne. If the curve has degree d then this is simply $(d-1)(d-2)/2$. It need *not* equal the geometric genus (the genus of the normalization of the curve).

EXAMPLE:

```
sage: x,y,z = PolynomialRing(GF(5), 3, 'xyz').gens()
sage: C = Curve(y^2*z^7 - x^9 - x*z^8); C
Projective Curve over Finite Field of size 5 defined by -x^9 + y^2*z^7 - x*z^8
sage: C.arithmetic_genus()
28
sage: C.genus()
4
```

`divisor_of_function`(*r*)

Return the divisor of a function on a curve.

INPUT: r is a rational function on X

OUTPUT:

- `list` - The divisor of r represented as a list of coefficients and points. (TODO: This will change to a more structural output in the future.)

EXAMPLES:

```
sage: FF = FiniteField(5)
sage: P2 = ProjectiveSpace(2, FF, names = ['x','y','z'])
sage: R = P2.coordinate_ring()
sage: x, y, z = R.gens()
sage: f = y^2*z^7 - x^9 - x*z^8
sage: C = Curve(f)
sage: K = FractionField(R)
sage: r = 1/x
sage: C.divisor_of_function(r)      # todo: not implemented  !!!!
[[-1, (0, 0, 1)]]
sage: r = 1/x^3
sage: C.divisor_of_function(r)      # todo: not implemented  !!!!
[[-3, (0, 0, 1)]]
```

`local_coordinates`(*pt, n*)

Return local coordinates to precision n at the given point.

Behaviour is flakey - some choices of n are worst that others.

INPUT:

- `pt` - an F-rational point on X which is not a point of ramification for the projection (x,y) - x.
- `n` - the number of terms desired

OUTPUT: x = x0 + t y = y0 + power series in t

EXAMPLES:

```
sage: FF = FiniteField(5)
sage: P2 = ProjectiveSpace(2, FF, names = ['x','y','z'])
sage: x, y, z = P2.coordinate_ring().gens()
sage: C = Curve(y^2*z^7-x^9-x*z^8)
sage: pt = C([2,3,1])
sage: C.local_coordinates(pt,9)      # todo: not implemented  !!!!
      [2 + t, 3 + 3*t^2 + t^3 + 3*t^4 + 3*t^6 + 3*t^7 + t^8 + 2*t^9 + 3*t^11 + 3*t^12]
```

plot(**args, **kwds*)

Plot the real points of an affine patch of this projective plane curve.

INPUT:

- `self` - an affine plane curve
- `patch` - (optional) the affine patch to be plotted; if not specified, the patch corresponding to the last projective coordinate being nonzero
- `*args` - optional tuples (variable, minimum, maximum) for plotting dimensions
- `**kwds` - optional keyword arguments passed on to `implicit_plot`

EXAMPLES:

A cuspidal curve:

```
sage: R.<x, y, z> = QQ[]
sage: C = Curve(x^3 - y^2*z)
sage: C.plot()
```

The other affine patches of the same curve:

```
sage: C.plot(patch=0)
sage: C.plot(patch=1)
```

An elliptic curve:

```
sage: E = EllipticCurve('101a')
sage: C = Curve(E)
sage: C.plot()
sage: C.plot(patch=0)
sage: C.plot(patch=1)
```

A hyperelliptic curve:

```
sage: P.<x> = QQ[]
sage: f = 4*x^5 - 30*x^3 + 45*x - 22
sage: C = HyperellipticCurve(f)
sage: C.plot()
sage: C.plot(patch=0)
sage: C.plot(patch=1)
```

class **ProjectiveCurve_prime_finite_field**(*A, f*)

rational_points(*algorithm='enum', sort=True*)

INPUT:

- `algorithm` - string:

- 'enum' - straightforward enumeration
- 'bn' - via Singular's brnoeth package.

EXAMPLE:

```
sage: x, y, z = PolynomialRing(GF(5), 3, 'xyz').gens()
sage: f = y^2*z^7 - x^9 - x*z^8
sage: C = Curve(f); C
Projective Curve over Finite Field of size 5 defined by -x^9 + y^2*z^7 - x*z^8
sage: C.rational_points()
[(0 : 0 : 1), (0 : 1 : 0), (2 : 2 : 1), (2 : 3 : 1), (3 : 1 : 1), (3 : 4 : 1)]
sage: C = Curve(x - y + z)
sage: C.rational_points()
[(0 : 1 : 1), (1 : 1 : 0), (1 : 2 : 1), (2 : 3 : 1), (3 : 4 : 1), (4 : 0 : 1)]
```

Note: The Brill-Noether package does not always work (i.e., the 'bn' algorithm. When it fails a RuntimeError exception is raised.

riemann_roch_basis(*D*)

Return a basis for the Riemann-Roch space corresponding to D.

Warning: This function calls a Singular function that appears to be very buggy and should not be trusted.

This uses Singular's Brill-Noether implementation.

INPUT:

- sort - bool (default: True), if True return the point list sorted. If False, returns the pointes in the order computed by Singular.

EXAMPLE:

```
sage: R.<x,y,z> = GF(2)[]
sage: f = x^3*y + y^3*z + x*z^3
sage: C = Curve(f); pts = C.rational_points()
sage: D = C.divisor([ (4, pts[0]), (0,pts[1]), (4, pts[2]) ])
sage: C.riemann_roch_basis(D)
[x/y, 1, z/y, z^2/y^2, z/x, z^2/(x*y)]
```

The following example illustrates that the Riemann-Roch space function in Singular doesn't *not* work correctly.

```
sage: R.<x,y,z> = GF(5)[]
sage: f = x^7 + y^7 + z^7
sage: C = Curve(f); pts = C.rational_points()
sage: D = C.divisor([ (3, pts[0]), (-1,pts[1]), (10, pts[5]) ])
sage: C.riemann_roch_basis(D)     # output is random (!!!!)
[x/(y + x), (z + y)/(y + x)]
```

The answer has dimension 2 (confirmed via Magma). But it varies between 1 and quite large with Singular.

class ProjectiveSpaceCurve_generic(*A, X*)

38.4 Elliptic curve constructor

AUTHORS:

- William Stein (2005): Initial version
- John Cremona (2008-01): EllipticCurve(j) fixed for all cases

EllipticCurve (*x=None, y=None, j=None*)

There are several ways to construct an elliptic curve:

$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6.$$

- EllipticCurve([a1,a2,a3,a4,a6]): Elliptic curve with given a-invariants. The invariants are coerced into the parent of the first element. If all are integers, they are coerced into the rational numbers.
- EllipticCurve([a4,a6]): Same as above, but a1=a2=a3=0.
- EllipticCurve(label): Returns the elliptic curve over Q from the Cremona database with the given label. The label is a string, such as "11a" or "37b2". The letters in the label *must* be lower case (Cremona's new labeling).
- EllipticCurve(R, [a1,a2,a3,a4,a6]): Create the elliptic curve over R with given a-invariants. Here R can be an arbitrary ring. Note that addition need not be defined.
- EllipticCurve(j): Return an elliptic curve with j-invariant j. Warning: this is deprecated. Use `EllipticCurve_from_j(j)` or `EllipticCurve(j=j)` instead.

EXAMPLES: We illustrate creating elliptic curves.

```
sage: EllipticCurve([0,0,1,-1,0])
Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field
```

We create a curve from a Cremona label:

```
sage: EllipticCurve('37b2')
Elliptic Curve defined by y^2 + y = x^3 + x^2 - 1873*x - 31833 over Rational Field
sage: EllipticCurve('5077a')
Elliptic Curve defined by y^2 + y = x^3 - 7*x + 6 over Rational Field
sage: EllipticCurve('389a')
Elliptic Curve defined by y^2 + y = x^3 + x^2 - 2*x over Rational Field
```

We create curves over a finite field as follows:

```
sage: EllipticCurve([GF(5)(0),0,1,-1,0])
Elliptic Curve defined by y^2 + y = x^3 + 4*x over Finite Field of size 5
sage: EllipticCurve(GF(5), [0, 0,1,-1,0])
Elliptic Curve defined by y^2 + y = x^3 + 4*x over Finite Field of size 5
```

Elliptic curves over $\mathbf{Z}/N\mathbf{Z}$ with N prime are of type "elliptic curve over a finite field":

```
sage: F = Zmod(101)
sage: EllipticCurve(F, [2, 3])
Elliptic Curve defined by y^2 = x^3 + 2*x + 3 over Ring of integers modulo 101
sage: E = EllipticCurve([F(2), F(3)])
sage: type(E)
<class 'sage.schemes.elliptic_curves.ell_finite_field.EllipticCurve_finite_field'>
```

In contrast, elliptic curves over $\mathbf{Z}/N\mathbf{Z}$ with N composite are of type "generic elliptic curve":

```
sage: F = Zmod(95)
sage: EllipticCurve(F, [2, 3])
Elliptic Curve defined by y^2 = x^3 + 2*x + 3 over Ring of integers modulo 95
sage: E = EllipticCurve([F(2), F(3)])
sage: type(E)
<class 'sage.schemes.elliptic_curves.ell_generic.EllipticCurve_generic'>
```

The following is a curve over the complex numbers:

```
sage: E = EllipticCurve(CC, [0,0,1,-1,0])
sage: E
Elliptic Curve defined by y^2 + 1.00000000000000*y = x^3 + (-1.00000000000000)*x over Complex Fi
sage: E.j_invariant()
2988.97297297297
```

We can also create elliptic curves by giving the Weierstrass equation:

```
sage: x, y = var('x,y')
sage: EllipticCurve(y^2 + y ==  x^3 + x - 9)
Elliptic Curve defined by y^2 + y = x^3 + x - 9 over Rational Field

sage: R.<x,y> = GF(5)[]
sage: EllipticCurve(x^3 + x^2 + 2 - y^2 - y*x)
Elliptic Curve defined by y^2 + x*y  = x^3 + x^2 + 2 over Finite Field of size 5
```

We can explicitly specify the j-invariant:

```
sage: E = EllipticCurve(j=1728); E; E.j_invariant(); E.label()
Elliptic Curve defined by y^2 = x^3 - x over Rational Field
1728
'32a2'

sage: E = EllipticCurve(j=GF(5)(2)); E; E.j_invariant()
Elliptic Curve defined by y^2 = x^3 + x + 1 over Finite Field of size 5
2
```

TESTS:

```
sage: R = ZZ['u', 'v']
sage: EllipticCurve(R, [1,1])
Elliptic Curve defined by y^2 = x^3 + x + 1 over Multivariate Polynomial Ring in u, v
over Integer Ring
```

We create a curve and a point over QQbar:

```
sage: E = EllipticCurve(QQbar,[0,1])
sage: E(0)
(0 : 1 : 0)
```

EllipticCurve_from_c4c6(*c4, c6*)

Return an elliptic curve with given c_4 and c_6 invariants.

EXAMPLES:

```
sage: E = EllipticCurve_from_c4c6(17, -2005)
sage: E
Elliptic Curve defined by y^2  = x^3 - 17/48*x + 2005/864 over Rational Field
sage: E.c_invariants()
(17, -2005)
```

EllipticCurve_from_cubic(*F, P*)

Given a nonsingular homogenous cubic polynomial F over $\mathbf{Q}$ in three variables x, y, z and a projective solution P=[a,b,c] to F(P)=0, find the minimal Weierstrass equation of the elliptic curve over $\mathbf{Q}$ that is isomorphic to the curve defined by $F = 0$.

Note: USES MAGMA - This function will not work on computers that do not have magma installed. (HELP WANTED - somebody implement this independent of MAGMA.)

EXAMPLES: First we find that the Fermat cubic is isomorphic to the curve with Cremona label 27a1:

```
sage: E = EllipticCurve_from_cubic('x^3 + y^3 + z^3', [1,-1,0])  # optional - magma
sage: E         # optional - magma
Elliptic Curve defined by y^2 + y = x^3 - 7 over Rational Field
sage: E.cremona_label()     # optional - magma
'27a1'
```

Next we find the minimal model and conductor of the Jacobian of the Selmer curve.

```
sage: E = EllipticCurve_from_cubic('x^3 + y^3 + 60*z^3', [1,-1,0])   # optional - magma
sage: E                # optional - magma
Elliptic Curve defined by y^2  = x^3 - 24300 over Rational Field
sage: E.conductor()    # optional - magma
24300
```

EllipticCurve_from_j(*j*)

Return an elliptic curve with given j-invariant.

EXAMPLES:

```
sage: E = EllipticCurve_from_j(0); E; E.j_invariant(); E.label()
Elliptic Curve defined by y^2 + y = x^3 over Rational Field
0
'27a3'

sage: E = EllipticCurve_from_j(1728); E; E.j_invariant(); E.label()
Elliptic Curve defined by y^2 = x^3 - x over Rational Field
1728
'32a2'

sage: E = EllipticCurve_from_j(1); E; E.j_invariant()
Elliptic Curve defined by y^2 + x*y = x^3 + 36*x + 3455 over Rational Field
1
```

EllipticCurves_with_good_reduction_outside_S(*S=, [], proof=None, verbose=False*)

Returns a sorted list of all elliptic curves defined over Q with good reduction outside the set S of primes.

INPUT:

- `S` - list of primes (default: empty list).
- `proof` - True/False (default True): the MW basis for auxiliary curves will be computed with this proof flag.
- `verbose` - True/False (default False): if True, some details of the computation will be output.

Note: Proof flag: The algorithm used requires determining all S-integral points on several auxiliary curves, which in turn requires the computation of their generators. This is not always possible (even in theory) using current knowledge.

The value of this flag is passed to the function which computes generators of various auxiliary elliptic curves, in order to find their S-integral points. Set to False if the default (True) causes warning messages, but note that you can then not rely on the set of curves returned being complete.

EXAMPLES:

```
sage: EllipticCurves_with_good_reduction_outside_S([])
[]
sage: elist = EllipticCurves_with_good_reduction_outside_S([2])
sage: elist
[Elliptic Curve defined by y^2 = x^3 + 4*x over Rational Field,
Elliptic Curve defined by y^2 = x^3 - x over Rational Field,
```

```
...
Elliptic Curve defined by y^2 = x^3 - x^2 - 13*x + 21 over Rational Field]
sage: len(elist)
24
sage: ', '.join([e.label() for e in elist])
'32a1, 32a2, 32a3, 32a4, 64a1, 64a2, 64a3, 64a4, 128a1, 128a2, 128b1, 128b2, 128c1, 128c2, 128d1
```

 # Without the "Proof=False", this example gives two warnings: sage: elist = EllipticCurves_with_good_reduction_outside_S([11],proof=False) sage: len(elist) 12 sage: ', '.join([e.label() for e in elist]) '11a1, 11a2, 11a3, 121a1, 121a2, 121b1, 121b2, 121c1, 121c2, 121d1, 121d2, 121d3'

sage: elist = EllipticCurves_with_good_reduction_outside_S([2,3]) # long time (~35s) sage: len(elist) # long time 752 sage: max([e.conductor() for e in elist]) # long time 62208 sage: [N.factor() for N in Set([e.conductor() for e in elist])] # long time [2^7, 2^8, 2^3 * 3^4, 2^2 * 3^3, 2^8 * 3^4, 2^4 * 3^4, 2^3 * 3, 2^7 * 3, 2^3 * 3^5, 3^3, 2^8 * 3, 2^5 * 3^4, 2^4 * 3, 2 * 3^4, 2^2 * 3^2, 2^6 * 3^4, 2^6, 2^7 * 3^2, 2^4 * 3^5, 2^4 * 3^3, 2 * 3^3, 2^6 * 3^3, 2^6 * 3, 2^5, 2^2 * 3^4, 2^3 * 3^2, 2^5 * 3, 2^7 * 3^4, 2^2 * 3^5, 2^8 * 3^2, 2^5 * 3^2, 2^7 * 3^5, 2^8 * 3^5, 2^3 * 3^3, 2^8 * 3^3, 2^5 * 3^5, 2^4 * 3^2, 2 * 3^5, 2^5 * 3^3, 2^6 * 3^5, 2^7 * 3^3, 3^5, 2^6 * 3^2]

38.5 Elliptic curves over a general ring.

Elliptic curves are always represented by 'Weierstrass Models' with five coefficients $[a_1, a_2, a_3, a_4, a_6]$ in standard notation. In Magma, 'Weierstrass Model' means a model with a1=a2=a3=0, which is called 'Short Weierstrass Model' in Sage; these only exist in characteristics other than 2 and 3.

EXAMPLES:

We construct an elliptic curve over an elaborate base ring:

```
sage: p = 97; a=1; b=3
sage: R, u = PolynomialRing(GF(p), 'u').objgen()
sage: S, v = PolynomialRing(R, 'v').objgen()
sage: T = S.fraction_field()
sage: E = EllipticCurve(T, [a, b]); E
Elliptic Curve defined by y^2  = x^3 + x + 3 over Fraction Field of Univariate Polynomial Ring in v o
sage: latex(E)
y^2  = x^3 + x + 3
```

AUTHORS:

- William Stein (2005): Initial version
- Robert Bradshaw et al....
- John Cremona (2008-01): isomorphisms, automorphisms and twists in all characteristics

class `EllipticCurve_generic` (*ainvs, extra=None*)

Elliptic curve over a generic base ring.

EXAMPLES:

```
sage: E = EllipticCurve([1,2,3/4,7,19]); E
Elliptic Curve defined by y^2 + x*y + 3/4*y = x^3 + 2*x^2 + 7*x + 19 over Rational Field
sage: loads(E.dumps()) == E
True
sage: E = EllipticCurve([1,3])
```

```
sage: P = E([-1,1,1])
sage: -5*P
(179051/80089 : -91814227/22665187 : 1)
```

a1()

Returns the a_1 invariant of this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([1,2,3,4,6])
sage: E.a1()
1
```

a2()

Returns the a_2 invariant of this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([1,2,3,4,6])
sage: E.a2()
2
```

a3()

Returns the a_3 invariant of this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([1,2,3,4,6])
sage: E.a3()
3
```

a4()

Returns the a_4 invariant of this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([1,2,3,4,6])
sage: E.a4()
4
```

a6()

Returns the a_6 invariant of this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([1,2,3,4,6])
sage: E.a6()
6
```

a_invariants()

The a-invariants of this elliptic curve, as a list.

OUTPUT:

(list) - a (new) list of the 5 a-invariants.

EXAMPLES:

```
sage: E = EllipticCurve([1,2,3,4,5])
sage: E.a_invariants()
[1, 2, 3, 4, 5]
sage: E = EllipticCurve([0,1])
sage: E
Elliptic Curve defined by y^2 = x^3 + 1 over Rational Field
sage: E.a_invariants()
[0, 0, 0, 0, 1]
sage: E = EllipticCurve([GF(7)(3),5])
```

```
sage: E.a_invariants()
[0, 0, 0, 3, 5]
```

We check that a new list is returned:

```
sage: E = EllipticCurve([1,0,0,0,1])
sage: E.a_invariants()[0] = 100000000
sage: E
Elliptic Curve defined by y^2 + x*y = x^3 + 1 over Rational Field
```

ainvs()

The a-invariants of this elliptic curve, as a list.

OUTPUT:

(list) - a (new) list of the 5 a-invariants.

EXAMPLES:

```
sage: E = EllipticCurve([1,2,3,4,5])
sage: E.a_invariants()
[1, 2, 3, 4, 5]
sage: E = EllipticCurve([0,1])
sage: E
Elliptic Curve defined by y^2 = x^3 + 1 over Rational Field
sage: E.a_invariants()
[0, 0, 0, 0, 1]
sage: E = EllipticCurve([GF(7)(3),5])
sage: E.a_invariants()
[0, 0, 0, 3, 5]
```

We check that a new list is returned:

```
sage: E = EllipticCurve([1,0,0,0,1])
sage: E.a_invariants()[0] = 100000000
sage: E
Elliptic Curve defined by y^2 + x*y = x^3 + 1 over Rational Field
```

automorphisms(*field=None*)

Return the set of isomorphisms from self to itself (as a list).

INPUT:

- `field` (default None) – a field into which the coefficients of the curve may be coerced (by default, uses the base field of the curve).

OUTPUT:

(list) A list of `WeierstrassIsomorphism` objects consisting of all the isomorphisms from the curve `self` to itself defined over `field`.

EXAMPLES:

```
sage: E = EllipticCurve_from_j(QQ(0)) # a curve with j=0 over QQ
sage: E.automorphisms();
[Generic endomorphism of Abelian group of points on Elliptic Curve defined by y^2 + y = x^3
Via:  (u,r,s,t) = (-1, 0, 0, -1), Generic endomorphism of Abelian group of points on Ellipti
Via:  (u,r,s,t) = (1, 0, 0, 0)]
```

We can also find automorphisms defined over extension fields:

```
sage: K.<a> = NumberField(x^2+3) # adjoin roots of unity
sage: E.automorphisms(K)
[Generic endomorphism of Abelian group of points on Elliptic Curve defined by y^2 + y = x^3
Via:  (u,r,s,t) = (1, 0, 0, 0),
...
```

```
Generic endomorphism of Abelian group of points on Elliptic Curve defined by y^2 + y = x^3 o
Via:  (u,r,s,t) = (-1/2*a - 1/2, 0, 0, 0)]

sage: [ len(EllipticCurve_from_j(GF(q,'a')(0)).automorphisms()) for q in [2,4,3,9,5,25,7,49]
[2, 24, 2, 12, 2, 6, 6, 6]
```

b2()

Returns the b_2 invariant of this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([1,2,3,4,5])
sage: E.b2()
9
```

b4()

Returns the b_4 invariant of this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([1,2,3,4,5])
sage: E.b4()
11
```

b6()

Returns the b_6 invariant of this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([1,2,3,4,5])
sage: E.b6()
29
```

b8()

Returns the b_8 invariant of this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([1,2,3,4,5])
sage: E.b8()
35
```

b_invariants()

Returns the b-invariants of this elliptic curve, as a tuple.

OUTPUT:

(tuple) - a 4-tuple of the b-invariants of this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([0, -1, 1, -10, -20])
sage: E.b_invariants()
(-4, -20, -79, -21)
sage: E = EllipticCurve([-4,0])
sage: E.b_invariants()
(0, -8, 0, -16)

sage: E = EllipticCurve([1,2,3,4,5])
sage: E.b_invariants()
(9, 11, 29, 35)
sage: E.b2()
9
sage: E.b4()
11
sage: E.b6()
```

```
29
sage: E.b8()
35
```

ALGORITHM:

These are simple functions of the a-invariants.

AUTHORS:

- William Stein (2005-04-25)

base_extend(*R*)

Returns a new curve with the same a-invariants but defined over a new ring.

INPUT:

- R – either a ring into which the curve's a-invariants may be coerced, or a morphism which may be applied to them.

OUTPUT:

A new elliptic curve with the same a-invariants, defined over the new ring.

EXAMPLES:

```
sage: E=EllipticCurve(GF(5),[1,1]); E
Elliptic Curve defined by y^2 = x^3 + x + 1 over Finite Field of size 5
sage: E1=E.base_extend(GF(125,'a')); E1
Elliptic Curve defined by y^2 = x^3 + x + 1 over Finite Field in a of size 5^3
sage: F2=GF(5^2,'a'); a=F2.gen()
sage: F4=GF(5^4,'b'); b=F4.gen()
sage: h=F2.hom([a.charpoly().roots(ring=F4,multiplicities=False)[0]],F4)
sage: E=EllipticCurve(F2,[1,a]); E
Elliptic Curve defined by y^2 = x^3 + x + a over Finite Field in a of size 5^2
sage: E.base_extend(h)
Elliptic Curve defined by y^2 = x^3 + x + (4*b^3+4*b^2+4*b+3) over Finite Field in b of size
```

base_ring()

Returns the base ring of the elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve(GF(49, 'a'), [3,5])
sage: E.base_ring()
Finite Field in a of size 7^2

sage: E = EllipticCurve([1,1])
sage: E.base_ring()
Rational Field

sage: E = EllipticCurve(ZZ, [3,5])
sage: E.base_ring()
Integer Ring
```

c4()

Returns the c_4 invariant of this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([0, -1, 1, -10, -20])
sage: E.c4()
496
```

c6()

Returns the c_6 invariant of this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([0, -1, 1, -10, -20])
sage: E.c6()
20008
```

c_invariants()

Returns the c-invariants of this elliptic curve, as a tuple.

OUTPUT:

(tuple) - a 2-tuple of the c-invariants of the elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([0, -1, 1, -10, -20])
sage: E.c_invariants()
(496, 20008)
sage: E = EllipticCurve([-4,0])
sage: E.c_invariants()
(192, 0)
```

ALGORITHM:

These are simple functions of the a-invariants.

AUTHORS:

- William Stein (2005-04-25)

change_ring(R)

Returns a new curve with the same a-invariants but defined over a new ring.

INPUT:

- R – either a ring into which the curve's a-invariants may be coerced, or a morphism which may be applied to them.

OUTPUT:

A new elliptic curve with the same a-invariants, defined over the new ring.

EXAMPLES:

```
sage: E=EllipticCurve(GF(5),[1,1]); E
Elliptic Curve defined by y^2 = x^3 + x + 1 over Finite Field of size 5
sage: E1=E.base_extend(GF(125,'a')); E1
Elliptic Curve defined by y^2 = x^3 + x + 1 over Finite Field in a of size 5^3
sage: F2=GF(5^2,'a'); a=F2.gen()
sage: F4=GF(5^4,'b'); b=F4.gen()
sage: h=F2.hom([a.charpoly().roots(ring=F4,multiplicities=False)[0]],F4)
sage: E=EllipticCurve(F2,[1,a]); E
Elliptic Curve defined by y^2 = x^3 + x + a over Finite Field in a of size 5^2
sage: E.base_extend(h)
Elliptic Curve defined by y^2 = x^3 + x + (4*b^3+4*b^2+4*b+3) over Finite Field in b of size
```

change_weierstrass_model(*$urst$)

Return a new Weierstrass model of self under the standard transformation $(u, r, s, , t)$

$$(x, y) \mapsto (x', y') = (u^2xr, u^3y + su^2x' + t).$$

EXAMPLES:

```
sage: E = EllipticCurve('15a')
sage: F1 = E.change_weierstrass_model([1/2,0,0,0]); F1
Elliptic Curve defined by y^2 + 2*x*y + 8*y = x^3 + 4*x^2 - 160*x - 640 over Rational Field
sage: F2 = E.change_weierstrass_model([7,2,1/3,5]); F2
Elliptic Curve defined by y^2 + 5/21*x*y + 13/343*y = x^3 + 59/441*x^2 - 10/7203*x - 58/1176
sage: F1.is_isomorphic(F2)
True
```

discriminant()

Returns the discriminant of this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([0,0,1,-1,0])
sage: E.discriminant()
37
sage: E = EllipticCurve([0, -1, 1, -10, -20])
sage: E.discriminant()
-161051

sage: E = EllipticCurve([GF(7)(2),1])
sage: E.discriminant()
1
```

division_polynomial(*m, x=None, two_torsion_multiplicity=2*)

Returns the m^{th} division polynomial of this elliptic curve evaluated at x.

INPUT:

- m - positive integer.
- x - optional ring element to use as the "x" variable. If x is None, then a new polynomial ring will be constructed over the base ring of the elliptic curve, and its generator will be used as x. Note that x does not need to be a generator of a polynomial ring; any ring element is ok. This permits fast calculation of the torsion polynomial *evaluated* on any element of a ring.
- two_torsion_multiplicity - 0,1 or 2

  If 0: for even m when x is None, a univariate polynomial over the base ring of the curve is returned, which omits factors whose roots are the x-coordinates of the 2-torsion points. Similarly when x is not none, the evaluation of such a polynomial at x is returned.
  If 2: for even m when x is None, a univariate polynomial over the base ring of the curve is returned, which includes a factor of degree 3 whose roots are the x-coordinates of the 2-torsion points. Similarly when x is not none, the evaluation of such a polynomial at x is returned.
  If 1: when x is None, a bivariate polynomial over the base ring of the curve is returned, which includes a factor $2 * y + a1 * x + a3$ which has simple zeros at the 2-torsion points. When x is not none, it should be a tuple of length 2, and the evaluation of such a polynomial at x is returned.

EXAMPLES:

```
sage: E = EllipticCurve([0,0,1,-1,0])
sage: E.division_polynomial(1)
1
sage: E.division_polynomial(2, two_torsion_multiplicity=0)
1
sage: E.division_polynomial(2, two_torsion_multiplicity=1)
2*y + 1
sage: E.division_polynomial(2, two_torsion_multiplicity=2)
4*x^3 - 4*x + 1
sage: E.division_polynomial(2)
4*x^3 - 4*x + 1
sage: [E.division_polynomial(3, two_torsion_multiplicity=i) for i in range(3)]
[3*x^4 - 6*x^2 + 3*x - 1, 3*x^4 - 6*x^2 + 3*x - 1, 3*x^4 - 6*x^2 + 3*x - 1]
sage: [type(E.division_polynomial(3, two_torsion_multiplicity=i)) for i in range(3)]
[<class 'sage.rings.polynomial.polynomial_element_generic.Polynomial_rational_dense'>,
<type 'sage.rings.polynomial.multi_polynomial_libsingular.MPolynomial_libsingular'>,
<class 'sage.rings.polynomial.polynomial_element_generic.Polynomial_rational_dense'>]
```

```
sage: E = EllipticCurve([0, -1, 1, -10, -20])
sage: R.<z>=PolynomialRing(QQ)
sage: E.division_polynomial(4,z,0)
2*z^6 - 4*z^5 - 100*z^4 - 790*z^3 - 210*z^2 - 1496*z - 5821
sage: E.division_polynomial(4,z)
8*z^9 - 24*z^8 - 464*z^7 - 2758*z^6 + 6636*z^5 + 34356*z^4 + 53510*z^3 + 99714*z^2 + 351024*
```

This does not work, since when two_torsion_multiplicity is 1, we compute a bivariate polynomial, and must evaluate at a tuple of length 2:

```
sage: E.division_polynomial(4,z,1)
...
ValueError: x should be a tuple of length 2 (or None) when two_torsion_multiplicity is 1
sage: R.<z,w>=PolynomialRing(QQ,2)
sage: E.division_polynomial(4,(z,w),1).factor()
(2*w + 1) * (2*z^6 - 4*z^5 - 100*z^4 - 790*z^3 - 210*z^2 - 1496*z - 5821)
```

We can also evaluate this bivariate polynomial at a point:

```
sage: P = E(5,5)
sage: E.division_polynomial(4,P,two_torsion_multiplicity=1)
-1771561
```

division_polynomial_0 (*n, x=None, cache=None*)

Returns the n^{th} torsion (division) polynomial, without the 2-torsion factor if n is even, as a polynomial in x.

These are the polynomials g_n defined in Mazur/Tate ("The p-adic sigma function"), but with the sign flipped for even n, so that the leading coefficient is always positive.

Note: This function is intended for internal use; users should use `division_polynomial()`.

See Also:

`multiple_x_numerator()` `multiple_x_denominator()` `division_polynomial()`

INPUT:

- `n` - positive integer, or the special values -1 and -2 which mean $B_6 = (2y + a_1x + a_3)^2$ and B_6^2 respectively (in the notation of Mazur/Tate).
- `x` - optional ring element to use as the "x" variable. If x is None, then a new polynomial ring will be constructed over the base ring of the elliptic curve, and its generator will be used as x. Note that x does not need to be a generator of a polynomial ring; any ring element is ok. This permits fast calculation of the torsion polynomial *evaluated* on any element of a ring.
- `cache` - optional dictionary, with integer keys. If the key m is in cache, then cache[m] is assumed to be the value of division_polynomial_0(m) for the supplied x. New entries will be added to the cache as they are computed.

ALGORITHM:

Recursion described in Mazur/Tate. The recursive formulae are evaluated $O((logn)^2)$ times.

AUTHORS:

- David Harvey (2006-09-24): initial version
- John Cremona (2008-08-26): unified division polynomial code

EXAMPLES:

```
sage: E = EllipticCurve("37a")
sage: E.division_polynomial_0(1)
1
sage: E.division_polynomial_0(2)
1
sage: E.division_polynomial_0(3)
3*x^4 - 6*x^2 + 3*x - 1
```

```
sage: E.division_polynomial_0(4)
2*x^6 - 10*x^4 + 10*x^3 - 10*x^2 + 2*x + 1
sage: E.division_polynomial_0(5)
5*x^12 - 62*x^10 + 95*x^9 - 105*x^8 - 60*x^7 + 285*x^6 - 174*x^5 - 5*x^4 - 5*x^3 + 35*x^2 -
sage: E.division_polynomial_0(6)
3*x^16 - 72*x^14 + 168*x^13 - 364*x^12 + 1120*x^10 - 1144*x^9 + 300*x^8 - 540*x^7 + 1120*x^6
sage: E.division_polynomial_0(7)
7*x^24 - 308*x^22 + 986*x^21 - 2954*x^20 + 28*x^19 + 17171*x^18 - 23142*x^17 + 511*x^16 - 50
sage: E.division_polynomial_0(8)
4*x^30 - 292*x^28 + 1252*x^27 - 5436*x^26 + 2340*x^25 + 39834*x^24 - 79560*x^23 + 51432*x^22

sage: E.division_polynomial_0(18) % E.division_polynomial_0(6) == 0
True
```

An example to illustrate the relationship with torsion points:

```
sage: F = GF(11)
sage: E = EllipticCurve(F, [0, 2]); E
Elliptic Curve defined by y^2  = x^3 + 2 over Finite Field of size 11
sage: f = E.division_polynomial_0(5); f
5*x^12 + x^9 + 8*x^6 + 4*x^3 + 7
sage: f.factor()
(5) * (x^2 + 5) * (x^2 + 2*x + 5) * (x^2 + 5*x + 7) * (x^2 + 7*x + 7) * (x^2 + 9*x + 5) * (x
```

This indicates that the x-coordinates of all the 5-torsion points of E are in $GF(11^2)$, and therefore the y-coordinates are in $\mathbf{F}_(11^4)$:

```
sage: K = GF(11^4, 'a')
sage: X = E.change_ring(K)
sage: f = X.division_polynomial_0(5)
sage: x_coords = f.roots(multiplicities=False); x_coords
[10*a^3 + 4*a^2 + 5*a + 6,
 9*a^3 + 8*a^2 + 10*a + 8,
 8*a^3 + a^2 + 4*a + 10,
 8*a^3 + a^2 + 4*a + 8,
 8*a^3 + a^2 + 4*a + 4,
 6*a^3 + 9*a^2 + 3*a + 4,
 5*a^3 + 2*a^2 + 8*a + 7,
 3*a^3 + 10*a^2 + 7*a + 8,
 3*a^3 + 10*a^2 + 7*a + 3,
 3*a^3 + 10*a^2 + 7*a + 1,
 2*a^3 + 3*a^2 + a + 7,
 a^3 + 7*a^2 + 6*a]
```

Now we check that these are exactly the x-coordinates of the 5-torsion points of E:

```
sage: for x in x_coords:
...       assert X.lift_x(x).order() == 5
```

The roots of the polynomial are the x-coordinates of the points P such that $mP = 0$ but $2P \neq 0$:

```
sage: E=EllipticCurve('14a1')
sage: T=E.torsion_subgroup()
sage: [n*T.0 for n in range(6)]
[(0 : 1 : 0),
(9 : 23 : 1),
(2 : 2 : 1),
(1 : -1 : 1),
(2 : -5 : 1),
(9 : -33 : 1)]
sage: pol=E.division_polynomial_0(6)
```

```
sage: xlist=pol.roots(multiplicities=False); xlist
[9, 2, -1/3, -5]
sage: [E.lift_x(x, all=True) for x in xlist]
[[(9 : 23 : 1), (9 : -33 : 1)], [(2 : 2 : 1), (2 : -5 : 1)], [], []]
```

Note: The point of order 2 and the identity do not appear. The points with $x = -1/3$ and $x = -5$ are not rational.

formal()

The formal group associated to this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve("37a")
sage: E.formal_group()
Formal Group associated to the Elliptic Curve defined by y^2 + y = x^3 - x over Rational Fie
```

formal_group()

The formal group associated to this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve("37a")
sage: E.formal_group()
Formal Group associated to the Elliptic Curve defined by y^2 + y = x^3 - x over Rational Fie
```

gen(i)

Function returning the i'th generator of this elliptic curve.

Note: Relies on gens() being implemented.

EXAMPLES:

```
sage: R.<a1,a2,a3,a4,a6>=QQ[]
sage: E=EllipticCurve([a1,a2,a3,a4,a6])
sage: E.gen(0)
...
NotImplementedError: not implemented.
```

gens()

Placeholder function to return generators of an elliptic curve.

Note: This functionality is implemented in certain derived classes, such as EllipticCurve_rational_field.

EXAMPLES:

```
sage: R.<a1,a2,a3,a4,a6>=QQ[]
sage: E=EllipticCurve([a1,a2,a3,a4,a6])
sage: E.gens()
...
NotImplementedError: not implemented.
sage: E=EllipticCurve(QQ,[1,1])
sage: E.gens()
[(0 : 1 : 1)]
```

hyperelliptic_polynomials()

Returns a pair of polynomials $g(x)$, $h(x)$ such that this elliptic curve can be defined by the standard hyperelliptic equation

$$y^2 + h(x)y = g(x).$$

EXAMPLES:

```
sage: R.<a1,a2,a3,a4,a6>=QQ[]
sage: E=EllipticCurve([a1,a2,a3,a4,a6])
```

```
sage: E.hyperelliptic_polynomials()
(x^3 + a2*x^2 + a4*x + a6, a1*x + a3)
```

is_isomorphic(*other, field=None*)

Returns whether or not self is isomorphic to other.

INPUT:

- `other` – another elliptic curve.
- `field` (default None) – a field into which the coefficients of the curves may be coerced (by default, uses the base field of the curves).

OUTPUT:

(bool) True if there is an isomorphism from curve `self` to curve `other` defined over `field`.

EXAMPLES:

```
sage: E = EllipticCurve('389a')
sage: F = E.change_weierstrass_model([2,3,4,5]); F
Elliptic Curve defined by y^2 + 4*x*y + 11/8*y = x^3 - 3/2*x^2 - 13/16*x over Rational Field
sage: E.is_isomorphic(F)
True
sage: E.is_isomorphic(F.change_ring(CC))
False
```

is_on_curve(*x, y*)

Returns True if (x, y) is an affine point on this curve.

INPUT:

- `x, y` - elements of the base ring of the curve.

EXAMPLES:

```
sage: E=EllipticCurve(QQ,[1,1])
sage: E.is_on_curve(0,1)
True
sage: E.is_on_curve(1,1)
False
```

is_x_coord(*x*)

Returns True if `x` is the x-coordinate of a point on this curve.

Note: See also `lift_x()` to find the point(s) with a given x-coordinate. This function may be useful in cases where testing an element of the base field for being a square is faster than finding its square root.

EXAMPLES:

```
sage: E = EllipticCurve('37a'); E
Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field
sage: E.is_x_coord(1)
True
sage: E.is_x_coord(2)
True
```

There are no rational points with x-coordinate 3:

```
sage: E.is_x_coord(3)
False
```

However, there are such points in $E(\mathbf{R})$:

```
sage: E.change_ring(RR).is_x_coord(3)
True
```

And of course it always works in $E(\mathbf{C})$:

```
sage: E.change_ring(RR).is_x_coord(-3)
False
sage: E.change_ring(CC).is_x_coord(-3)
True
```

AUTHORS:

•John Cremona (2008-08-07): adapted from lift_x()

TEST:

```
sage: E=EllipticCurve('5077a1')
sage: [x for x in srange(-10,10) if E.is_x_coord (x)]
[-3, -2, -1, 0, 1, 2, 3, 4, 8]

sage: F=GF(32,'a')
sage: E=EllipticCurve(F,[1,0,0,0,1])
sage: set([P[0] for P in E.points() if P!=E(0)]) == set([x for x in F if E.is_x_coord(x)])
True
```

isomorphism_to(*other*)

Given another weierstrass model `other` of self, return an isomorphism from self to `other`.

INPUT:

•`other` – an elliptic curve isomorphic to `self`.

OUTPUT:

(Weierstrassmorphism) An isomorphism from self to other.

Note: If the curves in question are not isomorphic, a ValueError is raised.

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: F = E.short_weierstrass_model()
sage: w = E.isomorphism_to(F); w
Generic morphism:
From: Abelian group of points on Elliptic Curve defined by y^2 + y = x^3 - x over Rational F
To:   Abelian group of points on Elliptic Curve defined by y^2  = x^3 - 16*x + 16 over Ratio
Via:  (u,r,s,t) = (1/2, 0, 0, -1/2)
sage: P = E(0,-1,1)
sage: w(P)
(0 : -4 : 1)
sage: w(5*P)
(1 : 1 : 1)
sage: 5*w(P)
(1 : 1 : 1)
sage: 120*w(P) == w(120*P)
True
```

We can also handle injections to different base rings:

```
sage: K.<a> = NumberField(x^3-7)
sage: E.isomorphism_to(E.change_ring(K))
Generic morphism:
  From: Abelian group of points on Elliptic Curve defined by y^2 + y = x^3 - x over Rational
  To:   Abelian group of points on Elliptic Curve defined by y^2 + y = x^3 + (-1)*x over Num
  Via:  (u,r,s,t) = (1, 0, 0, 0)
```

isomorphisms(*other, field=None*)

Return the set of isomorphisms from self to other (as a list).

INPUT:

•`other` – another elliptic curve.

- `field` (default None) – a field into which the coefficients of the curves may be coerced (by default, uses the base field of the curves).

OUTPUT:

(list) A list of `WeierstrassIsomorphism` objects consisting of all the isomorphisms from the curve `self` to the curve `other` defined over `field`.

EXAMPLES:

```
sage: E = EllipticCurve_from_j(QQ(0)) # a curve with j=0 over QQ
sage: F = EllipticCurve('27a3') # should be the same one
sage: E.isomorphisms(F);
[Generic morphism:
From: Abelian group of points on Elliptic Curve defined by y^2 + y = x^3 over Rational Field
To:   Abelian group of points on Elliptic Curve defined by y^2 + y = x^3 over Rational Field
Via:  (u,r,s,t) = (-1, 0, 0, -1), Generic morphism:
From: Abelian group of points on Elliptic Curve defined by y^2 + y = x^3 over Rational Field
To:   Abelian group of points on Elliptic Curve defined by y^2 + y = x^3 over Rational Field
Via:  (u,r,s,t) = (1, 0, 0, 0)]
```

We can also find istomorphisms defined over extension fields:

```
sage: E=EllipticCurve(GF(7),[0,0,0,1,1])
sage: F=EllipticCurve(GF(7),[0,0,0,1,-1])
sage: E.isomorphisms(F)
[]
sage: E.isomorphisms(F,GF(49,'a'))
[Generic morphism:
From: Abelian group of points on Elliptic Curve defined by y^2 = x^3 + x + 1 over Finite Fie
To:   Abelian group of points on Elliptic Curve defined by y^2 = x^3 + x + 6 over Finite Fie
Via:  (u,r,s,t) = (a + 3, 0, 0, 0), Generic morphism:
From: Abelian group of points on Elliptic Curve defined by y^2 = x^3 + x + 1 over Finite Fie
To:   Abelian group of points on Elliptic Curve defined by y^2 = x^3 + x + 6 over Finite Fie
Via:  (u,r,s,t) = (6*a + 4, 0, 0, 0)]
```

j_invariant()

Returns the j-invariant of this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([0,0,1,-1,0])
sage: E.j_invariant()
110592/37
sage: E = EllipticCurve([0, -1, 1, -10, -20])
sage: E.j_invariant()
-122023936/161051
sage: E = EllipticCurve([-4,0])
sage: E.j_invariant()
1728

sage: E = EllipticCurve([GF(7)(2),1])
sage: E.j_invariant()
1
```

lift_x(*x*, *all=False*)

Returns one or all points with given x-coordinate.

INPUT:

- `x` – an element of the base ring of the curve.
- `all` (bool, default False) – if True, return a (possibly empty) list of all points; if False, return just one point, or raise a ValueError if there are none.

Note: See also `is_x_coord()`.

EXAMPLES:

```
sage: E = EllipticCurve('37a'); E
Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field
sage: E.lift_x(1)
(1 : 0 : 1)
sage: E.lift_x(2)
(2 : 2 : 1)
sage: E.lift_x(1/4, all=True)
[(1/4 : -3/8 : 1), (1/4 : -5/8 : 1)]
```

There are no rational points with x-coordinate 3:

```
sage: E.lift_x(3)
...
ValueError: No point with x-coordinate 3 on Elliptic Curve defined by y^2 + y = x^3 - x over
```

However, there are two such points in $E(\mathbf{R})$:

```
sage: E.change_ring(RR).lift_x(3, all=True)
[(3.00000000000000 : 4.42442890089805 : 1.00000000000000), (3.00000000000000 : -5.4244289008
```

And of course it always works in $E(\mathbf{C})$:

```
sage: E.change_ring(RR).lift_x(.5, all=True)
[]
sage: E.change_ring(CC).lift_x(.5)
(0.500000000000000 : -0.500000000000000 + 0.353553390593274*I : 1.00000000000000)
```

We can perform these operations over finite fields too:

```
sage: E = E.change_ring(GF(17)); E
Elliptic Curve defined by y^2 + y = x^3 + 16*x over Finite Field of size 17
sage: E.lift_x(7)
(7 : 11 : 1)
sage: E.lift_x(3)
...
ValueError: No point with x-coordinate 3 on Elliptic Curve defined by y^2 + y = x^3 + 16*x o
```

Note that there is only one lift with x-coordinate 10 in $E(\mathbf{F}_{17})$:

```
sage: E.lift_x(10, all=True)
[(10 : 8 : 1)]
```

We can lift over more exotic rings too:

```
sage: E = EllipticCurve('37a');
sage: E.lift_x(pAdicField(17, 5)(6))
(6 + O(17^5) : 2 + 16*17 + 16*17^2 + 16*17^3 + 16*17^4 + O(17^5) : 1 + O(17^5))
sage: K.<t> = PowerSeriesRing(QQ, 't', 5)
sage: E.lift_x(1+t)
(1 + t : 2*t - t^2 + 5*t^3 - 21*t^4 + O(t^5) : 1)
sage: K.<a> = GF(16)
sage: E = E.change_ring(K)
sage: E.lift_x(a^3)
(a^3 : a^3 + a : 1)
```

AUTHOR:

- Robert Bradshaw (2007-04-24)

TEST:

```
sage: E = EllipticCurve('37a').short_weierstrass_model().change_ring(GF(17))
sage: E.lift_x(3, all=True)
```

```
[]
sage: E.lift_x(7, all=True)
[(7 : 3 : 1), (7 : 14 : 1)]
```

multiplication_by_m(*m, x_only=False*)

Return the multiplication-by-m map from self to self as a pair of rational functions in two variables x,'y'.

INPUT:

- m - a nonzero integer
- x_only - bool (default: False) if True, return only the x-coordinate of the map.

OUTPUT:

(2-tuple) $(f(x), g(x,y))$, where f and g are rational functions with the degree of y in $g(x,y)$ exactly 1.

EXAMPLES:

```
sage: E = EllipticCurve([-1,3])
```

We verify that multiplication by 1 is just the identity:

```
sage: E.multiplication_by_m(1)
(x, y)
```

Multiplication by 2 is more complicated:

```
sage: f = E.multiplication_by_m(2)
sage: f
((x^4 + 2*x^2 - 24*x + 1)/(4*x^3 - 4*x + 12), (8*x^6*y - 40*x^4*y + 480*x^3*y - 40*x^2*y + 9
```

Grab only the x-coordinate (less work):

```
sage: E.multiplication_by_m(2, x_only=True)
(x^4 + 2*x^2 - 24*x + 1)/(4*x^3 - 4*x + 12)
```

We check that it works on a point:

```
sage: P = E([2,3])
sage: eval = lambda f,P: [fi(P[0],P[1]) for fi in f]
sage: assert E(eval(f,P)) == 2*P
```

We do the same but with multiplication by 3:

```
sage: f = E.multiplication_by_m(3)
sage: assert E(eval(f,P)) == 3*P
```

And the same with multiplication by 4:

```
sage: f = E.multiplication_by_m(4)
sage: assert E(eval(f,P)) == 4*P
```

And the same with multiplication by -1,-2,-3,-4:

```
sage: for m in [-1,-2,-3,-4]:
...       f = E.multiplication_by_m(m)
...       assert E(eval(f,P)) == m*P
```

TESTS:

Verify for this fairly random looking curve and point that multiplication by m returns the right result for the first 10 integers:

```
sage: E = EllipticCurve([23,-105])
sage: P = E([129/4, 1479/8])
sage: for n in [1..10]:
...       f = E.multiplication_by_m(n)
...       Q = n*P
```

```
...       assert Q == E(eval(f,P))
...       f = E.multiplication_by_m(-n)
...       Q = -n*P
...       assert Q == E(eval(f,P))
```

The following test shows that #4364 is indeed fixed:

```
sage: p = next_prime(2^30-41)
sage: a = GF(p)(1)
sage: b = GF(p)(1)
sage: E = EllipticCurve([a, b])
sage: P = E.random_point()
sage: my_eval = lambda f,P: [fi(P[0],P[1]) for fi in f]
sage: f = E.multiplication_by_m(2)
sage: assert(E(eval(f,P)) == 2*P)
```

pari_curve(*prec=53*)

Return the PARI curve corresponding to this elliptic curve.

Note: The result is cached; on subsequent calls the cached value is returned provided that it has sufficient precision, otherwise pari is called again with the new precision.

EXAMPLES:

```
sage: E = EllipticCurve([RR(0), RR(0), RR(1), RR(-1), RR(0)])
sage: e = E.pari_curve()
sage: type(e)
<type 'sage.libs.pari.gen.gen'>
sage: e.type()
't_VEC'
sage: e.disc()
37.0000000000000
```

plot(*xmin=None, xmax=None, **args*)

Draw a graph of this elliptic curve.

INPUT:

- `xmin, xmax` - (optional) points will be computed at least within this range, but possibly farther.
- `**args` - all other options are passed to the line graphing primitive.

EXAMPLES:

```
sage: E = EllipticCurve([0,-1])
sage: plot(E, rgbcolor=hue(0.7))
sage: E = EllipticCurve('37a')
sage: plot(E)
sage: plot(E, xmin=25,xmax=25)
```

rst_transform(*r, s, t*)

Returns the transform of the curve by (r, s, t) (with $u = 1$).

INPUT:

- `r, s, t` – three elements of the base ring.

OUTPUT:

The elliptic curve obtained from self by the standard Weierstrass transformation (u, r, s, t) with $u = 1$.

Note: This is just a special case of `change_weierstrass_model()`, with $u = 1$.

EXAMPLES:

```
sage: R.<r,s,t>=QQ[]
sage: E=EllipticCurve([1,2,3,4,5])
sage: E.rst_transform(r,s,t)
Elliptic Curve defined by y^2 + (2*s+1)*x*y + (r+2*t+3)*y = x^3 + (-s^2+3*r-s+2)*x^2 + (3*r^
```

scale_curve(*u*)

Returns the transform of the curve by scale factor u.
INPUT:

•u – an invertible element of the base ring.

OUTPUT:
The elliptic curve obtained from self by the standard Weierstrass transformation (u, r, s, t) with $r = s = t = 0$.
Note: This is just a special case of change_weierstrass_model(), with $r = s = t = 0$.

EXAMPLES:

```
sage: K=Frac(PolynomialRing(QQ,'u'))
sage: u=K.gen()
sage: E=EllipticCurve([1,2,3,4,5])
sage: E.scale_curve(u)
Elliptic Curve defined by y^2 + u*x*y + 3*u^3*y = x^3 + 2*u^2*x^2 + 4*u^4*x + 5*u^6 over Fra
```

short_weierstrass_model(*complete_cube=True*)

Returns a short Weierstrass model for self.
INPUT:

•complete_cube - bool (default: True); for meaning, see below.

OUTPUT:
An elliptic curve.
If complete_cube=True: Return a model of the form $y^2 = x^3 + a * x + b$ for this curve. The characteristic must not be 2; in characteristic 3, it is only possible if $b_2 = 0$.
If complete_cube=False: Return a model of the form $y^2 = x^3 + ax^2 + bx + c$ for this curve. The characteristic must not be 2.
EXAMPLES:

```
sage: E = EllipticCurve([1,2,3,4,5])
sage: print E
Elliptic Curve defined by y^2 + x*y + 3*y = x^3 + 2*x^2 + 4*x + 5 over Rational Field
sage: F = E.short_weierstrass_model()
sage: print F
Elliptic Curve defined by y^2  = x^3 + 4941*x + 185166 over Rational Field
sage: E.is_isomorphic(F)
True
sage: F = E.short_weierstrass_model(complete_cube=False)
sage: print F
Elliptic Curve defined by y^2  = x^3 + 9*x^2 + 88*x + 464 over Rational Field
sage: print E.is_isomorphic(F)
True

sage: E = EllipticCurve(GF(3),[1,2,3,4,5])
sage: E.short_weierstrass_model(complete_cube=False)
Elliptic Curve defined by y^2 = x^3 + x + 2 over Finite Field of size 3
```

This used to be different see trac #3973:

```
sage: E.short_weierstrass_model()
Elliptic Curve defined by y^2 = x^3 + x + 2 over Finite Field of size 3
```

More tests in characteristic 3:

```
sage: E = EllipticCurve(GF(3),[0,2,1,2,1])
sage: E.short_weierstrass_model()
...
ValueError: short_weierstrass_model(): no short model for Elliptic Curve defined by y^2 + y
```

```
sage: E.short_weierstrass_model(complete_cube=False)
Elliptic Curve defined by y^2 = x^3 + 2*x^2 + 2*x + 2 over Finite Field of size 3
sage: E.short_weierstrass_model(complete_cube=False).is_isomorphic(E)
True
```

torsion_polynomial(*m, x=None, two_torsion_multiplicity=2*)

Returns the m^{th} division polynomial of this elliptic curve evaluated at x.

INPUT:

- m - positive integer.
- x - optional ring element to use as the "x" variable. If x is None, then a new polynomial ring will be constructed over the base ring of the elliptic curve, and its generator will be used as x. Note that x does not need to be a generator of a polynomial ring; any ring element is ok. This permits fast calculation of the torsion polynomial *evaluated* on any element of a ring.
- two_torsion_multiplicity - 0,1 or 2

  If 0: for even m when x is None, a univariate polynomial over the base ring of the curve is returned, which omits factors whose roots are the x-coordinates of the 2-torsion points. Similarly when x is not none, the evaluation of such a polynomial at x is returned.
  If 2: for even m when x is None, a univariate polynomial over the base ring of the curve is returned, which includes a factor of degree 3 whose roots are the x-coordinates of the 2-torsion points. Similarly when x is not none, the evaluation of such a polynomial at x is returned.
  If 1: when x is None, a bivariate polynomial over the base ring of the curve is returned, which includes a factor $2 * y + a1 * x + a3$ which has simple zeros at the 2-torsion points. When x is not none, it should be a tuple of length 2, and the evaluation of such a polynomial at x is returned.

EXAMPLES:

```
sage: E = EllipticCurve([0,0,1,-1,0])
sage: E.division_polynomial(1)
1
sage: E.division_polynomial(2, two_torsion_multiplicity=0)
1
sage: E.division_polynomial(2, two_torsion_multiplicity=1)
2*y + 1
sage: E.division_polynomial(2, two_torsion_multiplicity=2)
4*x^3 - 4*x + 1
sage: E.division_polynomial(2)
4*x^3 - 4*x + 1
sage: [E.division_polynomial(3, two_torsion_multiplicity=i) for i in range(3)]
[3*x^4 - 6*x^2 + 3*x - 1, 3*x^4 - 6*x^2 + 3*x - 1, 3*x^4 - 6*x^2 + 3*x - 1]
sage: [type(E.division_polynomial(3, two_torsion_multiplicity=i)) for i in range(3)]
[<class 'sage.rings.polynomial.polynomial_element_generic.Polynomial_rational_dense'>,
<type 'sage.rings.polynomial.multi_polynomial_libsingular.MPolynomial_libsingular'>,
<class 'sage.rings.polynomial.polynomial_element_generic.Polynomial_rational_dense'>]

sage: E = EllipticCurve([0, -1, 1, -10, -20])
sage: R.<z>=PolynomialRing(QQ)
sage: E.division_polynomial(4,z,0)
2*z^6 - 4*z^5 - 100*z^4 - 790*z^3 - 210*z^2 - 1496*z - 5821
sage: E.division_polynomial(4,z)
8*z^9 - 24*z^8 - 464*z^7 - 2758*z^6 + 6636*z^5 + 34356*z^4 + 53510*z^3 + 99714*z^2 + 351024*
```

This does not work, since when two_torsion_multiplicity is 1, we compute a bivariate polynomial, and must evaluate at a tuple of length 2:

```
sage: E.division_polynomial(4,z,1)
...
ValueError: x should be a tuple of length 2 (or None) when two_torsion_multiplicity is 1
sage: R.<z,w>=PolynomialRing(QQ,2)
sage: E.division_polynomial(4,(z,w),1).factor()
(2*w + 1) * (2*z^6 - 4*z^5 - 100*z^4 - 790*z^3 - 210*z^2 - 1496*z - 5821)
```

We can also evaluate this bivariate polynomial at a point:

```
sage: P = E(5,5)
sage: E.division_polynomial(4,P,two_torsion_multiplicity=1)
-1771561
```

two_division_polynomial(*x=None*)

Returns the 2-division polynomial of this elliptic curve evaluated at `x`.

INPUT:

- `x` - optional ring element to use as the x variable. If `x` is `None`, then a new polynomial ring will be constructed over the base ring of the elliptic curve, and its generator will be used as `x`. Note that `x` does not need to be a generator of a polynomial ring; any ring element is ok. This permits fast calculation of the torsion polynomial *evaluated* on any element of a ring.

EXAMPLES:

```
sage: E=EllipticCurve('5077a1')
sage: E.two_division_polynomial()
4*x^3 - 28*x + 25
sage: E=EllipticCurve(GF(3^2,'a'),[1,1,1,1,1])
sage: E.two_division_polynomial()
x^3 + 2*x^2 + 2
sage: E.two_division_polynomial().roots()
[(2, 1), (2*a, 1), (a + 2, 1)]
```

is_EllipticCurve(*x*)

Utility function to test if `x` is an instance of an Elliptic Curve class.

EXAMPLES:

```
sage: from sage.schemes.elliptic_curves.ell_generic import is_EllipticCurve
sage: E = EllipticCurve([1,2,3/4,7,19])
sage: is_EllipticCurve(E)
True
sage: is_EllipticCurve(0)
False
```

38.6 Elliptic curves over a general field

This module defines the class `EllipticCurve_field`, based on `EllipticCurve_generic`, for elliptic curves over general fields.

class EllipticCurve_field(*ainvs, extra=None*)

base_field()

Returns the base ring of the elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve(GF(49, 'a'), [3,5])
sage: E.base_ring()
Finite Field in a of size 7^2

sage: E = EllipticCurve([1,1])
sage: E.base_ring()
Rational Field

sage: E = EllipticCurve(ZZ, [3,5])
sage: E.base_ring()
Integer Ring
```

is_quadratic_twist(*other*)

Determine whether this curve is a quadratic twist of another.

INPUT:

- `other` – an elliptic curves with the same base field as self.

OUTPUT:

Either 0, if the curves are not quadratic twists, or D if `other` is `self.quadratic_twist(D)` (up to isomorphism). If `self` and `other` are isomorphic, returns 1.

Note: Not fully implemented in characteristic 2, or in characteristic 3 when both j-invariants are 0.

EXAMPLES:

```
sage: E = EllipticCurve('11a1')
sage: Et = E.quadratic_twist(-24)
sage: E.is_quadratic_twist(Et)
-6

sage: E1=EllipticCurve([0,0,1,0,0])
sage: E1.j_invariant()
0
sage: E2=EllipticCurve([0,0,0,0,2])
sage: E1.is_quadratic_twist(E2)
2

sage: E1=EllipticCurve([0,0,0,1,0])
sage: E1.j_invariant()
1728
sage: E2=EllipticCurve([0,0,0,2,0])
sage: E1.is_quadratic_twist(E2)
0
sage: E2=EllipticCurve([0,0,0,25,0])
sage: E1.is_quadratic_twist(E2)
5

sage: F = GF(101)
sage: E1 = EllipticCurve(F,[4,7])
sage: E2 = E1.quadratic_twist()
sage: D = E1.is_quadratic_twist(E2); D!=0
True
sage: F = GF(101)
sage: E1 = EllipticCurve(F,[4,7])
sage: E2 = E1.quadratic_twist()
sage: D = E1.is_quadratic_twist(E2)
sage: E1.quadratic_twist(D).is_isomorphic(E2)
True
sage: E1.is_isomorphic(E2)
False
```

```
sage: F2 = GF(101^2,'a')
sage: E1.change_ring(F2).is_isomorphic(E2.change_ring(F2))
True
```

A characteristic 3 example:

```
sage: F = GF(3^5,'a')
sage: E1 = EllipticCurve_from_j(F(1))
sage: E2 = E1.quadratic_twist(-1)
sage: D = E1.is_quadratic_twist(E2); D!=0
True
sage: E1.quadratic_twist(D).is_isomorphic(E2)
True

sage: E1 = EllipticCurve_from_j(F(0))
sage: E2 = E1.quadratic_twist()
sage: D = E1.is_quadratic_twist(E2); D
1
sage: E1.is_isomorphic(E2)
True
```

is_quartic_twist(*other*)

Determine whether this curve is a quartic twist of another.

INPUT:

- `other` – an elliptic curves with the same base field as self.

OUTPUT:

Either 0, if the curves are not quartic twists, or D if `other` is `self.quartic_twist(D)` (up to isomorphism). If `self` and `other` are isomorphic, returns 1.

Note: Not fully implemented in characteristics 2 or 3.

EXAMPLES:

```
sage: E = EllipticCurve_from_j(GF(13)(1728))
sage: E1 = E.quartic_twist(2)
sage: D = E.is_quartic_twist(E1); D!=0
True
sage: E.quartic_twist(D).is_isomorphic(E1)
True

sage: E = EllipticCurve_from_j(1728)
sage: E1 = E.quartic_twist(12345)
sage: D = E.is_quartic_twist(E1); D
15999120
sage: (D/12345).is_perfect_power(4)
True
```

is_sextic_twist(*other*)

Determine whether this curve is a sextic twist of another.

INPUT:

- `other` – an elliptic curves with the same base field as self.

OUTPUT:

Either 0, if the curves are not sextic twists, or D if `other` is `self.sextic_twist(D)` (up to isomorphism). If `self` and `other` are isomorphic, returns 1.

Note: Not fully implemented in characteristics 2 or 3.

EXAMPLES:

```
sage: E = EllipticCurve_from_j(GF(13)(0))
sage: E1 = E.sextic_twist(2)
sage: D = E.is_sextic_twist(E1); D!=0
True
sage: E.sextic_twist(D).is_isomorphic(E1)
True

sage: E = EllipticCurve_from_j(0)
sage: E1 = E.sextic_twist(12345)
sage: D = E.is_sextic_twist(E1); D
575968320
sage: (D/12345).is_perfect_power(6)
True
```

quadratic_twist(*D=None*)

Return the quadratic twist of this curve by D.

INPUT:

- D (default None) the twisting parameter (see below).

In characteristics other than 2, D must be nonzero, and the twist is isomorphic to self after adjoining $\sqrt{(D)}$ to the base.

In characteristic 2, D is arbitrary, and the twist is isomorphic to self after adjoining a root of $x^2 + x + D$ to the base.

In characteristic 2 when $j = 0$, this is not implemented.

If the base field F is finite, D need not be specified, and the curve returned is the unique curve (up to isomorphism) defined over F isomorphic to the original curve over the quadratic extension of F but not over F itself. Over infinte fields, an error is raised if D is not given.

EXAMPLES:

```
sage: E = EllipticCurve([GF(1103)(1), 0, 0, 107, 340]); E
Elliptic Curve defined by y^2 + x*y  = x^3 + 107*x + 340 over Finite Field of size 1103
sage: F=E.quadratic_twist(-1); F
Elliptic Curve defined by y^2  = x^3 + 1102*x^2 + 609*x + 300 over Finite Field of size 1103
sage: E.is_isomorphic(F)
False
sage: E.is_isomorphic(F,GF(1103^2,'a'))
True
```

A characteristic 2 example:

```
sage: E=EllipticCurve(GF(2),[1,0,1,1,1])
sage: E1=E.quadratic_twist(1)
sage: E.is_isomorphic(E1)
False
sage: E.is_isomorphic(E1,GF(4,'a'))
True
```

Over finite fields, the twisting parameter may be omitted:

```
sage: k.<a> = GF(2^10)
sage: E = EllipticCurve(k,[a^2,a,1,a+1,1])
sage: Et = E.quadratic_twist()
sage: Et # random (only determined up to isomorphism)
Elliptic Curve defined by y^2 + x*y  = x^3 + (a^7+a^4+a^3+a^2+a+1)*x^2 + (a^8+a^6+a^4+1) ove
sage: E.is_isomorphic(Et)
False
sage: E.j_invariant()==Et.j_invariant()
True
```

```
sage: p=next_prime(10^10)
sage: k = GF(p)
sage: E = EllipticCurve(k,[1,2,3,4,5])
sage: Et = E.quadratic_twist()
sage: Et # random (only determined up to isomorphism)
Elliptic Curve defined by y^2  = x^3 + 7860088097*x^2 + 9495240877*x + 3048660957 over Finit
sage: E.is_isomorphic(Et)
False
sage: k2 = GF(p^2,'a')
sage: E.change_ring(k2).is_isomorphic(Et.change_ring(k2))
True
```

quartic_twist(*D*)

Return the quartic twist of this curve by D.

INPUT:

•D (must be nonzero) – the twisting parameter..

Note: The characteristic must not be 2 or 3, and the j-invariant must be 1728.

EXAMPLES:

```
sage: E=EllipticCurve_from_j(GF(13)(1728)); E
Elliptic Curve defined by y^2  = x^3 + x over Finite Field of size 13
sage: E1=E.quartic_twist(2); E1
Elliptic Curve defined by y^2  = x^3 + 5*x over Finite Field of size 13
sage: E.is_isomorphic(E1)
False
sage: E.is_isomorphic(E1,GF(13^2,'a'))
False
sage: E.is_isomorphic(E1,GF(13^4,'a'))
True
```

sextic_twist(*D*)

Return the quartic twist of this curve by D.

INPUT:

•D (must be nonzero) – the twisting parameter..

Note: The characteristic must not be 2 or 3, and the j-invariant must be 0.

EXAMPLES:

```
sage: E=EllipticCurve_from_j(GF(13)(0)); E
Elliptic Curve defined by y^2 = x^3 + 1 over Finite Field of size 13
sage: E1=E.sextic_twist(2); E1
Elliptic Curve defined by y^2 = x^3 + 11 over Finite Field of size 13
sage: E.is_isomorphic(E1)
False
sage: E.is_isomorphic(E1,GF(13^2,'a'))
False
sage: E.is_isomorphic(E1,GF(13^4,'a'))
False
sage: E.is_isomorphic(E1,GF(13^6,'a'))
True
```

38.7 Elliptic curves over the rational numbers

AUTHORS:

- William Stein (2005): first version

- William Stein (2006-02-26): fixed Lseries_extended which didn't work because of changes elsewhere in Sage.
- David Harvey (2006-09): Added padic_E2, padic_sigma, padic_height, padic_regulator methods.
- David Harvey (2007-02): reworked padic-height related code
- Christian Wuthrich (2007): added padic sha computation
- David Roe (2007-09): moved sha, l-series and p-adic functionality to separate files.
- John Cremona (2008-01)
- Tobias Nagel and Michael Mardaus (2008-07): added integral_points
- John Cremona (2008-07): further work on integral_points

class **EllipticCurve_rational_field**(*ainvs, extra=None*)

Elliptic curve over the Rational Field.

INPUT:

- `ainvs` (list or string) – either $[a_1, a_2, a_3, a_4, a_6]$ or $[a_4, a_6]$ (with $a_1 = a_2 = a_3 = 0$) or a valid label from the database.

Note: See constructor.py for more variants.

EXAMPLES:

Construction from Weierstrass coeffiecients (a-invariants), long form:

```
sage: E = EllipticCurve([1,2,3,4,5]); E
Elliptic Curve defined by y^2 + x*y + 3*y = x^3 + 2*x^2 + 4*x + 5 over Rational Field
```

Construction from Weierstrass coeffiecients (a-invariants), short form (sets $a_1 = a_2 = a_3 = 0$):

```
sage: EllipticCurve([4,5]).ainvs()
[0, 0, 0, 4, 5]
```

Construction from a database label:

```
sage: EllipticCurve('389a1')
Elliptic Curve defined by y^2 + y = x^3 + x^2 - 2*x over Rational Field
```

CPS_height_bound()

Return the Cremona-Prickett-Siksek height bound. This is a floating point number B such that if P is a point on the curve, then the naive logarithmic height of P differs from the canonical height by at most B.

EXAMPLES:

```
sage: E = EllipticCurve("11a")
sage: E.CPS_height_bound()
2.8774743273580445
sage: E = EllipticCurve("5077a")
sage: E.CPS_height_bound()
0.0
sage: E = EllipticCurve([1,2,3,4,1])
sage: E.CPS_height_bound()
...
RuntimeError: curve must be minimal.
sage: F = E.quadratic_twist(-19)
sage: F
Elliptic Curve defined by y^2 + x*y + y = x^3 - x^2 + 1376*x - 130 over Rational Field
sage: F.CPS_height_bound()
0.65551583769728516
```

IMPLEMENTATION:

Call the corresponding mwrank C++ library function.

Lambda (*s, prec*)

Returns the value of the Lambda-series of the elliptic curve E at s, where s can be any complex number.

IMPLEMENTATION: Fairly *slow* computation using the definitions and implemented in Python.

Uses prec terms of the power series.

EXAMPLES:

```
sage: E = EllipticCurve('389a')
sage: E.Lambda(1.4+0.5*I, 50)
-0.354172680517... + 0.874518681720...*I
```

Np (*p*)

The number of points on E modulo p.

INPUT:

- p (int) – a prime, not necessarily of good reduction.

OUTPUT:

(int) The number ofpoints on the reduction of E modulo p (including the singular point when p is a prime of bad reduction).

EXAMPLES:

```
sage: E = EllipticCurve([0, -1, 1, -10, -20])
sage: E.Np(2)
5
sage: E.Np(3)
5
sage: E.conductor()
11
sage: E.Np(11)
11
```

S_integral_points (*S, mw_base='auto', both_signs=False, verbose=False, proof=None*)

Computes all S-integral points (up to sign) on this elliptic curve.

INPUT:

- S - list of primes
- mw_base - list of EllipticCurvePoint generating the Mordell-Weil group of E (default: 'auto' - calls gens())
- both_signs - True/False (default False): if True the output contains both P and -P, otherwise only one of each pair.
- verbose - True/False (default False): if True, some details of the computation are output.
- proof - True/False (default True): if True ALL S-integral points will be returned. If False, the MW basis will be computed with the proof=False flag, and also the time-consuming final call to S_integral_x_coords_with_abs_bounded_by(abs_bound) is omitted. Use this only if the computation takes too long, but be warned that then it cannot be guaranteed that all S-integral points will be found.

OUTPUT:

A sorted list of all the S-integral points on E (up to sign unless both_signs is True)

Note: The complexity increases exponentially in the rank of curve E and in the length of S. The computation time (but not the output!) depends on the Mordell-Weil basis. If mw_base is given but is not a basis for the Mordell-Weil group (modulo torsion), S-integral points which are not in the subgroup generated by the given points will almost certainly not be listed.

EXAMPLES:

A curve of rank 3 with no torsion points:

```
sage: E=EllipticCurve([0,0,1,-7,6])
sage: P1=E.point((2,0)); P2=E.point((-1,3)); P3=E.point((4,6))
sage: a=E.S_integral_points(S=[2,3], mw_base=[P1,P2,P3], verbose=True);a
max_S: 3 len_S: 3 len_tors: 1

bound_list [58, 58, 58]
bound_list [8, 9, 9]
bound_list [8, 7, 7]
bound_list [8, 7, 7]
starting search of points using coefficient bound  8
x-coords of S-integral points via linear combination of mw_base and torsion:
[-3, -26/9, -8159/2916, -2759/1024, -151/64, -1343/576, -2, -7/4, -1, -47/256, 0, 1/4, 4/9,
starting search of extra S-integer points with absolute value bounded by 3.89321964979420
x-coords of points with bounded absolute value
[-3, -2, -1, 0, 1, 2]
Total number of S-integral points: 43
[(-3 : 0 : 1), (-26/9 : 28/27 : 1), (-8159/2916 : 233461/157464 : 1), (-2759/1024 : 60819/32
```

It is not necessary to specify mw_base; if it is not provided, then the Mordell-Weil basis must be computed, which may take much longer.

```
sage: a = E.S_integral_points([2,3])
sage: len(a)
43
```

An example with negative discriminant:

```
sage: EllipticCurve('900d1').S_integral_points([17], both_signs=True)
[(-11 : -27 : 1), (-11 : 27 : 1), (-4 : -34 : 1), (-4 : 34 : 1), (4 : -18 : 1), (4 : 18 : 1)
```

Output checked with Magma (corrected in 3 cases):

```
sage: [len(e.S_integral_points([2], both_signs=False)) for e in cremona_curves([11..100])] #
[2, 0, 2, 3, 3, 1, 3, 1, 3, 5, 3, 5, 4, 1, 1, 2, 2, 2, 3, 1, 2, 1, 0, 1, 3, 3, 1, 1, 5, 3, 4
```

An example from [PZGH]:

```
sage: E = EllipticCurve([0,0,0,-172,505])
sage: E.rank(), len(E.S_integral_points([3,5,7]))  # long time (~7s)
(4, 72)
```

This is curve "7690e1" which failed until #4805 was fixed:

```
sage: EllipticCurve([1,1,1,-301,-1821]).S_integral_points([13,2])
[(-13 : 16 : 1),
(-9 : 20 : 1),
(-7 : 4 : 1),
(21 : 30 : 1),
(23 : 52 : 1),
```

```
(63 : 452 : 1),
(71 : 548 : 1),
(87 : 756 : 1),
(2711 : 139828 : 1),
(7323 : 623052 : 1),
(17687 : 2343476 : 1)]
```

- John Cremona (2008-12)

an(*n*)

The n-th Fourier coefficient of the modular form corresponding to this elliptic curve, where n is a positive integer.

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: [E.an(n) for n in range(20) if n>0]
[1, -2, -3, 2, -2, 6, -1, 0, 6, 4, -5, -6, -2, 2, 6, -4, 0, -12, 0]
```

analytic_rank(*algorithm='cremona'*)

Return an integer that is *probably* the analytic rank of this elliptic curve.

INPUT:

- algorithm -
  - 'cremona' (default) - Use the Buhler-Gross algorithm as implemented in GP by Tom Womack and John Cremona, who note that their implementation is practical for any rank and conductor $\leq 10^{10}$ in 10 minutes.
  - 'sympow' -use Watkins's program sympow
  - 'rubinstein' - use Rubinstein's L-function C++ program lcalc.
  - 'magma' - use MAGMA
  - 'all' - compute with all other free algorithms, check that the answers agree, and return the common answer.

Note: If the curve is loaded from the large Cremona database, then the modular degree is taken from the database.

Of the three above, probably Rubinstein's is the most efficient (in some limited testing I've done).

Note: It is an open problem to *prove* that *any* particular elliptic curve has analytic rank ≥ 4.

EXAMPLES:

```
sage: E = EllipticCurve('389a')
sage: E.analytic_rank(algorithm='cremona')
2
sage: E.analytic_rank(algorithm='rubinstein')
2
sage: E.analytic_rank(algorithm='sympow')
2
sage: E.analytic_rank(algorithm='magma')     # optional - magma
2
sage: E.analytic_rank(algorithm='all')
2
```

TESTS:

When the input is horrendous, some of the algorithms just bomb out with a RuntimeError:

```
sage: EllipticCurve([1234567,89101112]).analytic_rank(algorithm='rubinstein')
...
RuntimeError: unable to compute analytic rank using rubinstein algorithm ('unable to convert
sage: EllipticCurve([1234567,89101112]).analytic_rank(algorithm='sympow')
...
RuntimeError: failed to compute analytic rank
```

anlist(*n, python_ints=False*)

The Fourier coefficients up to and including a_n of the modular form attached to this elliptic curve. The i-th element of the return list is a[i].

INPUT:

- n - integer
- python_ints - bool (default: False); if True return a list of Python ints instead of Sage integers.

OUTPUT: list of integers

EXAMPLES:

```
sage: E = EllipticCurve([0, -1, 1, -10, -20])
sage: E.anlist(3)
[0, 1, -2, -1]

sage: E = EllipticCurve([0,1])
sage: E.anlist(20)
[0, 1, 0, 0, 0, 0, 0, -4, 0, 0, 0, 0, 0, 2, 0, 0, 0, 0, 0, 8, 0]
```

antilogarithm(*z, prec=None*)

Returns the rational point (if any) associated to this complex number; the inverse of the elliptic logarithm function.

INPUT:

- z - a complex number representing an element of CC/L where L is the period lattice of the elliptic curve
- precision - an integer specifying the precision (in bits) which will be used for the computation (default real precision if None)

OUTPUT: The rational point which is the image of z under the Weierstrass parametrization, if it exists and can be determined from z with default precision.

Note: This uses the function ellztopoint from the pari library

TODO: Extend the wrapping of ellztopoint() to allow passing of the precision parameter.

ap(*p*)

The p-th Fourier coefficient of the modular form corresponding to this elliptic curve, where p is prime.

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: [E.ap(p) for p in prime_range(50)]
[-2, -3, -2, -1, -5, -2, 0, 0, 2, 6, -4, -1, -9, 2, -9]
```

aplist(*n, python_ints=False*)

The Fourier coefficients a_p of the modular form attached to this elliptic curve, for all primes $p \leq n$.

INPUT:

- n - integer
- python_ints - bool (default: False); if True return a list of Python ints instead of Sage integers.

OUTPUT: list of integers

EXAMPLES:

```
sage: e = EllipticCurve('37a')
sage: e.aplist(1)
[]
sage: e.aplist(2)
[-2]
sage: e.aplist(10)
[-2, -3, -2, -1]
sage: v = e.aplist(13); v
[-2, -3, -2, -1, -5, -2]
sage: type(v[0])
<type 'sage.rings.integer.Integer'>
sage: type(e.aplist(13, python_ints=True)[0])
<type 'int'>
```

cm_discriminant()

Returns the associated quadratic discriminant if this elliptic curve has Complex Multiplication.

A ValueError is raised if the curve does not have CM (see the function has_cm()).

EXAMPLES:

```
sage: E=EllipticCurve('32a1')
sage: E.cm_discriminant()
-4
sage: E=EllipticCurve('121b1')
sage: E.cm_discriminant()
-11
sage: E=EllipticCurve('37a1')
sage: E.cm_discriminant()
...
ValueError: Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field does not have CM
```

conductor(*algorithm='pari'*)

Returns the conductor of the elliptic curve.

INPUT:

- `algorithm` - str, (default: "pari")
  - `"pari"` - use the PARI C-library ellglobalred implementation of Tate's algorithm
  - `"mwrank"` - use Cremona's mwrank implementation of Tate's algorithm; can be faster if the curve has integer coefficients (TODO: limited to small conductor until mwrank gets integer factorization)
  - `"gp"` - use the GP interpreter.
  - `"generic"` - use the general number field implementation
  - `"all"` - use all four implementations, verify that the results are the same (or raise an error), and output the common value.

EXAMPLE:

```
sage: E = EllipticCurve([1, -1, 1, -29372, -1932937])
sage: E.conductor(algorithm="pari")
3006
sage: E.conductor(algorithm="mwrank")
3006
sage: E.conductor(algorithm="gp")
3006
sage: E.conductor(algorithm="generic")
3006
sage: E.conductor(algorithm="all")
3006
```

Note: The conductor computed using each algorithm is cached separately. Thus calling `E.conductor('pari')`, then `E.conductor('mwrank')` and getting the same result checks that both systems compute the same answer.

congruence_number()

Let X be the subspace of $S_2(\Gamma_0(N))$ spanned by the newform associated with this elliptic curve, and Y be orthogonal compliment of X under the Petersson inner product. Let S_X and S_Y be the intersections of X and Y with $S_2(\Gamma_0(N)m\mathbf{Z})$. The congruence number is defined to be $[S_X \oplus S_Y : S_2(\Gamma_0(N), \mathbf{Z})]$. It measures congruences between f and elements of $S_2(\Gamma_0(N), \mathbf{Z})$ orthogonal to f.

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: E.congruence_number()
2
sage: E.congruence_number()
2
sage: E = EllipticCurve('54b')
sage: E.congruence_number()
6
sage: E.modular_degree()
2
sage: E = EllipticCurve('242a1')
sage: E.modular_degree()
16
sage: E.congruence_number()  # long time
176
```

It is a theorem of Ribet that the congruence number is equal to the modular degree in the case of square free conductor. It is a conjecture of Agashe, Ribet, and Stein that $ord_p(c_f/m_f) \leq ord_p(N)/2$.

TESTS:

```
sage: E = EllipticCurve('11a')
sage: E.congruence_number()
1
```

cremona_label(*space=False*)

Return the Cremona label associated to (the minimal model) of this curve, if it is known. If not, raise a RuntimeError exception.

EXAMPLES:

```
sage: E=EllipticCurve('389a1')
sage: E.cremona_label()
'389a1'
```

The default database only contains conductors up to 10000, so any curve with conductor greater than that will cause an error to be raised. The optional package 'database_cremona_ellcurve-20071019' contains more curves, with conductors up to 130000.

```
sage: E = EllipticCurve([1, -1, 0, -79, 289])
sage: E.conductor()
234446
sage: E.cremona_label()
...
RuntimeError: Cremona label not known for Elliptic Curve defined by y^2 + x*y = x^3 - x^2 -
```

database_curve()

Return the curve in the elliptic curve database isomorphic to this curve, if possible. Otherwise raise a RuntimeError exception.

EXAMPLES:

```
sage: E = EllipticCurve([0,1,2,3,4])
sage: E.database_curve()
Elliptic Curve defined by y^2  = x^3 + x^2 + 3*x + 5 over Rational Field
```

Note: The model of the curve in the database can be different from the Weierstrass model for this curve, e.g., database models are always minimal.

eval_modular_form(*points, prec*)

Evaluate the L-series of this elliptic curve at points in CC

INPUT:

- points - a list of points in the half-plane of convergence
- prec - precision

OUTPUT: A list of values L(E,s) for s in points

Note: Better examples are welcome.

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: E.eval_modular_form([1.5+I,2.0+I,2.5+I],0.000001)
[0, 0, 0]
```

gens(*verbose=False, rank1_search=10, algorithm='mwrank_shell', only_use_mwrank=True, proof=None, use_database=True*)

Compute and return generators for the Mordell-Weil group E(Q) *modulo* torsion.

HINT: If you would like to control the height bounds used in the 2-descent, first call the two_descent function with those height bounds. However that function, while it displays a lot of output, returns no values.

TODO: Allow passing of command-line parameters to mwrank.

Warning: If the program fails to give a provably correct result, it prints a warning message, but does not raise an exception. Use the gens_certain command to find out if this warning message was printed.

INPUT:

- verbose - (default: None), if specified changes the verbosity of mwrank computations.
- rank1_search - (default: 16), if the curve has analytic rank 1, try to find a generator by a direct search up to this logarithmic height. If this fails the usual mwrank procedure is called. algorithm -
- – 'mwrank_shell' (default) - call mwrank shell command
- – 'mwrank_lib' - call mwrank c library
- only_use_mwrank - bool (default True) if False, attempts to first use more naive, natively implemented methods.
- proof - bool or None (default None, see proof.elliptic_curve or sage.structure.proof).
- use_database - bool (default True) if True, attempts to find curve and gens in the (optional) database

OUTPUT:

- generators - List of generators for the Mordell-Weil group modulo torsion.

IMPLEMENTATION: Uses Cremona's mwrank C library.

EXAMPLES:

```
sage: E = EllipticCurve('389a')
sage: E.gens()                  # random output
[(-1 : 1 : 1), (0 : 0 : 1)]
```

A non-integral example:

```
sage: E = EllipticCurve([-3/8,-2/3])
sage: E.gens() # random (up to sign)
[(10/9 : 29/54 : 1)]
```

A non-minimal example:

```
sage: E = EllipticCurve('389a1')
sage: E1 = E.change_weierstrass_model([1/20,0,0,0]); E1
Elliptic Curve defined by y^2 + 8000*y = x^3 + 400*x^2 - 320000*x over Rational Field
sage: E1.gens() # random (if database not used)
[(-400 : 8000 : 1), (0 : -8000 : 1)]
```

gens_certain()

Return True if the generators have been proven correct.

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: E.gens()                    # random (up to sign)
[(0 : -1 : 1)]
sage: E.gens_certain()
True
```

global_integral_model()

Return a model of self which is integral at all primes.

EXAMPLES:

```
sage: E = EllipticCurve([0, 0, 1/216, -7/1296, 1/7776])
sage: F = E.global_integral_model(); F
Elliptic Curve defined by y^2 + y = x^3 - 7*x + 6 over Rational Field
sage: F == EllipticCurve('5077a1')
True
```

has_cm()

Returns True iff this elliptic curve has Complex Multiplication.

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: E.has_cm()
False
sage: E=EllipticCurve('32a1')
sage: E.has_cm()
True
sage: E.j_invariant()
1728
```

has_good_reduction_outside_S(*S=, []*)

Tests if this elliptic curve has good reduction outside S.

INPUT:

- S - list of primes (default: empty list).

Note: Primality of elements of S is not checked, and the output is undefined if S is not a list or contains non-primes.

This only tests the given model, so should only be applied to minimal models.

EXAMPLES:

```
sage: EllipticCurve('11a1').has_good_reduction_outside_S([11])
True
sage: EllipticCurve('11a1').has_good_reduction_outside_S([2])
False
```

```
sage: EllipticCurve('2310a1').has_good_reduction_outside_S([2,3,5,7])
False
sage: EllipticCurve('2310a1').has_good_reduction_outside_S([2,3,5,7,11])
True
```

heegner_discriminants(*bound*)

Return the list of self's Heegner discriminants between -1 and -bound.

INPUT:

- `bound (int)` - upper bound for -discriminant

OUTPUT: The list of Heegner discriminants between -1 and -bound for the given elliptic curve.

EXAMPLES:

```
sage: E=EllipticCurve('11a')
sage: E.heegner_discriminants(30)
[-7, -8, -19, -24]
```

heegner_discriminants_list(*n*)

Return the list of self's first n Heegner discriminants smaller than -5.

INPUT:

- `n (int)` - the number of discriminants to compute

OUTPUT: The list of the first n Heegner discriminants smaller than -5 for the given elliptic curve.

EXAMPLE:

```
sage: E=EllipticCurve('11a')
sage: E.heegner_discriminants_list(4)
[-7, -8, -19, -24]
```

heegner_index(*D, min_p=2, prec=5, verbose=False*)

Return an interval that contains the index of the Heegner point y_K in the group of K-rational points modulo torsion on this elliptic curve, computed using the Gross-Zagier formula and/or a point search, or the index divided by 2.

Note: If `min_p` is bigger than 2 then the index can be off by any prime less than `min_p`. This function returns the index divided by 2 exactly when $E(\mathbf{Q})_{/tor}$ has index 2 in $E(K)_{/tor}$.

INPUT:

- `D (int)` - Heegner discriminant
- `min_p (int)` - (default: 2) only rule out primes = min_p dividing the index.
- `verbose (bool)` - (default: False); print lots of mwrank search status information when computing regulator
- `prec (int)` - (default: 5), use prec*sqrt(N) + 20 terms of L-series in computations, where N is the conductor.

OUTPUT: an interval that contains the index

EXAMPLES:

```
sage: E = EllipticCurve('11a')
sage: E.heegner_discriminants(50)
[-7, -8, -19, -24, -35, -39, -40, -43]
sage: E.heegner_index(-7)
1.00000?

sage: E = EllipticCurve('37b')
sage: E.heegner_discriminants(100)
[-3, -4, -7, -11, -40, -47, -67, -71, -83, -84, -95]
sage: E.heegner_index(-95)           # long time (1 second)
2.00000?
```

This tests doing direct computation of the Mordell-Weil group.

```
sage: EllipticCurve('675b').heegner_index(-11)
3.0000?
```

Currently discriminants -3 and -4 are not supported:

```
sage: E.heegner_index(-3)
...
ArithmeticError: Discriminant (=-3) must not be -3 or -4.
```

The curve 681b returns an interval that contains $3/2$. This is because $E(\mathbf{Q})$ is not saturated in $E(K)$. The true index is 3:

```
sage: E = EllipticCurve('681b')
sage: I = E.heegner_index(-8); I
1.50000?
sage: 2*I
3.0000?
```

In fact, whenever the returned index has a denominator of 2, the true index is got by multiplying the returned index by 2. Unfortunately, this is not an if and only if condition, i.e., sometimes the index must be multiplied by 2 even though the denominator is not 2.

heegner_index_bound(*D=0, prec=5, verbose=True, max_height=21*)

Assume self has rank 0.

Return a list v of primes such that if an odd prime p divides the index of the Heegner point in the group of rational points *modulo torsion*, then p is in v.

If 0 is in the interval of the height of the Heegner point computed to the given prec, then this function returns v = 0. This does not mean that the Heegner point is torsion, just that it is very likely torsion.

If we obtain no information from a search up to max_height, e.g., if the Siksek et al. bound is bigger than max_height, then we return v = -1.

INPUT:

- `D (int)` - (default: 0) Heegner discriminant; if 0, use the first discriminant -4 that satisfies the Heegner hypothesis
- `verbose (bool)` - (default: True)
- `prec (int)` - (default: 5), use prec*sqrt(N) + 20 terms of L-series in computations, where N is the conductor.
- `max_height (float)` - should be = 21; bound on logarithmic naive height used in point searches. Make smaller to make this function faster, at the expense of possibly obtaining a worse answer. A good range is between 13 and 21.

OUTPUT:

- `v` - list or int (bad primes or 0 or -1)
- `D` - the discriminant that was used (this is useful if D was automatically selected).

EXAMPLES:

```
sage: E = EllipticCurve('11a1')
sage: E.heegner_index_bound(verbose=False)
([2], -7)
```

heegner_point_height(*D, prec=2*)

Use the Gross-Zagier formula to compute the Neron-Tate canonical height over K of the Heegner point corresponding to D, as an Interval (since it's computed to some precision using L-functions).

INPUT:

- `D (int)` - fundamental discriminant (=/= -3, -4)
- `prec (int)` - (default: 2), use prec*sqrt(N) + 20 terms of L-series in computations, where N is the conductor.

OUTPUT: Interval that contains the height of the Heegner point.

EXAMPLE:

```
sage: E = EllipticCurve('11a')
sage: E.heegner_point_height(-7)
0.22227?
```

heegner_sha_an (*D, prec=53*)

Return the conjectural (analytic) order of Sha

INPUT:

- D – negative integer; the Heegner discriminant
- prec – integer (default: 53); bits of precision to compute analytic order of Sha

OUTPUT:

(floating point number) an approximation to the conjectural order of Sha.

Note: Often you'll want to do `proof.elliptic_curve(False)` when using this function, since often the twisted elliptic curves that come up have enormous conductor, and Sha is nontrivial, which makes provably finding the Mordell-Weil group using 2-descent difficult.

EXAMPLES:

An example where E has conductor 11:

```
sage: E = EllipticCurve('11a')
sage: E.heegner_sha_an(-7)                                  # long
1.00000000000000
```

The cache works:

```
sage: E.heegner_sha_an(-7) is E.heegner_sha_an(-7)          # long
True
```

Lower precision:

```
sage: E.heegner_sha_an(-7,10)                               # long
1.0
```

Checking that the cache works for any precision:

```
sage: E.heegner_sha_an(-7,10) is E.heegner_sha_an(-7,10)    # long
True
```

A rank 1 curve with nontrivial Sha over the quadratic imaginary field K; however, there is no Sha for E over QQ or for the quadratic twist of E:

```
sage: E = EllipticCurve('37a')
sage: E.heegner_sha_an(-40)                                 # long
4.00000000000000
sage: E.quadratic_twist(-40).sha().an()                     # long
1
sage: E.sha().an()                                          # long
1
```

A rank 2 curve:

```
sage: E = EllipticCurve('389a')                             # long
sage: E.heegner_sha_an(-7)                                  # long
1.00000000000000
```

If we remove the hypothesis that E(K) has rank 1 in Conjecture 2.3 in [Gross-Zagier, 1986, page 311], then that conjecture is false, as the following example shows:

```
sage: E = EllipticCurve('65a')                              # long
sage: E.heegner_sha_an(-56)                                 # long
```

```
1.00000000000000
sage: E.torsion_order()                                    # long
2
sage: E.tamagawa_product()                                 # long
1
sage: E.quadratic_twist(-56).rank()                        # long
2
```

height (*precision=None*)

Returns the real height of this elliptic curve. This is used in integral_points()

INPUT:

- `precision` - desired real precision of the result (default real precision if None)

EXAMPLES:

```
sage: E=EllipticCurve('5077a1')
sage: E.height()
17.4513334798896
sage: E.height(100)
17.451333479889612702508579399
sage: E=EllipticCurve([0,0,0,0,1])
sage: E.height()
1.38629436111989
sage: E=EllipticCurve([0,0,0,1,0])
sage: E.height()
7.45471994936400
```

height_pairing_matrix (*points=None, precision=None*)

Returns the height pairing matrix of the given points on this curve, which must be defined over $\mathbf{Q}$.

INPUT:

- points - either a list of points, which must be on this curve, or (default) None, in which case self.gens() will be used. precision - number of bits of precision of result (default: None, for default RealField precision)

EXAMPLES:

```
sage: E = EllipticCurve([0, 0, 1, -1, 0])
sage: E.height_pairing_matrix()
[0.0511114082399688]
```

For rank 0 curves, the result is a valid 0x0 matrix:

```
sage: EllipticCurve('11a').height_pairing_matrix()
[]
sage: E=EllipticCurve('5077a1')
sage: E.height_pairing_matrix([E.lift_x(x) for x in [-2,-7/4,1]], precision=100)
[  1.3685725053539301120518194471  -1.3095767070865761992624519454 -0.6348671578371559206447
[ -1.3095767070865761992624519454   2.7173593928122930896610589220   1.0998184305667292139777571432  0.6682051656519279350331
```

integral_model ()

Return a model of self which is integral at all primes.

EXAMPLES:

```
sage: E = EllipticCurve([0, 0, 1/216, -7/1296, 1/7776])
sage: F = E.global_integral_model(); F
Elliptic Curve defined by y^2 + y = x^3 - 7*x + 6 over Rational Field
sage: F == EllipticCurve('5077a1')
True
```

integral_points(*mw_base='auto', both_signs=False, verbose=False*)

Computes all integral points (up to sign) on this elliptic curve.

INPUT:

- `mw_base` - list of EllipticCurvePoint generating the Mordell-Weil group of E (default: 'auto' - calls self.gens())
- `both_signs` - True/False (default False): if True the output contains both P and -P, otherwise only one of each pair.
- `verbose` - True/False (default False): if True, some details of the computation are output

OUTPUT: A sorted list of all the integral points on E (up to sign unless both_signs is True)

Note: The complexity increases exponentially in the rank of curve E. The computation time (but not the output!) depends on the Mordell-Weil basis. If mw_base is given but is not a basis for the Mordell-Weil group (modulo torsion), integral points which are not in the subgroup generated by the given points will almost certainly not be listed.

EXAMPLES: A curve of rank 3 with no torsion points

```
sage: E=EllipticCurve([0,0,1,-7,6])
sage: P1=E.point((2,0)); P2=E.point((-1,3)); P3=E.point((4,6))
sage: a=E.integral_points([P1,P2,P3]); a
[(-3 : 0 : 1), (-2 : 3 : 1), (-1 : 3 : 1), (0 : 2 : 1), (1 : 0 : 1), (2 : 0 : 1), (3 : 3 : 1
```

```
sage: a = E.integral_points([P1,P2,P3], verbose=True)
Using mw_basis  [(2 : 0 : 1), (3 : -4 : 1), (8 : -22 : 1)]
e1,e2,e3:  -3.0124303725933... 1.0658205476962... 1.94660982489710
Minimal eigenvalue of height pairing matrix:  0.63792081458500...
x-coords of points on compact component with  -3 <=x<= 1
[-3, -2, -1, 0, 1]
x-coords of points on non-compact component with  2 <=x<= 6
[2, 3, 4]
starting search of remaining points using coefficient bound  5
x-coords of extra integral points:
[2, 3, 4, 8, 11, 14, 21, 37, 52, 93, 342, 406, 816]
Total number of integral points: 18
```

It is not necessary to specify mw_base; if it is not provided, then the Mordell-Weil basis must be computed, which may take much longer.

```
sage: E=EllipticCurve([0,0,1,-7,6])
sage: a=E.integral_points(both_signs=True); a
[(-3 : -1 : 1), (-3 : 0 : 1), (-2 : -4 : 1), (-2 : 3 : 1), (-1 : -4 : 1), (-1 : 3 : 1), (0 :
```

An example with negative discriminant:

```
sage: EllipticCurve('900d1').integral_points()
[(-11 : 27 : 1), (-4 : 34 : 1), (4 : 18 : 1), (16 : 54 : 1)]
```

Another example with rank 5 and no torsion points

```
sage: E=EllipticCurve([-879984,319138704])
sage: P1=E.point((540,1188)); P2=E.point((576,1836))
sage: P3=E.point((468,3132)); P4=E.point((612,3132))
sage: P5=E.point((432,4428))
sage: a=E.integral_points([P1,P2,P3,P4,P5]); len(a)  # long time (400s!)
54
```

The bug reported on trac #4525 is now fixed:

```
sage: EllipticCurve('91b1').integral_points()
[(-1 : 3 : 1), (1 : 0 : 1), (3 : 4 : 1)]
```

```
sage: [len(e.integral_points(both_signs=False)) for e in cremona_curves([11..100])] # long t
[2, 0, 2, 3, 2, 1, 3, 0, 2, 4, 2, 4, 3, 0, 0, 1, 2, 1, 2, 0, 2, 1, 0, 1, 3, 3, 1, 1, 4, 2, 3
```

The bug reported at #4897 is now fixed:

```
sage: [P[0] for P in EllipticCurve([0,0,0,-468,2592]).integral_points()]
[-24, -18, -14, -6, -3, 4, 6, 18, 21, 24, 36, 46, 102, 168, 186, 381, 1476, 2034, 67246]
```

Note: This function uses the algorithm given in [Co1].

integral_short_weierstrass_model()

Return a model of the form $y^2 = x^3 + a * x + b$ for this curve with $a, b \in \mathbf{Z}$.

EXAMPLES:

```
sage: E = EllipticCurve('17a1')
sage: E.integral_short_weierstrass_model()
Elliptic Curve defined by y^2  = x^3 - 11*x - 890 over Rational Field
```

integral_weierstrass_model()

Return a model of the form $y^2 = x^3 + a * x + b$ for this curve with $a, b \in \mathbf{Z}$.

Note that this function is deprecated, and that you should use integral_short_weierstrass_model instead as this will be disappearing in the near future.

EXAMPLES:

```
sage: E = EllipticCurve('17a1')
sage: E.integral_weierstrass_model() #random
doctest:1: DeprecationWarning: integral_weierstrass_model is deprecated, use integral_short_
Elliptic Curve defined by y^2  = x^3 - 11*x - 890 over Rational Field
```

integral_x_coords_in_interval(*xmin, xmax*)

Returns the set of integers x with $xmin \leq x \leq xmax$ which are x-coordinates of points on this curve.

is_global_integral_model()

Return true iff self is integral at all primes.

EXAMPLES:

```
sage: E=EllipticCurve([1/2,1/5,1/5,1/5,1/5])
sage: E.is_global_integral_model()
False
sage: Emin=E.global_integral_model()
sage: Emin.is_global_integral_model()
True
```

is_good(*p, check=True*)

Return True if p is a prime of good reduction for E.

INPUT:

•p - a prime

OUTPUT: bool

EXAMPLES:

```
sage: e = EllipticCurve('11a')
sage: e.is_good(-8)
...
ValueError: p must be prime
sage: e.is_good(-8, check=False)
True
```

is_integral()

Returns True if this elliptic curve has integral coefficients (in Z)

EXAMPLES:

```
sage: E=EllipticCurve(QQ,[1,1]); E
Elliptic Curve defined by y^2 = x^3 + x + 1 over Rational Field
sage: E.is_integral()
True
sage: E2=E.change_weierstrass_model(2,0,0,0); E2
Elliptic Curve defined by y^2 = x^3 + 1/16*x + 1/64 over Rational Field
sage: E2.is_integral()
False
```

is_irreducible(p)

Return True if the mod p representation is irreducible.

EXAMPLES:

```
sage: e = EllipticCurve('37b')
sage: e.is_irreducible(2)
True
sage: e.is_irreducible(3)
False
sage: e.is_reducible(2)
False
sage: e.is_reducible(3)
True
```

is_local_integral_model(*p)

Tests if self is integral at the prime p, or at all the primes if p is a list or tuple of primes

EXAMPLES:

```
sage: E=EllipticCurve([1/2,1/5,1/5,1/5,1/5])
sage: [E.is_local_integral_model(p) for p in (2,3,5)]
[False, True, False]
sage: E.is_local_integral_model(2,3,5)
False
sage: Eint2=E.local_integral_model(2)
sage: Eint2.is_local_integral_model(2)
True
```

is_minimal()

Return True iff this elliptic curve is a reduced minimal model.

The unique minimal Weierstrass equation for this elliptic curve. This is the model with minimal discriminant and $a_1, a_2, a_3 \in \{0, \pm 1\}$.

TO DO: This is not very efficient since it just computes the minimal model and compares. A better implementation using the Kraus conditions would be preferable.

EXAMPLES:

```
sage: E=EllipticCurve([10,100,1000,10000,1000000])
sage: E.is_minimal()
False
```

```
sage: E=E.minimal_model()
sage: E.is_minimal()
True
```

is_ordinary(*p, ell=None*)

Return True precisely when the mod-p representation attached to this elliptic curve is ordinary at ell.

INPUT:

- p - a prime ell - a prime (default: p)

OUTPUT: bool

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: E.is_ordinary(37)
True
sage: E=EllipticCurve('32a1')
sage: E.is_ordinary(2)
False
sage: [p for p in prime_range(50) if E.is_ordinary(p)]
[5, 13, 17, 29, 37, 41]
```

is_p_integral(*p*)

Returns True if this elliptic curve has p-integral coefficients.

INPUT:

- p - a prime integer

EXAMPLES:

```
sage: E=EllipticCurve(QQ,[1,1]); E
Elliptic Curve defined by y^2 = x^3 + x + 1 over Rational Field
sage: E.is_p_integral(2)
True
sage: E2=E.change_weierstrass_model(2,0,0,0); E2
Elliptic Curve defined by y^2 = x^3 + 1/16*x + 1/64 over Rational Field
sage: E2.is_p_integral(2)
False
sage: E2.is_p_integral(3)
True
```

is_p_minimal(*p*)

Tests if curve is p-minimal at a given prime p.

INPUT: p - a primeOUTPUT: True - if curve is p-minimal

- False - if curve isn't p-minimal

EXAMPLES:

```
sage: E = EllipticCurve('441a2')
sage: E.is_p_minimal(7)
True

sage: E = EllipticCurve([0,0,0,0,(2*5*11)**10])
sage: [E.is_p_minimal(p) for p in prime_range(2,24)]
[False, True, False, True, False, True, True, True, True]
```

is_reducible(*p*)

Return True if the mod-p representation attached to E is reducible.

INPUT:

- p - a prime number

Note: The answer is cached.

EXAMPLES:

```
sage: E = EllipticCurve('121a'); E
Elliptic Curve defined by y^2 + x*y + y = x^3 + x^2 - 30*x - 76 over Rational Field
sage: E.is_reducible(7)
False
sage: E.is_reducible(11)
True
sage: EllipticCurve('11a').is_reducible(5)
True
sage: e = EllipticCurve('11a2')
sage: e.is_reducible(5)
True
sage: e.torsion_order()
1
```

is_semistable()

Return True iff this elliptic curve is semi-stable at all primes.

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: E.is_semistable()
True
sage: E=EllipticCurve('90a1')
sage: E.is_semistable()
False
```

is_supersingular(*p, ell=None*)

Return True precisely when p is a prime of good reduction and the mod-p representation attached to this elliptic curve is supersingular at ell.

INPUT:

- p - a prime ell - a prime (default: p)

OUTPUT: bool

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: E.is_supersingular(37)
False
sage: E=EllipticCurve('32a1')
sage: E.is_supersingular(2)
False
sage: E.is_supersingular(7)
True
sage: [p for p in prime_range(50) if E.is_supersingular(p)]
[3, 7, 11, 19, 23, 31, 43, 47]
```

is_surjective(*p, A=1000*)

Return True if the mod-p representation attached to E is surjective, False if it is not, or None if we were unable to determine whether it is or not.

Note: The answer is cached.

INPUT:

- p - int (a prime number)
- A - int (a bound on the number of a_p to use)

OUTPUT:

A 2-tuple:

- surjective or (probably) not
- information about what it is if not surjective

EXAMPLES:

```
sage: e = EllipticCurve('37b')
sage: e.is_surjective(2)
(True, None)
sage: e.is_surjective(3)
(False, '3-torsion')
```

REMARKS:

1. If $p = 5$ then the mod-p representation is surjective if and only if the p-adic representation is surjective. When $p = 2, 3$ there are counterexamples. See a very recent paper of Elkies for more details when $p = 3$.
2. When p = 3 this function always gives the correct result irregardless of A, since it explicitly determines the p-division polynomial.

isogeny_class(*algorithm='mwrank', verbose=False*)

Return all curves over $\mathbf{Q}$ in the isogeny class of this elliptic curve.

WARNING: The result is emph{not} provably correct, in the sense that when the numbers are huge isogenies could be missed because of precision issues.

INPUT:

- `verbose` – bool (default: False)
- `algorithm` - string:
  - "mwrank" - (default) use the mwrank C++ library
  - "database" - use the Cremona database (only works if curve is isomorphic to a curve in the database)

OUTPUT: Returns the sorted list of the curves isogenous to self. If algorithm is "mwrank", also returns the isogeny matrix (otherwise returns None as second return value).

Note: The ordering depends on which algorithm is used.

EXAMPLES:

```
sage: I, A = EllipticCurve('37b').isogeny_class('mwrank')
sage: I   # randomly ordered
[Elliptic Curve defined by y^2 + y = x^3 + x^2 - 23*x - 50 over Rational Field,
 Elliptic Curve defined by y^2 + y = x^3 + x^2 - 1873*x - 31833 over Rational Field,
 Elliptic Curve defined by y^2 + y = x^3 + x^2 - 3*x +1 over Rational Field]
sage: A
[0 3 3]
[3 0 0]
[3 0 0]

sage: I, _ = EllipticCurve('37b').isogeny_class('database'); I
[Elliptic Curve defined by y^2 + y = x^3 + x^2 - 1873*x - 31833 over Rational Field,
 Elliptic Curve defined by y^2 + y = x^3 + x^2 - 23*x - 50 over Rational Field,
 Elliptic Curve defined by y^2 + y = x^3 + x^2 - 3*x + 1 over Rational Field]
```

This is an example of a curve with a 37-isogeny:

```
sage: E = EllipticCurve([1,1,1,-8,6])
sage: E.isogeny_class ()
([Elliptic Curve defined by y^2 + x*y + y = x^3 + x^2 - 8*x + 6 over Rational Field,
  Elliptic Curve defined by y^2 + x*y + y = x^3 + x^2 - 208083*x - 36621194 over Rational Fi
 [ 0 37]
 [37  0])
```

This curve had numerous 2-isogenies:

```
sage: e=EllipticCurve([1,0,0,-39,90])
sage: e.isogeny_class ()
([Elliptic Curve defined by y^2 + x*y = x^3 - 39*x + 90 over Rational Field,
  Elliptic Curve defined by y^2 + x*y = x^3 - 4*x - 1 over Rational Field,
  Elliptic Curve defined by y^2 + x*y = x^3 + x over Rational Field,
  Elliptic Curve defined by y^2 + x*y = x^3 - 49*x - 136 over Rational Field,
  Elliptic Curve defined by y^2 + x*y = x^3 - 34*x - 217 over Rational Field,
  Elliptic Curve defined by y^2 + x*y = x^3 - 784*x - 8515 over Rational Field],
 [0 2 0 0 0 0]
 [2 0 2 2 0 0]
 [0 2 0 0 0 0]
 [0 2 0 0 2 2]
 [0 0 0 2 0 0]
 [0 0 0 2 0 0])
```

See http://math.harvard.edu/~elkies/nature.html for more interesting examples of isogeny structures.

isogeny_graph()

Returns a graph representing the isogeny class of this elliptic curve, where the vertices are isogenous curves over $\mathbf{Q}$ and the edges are prime degree isogenies

Warning: The result is *not* provably correct, in the sense that when the numbers are huge isogenies could be missed because of precision issues.

EXAMPLES:

```
sage: LL = []
sage: for e in cremona_optimal_curves(range(1, 38)):
...     G = e.isogeny_graph()
...     already = False
...     for H in LL:
...         if G.is_isomorphic(H):
...             already = True
...             break
...     if not already:
...         LL.append(G)
...
sage: graphs_list.show_graphs(LL)

sage: E = EllipticCurve('195a')
sage: G = E.isogeny_graph()
sage: for v in G: print v, G.get_vertex(v)
...
0 Elliptic Curve defined by y^2 + x*y  = x^3 - 110*x + 435 over Rational Field
1 Elliptic Curve defined by y^2 + x*y  = x^3 - 115*x + 392 over Rational Field
2 Elliptic Curve defined by y^2 + x*y  = x^3 + 210*x + 2277 over Rational Field
3 Elliptic Curve defined by y^2 + x*y  = x^3 - 520*x - 4225 over Rational Field
4 Elliptic Curve defined by y^2 + x*y  = x^3 + 605*x - 19750 over Rational Field
5 Elliptic Curve defined by y^2 + x*y  = x^3 - 8125*x - 282568 over Rational Field
6 Elliptic Curve defined by y^2 + x*y  = x^3 - 7930*x - 296725 over Rational Field
7 Elliptic Curve defined by y^2 + x*y  = x^3 - 130000*x - 18051943 over Rational Field
sage: G.plot(edge_labels=True)
```

kodaira_symbol(p)

Local Kodaira type of the elliptic curve at p.

INPUT:

- p, an integral prime

OUTPUT:

•the Kodaira type of this elliptic curve at p, as a KodairaSymbol.

EXAMPLES:

```
sage: E = EllipticCurve('124a')
sage: E.kodaira_type(2)
IV
```

kodaira_type(*p*)

Local Kodaira type of the elliptic curve at p.

INPUT:

•p, an integral prime

OUTPUT:

•the Kodaira type of this elliptic curve at p, as a KodairaSymbol.

EXAMPLES:

```
sage: E = EllipticCurve('124a')
sage: E.kodaira_type(2)
IV
```

kodaira_type_old(*p*)

Local Kodaira type of the elliptic curve at p.

INPUT:

•p, an integral prime

OUTPUT:

•the kodaira type of this elliptic curve at p, as a KodairaSymbol.

EXAMPLES:

```
sage: E = EllipticCurve('124a')
sage: E.kodaira_type_old(2)
IV
```

label(*space=False*)

Return the Cremona label associated to (the minimal model) of this curve, if it is known. If not, raise a RuntimeError exception.

EXAMPLES:

```
sage: E=EllipticCurve('389a1')
sage: E.cremona_label()
'389a1'
```

The default database only contains conductors up to 10000, so any curve with conductor greater than that will cause an error to be raised. The optional package 'database_cremona_ellcurve-20071019' contains more curves, with conductors up to 130000.

```
sage: E = EllipticCurve([1, -1, 0, -79, 289])
sage: E.conductor()
234446
sage: E.cremona_label()
...
RuntimeError: Cremona label not known for Elliptic Curve defined by y^2 + x*y = x^3 - x^2 -
```

lll_reduce(*points, height_matrix=None*)

Returns an LLL-reduced basis from a given basis, with transform matrix.

INPUT:

•`points` - a list of points on this elliptic curve, which should be independent.

•`height_matrix` - the height-pairing matrix of the points, or None. If None, it will be computed.

OUTPUT: A tuple (newpoints,U) where U is a unimodular integer matrix, new_points is the transform of points by U, such that new_points has LLL-reduced height pairing matrix

Note: If the input points are not independent, the output depends on the undocumented behaviour of pari's `qflllgram()` function when applied to a gram matrix which is not positive definite.

EXAMPLE:

```
sage: E = EllipticCurve([0, 1, 1, -2, 42])
sage: Pi = E.gens(); Pi
[(-4 : 1 : 1), (-3 : 5 : 1), (-11/4 : 43/8 : 1), (-2 : 6 : 1)]
sage: Qi, U = E.lll_reduce(Pi)
sage: Qi
[(0 : 6 : 1), (1 : -7 : 1), (-4 : 1 : 1), (-3 : 5 : 1)]
sage: U.det()
1
sage: E.regulator_of_points(Pi)
4.59088036960574
sage: E.regulator_of_points(Qi)
4.59088036960574

sage: E = EllipticCurve([1,0,1,-120039822036992245303534619191166796374,504224992484910670010
sage: xi = [2005024558054813068,            -4690836759490453344,            4700156326649800
sage: points = [E.lift_x(x) for x in xi]
sage: newpoints, U = E.lll_reduce(points) # long time (2m)
sage: [P[0] for P in newpoints]           # long time
[6823803569166584943, 5949539878899294213, 2005024558054813068, 5864879778877955778, 2395526
```

local_integral_model(*p*)

Return a model of self which is integral at the prime p.

EXAMPLES:

```
sage: E=EllipticCurve([0, 0, 1/216, -7/1296, 1/7776])
sage: E.local_integral_model(2)
Elliptic Curve defined by y^2 + 1/27*y = x^3 - 7/81*x + 2/243 over Rational Field
sage: E.local_integral_model(3)
Elliptic Curve defined by y^2 + 1/8*y = x^3 - 7/16*x + 3/32 over Rational Field
sage: E.local_integral_model(2).local_integral_model(3) == EllipticCurve('5077a1')
True
```

lseries()

Returns the L-series of this elliptic curve.

Further documentation is available for the functions which apply to the L-series.

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: E.lseries()
Complex L-series of the Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field
```

manin_constant()

Return the Manin constant of this elliptic curve.

OUTPUT:

an integer

This function only works if the curve is in the installed Cremona database. Sage includes by default a small databases; for the full database you have to install an optional package.

Warning: The result is *not* provably correct, in the sense that when the numbers are huge isogenies could be missed because of precision issues.

EXAMPLES:

```
sage: EllipticCurve('11a1').manin_constant()
1
sage: EllipticCurve('11a2').manin_constant()
5
sage: EllipticCurve('11a3').manin_constant()
5
```

Check that it works even if the curve is non-minimal:

```
sage: EllipticCurve('11a1').short_weierstrass_model().manin_constant()
1
```

An example where the isogeny class is large, so it's not completely trivial to find the minimal degree of an isogeny to the optimal curve:

```
sage: [EllipticCurve('210b%s'%i).manin_constant() for i in [1..8]]
[1, 2, 3, 4, 4, 6, 12, 12]
```

Make sure the special case 990h is treated correctly, i.e., that 990h3 has Manin constant 1:

```
sage: [EllipticCurve('990h%s'%i).manin_constant() for i in [1..4]]
[3, 6, 1, 2]
```

This plots helps you see that the above Manin constants are right. Note that the vertex labels are 0-based unlinke the Cremona isogeny labels:

```
sage: EllipticCurve('210b1').isogeny_graph().plot(edge_labels=True)
```

matrix_of_frobenius (*p, prec=20, check=False, check_hypotheses=True, algorithm='auto'*)
See the parameters and documentation for padic_E2.

minimal_model()
Return the unique minimal Weierstrass equation for this elliptic curve. This is the model with minimal discriminant and $a_1, a_2, a_3 \in \{0, \pm 1\}$.

EXAMPLES:

```
sage: E=EllipticCurve([10,100,1000,10000,1000000])
sage: E.minimal_model()
Elliptic Curve defined by y^2 + x*y + y = x^3 + x^2 + x + 1 over Rational Field
```

minimal_quadratic_twist()
Determines a quadratic twist with minimal conductor. Returns a global minimal model of the twist and the fundamental discriminant of the quadratic field over which they are isomorphic.

Note: If there is more than one curve with minimal conductor, the one returned is the one with smallest label (if in the database), or the one with minimal a-invariant list (otherwise).

EXAMPLES:

```
sage: E = EllipticCurve('121d1')
sage: E.minimal_quadratic_twist()
(Elliptic Curve defined by y^2 + y = x^3 - x^2 over Rational Field, -11)
sage: Et, D = EllipticCurve('32a1').minimal_quadratic_twist()
sage: D
1

sage: E = EllipticCurve('11a1')
sage: Et, D = E.quadratic_twist(-24).minimal_quadratic_twist()
sage: E == Et
True
sage: D
-24
```

```
sage: E = EllipticCurve([0,0,0,0,1000])
sage: E.minimal_quadratic_twist()
(Elliptic Curve defined by y^2 = x^3 + 1 over Rational Field, 40)
sage: E = EllipticCurve([0,0,0,1600,0])
sage: E.minimal_quadratic_twist()
(Elliptic Curve defined by y^2 = x^3 + 4*x over Rational Field, 5)
```

mod5family()

Return the family of all elliptic curves with the same mod-5 representation as self.

EXAMPLES:

```
sage: E=EllipticCurve('32a1')
sage: E.mod5family()
Elliptic Curve defined by y^2  = x^3 + 4*x over Fraction Field of Univariate Polynomial Ring
```

modular_degree(*algorithm='sympow'*)

Return the modular degree of this elliptic curve.

The result is cached. Subsequent calls, even with a different algorithm, just returned the cached result.

INPUT:

- `algorithm` - string:
- `'sympow'` - (default) use Mark Watkin's (newer) C program sympow
- `'magma'` - requires that MAGMA be installed (also implemented by Mark Watkins)

Note: On 64-bit computers ec does not work, so Sage uses sympow even if ec is selected on a 64-bit computer.

The correctness of this function when called with algorithm "sympow" is subject to the following three hypothesis:

- Manin's conjecture: the Manin constant is 1
- Steven's conjecture: the $X_1(N)$-optimal quotient is the curve with minimal Faltings height. (This is proved in most cases.)
- The modular degree fits in a machine double, so it better be less than about 50-some bits. (If you use sympow this constraint does not apply.)

Moreover for all algorithms, computing a certain value of an L-function "uses a heuristic method that discerns when the real-number approximation to the modular degree is within epsilon [=0.01 for algorithm="sympow"] of the same integer for 3 consecutive trials (which occur maybe every 25000 coefficients or so). Probably it could just round at some point. For rigour, you would need to bound the tail by assuming (essentially) that all the a_n are as large as possible, but in practise they exhibit significant (square root) cancellation. One difficulty is that it doesn't do the sum in 1-2-3-4 order; it uses 1-2-4-8–3-6-12-24-9-18- (Euler product style) instead, and so you have to guess ahead of time at what point to curtail this expansion." (Quote from an email of Mark Watkins.)

Note: If the curve is loaded from the large Cremona database, then the modular degree is taken from the database.

EXAMPLES:

```
sage: E = EllipticCurve([0, -1, 1, -10, -20])
sage: E
Elliptic Curve defined by y^2 + y = x^3 - x^2 - 10*x - 20 over Rational Field
sage: E.modular_degree()
1
sage: E = EllipticCurve('5077a')
sage: E.modular_degree()
1984
sage: factor(1984)
2^6 * 31
```

```
sage: EllipticCurve([0, 0, 1, -7, 6]).modular_degree()
1984
sage: EllipticCurve([0, 0, 1, -7, 6]).modular_degree(algorithm='sympow')
1984
sage: EllipticCurve([0, 0, 1, -7, 6]).modular_degree(algorithm='magma')  # optional - magma
1984
```

We compute the modular degree of the curve with rank 4 having smallest (known) conductor:

```
sage: E = EllipticCurve([1, -1, 0, -79, 289])
sage: factor(E.conductor())  # conductor is 234446
2 * 117223
sage: factor(E.modular_degree())
2^7 * 2617
```

modular_form()

Return the cuspidal modular form associated to this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: f = E.modular_form()
sage: f
q - 2*q^2 - 3*q^3 + 2*q^4 - 2*q^5 + O(q^6)
```

If you need to see more terms in the q-expansion:

```
sage: f.q_expansion(20)
q - 2*q^2 - 3*q^3 + 2*q^4 - 2*q^5 + 6*q^6 - q^7 + 6*q^9 + 4*q^10 - 5*q^11 - 6*q^12 - 2*q^13
```

Note: If you just want the q-expansion, use `q_expansion()`.

modular_parametrization()

Computes and returns the modular parametrization of this elliptic curve.

The curve is converted to a minimal model.

OUTPUT: A list of two Laurent series [X(x),Y(x)] of degrees -2, -3 respectively, which satisfy the equation of the (minimal model of the) elliptic curve. There are modular functions on $\Gamma_0(N)$ where N is the conductor.

X.deriv()/(2*Y+a1*X+a3) should equal f(q)dq/q where f is self.q_expansion().

EXAMPLES:

```
sage: E=EllipticCurve('389a1')
sage: X,Y=E.modular_parametrization()
sage: X
q^-2 + 2*q^-1 + 4 + 7*q + 13*q^2 + 18*q^3 + 31*q^4 + 49*q^5 + 74*q^6 + 111*q^7 + 173*q^8 + 2
sage: Y
-q^-3 - 3*q^-2 - 8*q^-1 - 17 - 33*q - 61*q^2 - 110*q^3 - 186*q^4 - 320*q^5 - 528*q^6 - 861*q
```

The following should give 0, but only approximately:

```
sage: q = X.parent().gen()
sage: E.defining_polynomial()(X,Y,1) + O(q^11) == 0
True
```

Note that below we have to change variable from x to q

```
sage: a1,_,a3,_,_=E.a_invariants()
sage: f=E.q_expansion(17)
sage: q=f.parent().gen()
sage: f/q == (X.derivative()/(2*Y+a1*X+a3))
True
```

modular_symbol (*sign=1, use_eclib=False, normalize='L_ratio'*)

Return the modular symbol associated to this elliptic curve, with given sign and base ring. This is the map that sends r/s to a fixed multiple of the integral of $2\pi i f(z)dz$ from ∞ to r/s, normalized so that all values of this map take values in $\mathbf{Q}$.

The normalization is such that for sign +1, the value at the cusp 0 is equal to the quotient of $L(E,1)$ by the least positive period of E (unlike in `L_ratio` of `lseries()`, where the value is also divided by the number of connected components of $E(\mathbf{R})$). In particular the modular symbol depends on E and not only the isogeny class of E.

INPUT:

- `sign` - -1, or 1
- `base_ring` - a ring
- `normalize` - (default: True); if True, the modular symbol is correctly normalized (up to possibly a factor of -1 or 2). If False, the modular symbol is almost certainly not correctly normalized, i.e., all values will be a fixed scalar multiple of what they should be. But the initial computation of the modular symbol is much faster, though evaluation of it after computing it won't be any faster.
- `use_eclib` - (default: False); if True the computation is done with John Cremona's implementation of modular symbols in `eclib`. But this is only possible for `sign` = +1.
- `normalize` - (default: 'L_ratio'); either 'L_ratio', 'period', or 'none'; For 'L_ratio', the modular symbol is correctly normalized as explained above by comparing it to `L_ratio` for the curve and some small twists. The normalization 'period' is only available if `use_eclib=False`. It uses the `integral_period_map` for modular symbols and is known to be equal to the above normalization up to the sign and a possible power of 2. For 'none', the modular symbol is almost certainly not correctly normalized, i.e. all values will be a fixed scalar multiple of what they should be. But the initial computation of the modular symbol is much faster if `use_eclib=False`, though evaluation of it after computing it won't be any faster.

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: M=E.modular_symbol(); M
Modular symbol with sign 1 over Rational Field attached to Elliptic Curve defined by y^2 + y
sage: M(1/2)
0
sage: M(1/5)
1

sage: E=EllipticCurve('121b1')
sage: M=E.modular_symbol()
sage: M(1/7)
2

sage: E=EllipticCurve('11a1')
sage: E.modular_symbol()(0)
1/5
sage: E=EllipticCurve('11a2')
sage: E.modular_symbol()(0)
1
sage: E=EllipticCurve('11a3')
sage: E.modular_symbol()(0)
1/25

sage: E=EllipticCurve('11a2')
sage: E.modular_symbol(use_eclib=True, normalize='L_ratio')(0)
1
sage: E.modular_symbol(use_eclib=True, normalize='none')(0)
1/5
```

```
sage: E.modular_symbol(use_eclib=True, normalize='period')(0)
...
ValueError: no normalization 'period' known for modular symbols using John Cremona's eclib
sage: E.modular_symbol(use_eclib=False, normalize='L_ratio')(0)
1
sage: E.modular_symbol(use_eclib=False, normalize='none')(0)
1
sage: E.modular_symbol(use_eclib=False, normalize='period')(0)
1

sage: E=EllipticCurve('11a3')
sage: E.modular_symbol(use_eclib=True, normalize='L_ratio')(0)
1/25
sage: E.modular_symbol(use_eclib=True, normalize='none')(0)
1/5
sage: E.modular_symbol(use_eclib=True, normalize='period')(0)
...
ValueError: no normalization 'period' known for modular symbols using John Cremona's eclib
sage: E.modular_symbol(use_eclib=False, normalize='L_ratio')(0)
1/25
sage: E.modular_symbol(use_eclib=False, normalize='none')(0)
1
sage: E.modular_symbol(use_eclib=False, normalize='period')(0)
1/25
```

modular_symbol_space(*sign=1, base_ring=Rational Field, bound=None*)

Return the space of cuspidal modular symbols associated to this elliptic curve, with given sign and base ring.

INPUT:

- `sign` - 0, -1, or 1
- `base_ring` - a ring

EXAMPLES:

```
sage: f = EllipticCurve('37b')
sage: f.modular_symbol_space()
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 for Gamma_0(
sage: f.modular_symbol_space(-1)
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 2 for Gamma_0(
sage: f.modular_symbol_space(0, bound=3)
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 5 for Gamma_0(
```

Note: If you just want the q-expansion, use `q_expansion()`.

mwrank(*options=''*)

Run Cremona's mwrank program on this elliptic curve and return the result as a string.

INPUT:

- `options` (string) – run-time options passed when starting mwrank. The format is as follows (see below for examples of usage):
  - `-v n` (verbosity level) sets verbosity to n (default=1)
  - `-o` (PARI/GP style output flag) turns ON extra PARI/GP short output (default is OFF)
  - `-p n` (precision) sets precision to n decimals (default=15)
  - `-b n` (quartic bound) bound on quartic point search (default=10)
  - `-x n` (n_aux) number of aux primes used for sieving (default=6)
  - `-l` (generator list flag) turns ON listing of points (default ON unless v=0)
  - `-s` (selmer_only flag) if set, computes Selmer rank only (default: not set)

– -d (skip_2nd_descent flag) if set, skips the second descent for curves with 2-torsion (default: not set)

– -S n (sat_bd) upper bound on saturation primes (default=100, -1 for automatic)

OUTPUT:

- string - output of mwrank on this curve

Note: The output is a raw string and completely illegible using automatic display, so it is recommended to use print for legible output.

EXAMPLES:

```
sage: E = EllipticCurve('37a1')
sage: E.mwrank() #random
...
sage: print E.mwrank()
Curve [0,0,1,-1,0] :        Basic pair: I=48, J=-432
disc=255744
...
Generator 1 is [0:-1:1]; height 0.05111...

Regulator = 0.05111...

The rank and full Mordell-Weil basis have been determined unconditionally.
...
```

Options to mwrank can be passed:

```
sage: E = EllipticCurve([0,0,0,877,0])
```

Run mwrank with 'verbose' flag set to 0 but list generators if found

```
sage: print E.mwrank('-v0 -l')
Curve [0,0,0,877,0] :   0 <= rank <= 1
Regulator = 1
```

Run mwrank again, this time with a higher bound for point searching on homogeneous spaces:

```
sage: print E.mwrank('-v0 -l -b11')
Curve [0,0,0,877,0] :   Rank = 1
Generator 1 is [29604565304828237474403861024284371796799791624792913256602210:-25625626798
Regulator = 95.980371987964
```

mwrank_curve(*verbose=False*)

Construct an mwrank_EllipticCurve from this elliptic curve

The resulting mwrank_EllipticCurve has available methods from John Cremona's eclib library.

EXAMPLES:

```
sage: E=EllipticCurve('11a1')
sage: EE=E.mwrank_curve()
sage: EE
y^2+ y = x^3 - x^2 - 10*x - 20
sage: type(EE)
<class 'sage.libs.mwrank.interface.mwrank_EllipticCurve'>
sage: EE.isogeny_class()
([[0, -1, 1, -10, -20], [0, -1, 1, -7820, -263580], [0, -1, 1, 0, 0]],
[[0, 5, 5], [5, 0, 0], [5, 0, 0]])
```

newform()

Same as self.modular_form().

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: E.newform()
q - 2*q^2 - 3*q^3 + 2*q^4 - 2*q^5 + O(q^6)
sage: E.newform() == E.modular_form()
True
```

ngens (*proof=None*)

Return the number of generators of this elliptic curve.

Note: See :meth:'.gens' for further documentation. The function `ngens()` calls `gens()` if not already done, but only with default parameters. Better results may be obtained by calling `mwrank()` with carefully chosen parameters.

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: E.ngens()
1
```

TO DO: This example should not cause a run-time error.

```
sage: E=EllipticCurve([0,0,0,877,0])
sage: # E.ngens()  ######## causes run-time error

sage: print E.mwrank('-v0 -b12 -l')
Curve [0,0,0,877,0] :   Rank = 1
Generator 1 is [29604565304828237474403861024284371796799791624792913256602210:-256256267988
Regulator = 95.980...
```

non_surjective (*A=1000*)

Returns a list of primes p such that the mod-p representation $\rho_{E,p}$ *might* not be surjective (this list usually contains 2, because of shortcomings of the algorithm). If p is not in the returned list, then rho_E,p is provably surjective (see A. Cojocaru's paper). If the curve has CM then infinitely many representations are not surjective, so we simply return the sequence [(0,"cm")] and do no further computation.

INPUT:

- `A` - an integer

OUTPUT:

- `list` - if curve has CM, returns [(0,"cm")]. Otherwise, returns a list of primes where mod-p representation is very likely not surjective. At any prime not in this list, the representation is definitely surjective.

EXAMPLES:

```
sage: E = EllipticCurve([0, 0, 1, -38, 90])  # 361A
sage: E.non_surjective()   # CM curve
[(0, 'cm')]

sage: E = EllipticCurve([0, -1, 1, 0, 0]) # X_1(11)
sage: E.non_surjective()
[(5, '5-torsion')]

sage: E = EllipticCurve([0, 0, 1, -1, 0]) # 37A
sage: E.non_surjective()
[]

sage: E = EllipticCurve([0,-1,1,-2,-1])   # 141C
sage: E.non_surjective()
[(13, [1])]
```

ALGORITHM: When p=3 use division polynomials. For 5 = p = B, where B is Cojocaru's bound, use the results in Section 2 of Serre's inventiones paper"Sur Les Representations Modulaires Deg Degre 2 de Galqbar Over Q."

optimal_curve()

Given an elliptic curve that is in the installed Cremona database, return the optimal curve isogenous to it.

EXAMPLES:

The following curve is not optimal:

```
sage: E = EllipticCurve('11a2'); E
Elliptic Curve defined by y^2 + y = x^3 - x^2 - 7820*x - 263580 over Rational Field
sage: E.optimal_curve()
Elliptic Curve defined by y^2 + y = x^3 - x^2 - 10*x - 20 over Rational Field
sage: E.optimal_curve().cremona_label()
'11a1'
```

Note that 990h is the special case where the optimal curve isn't the first in the Cremona labeling:

```
sage: E = EllipticCurve('990h4'); E
Elliptic Curve defined by y^2 + x*y + y = x^3 - x^2 + 6112*x - 41533 over Rational Field
sage: F = E.optimal_curve(); F
Elliptic Curve defined by y^2 + x*y + y = x^3 - x^2 - 1568*x - 4669 over Rational Field
sage: F.cremona_label()
'990h3'
sage: EllipticCurve('990a1').optimal_curve().cremona_label()    # a isn't h.
'990a1'
```

If the input curve is optimal, this function returns that curve (not just a copy of it or a curve isomorphic to it!):

```
sage: E = EllipticCurve('37a1')
sage: E.optimal_curve() is E
True
```

Also, if this curve is optimal but not given by a minimal model, this curve will still be returned, so this function need not return a minimal model in general.

```
sage: F = E.short_weierstrass_model(); F
Elliptic Curve defined by y^2  = x^3 - 16*x + 16 over Rational Field
sage: F.optimal_curve()
Elliptic Curve defined by y^2  = x^3 - 16*x + 16 over Rational Field
```

ordinary_primes(*B*)

Return a list of all ordinary primes for this elliptic curve up to and possibly including B.

EXAMPLES:

```
sage: e = EllipticCurve('11a')
sage: e.aplist(20)
[-2, -1, 1, -2, 1, 4, -2, 0]
sage: e.ordinary_primes(97)
[3, 5, 7, 11, 13, 17, 23, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, 97]
sage: e = EllipticCurve('49a')
sage: e.aplist(20)
[1, 0, 0, 0, 4, 0, 0, 0]
sage: e.supersingular_primes(97)
[3, 5, 13, 17, 19, 31, 41, 47, 59, 61, 73, 83, 89, 97]
sage: e.ordinary_primes(97)
[2, 11, 23, 29, 37, 43, 53, 67, 71, 79]
sage: e.ordinary_primes(3)
[2]
sage: e.ordinary_primes(2)
```

```
[2]
sage: e.ordinary_primes(1)
[]
```

p_isogenous_curves (*p=None*)

Return a list of pairs (p, L) where p is a prime and L is a list of the elliptic curves over $\mathbf{Q}$ that are p-isogenous to this elliptic curve.

INPUT:

- p - prime or None (default: None); if a prime, returns a list of the p-isogenous curves. Otherwise, returns a list of all prime-degree isogenous curves sorted by isogeny degree.

This is implemented using Cremona's GP script allisog.gp.

EXAMPLES:

```
sage: E = EllipticCurve([0,-1,0,-24649,1355209])
sage: E.p_isogenous_curves()
[(2, [Elliptic Curve defined by y^2  = x^3 - x^2 - 91809*x - 9215775 over Rational Field, El
```

The isogeny class of the curve 11a2 has three curves in it. But p_isogenous_curves only returns one curves, since there is only one curve 5-isogenous to 11a2.

```
sage: E = EllipticCurve('11a2')
sage: E.p_isogenous_curves()
[(5, [Elliptic Curve defined by y^2 + y = x^3 - x^2 - 10*x - 20 over Rational Field])]
sage: E.p_isogenous_curves(5)
[Elliptic Curve defined by y^2 + y = x^3 - x^2 - 10*x - 20 over Rational Field]
sage: E.p_isogenous_curves(3)
[]
```

In contrast, the curve 11a1 admits two 5-isogenies:

```
sage: E = EllipticCurve('11a1')
sage: E.p_isogenous_curves(5)
[Elliptic Curve defined by y^2 + y = x^3 - x^2 - 7820*x - 263580 over Rational Field,
 Elliptic Curve defined by y^2 + y = x^3 - x^2 over Rational Field]
```

padic_E2 (*p, prec=20, check=False, check_hypotheses=True, algorithm='auto'*)

Returns the value of the p-adic modular form $E2$ for (E, ω) where ω is the usual invariant differential $dx/(2y + a_1x + a_3)$.

INPUT:

- p - prime (= 5) for which E is good and ordinary
- prec - (relative) p-adic precision (= 1) for result
- check - boolean, whether to perform a consistency check. This will slow down the computation by a constant factor 2. (The consistency check is to compute the whole matrix of frobenius on Monsky-Washnitzer cohomology, and verify that its trace is correct to the specified precision. Otherwise, the trace is used to compute one column from the other one (possibly after a change of basis).)
- check_hypotheses - boolean, whether to check that this is a curve for which the p-adic sigma function makes sense
- algorithm - one of "standard", "sqrtp", or "auto". This selects which version of Kedlaya's algorithm is used. The "standard" one is the one described in Kedlaya's paper. The "sqrtp" one has better performance for large p, but only works when $p > 6N$ (N = prec). The "auto" option selects "sqrtp" whenever possible.
  Note that if the "sqrtp" algorithm is used, a consistency check will automatically be applied, regardless of the setting of the "check" flag.

OUTPUT: p-adic number to precision prec

Note: If the discriminant of the curve has nonzero valuation at p, then the result will not be returned mod p^{prec}, but it still *will* have prec *digits* of precision.

TODO: - Once we have a better implementation of the "standard" algorithm, the algorithm selection strategy for "auto" needs to be revisited.

AUTHORS:

- David Harvey (2006-09-01): partly based on code written by Robert Bradshaw at the MSRI 2006 modular forms workshop

ACKNOWLEDGMENT: - discussion with Eyal Goren that led to the trace trick.

EXAMPLES: Here is the example discussed in the paper "Computation of p-adic Heights and Log Convergence" (Mazur, Stein, Tate):

```
sage: EllipticCurve([-1, 1/4]).padic_E2(5)
2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + 4*5^10 + 2*5^11 + 2*5^12 + 2*5^14 + 3*
```

Let's try to higher precision (this is the same answer the MAGMA implementation gives):

```
sage: EllipticCurve([-1, 1/4]).padic_E2(5, 100)
2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + 4*5^10 + 2*5^11 + 2*5^12 + 2*5^14 + 3*
```

Check it works at low precision too:

```
sage: EllipticCurve([-1, 1/4]).padic_E2(5, 1)
2 + O(5)
sage: EllipticCurve([-1, 1/4]).padic_E2(5, 2)
2 + 4*5 + O(5^2)
sage: EllipticCurve([-1, 1/4]).padic_E2(5, 3)
2 + 4*5 + O(5^3)
```

TODO: With the old(-er), i.e., = sage-2.4 p-adics we got $5 + O(5^2)$ as output, i.e., relative precision 1, but with the newer p-adics we get relative precision 0 and absolute precision 1.

```
sage: EllipticCurve([1, 1, 1, 1, 1]).padic_E2(5, 1)
O(5)
```

Check it works for different models of the same curve (37a), even when the discriminant changes by a power of p (note that E2 depends on the differential too, which is why it gets scaled in some of the examples below):

```
sage: X1 = EllipticCurve([-1, 1/4])
sage: X1.j_invariant(), X1.discriminant()
 (110592/37, 37)
sage: X1.padic_E2(5, 10)
 2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + O(5^10)

sage: X2 = EllipticCurve([0, 0, 1, -1, 0])
sage: X2.j_invariant(), X2.discriminant()
 (110592/37, 37)
sage: X2.padic_E2(5, 10)
 2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + O(5^10)

sage: X3 = EllipticCurve([-1*(2**4), 1/4*(2**6)])
sage: X3.j_invariant(), X3.discriminant() / 2**12
 (110592/37, 37)
sage: 2**(-2) * X3.padic_E2(5, 10)
 2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + O(5^10)

sage: X4 = EllipticCurve([-1*(7**4), 1/4*(7**6)])
sage: X4.j_invariant(), X4.discriminant() / 7**12
 (110592/37, 37)
sage: 7**(-2) * X4.padic_E2(5, 10)
 2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + O(5^10)
```

```
sage: X5 = EllipticCurve([-1*(5**4), 1/4*(5**6)])
sage: X5.j_invariant(), X5.discriminant() / 5**12
 (110592/37, 37)
sage: 5**(-2) * X5.padic_E2(5, 10)
 2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + O(5^10)

sage: X6 = EllipticCurve([-1/(5**4), 1/4/(5**6)])
sage: X6.j_invariant(), X6.discriminant() * 5**12
 (110592/37, 37)
sage: 5**2 * X6.padic_E2(5, 10)
 2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + O(5^10)
```

Test check=True vs check=False:

```
sage: EllipticCurve([-1, 1/4]).padic_E2(5, 1, check=False)
2 + O(5)
sage: EllipticCurve([-1, 1/4]).padic_E2(5, 1, check=True)
2 + O(5)
sage: EllipticCurve([-1, 1/4]).padic_E2(5, 30, check=False)
2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + 4*5^10 + 2*5^11 + 2*5^12 + 2*5^14 + 3*
sage: EllipticCurve([-1, 1/4]).padic_E2(5, 30, check=True)
2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + 4*5^10 + 2*5^11 + 2*5^12 + 2*5^14 + 3*
```

Here's one using the $p^{1/2}$ algorithm:

```
sage: EllipticCurve([-1, 1/4]).padic_E2(3001, 3, algorithm="sqrtp")
1907 + 2819*3001 + 1124*3001^2 + O(3001^3)
```

padic_height (*p, prec=20, sigma=None, check_hypotheses=True*)

Computes the cyclotomic p-adic height.

The equation of the curve must be minimal at p.

INPUT:

- `p` - prime = 5 for which the curve has semi-stable reduction
- `prec` - integer = 1, desired precision of result
- `sigma` - precomputed value of sigma. If not supplied, this function will call padic_sigma to compute it.
- `check_hypotheses` - boolean, whether to check that this is a curve for which the p-adic height makes sense

OUTPUT: A function that accepts two parameters:

- a Q-rational point on the curve whose height should be computed
- optional boolean flag 'check': if False, it skips some input checking, and returns the p-adic height of that point to the desired precision.
- The normalization (sign and a factor 1/2 with respect to some other normalizations that appear in the literature) is chosen in such a way as to make the p-adic Birch Swinnerton-Dyer conjecture hold as stated in [Mazur-Tate-Teitelbaum].

AUTHORS:

- Jennifer Balakrishnan: original code developed at the 2006 MSRI graduate workshop on modular forms
- David Harvey (2006-09-13): integrated into Sage, optimised to speed up repeated evaluations of the returned height function, addressed some thorny precision questions
- David Harvey (2006-09-30): rewrote to use division polynomials for computing denominator of nP.
- David Harvey (2007-02): cleaned up according to algorithms in "Efficient Computation of p-adic Heights"
- Chris Wuthrich (2007-05): added supersingular and multiplicative heights

EXAMPLES:

```
sage: E = EllipticCurve("37a")
sage: P = E.gens()[0]
sage: h = E.padic_height(5, 10)
sage: h(P)
5 + 5^2 + 5^3 + 3*5^6 + 4*5^7 + 5^9 + O(5^10)
```

An anomalous case:

```
sage: h = E.padic_height(53, 10)
sage: h(P)
26*53^-1 + 30 + 20*53 + 47*53^2 + 10*53^3 + 32*53^4 + 9*53^5 + 22*53^6 + 35*53^7 + 30*53^8 +
```

Boundary case:

```
sage: E.padic_height(5, 3)(P)
5 + 5^2 + O(5^3)
```

A case that works the division polynomial code a little harder:

```
sage: E.padic_height(5, 10)(5*P)
5^3 + 5^4 + 5^5 + 3*5^8 + 4*5^9 + O(5^10)
```

Check that answers agree over a range of precisions:

```
sage: max_prec = 30    # make sure we get past p^2    # long time
sage: full = E.padic_height(5, max_prec)(P)           # long time
sage: for prec in range(1, max_prec):                 # long time
...       assert E.padic_height(5, prec)(P) == full   # long time
```

A supersingular prime for a curve:

```
sage: E = EllipticCurve('37a')
sage: E.is_supersingular(3)
True
sage: h = E.padic_height(3, 5)
sage: h(E.gens()[0])
(3 + 3^3 + O(3^6), 2*3^2 + 3^3 + 3^4 + 3^5 + 2*3^6 + O(3^7))
sage: E.padic_regulator(5)
5 + 5^2 + 5^3 + 3*5^6 + 4*5^7 + 5^9 + 5^10 + 3*5^11 + 3*5^12 + 5^13 + 4*5^14 + 5^15 + 2*5^16
sage: E.padic_regulator(3, 5)
(3 + 2*3^2 + 3^3 + O(3^4), 3^2 + 2*3^3 + 3^4 + O(3^5))
```

A torsion point in both the good and supersingular cases:

```
sage: E = EllipticCurve('11a')
sage: P = E.torsion_subgroup().gens()[0]; P
(5 : 5 : 1)
sage: h = E.padic_height(19, 5)
sage: h(P)
0
sage: h = E.padic_height(5, 5)
sage: h(P)
0
```

The result is not dependend on the model for the curve: sage: E = EllipticCurve([0,0,0,0,2^12*17]) sage: Em = E.minimal_model() sage: P = E.gens()[0] sage: Pm = Em.gens()[0] sage: h = E.padic_height(7) sage: hm = Em.padic_height(7) sage: h(P) == hm(Pm) True

padic_height_pairing_matrix(*p, prec=20, height=None, check_hypotheses=True*)

Computes the cyclotomic p-adic height pairing matrix of this curve with respect to the basis self.gens() for the Mordell-Weil group for a given odd prime p of good ordinary reduction.

INPUT:

- p - prime = 5
- prec - answer will be returned modulo p^{prec}
- height - precomputed height function. If not supplied, this function will call padic_height to compute it.
- check_hypotheses - boolean, whether to check that this is a curve for which the p-adic height makes sense

OUTPUT: The p-adic cyclotomic height pairing matrix of this curve to the given precision.

TODO: - remove restriction that curve must be in minimal weierstrass form. This is currently required for E.gens().

AUTHORS:

- David Harvey, Liang Xiao, Robert Bradshaw, Jennifer Balakrishnan: original implementation at the 2006 MSRI graduate workshop on modular forms
- David Harvey (2006-09-13): cleaned up and integrated into Sage, removed some redundant height computations

EXAMPLES:

```
sage: E = EllipticCurve("37a")
sage: E.padic_height_pairing_matrix(5, 10)
[5 + 5^2 + 5^3 + 3*5^6 + 4*5^7 + 5^9 + O(5^10)]
```

A rank two example:

```
sage: e =EllipticCurve('389a')
sage: e._set_gens([e(-1, 1), e(1,0)])  # avoid platform dependent gens
sage: e.padic_height_pairing_matrix(5,10)
[                      3*5 + 2*5^2 + 5^4 + 5^5 + 5^7 + 4*5^9 + O(5^10) 5 + 4*5^2 + 5^3 + 2*5
[5 + 4*5^2 + 5^3 + 2*5^4 + 3*5^5 + 4*5^6 + 5^7 + 5^8 + 2*5^9 + O(5^10)
```

An anomalous rank 3 example:

```
sage: e = EllipticCurve("5077a")
sage: e._set_gens([e(-1,3), e(2,0), e(4,6)])
sage: e.padic_height_pairing_matrix(5,4)
[4 + 3*5 + 4*5^2 + 4*5^3 + O(5^4)       4 + 4*5^2 + 2*5^3 + O(5^4)       3*5 + 4*5^2 + 5^3 +
[      4 + 4*5^2 + 2*5^3 + O(5^4)   3 + 4*5 + 3*5^2 + 5^3 + O(5^4)                 2 + 4*5 +
[      3*5 + 4*5^2 + 5^3 + O(5^4)                 2 + 4*5 + O(5^4)     1 + 3*5 + 5^2 + 5^3 +
```

padic_height_via_multiply(*p, prec=20, E2=None, check_hypotheses=True*)

Computes the cyclotomic p-adic height.

The equation of the curve must be minimal at p.

INPUT:

- p - prime = 5 for which the curve has good ordinary reduction
- prec - integer = 2, desired precision of result
- E2 - precomputed value of E2. If not supplied, this function will call padic_E2 to compute it. The value supplied must be correct mod $p^(prec - 2)$ (or slightly higher in the anomalous case; see the code for details).
- check_hypotheses - boolean, whether to check that this is a curve for which the p-adic height makes sense

OUTPUT: A function that accepts two parameters:

- a Q-rational point on the curve whose height should be computed
- optional boolean flag 'check': if False, it skips some input checking, and returns the p-adic height of that point to the desired precision.
- The normalization (sign and a factor 1/2 with respect to some other normalizations that appear in the literature) is chosen in such a way as to make the p-adic Birch Swinnerton-Dyer conjecture hold as stated in [Mazur-Tate-Teitelbaum].

AUTHORS:

- David Harvey (2008-01): based on the padic_height() function, using the algorithm of"Computing p-adic heights via point multiplication"

EXAMPLES:

```
sage: E = EllipticCurve("37a")
sage: P = E.gens()[0]
sage: h = E.padic_height_via_multiply(5, 10)
sage: h(P)
5 + 5^2 + 5^3 + 3*5^6 + 4*5^7 + 5^9 + O(5^10)
```

An anomalous case:

```
sage: h = E.padic_height_via_multiply(53, 10)
sage: h(P)
26*53^-1 + 30 + 20*53 + 47*53^2 + 10*53^3 + 32*53^4 + 9*53^5 + 22*53^6 + 35*53^7 + 30*53^8 +
```

Supply the value of E2 manually:

```
sage: E2 = E.padic_E2(5, 8)
sage: E2
2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + O(5^8)
sage: h = E.padic_height_via_multiply(5, 10, E2=E2)
sage: h(P)
5 + 5^2 + 5^3 + 3*5^6 + 4*5^7 + 5^9 + O(5^10)
```

Boundary case:

```
sage: E.padic_height_via_multiply(5, 3)(P)
5 + 5^2 + O(5^3)
```

Check that answers agree over a range of precisions:

```
sage: max_prec = 30    # make sure we get past p^2    # long time
sage: full = E.padic_height(5, max_prec)(P)           # long time
sage: for prec in range(2, max_prec):                 # long time
...       assert E.padic_height_via_multiply(5, prec)(P) == full   # long time
```

padic_lseries(*p, normalize='L_ratio', use_eclib=False*)

Return the p-adic L-series of self at p, which is an object whose approx method computes approximation to the true p-adic L-series to any desired precision.

INPUT:

- p - prime
- use_eclib - bool (default:False); whether or not to use John Cremona's eclib for the computation of modular symbols
- normalize - 'L_ratio' (default), 'period' or 'none'; this is describes the way the modular symbols are normalized. See modular_symbol for more details.

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: L = E.padic_lseries(5); L
5-adic L-series of Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field
sage: type(L)
<class 'sage.schemes.elliptic_curves.padic_lseries.pAdicLseriesOrdinary'>
```

We compute the 3-adic L-series of two curves of rank 0 and in each case verify the interpolation property for their leading coefficient (i.e., value at 0):

```
sage: e = EllipticCurve('11a')
sage: ms = e.modular_symbol()
```

```
sage: [ms(1/11), ms(1/3), ms(0), ms(oo)]
[0, -3/10, 1/5, 0]
sage: ms(0)
1/5
sage: L = e.padic_lseries(3)
sage: P = L.series(5)
sage: P(0)
2 + 3 + 3^2 + 2*3^3 + 2*3^5 + 3^6 + O(3^7)
sage: alpha = L.alpha(9); alpha
2 + 3^2 + 2*3^3 + 2*3^4 + 2*3^6 + 3^8 + O(3^9)
sage: R.<x> = QQ[]
sage: f = x^2 - e.ap(3)*x + 3
sage: f(alpha)
O(3^9)
sage: r = e.lseries().L_ratio(); r
1/5
sage: (1 - alpha^(-1))^2 * r
2 + 3 + 3^2 + 2*3^3 + 2*3^5 + 3^6 + 3^7 + O(3^9)
sage: P(0)
2 + 3 + 3^2 + 2*3^3 + 2*3^5 + 3^6 + O(3^7)
```

Next consider the curve 37b:

```
sage: e = EllipticCurve('37b')
sage: L = e.padic_lseries(3)
sage: P = L.series(5)
sage: alpha = L.alpha(9); alpha
1 + 2*3 + 3^2 + 2*3^5 + 2*3^7 + 3^8 + O(3^9)
sage: r = e.lseries().L_ratio(); r
1/3
sage: (1 - alpha^(-1))^2 * r
3 + 3^2 + 2*3^4 + 2*3^5 + 2*3^6 + 3^7 + O(3^9)
sage: P(0)
3 + 3^2 + 2*3^4 + 2*3^5 + O(3^6)
```

We can use eclib to compute the L-series:

```
sage: e = EllipticCurve('11a')
sage: L = e.padic_lseries(3,use_eclib=True)
sage: L.series(5,prec=10)
1 + 2*3^3 + 3^6 + O(3^7) + (2 + 2*3 + 3^2 + O(3^4))*T + (2 + 3 + 3^2 + 2*3^3 + O(3^4))*T^2 +
```

padic_regulator(*p, prec=20, height=None, check_hypotheses=True*)

Computes the cyclotomic p-adic regulator of this curve.

INPUT:

- p - prime = 5
- prec - answer will be returned modulo p^{prec}
- height - precomputed height function. If not supplied, this function will call padic_height to compute it.
- check_hypotheses - boolean, whether to check that this is a curve for which the p-adic height makes sense

OUTPUT: The p-adic cyclotomic regulator of this curve, to the requested precision.

If the rank is 0, we output 1.

TODO: - remove restriction that curve must be in minimal weierstrass form. This is currently required for E.gens().

AUTHORS:

- Liang Xiao: original implementation at the 2006 MSRI graduate workshop on modular forms

- David Harvey (2006-09-13): cleaned up and integrated into Sage, removed some redundant height computations
- Chris Wuthrich (2007-05-22): added multiplicative and supersingular cases
- David Harvey (2007-09-20): fixed some precision loss that was occurring

EXAMPLES:

```
sage: E = EllipticCurve("37a")
sage: E.padic_regulator(5, 10)
5 + 5^2 + 5^3 + 3*5^6 + 4*5^7 + 5^9 + O(5^10)
```

An anomalous case:

```
sage: E.padic_regulator(53, 10)
26*53^-1 + 30 + 20*53 + 47*53^2 + 10*53^3 + 32*53^4 + 9*53^5 + 22*53^6 + 35*53^7 + 30*53^8 +
```

An anomalous case where the precision drops some:

```
sage: E = EllipticCurve("5077a")
sage: E.padic_regulator(5, 10)
5 + 5^2 + 4*5^3 + 2*5^4 + 2*5^5 + 2*5^6 + 4*5^7 + 2*5^8 + 5^9 + O(5^10)
```

Check that answers agree over a range of precisions:

```
sage: max_prec = 30     # make sure we get past p^2     # long time
sage: full = E.padic_regulator(5, max_prec)             # long time
sage: for prec in range(1, max_prec):                   # long time
...       assert E.padic_regulator(5, prec) == full     # long time
```

A case where the generator belongs to the formal group already (trac #3632):

```
sage: E = EllipticCurve([37,0])
sage: E.padic_regulator(5,10)
2*5^2 + 2*5^3 + 5^4 + 5^5 + 4*5^6 + 3*5^8 + 4*5^9 + O(5^10)
```

The result is not dependend on the model for the curve:

```
sage: E = EllipticCurve([0,0,0,0,2^12*17])
sage: Em = E.minimal_model()
sage: E.padic_regulator(7) == Em.padic_regulator(7)
True
```

padic_sigma(*p, N=20, E2=None, check=False, check_hypotheses=True*)

Computes the p-adic sigma function with respect to the standard invariant differential $dx/(2y+a_1x+a_3)$, as defined by Mazur and Tate, as a power series in the usual uniformiser t at the origin.

The equation of the curve must be minimal at p.

INPUT:

- `p` - prime = 5 for which the curve has good ordinary reduction
- `N` - integer = 1, indicates precision of result; see OUTPUT section for description
- `E2` - precomputed value of E2. If not supplied, this function will call padic_E2 to compute it. The value supplied must be correct mod p^{N-2}.
- `check` - boolean, whether to perform a consistency check (i.e. verify that the computed sigma satisfies the defining
- `differential equation` - note that this does NOT guarantee correctness of all the returned digits, but it comes pretty close :-))
- `check_hypotheses` - boolean, whether to check that this is a curve for which the p-adic sigma function makes sense

OUTPUT: A power series $t + \cdots$ with coefficients in $\mathbf{Z}_p$.

The output series will be truncated at $O(t^{N+1})$, and the coefficient of t^n for $n \geq 1$ will be correct to precision $O(p^{N-n+1})$.

In practice this means the following. If $t_0 = p^k u$, where u is a p-adic unit with at least N digits of precision, and $k \geq 1$, then the returned series may be used to compute $\sigma(t_0)$ correctly modulo p^{N+k} (i.e. with N correct p-adic digits).

ALGORITHM: Described in "Efficient Computation of p-adic Heights" (David Harvey), which is basically an optimised version of the algorithm from "p-adic Heights and Log Convergence" (Mazur, Stein, Tate).

Running time is soft-$O(N^2 \log p)$, plus whatever time is necessary to compute E_2.

AUTHORS:

- David Harvey (2006-09-12)
- David Harvey (2007-02): rewrote

EXAMPLES:

```
sage: EllipticCurve([-1, 1/4]).padic_sigma(5, 10)
O(5^11) + (1 + O(5^10))*t + O(5^9)*t^2 + (3 + 2*5^2 + 3*5^3 + 3*5^6 + 4*5^7 + O(5^8))*t^3 +
```

Run it with a consistency check:

```
sage: EllipticCurve("37a").padic_sigma(5, 10, check=True)
O(5^11) + (1 + O(5^10))*t + O(5^9)*t^2 + (3 + 2*5^2 + 3*5^3 + 3*5^6 + 4*5^7 + O(5^8))*t^3 +
```

Boundary cases:

```
sage: EllipticCurve([1, 1, 1, 1, 1]).padic_sigma(5, 1)
 (1 + O(5))*t + O(t^2)
sage: EllipticCurve([1, 1, 1, 1, 1]).padic_sigma(5, 2)
 (1 + O(5^2))*t + (3 + O(5))*t^2 + O(t^3)
```

Supply your very own value of E2:

```
sage: X = EllipticCurve("37a")
sage: my_E2 = X.padic_E2(5, 8)
sage: my_E2 = my_E2 + 5**5    # oops!!!
sage: X.padic_sigma(5, 10, E2=my_E2)
O(5^11) + (1 + O(5^10))*t + O(5^9)*t^2 + (3 + 2*5^2 + 3*5^3 + 4*5^5 + 2*5^6 + 3*5^7 + O(5^8)
```

Check that sigma is "weight 1".

```
sage: f = EllipticCurve([-1, 3]).padic_sigma(5, 10)
sage: g = EllipticCurve([-1*(2**4), 3*(2**6)]).padic_sigma(5, 10)
sage: t = f.parent().gen()
sage: f(2*t)/2
(1 + O(5^10))*t + (4 + 3*5 + 3*5^2 + 3*5^3 + 4*5^4 + 4*5^5 + 3*5^6 + 5^7 + O(5^8))*t^3 + (3
sage: g
O(5^11) + (1 + O(5^10))*t + O(5^9)*t^2 + (4 + 3*5 + 3*5^2 + 3*5^3 + 4*5^4 + 4*5^5 + 3*5^6 +
sage: f(2*t)/2 -g
O(t^11)
```

Test that it returns consistent results over a range of precision:

```
sage: max_N = 30   # get up to at least p^2          # long time
sage: E = EllipticCurve([1, 1, 1, 1, 1])             # long time
sage: p = 5                                          # long time
sage: E2 = E.padic_E2(5, max_N)                      # long time
sage: max_sigma = E.padic_sigma(p, max_N, E2=E2)     # long time
sage: for N in range(3, max_N):                      # long time
...       sigma = E.padic_sigma(p, N, E2=E2)         # long time
...       assert sigma == max_sigma
```

padic_sigma_truncated(*p, N=20, lamb=0, E2=None, check_hypotheses=True*)

Computes the p-adic sigma function with respect to the standard invariant differential $dx/(2y+a_1x+a_3)$, as defined by Mazur and Tate, as a power series in the usual uniformiser t at the origin.

The equation of the curve must be minimal at p.

This function differs from padic_sigma() in the precision profile of the returned power series; see OUTPUT below.

INPUT:

- `p` - prime = 5 for which the curve has good ordinary reduction
- `N` - integer = 2, indicates precision of result; see OUTPUT section for description
- `lamb` - integer = 0, see OUTPUT section for description
- `E2` - precomputed value of E2. If not supplied, this function will call padic_E2 to compute it. The value supplied must be correct mod p^{N-2}.
- `check_hypotheses` - boolean, whether to check that this is a curve for which the p-adic sigma function makes sense

OUTPUT: A power series $t + \cdots$ with coefficients in $\mathbf{Z}_p$.

The coefficient of t^j for $j \geq 1$ will be correct to precision $O(p^{N-2+(3-j)(lamb+1)})$.

ALGORITHM: Described in "Efficient Computation of p-adic Heights" (David Harvey, to appear in LMS JCM), which is basically an optimised version of the algorithm from "p-adic Heights and Log Convergence" (Mazur, Stein, Tate), and "Computing p-adic heights via point multiplication" (David Harvey, still draft form).

Running time is soft-$O(N^2 \lambda^{-1} \log p)$, plus whatever time is necessary to compute E_2.

AUTHOR:

- David Harvey (2008-01): wrote based on previous padic_sigma function

EXAMPLES:

```
sage: E = EllipticCurve([-1, 1/4])
sage: E.padic_sigma_truncated(5, 10)
O(5^11) + (1 + O(5^10))*t + O(5^9)*t^2 + (3 + 2*5^2 + 3*5^3 + 3*5^6 + 4*5^7 + O(5^8))*t^3 +
```

Note the precision of the t^3 coefficient depends only on N, not on lamb:

```
sage: E.padic_sigma_truncated(5, 10, lamb=2)
O(5^17) + (1 + O(5^14))*t + O(5^11)*t^2 + (3 + 2*5^2 + 3*5^3 + 3*5^6 + 4*5^7 + O(5^8))*t^3 +
```

Compare against plain padic_sigma() function over a dense range of N and lamb

```
sage: E = EllipticCurve([1, 2, 3, 4, 7])                                  # long time
sage: E2 = E.padic_E2(5, 50)                                              # long time
sage: for N in range(2, 10):                                              # long time
...       for lamb in range(10):                                          # long time
...           correct = E.padic_sigma(5, N + 3*lamb, E2=E2)               # long time
...           compare = E.padic_sigma_truncated(5, N=N, lamb=lamb, E2=E2)     # long time
...           assert compare == correct                                   # long time
```

pari_curve(*prec=None, factor=1*)

Return the PARI curve corresponding to this elliptic curve.

INPUT:

- `prec` - The precision of quantities calculated for the returned curve, in bits. If None, defaults to factor multiplied by the precision of the largest cached curve (or the default real precision if none yet computed).
- `factor` - The factor by which to increase the precision over the maximum previously computed precision. Only used if prec (which gives an explicit precision) is None.

EXAMPLES:

```
sage: E = EllipticCurve([0, 0, 1, -1, 0])
sage: e = E.pari_curve()
sage: type(e)
```

```
<type 'sage.libs.pari.gen.gen'>
sage: e.type()
't_VEC'
sage: e.ellan(10)
[1, -2, -3, 2, -2, 6, -1, 0, 6, 4]

sage: E = EllipticCurve(RationalField(), ['1/3', '2/3'])
sage: e = E.pari_curve(prec = 100)
sage: E._pari_curve.has_key(100)
True
sage: e.type()
't_VEC'
sage: e[:5]
[0, 0, 0, 1/3, 2/3]
```

This shows that the bug uncovered by trac #3954 is fixed:

```
sage: E._pari_curve.has_key(100)
True

sage: E = EllipticCurve('37a1').pari_curve()
sage: E[14].python().prec()
64
sage: [a.precision() for a in E]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 4, 4, 4, 4, 4] # 32-bit
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 3, 3, 3, 3, 3] # 64-bit
```

This shows that the bug uncovered by trac #4715 is fixed:

```
sage: Ep = EllipticCurve('903b3').pari_curve()
```

pari_mincurve(*prec=None, factor=1*)

Return the PARI curve corresponding to a minimal model for this elliptic curve.

INPUT:

- `prec` - The precision of quantities calculated for the returned curve, in bits. If None, defaults to factor multiplied by the precision of the largest cached curve (or the default real precision if none yet computed).
- `factor` - The factor by which to increase the precision over the maximum previously computed precision. Only used if prec (which gives an explicit precision) is None.

EXAMPLES:

```
sage: E = EllipticCurve(RationalField(), ['1/3', '2/3'])
sage: e = E.pari_mincurve()
sage: e[:5]
[0, 0, 0, 27, 486]
sage: E.conductor()
47232
sage: e.ellglobalred()
[47232, [1, 0, 0, 0], 2]
```

period_lattice(*embedding=None*)

Returns the period lattice of the elliptic curve.

INPUT:

- `embedding` - ignored (for compatibility with the period_lattice function for elliptic_curve_number_field)

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: E.period_lattice()
Period lattice associated to Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field
```

point_search(*height_limit, verbose=True*)

Search for points on a curve up to an input bound on the naive logarithmic height.

INPUT:

- `height_limit (float)` - bound on naive height (at most 21,
- `or mwrank overflows` - see below)
- `verbose (bool)` - (default: True)
  If True, report on each point as found together with linear relations between the points found and the saturation process.
  If False, just return the result.

OUTPUT: points (list) - list of independent points which generate the subgroup of the Mordell-Weil group generated by the points found and then p-saturated for p20.

Warning: height_limit is logarithmic, so increasing by 1 will cause the running time to increase by a factor of approximately 4.5 (=exp(1.5)). The limit of 21 is to prevent overflow, but in any case using height_limit=20 takes rather a long time!

IMPLEMENTATION: Uses Cremona's mwrank package. At the heart of this function is Cremona's port of Stoll's ratpoints program (version 1.4).

EXAMPLES:

```
sage: E=EllipticCurve('389a1')
sage: E.point_search(5, verbose=False)
[(0 : -1 : 1), (-1 : 1 : 1)]
```

Increasing the height_limit takes longer, but finds no more points:

```
sage: E.point_search(10, verbose=False)
[(0 : -1 : 1), (-1 : 1 : 1)]
```

In fact this curve has rank 2 so no more than 2 points will ever be output, but we are not using this fact.

```
sage: E.saturation(_)
([(0 : -1 : 1), (-1 : 1 : 1)], '1', 0.152460172772408)
```

What this shows is that if the rank is 2 then the points listed do generate the Mordell-Weil group (mod torsion). Finally,

```
sage: E.rank()
2
```

q_eigenform(*prec*)

Synonym for `self.q_expansion(prec)`.

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: E.q_eigenform(10)
q - 2*q^2 - 3*q^3 + 2*q^4 - 2*q^5 + 6*q^6 - q^7 + 6*q^9 + O(q^10)
sage: E.q_eigenform(10) == E.q_expansion(10)
True
```

q_expansion(*prec*)

Return the q-expansion to precision prec of the newform attached to this elliptic curve.

INPUT:

- `prec` - an integer

OUTPUT:

a power series (in th evariable 'q')

Note: If you want the output to be a modular form and not just a q-expansion, use `modular_form()`.

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: E.q_expansion(20)
q - 2*q^2 - 3*q^3 + 2*q^4 - 2*q^5 + 6*q^6 - q^7 + 6*q^9 + 4*q^10 - 5*q^11 - 6*q^12 - 2*q^13
```

quadratic_twist(*D*)

Return the global minimal model of the quadratic twist of this curve by D.

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: E7=E.quadratic_twist(7); E7
Elliptic Curve defined by y^2  = x^3 - 784*x + 5488 over Rational Field
sage: E7.conductor()
29008
sage: E7.quadratic_twist(7) == E
True
```

rank(*use_database=False, verbose=False, only_use_mwrank=True, algorithm='mwrank_shell', proof=None*)

Return the rank of this elliptic curve, assuming no conjectures.

If we fail to provably compute the rank, raises a RuntimeError exception.

INPUT:

- `use_database (bool)` - (default: False), if True, try to look up the regulator in the Cremona database.
- `verbose` - (default: None), if specified changes the verbosity of mwrank computations. algorithm -
- – `'mwrank_shell'` - call mwrank shell command
- – `'mwrank_lib'` - call mwrank c library
- `only_use_mwrank` - (default: True) if False try using analytic rank methods first.
- `proof` - bool or None (default: None, see proof.elliptic_curve or sage.structure.proof). Note that results obtained from databases are considered proof = True

OUTPUT:

- `rank (int)` - the rank of the elliptic curve.

IMPLEMENTATION: Uses L-functions, mwrank, and databases.

EXAMPLES:

```
sage: EllipticCurve('11a').rank()
0
sage: EllipticCurve('37a').rank()
1
sage: EllipticCurve('389a').rank()
2
sage: EllipticCurve('5077a').rank()
3
sage: EllipticCurve([1, -1, 0, -79, 289]).rank()    # long time.  This will use the default p
4
sage: EllipticCurve([0, 0, 1, -79, 342]).rank(proof=False)  # long time -- but under a minut
5
sage: EllipticCurve([0, 0, 1, -79, 342]).simon_two_descent()[0]  # much faster -- almost ins
5
```

Examples with denominators in defining equations:

```
sage: E = EllipticCurve( [0, 0, 0, 0, -675/4])
sage: E.rank()
0
sage: E = EllipticCurve( [0, 0, 1/2, 0, -1/5])
sage: E.rank()
1
sage: E.minimal_model().rank()
1
```

A large example where mwrank doesn't determine the result with certainty:

```
sage: EllipticCurve([1,0,0,0,37455]).rank(proof=False)
0
sage: EllipticCurve([1,0,0,0,37455]).rank(proof=True)
...
RuntimeError: Rank not provably correct.
```

real_components()

Returns 1 if there is 1 real component and 2 if there are 2.

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: E.real_components ()
2
sage: E = EllipticCurve('37b')
sage: E.real_components ()
2
sage: E = EllipticCurve('11a')
sage: E.real_components ()
1
```

reducible_primes()

Returns a list of the primes p such that the mod p representation $\rho_{E,p}$ is reducible. For all other primes the representation is irreducible.

Note: This is *not* provably correct in general. See the documentation for `isogeny_class()`.

EXAMPLES:

```
sage: E = EllipticCurve('225a')
sage: E.reducible_primes()
[3]
```

reduction(p)

Return the reduction of the elliptic curve at a prime of good reduction.

Note: All is done in `self.change_ring(GF(p))`; all we do is check that p is prime and does not divide the discriminant.

INPUT:

- p - a (positive) prime number

OUTPUT: an elliptic curve over the finite field GF(p)

EXAMPLES:

```
sage: E = EllipticCurve('389a1')
sage: E.reduction(2)
Elliptic Curve defined by y^2 + y = x^3 + x^2 over Finite Field of size 2
sage: E.reduction(3)
Elliptic Curve defined by y^2 + y = x^3 + x^2 + x over Finite Field of size 3
sage: E.reduction(5)
Elliptic Curve defined by y^2 + y = x^3 + x^2 + 3*x over Finite Field of size 5
sage: E.reduction(38)
```

```
...
AttributeError: p must be prime.
sage: E.reduction(389)
...
AttributeError: The curve must have good reduction at p.
```

regulator(*use_database=True, proof=None, precision=None*)

Returns the regulator of this curve, which must be defined over Q.

INPUT:

- `use_database` - bool (default: False), if True, try to look up the generators in the Cremona database.
- `proof` - bool or None (default: None, see proof.[tab] or sage.structure.proof). Note that results from databases are considered proof = True
- `precision` - int or None (default: None): the precision in bits of the result (default real precision if None)

EXAMPLES:

```
sage: E = EllipticCurve([0, 0, 1, -1, 0])
sage: E.regulator()               # long time (1 second)
0.0511114082399688
sage: EllipticCurve('11a').regulator()
1.00000000000000
sage: EllipticCurve('37a').regulator()
0.0511114082399688
sage: EllipticCurve('389a').regulator()
0.152460177943144
sage: EllipticCurve('5077a').regulator()
0.41714355875838...
sage: EllipticCurve([1, -1, 0, -79, 289]).regulator()  # long time (seconds)
1.50434488827528
sage: EllipticCurve([0, 0, 1, -79, 342]).regulator(proof=False)  # long time (seconds)
14.790527570131...
```

regulator_of_points(*points=, [], precision=None*)

Returns the regulator of the given points on this curve.

INPUT:

- `points` -(default: empty list) a list of points on this curve
- `precision` - int or None (default: None): the precision in bits of the result (default real precision if None)

EXAMPLES:

```
sage: E = EllipticCurve('37a1')
sage: P = E(0,0)
sage: Q = E(1,0)
sage: E.regulator_of_points([P,Q])
0.000000000000000
sage: 2*P==Q
True

sage: E = EllipticCurve('5077a1')
sage: points = [E.lift_x(x) for x in [-2,-7/4,1]]
sage: E.regulator_of_points(points)
0.417143558758384
sage: E.regulator_of_points(points,precision=100)
0.41714355875838396981711954462
```

```
sage: E = EllipticCurve('389a')
sage: E.regulator_of_points()
1.00000000000000
sage: points = [P,Q] = [E(-1,1),E(0,-1)]
sage: E.regulator_of_points(points)
0.152460177943144
sage: E.regulator_of_points(points, precision=100)
0.15246017794314375162432475705
sage: E.regulator_of_points(points, precision=200)
0.152460177943143751624324757049455823243727077486630817840280980046053225683562463604114816
sage: E.regulator_of_points(points, precision=300)
0.152460177943143751624324757049455823243727077486630817840280980046053225683562463604114816
```

root_number()

Returns the root number of this elliptic curve.

This is 1 if the order of vanishing of the L-function L(E,s) at 1 is even, and -1 if it is odd.

EXAMPLES:

```
sage: EllipticCurve('11a1').root_number()
1
sage: EllipticCurve('37a1').root_number()
-1
sage: EllipticCurve('389a1').root_number()
1
```

satisfies_heegner_hypothesis(*D*)

Returns True precisely when D is a fundamental discriminant that satisfies the Heegner hypothesis for this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve('11a1')
sage: E.satisfies_heegner_hypothesis(-7)
True
sage: E.satisfies_heegner_hypothesis(-11)
False
```

saturation(*points, verbose=False, max_prime=0, odd_primes_only=False*)

Given a list of rational points on E, compute the saturation in E(Q) of the subgroup they generate.

INPUT:

- `points (list)` - list of points on E
- `verbose (bool)` - (default: False), if True, give verbose output
- `max_prime (int)` - (default: 0), saturation is performed for all primes up to max_prime. If max_prime==0, perform saturation at *all* primes, i.e., compute the true saturation.
- `odd_primes_only (bool)` - only do saturation at odd primes

OUTPUT:

- `saturation (list)` - points that form a basis for the saturation
- `index (int)` - the index of the group generated by points in their saturation
- `regulator (real with default precision)` - regulator of saturated points.

IMPLEMENTATION: Uses Cremona's mwrank package. With max_prime=0, we call mwrank with successively larger prime bounds until the full saturation is provably found. The results of saturation at the previous primes is stored in each case, so this should be reasonably fast.

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: P=E(0,0)
sage: Q=5*P; Q
(1/4 : -5/8 : 1)
sage: E.saturation([Q])
([(0 : 0 : 1)], '5', 0.0511114075779915)
```

sea(*p, early_abort=False*)

Return the number of points on E over $\mathbf{F}_p$ computed using the SEA algorithm, as implemented in PARI by Christophe Doche and Sylvain Duquesne.

INPUT:

- `p` - a prime number
- `early_abort` - bool (default: False); if True an early abort technique is used and the computation is interrupted as soon as a small divisor of the order is detected.

Note: As of 2006-02-02 this function does not work on Microsoft Windows under Cygwin (though it works under VMWare of course).

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: E.sea(next_prime(10^30))
1000000000000001426441464441649
```

selmer_rank_bound()

Bound on the rank of the curve, computed using the 2-selmer group. This is the rank of the curve minus the rank of the 2-torsion, minus a number determined by whatever mwrank was able to determine related to Sha[2]. Thus in many cases, this is the actual rank of the curve.

EXAMPLE: The following is the curve 960D1, which has rank 0, but Sha of order 4.

```
sage: E = EllipticCurve([0, -1, 0, -900, -10098])
sage: E.selmer_rank_bound()
0
```

It gives 0 instead of 2, because it knows Sha is nontrivial. In contrast, for the curve 571A, also with rank 0 and Sha of order 4, we get a worse bound:

```
sage: E = EllipticCurve([0, -1, 1, -929, -10595])
sage: E.selmer_rank_bound()
2
sage: E.rank(only_use_mwrank=False)    # uses L-function
0
```

sha()

Return an object of class 'sage.schemes.elliptic_curves.sha_tate.Sha' attached to this elliptic curve.

This can be used in functions related to bounding the order of Sha (The Tate-Shafarevich group of the curve).

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: S=E.sha()
sage: S
Shafarevich-Tate group for the Elliptic Curve defined by y^2 + y = x^3 - x over Rational Fie
sage: S.bound_kolyvagin()
([2], 1)
```

silverman_height_bound()

Return the Silverman height bound. This is a positive real (floating point) number B such that for all rational points P on the curve,

$$h(P) \leq \hat{h}(P) + B$$

where h(P) is the logarithmic height of P and $\hat{h}(P)$ is the canonical height.

Note that the CPS_height_bound is often better (i.e. smaller) than the Silverman bound.

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: E.silverman_height_bound()
4.8254007581809182
sage: E.CPS_height_bound()
0.16397076103046915
```

simon_two_descent (*verbose=0, lim1=5, lim3=50, limtriv=10, maxprob=20, limbigprime=30*)

Given a curve with no 2-torsion, computes (probably) the rank of the Mordell-Weil group, with certainty the rank of the 2-Selmer group, and a list of independent points on the curve.

INPUT:

- `verbose` - integer, 0,1,2,3; (default: 0), the verbosity level
- `lim1` - (default: 5) limite des points triviaux sur les quartiques
- `lim3` - (default: 50) limite des points sur les quartiques ELS
- `limtriv` - (default: 10) limite des points triviaux sur la courbe elliptique
- `maxprob` - (default: 20)
- `limbigprime` - (default: 30) to distinguish between small and large prime numbers. Use probabilistic tests for large primes. If 0, don't any probabilistic tests.

OUTPUT:

- `integer` - "probably" the rank of self
- `integer` - the 2-rank of the Selmer group
- `list` - list of independent points on the curve.

IMPLEMENTATION: Uses Denis Simon's GP/PARI scripts from http://www.math.unicaen.fr/~simon/

EXAMPLES: These computations use pseudo-random numbers, so we set the seed for reproducible testing.

We compute the ranks of the curves of lowest known conductor up to rank 8. Amazingly, each of these computations finishes almost instantly!

```
sage: E = EllipticCurve('11a1')
sage: set_random_seed(0)
sage: E.simon_two_descent()
(0, 0, [])
sage: E = EllipticCurve('37a1')
sage: set_random_seed(0)
sage: E.simon_two_descent()
(1, 1, [(0 : 0 : 1)])
sage: E = EllipticCurve('389a1')
sage: set_random_seed(0)
sage: E.simon_two_descent()
(2, 2, [(1 : 0 : 1), (-11/9 : -55/27 : 1)])
sage: E = EllipticCurve('5077a1')
sage: set_random_seed(0)
sage: E.simon_two_descent()
(3, 3, [(1 : 0 : 1), (2 : -1 : 1), (0 : 2 : 1)])
```

In this example Simon's program does not find any points, though it does correctly compute the rank of the 2-Selmer group.

```
sage: E = EllipticCurve([1, -1, 0, -751055859, -7922219731979])     # long (0.6 seconds)
sage: set_random_seed(0)
sage: E.simon_two_descent ()
(1, 1, [])
```

The rest of these entries were taken from Tom Womack's page http://tom.womack.net/maths/conductors.htm

```
sage: E = EllipticCurve([1, -1, 0, -79, 289])
sage: set_random_seed(0)
sage: E.simon_two_descent()
(4, 4, [(6 : -5 : 1), (4 : 3 : 1), (5 : -3 : 1), (8 : -15 : 1)])
sage: E = EllipticCurve([0, 0, 1, -79, 342])
sage: set_random_seed(0)
sage: E.simon_two_descent()
(5, 5, [(5 : 8 : 1), (10 : 23 : 1), (3 : 11 : 1), (4 : -10 : 1), (0 : 18 : 1)])
sage: E = EllipticCurve([1, 1, 0, -2582, 48720])
sage: set_random_seed(0)
sage: r, s, G = E.simon_two_descent(); r,s
(6, 6)
sage: E = EllipticCurve([0, 0, 0, -10012, 346900])
sage: set_random_seed(0)
sage: r, s, G = E.simon_two_descent(); r,s
(7, 7)
sage: E = EllipticCurve([0, 0, 1, -23737, 960366])
sage: set_random_seed(0)
sage: r, s, G = E.simon_two_descent(); r,s
(8, 8)
```

supersingular_primes(*B*)

Return a list of all supersingular primes for this elliptic curve up to and possibly including B.

EXAMPLES:

```
sage: e = EllipticCurve('11a')
sage: e.aplist(20)
[-2, -1, 1, -2, 1, 4, -2, 0]
sage: e.supersingular_primes(1000)
[2, 19, 29, 199, 569, 809]

sage: e = EllipticCurve('27a')
sage: e.aplist(20)
[0, 0, 0, -1, 0, 5, 0, -7]
sage: e.supersingular_primes(97)
[2, 5, 11, 17, 23, 29, 41, 47, 53, 59, 71, 83, 89]
sage: e.ordinary_primes(97)
[7, 13, 19, 31, 37, 43, 61, 67, 73, 79, 97]
sage: e.supersingular_primes(3)
[2]
sage: e.supersingular_primes(2)
[2]
sage: e.supersingular_primes(1)
[]
```

tamagawa_exponent(*p*)

The Tamagawa index of the elliptic curve at p.

This is the index of the component group $E(\mathbf{Q}_p)/E^0(\mathbf{Q}_p)$. It equals the Tamagawa number (as the component group is cyclic) except for types I_m^* (m even) when the group can be $C_2 times C_2$.

EXAMPLES:

```
sage: E = EllipticCurve('816a1')
sage: E.tamagawa_number(2)
4
sage: E.tamagawa_exponent(2)
2
```

```
sage: E.kodaira_symbol(2)
I2*

sage: E = EllipticCurve('200c4')
sage: E.kodaira_symbol(5)
I4*
sage: E.tamagawa_number(5)
4
sage: E.tamagawa_exponent(5)
2
```

See #4715:

```
sage: E=EllipticCurve('117a3')
sage: E.tamagawa_exponent(13)
4
```

tamagawa_number(p)

The Tamagawa number of the elliptic curve at p.

This is the order of the component group $E(\mathbf{Q}_p)/E^0(\mathbf{Q}_p)$.

EXAMPLES:

```
sage: E = EllipticCurve('11a')
sage: E.tamagawa_number(11)
5
sage: E = EllipticCurve('37b')
sage: E.tamagawa_number(37)
3
```

tamagawa_number_old(p)

The Tamagawa number of the elliptic curve at p.

This is the order of the component group $E(\mathbf{Q}_p)/E^0(\mathbf{Q}_p)$.

EXAMPLES:

```
sage: E = EllipticCurve('11a')
sage: E.tamagawa_number_old(11)
5
sage: E = EllipticCurve('37b')
sage: E.tamagawa_number_old(37)
3
```

tamagawa_numbers()

Return a list of all Tamagawa numbers for all prime divisors of the conductor (in order).

EXAMPLES:

```
sage: e = EllipticCurve('30a1')
sage: e.tamagawa_numbers()
[2, 3, 1]
sage: vector(e.tamagawa_numbers())
(2, 3, 1)
```

tamagawa_product()

Returns the product of the Tamagawa numbers.

EXAMPLES:

```
sage: E = EllipticCurve('54a')
sage: E.tamagawa_product ()
3
```

tate_curve(*p*)

Creates the Tate Curve over the p-adics associated to this elliptic curves.

This Tate curve a p-adic curve with split multiplicative reduction of the form $y^2 + xy = x^3 + s_4x + s_6$ which is isomorphic to the given curve over the algebraic closure of $\mathbf{Q}_p$. Its points over $\mathbf{Q}_p$ are isomorphic to $\mathbf{Q}_p^\times/q^{\mathbf{Z}}$ for a certain parameter $q \in \mathbf{Z}_p$.

INPUT:

p - a prime where the curve has multiplicative reduction.

EXAMPLES:

```
sage: e = EllipticCurve('130a1')
sage: e.tate_curve(2)
2-adic Tate curve associated to the Elliptic Curve defined by y^2 + x*y + y = x^3 - 33*x + 6
```

The input curve must have multiplicative reduction at the prime.

```
sage: e.tate_curve(3)
...
ValueError: The elliptic curve must have multiplicative reduction at 3
```

We compute with $p = 5$:

```
sage: T = e.tate_curve(5); T
5-adic Tate curve associated to the Elliptic Curve defined by y^2 + x*y + y = x^3 - 33*x + 6
```

We find the Tate parameter q:

```
sage: T.parameter(prec=5)
3*5^3 + 3*5^4 + 2*5^5 + 2*5^6 + 3*5^7 + O(5^8)
```

We compute the $\mathcal{L}$-invariant of the curve:

```
sage: T.L_invariant(prec=10)
5^3 + 4*5^4 + 2*5^5 + 2*5^6 + 2*5^7 + 3*5^8 + 5^9 + O(5^10)
```

three_selmer_rank(*algorithm='UseSUnits'*)

Return the 3-selmer rank of this elliptic curve, computed using Magma.

INPUT:

- `algorithm` - 'Heuristic' (which is usually much faster in large examples), 'FindCubeRoots', or 'UseSUnits' (default)

OUTPUT: nonnegative integer

EXAMPLES: A rank 0 curve:

```
sage: EllipticCurve('11a').three_selmer_rank()       # optional - magma
0
```

A rank 0 curve with rational 3-isogeny but no 3-torsion

```
sage: EllipticCurve('14a3').three_selmer_rank()      # optional - magma
0
```

A rank 0 curve with rational 3-torsion:

```
sage: EllipticCurve('14a1').three_selmer_rank()      # optional - magma
1
```

A rank 1 curve with rational 3-isogeny:

```
sage: EllipticCurve('91b').three_selmer_rank()       # optional - magma
2
```

A rank 0 curve with nontrivial 3-Sha. The Heuristic option makes this about twice as fast as without it.

```
sage: EllipticCurve('681b').three_selmer_rank(algorithm='Heuristic')    # long (10 seconds);
2
```

torsion_order()

Return the order of the torsion subgroup.

EXAMPLES:

```
sage: e = EllipticCurve('11a')
sage: e.torsion_order()
5
sage: type(e.torsion_order())
<type 'sage.rings.integer.Integer'>
sage: e = EllipticCurve([1,2,3,4,5])
sage: e.torsion_order()
1
sage: type(e.torsion_order())
<type 'sage.rings.integer.Integer'>
```

torsion_points(*algorithm='pari'*)

Returns the torsion points of this elliptic curve as a sorted list.

INPUT:

- `algorithm` - string:
  - "pari" - (default) use the pari library
  - "doud" - use Doud's algorithm
  - "lutz_nagell" - use the Lutz-Nagell theorem

OUTPUT: A list of all the torsion points on this elliptic curve.

EXAMPLES:

```
sage: EllipticCurve('11a').torsion_points()
[(0 : 1 : 0), (5 : -6 : 1), (5 : 5 : 1), (16 : -61 : 1), (16 : 60 : 1)]
sage: EllipticCurve('37b').torsion_points()
[(0 : 1 : 0), (8 : -19 : 1), (8 : 18 : 1)]

sage: E=EllipticCurve([-1386747,368636886])
sage: T=E.torsion_subgroup(); T
Torsion Subgroup isomorphic to Multiplicative Abelian Group isomorphic to C8 x C2 associated
sage: T == E.torsion_subgroup(algorithm="doud")
True
sage: T == E.torsion_subgroup(algorithm="lutz_nagell")
True
sage: E.torsion_points()
[(-1293 : 0 : 1),
(-933 : -29160 : 1),
(-933 : 29160 : 1),
(-285 : -27216 : 1),
(-285 : 27216 : 1),
(0 : 1 : 0),
(147 : -12960 : 1),
(147 : 12960 : 1),
(282 : 0 : 1),
(1011 : 0 : 1),
(1227 : -22680 : 1),
(1227 : 22680 : 1),
(2307 : -97200 : 1),
(2307 : 97200 : 1),
(8787 : -816480 : 1),
(8787 : 816480 : 1)]
```

torsion_subgroup(*algorithm='pari'*)

Returns the torsion subgroup of this elliptic curve.

INPUT:

- `algorithm` - string:
- `"pari"` - (default) use the pari library
- `"doud"` - use Doud's algorithm
- `"lutz_nagell"` - use the Lutz-Nagell theorem

OUTPUT: The EllipticCurveTorsionSubgroup instance associated to this elliptic curve.

Note: To see the torsion points as a list, use `torsion_points()`.

EXAMPLES:

```
sage: EllipticCurve('11a').torsion_subgroup()
Torsion Subgroup isomorphic to Multiplicative Abelian Group isomorphic to C5 associated to t
sage: EllipticCurve('37b').torsion_subgroup()
Torsion Subgroup isomorphic to Multiplicative Abelian Group isomorphic to C3 associated to t

sage: e = EllipticCurve([-1386747,368636886]);e
Elliptic Curve defined by y^2  = x^3 - 1386747*x + 368636886 over Rational Field
sage: G = e.torsion_subgroup(); G
Torsion Subgroup isomorphic to Multiplicative Abelian
Group isomorphic to C8 x C2 associated to the Elliptic
Curve defined by y^2 = x^3 - 1386747*x + 368636886 over
Rational Field
sage: G.0
(1227 : 22680 : 1)
sage: G.1
(282 : 0 : 1)
sage: list(G)
[1, P1, P0, P0*P1, P0^2, P0^2*P1, P0^3, P0^3*P1, P0^4, P0^4*P1, P0^5, P0^5*P1, P0^6, P0^6*P1
```

two_descent(*verbose=True, selmer_only=False, first_limit=20, second_limit=8, n_aux=-1, second_descent=1*)

Compute 2-descent data for this curve.

INPUT:

- `verbose` - (default: True) print what mwrank is doing. If False, **no output** is printed.
- `selmer_only` - (default: False) selmer_only switch
- `first_limit` - (default: 20) firstlim is bound on x+z second_limit- (default: 8) secondlim is bound on log max x,z , i.e. logarithmic
- `n_aux` - (default: -1) n_aux only relevant for general 2-descent when 2-torsion trivial; n_aux=-1 causes default to be used (depends on method)
- `second_descent` - (default: True) second_descent only relevant for descent via 2-isogeny

OUTPUT:

Nothing - nothing is returned (though much is printed unless verbose=False)

EXAMPLES:

```
sage: E=EllipticCurve('37a1')
sage: E.two_descent(verbose=False) # no output
```

two_descent_simon(*verbose=0, lim1=5, lim3=50, limtriv=10, maxprob=20, limbigprime=30*)

Given a curve with no 2-torsion, computes (probably) the rank of the Mordell-Weil group, with certainty the rank of the 2-Selmer group, and a list of independent points on the curve.

INPUT:

- `verbose` - integer, 0,1,2,3; (default: 0), the verbosity level
- `lim1` - (default: 5) limite des points triviaux sur les quartiques

- `lim3` - (default: 50) limite des points sur les quartiques ELS
- `limtriv` - (default: 10) limite des points triviaux sur la courbe elliptique
- `maxprob` - (default: 20)
- `limbigprime` - (default: 30) to distinguish between small and large prime numbers. Use probabilistic tests for large primes. If 0, don't any probabilistic tests.

OUTPUT:

- `integer` - "probably" the rank of self
- `integer` - the 2-rank of the Selmer group
- `list` - list of independent points on the curve.

IMPLEMENTATION: Uses Denis Simon's GP/PARI scripts from http://www.math.unicaen.fr/~simon/

EXAMPLES: These computations use pseudo-random numbers, so we set the seed for reproducible testing.

We compute the ranks of the curves of lowest known conductor up to rank 8. Amazingly, each of these computations finishes almost instantly!

```
sage: E = EllipticCurve('11a1')
sage: set_random_seed(0)
sage: E.simon_two_descent()
(0, 0, [])
sage: E = EllipticCurve('37a1')
sage: set_random_seed(0)
sage: E.simon_two_descent()
(1, 1, [(0 : 0 : 1)])
sage: E = EllipticCurve('389a1')
sage: set_random_seed(0)
sage: E.simon_two_descent()
(2, 2, [(1 : 0 : 1), (-11/9 : -55/27 : 1)])
sage: E = EllipticCurve('5077a1')
sage: set_random_seed(0)
sage: E.simon_two_descent()
(3, 3, [(1 : 0 : 1), (2 : -1 : 1), (0 : 2 : 1)])
```

In this example Simon's program does not find any points, though it does correctly compute the rank of the 2-Selmer group.

```
sage: E = EllipticCurve([1, -1, 0, -751055859, -7922219731979])     # long (0.6 seconds)
sage: set_random_seed(0)
sage: E.simon_two_descent ()
(1, 1, [])
```

The rest of these entries were taken from Tom Womack's page http://tom.womack.net/maths/conductors.htm

```
sage: E = EllipticCurve([1, -1, 0, -79, 289])
sage: set_random_seed(0)
sage: E.simon_two_descent()
(4, 4, [(6 : -5 : 1), (4 : 3 : 1), (5 : -3 : 1), (8 : -15 : 1)])
sage: E = EllipticCurve([0, 0, 1, -79, 342])
sage: set_random_seed(0)
sage: E.simon_two_descent()
(5, 5, [(5 : 8 : 1), (10 : 23 : 1), (3 : 11 : 1), (4 : -10 : 1), (0 : 18 : 1)])
sage: E = EllipticCurve([1, 1, 0, -2582, 48720])
sage: set_random_seed(0)
sage: r, s, G = E.simon_two_descent(); r,s
(6, 6)
sage: E = EllipticCurve([0, 0, 0, -10012, 346900])
sage: set_random_seed(0)
```

```
sage: r, s, G = E.simon_two_descent(); r,s
(7, 7)
sage: E = EllipticCurve([0, 0, 1, -23737, 960366])
sage: set_random_seed(0)
sage: r, s, G = E.simon_two_descent(); r,s
(8, 8)
```

two_torsion_rank()

Return the dimension of the 2-torsion subgroup of $E(\mathbf{Q})$.

This will be 0, 1 or 2.

Note: As a side-effect of calling this function, the full torsion subgroup of the curve is computed (if not already cached). A simpler implementation of this function would be possible (by counting the roots of the 2-division polynomial), but the full torsion subgroup computation is not expensive.

EXAMPLES:

```
sage: EllipticCurve('11a1').two_torsion_rank()
0
sage: EllipticCurve('14a1').two_torsion_rank()
1
sage: EllipticCurve('15a1').two_torsion_rank()
2
```

cremona_curves(*conductors*)

Return iterator over all known curves (in database) with conductor in the list of conductors.

EXAMPLES:

```
sage: [(E.label(), E.rank()) for E in cremona_curves(srange(35,40))]
[('35a1', 0),
('35a2', 0),
('35a3', 0),
('36a1', 0),
('36a2', 0),
('36a3', 0),
('36a4', 0),
('37a1', 1),
('37b1', 0),
('37b2', 0),
('37b3', 0),
('38a1', 0),
('38a2', 0),
('38a3', 0),
('38b1', 0),
('38b2', 0),
('39a1', 0),
('39a2', 0),
('39a3', 0),
('39a4', 0)]
```

cremona_optimal_curves(*conductors*)

Return iterator over all known optimal curves (in database) with conductor in the list of conductors.

EXAMPLES:

```
sage: [(E.label(), E.rank()) for E in cremona_optimal_curves(srange(35,40))]
[('35a1', 0),
('36a1', 0),
('37a1', 1),
```

```
('37b1', 0),
('38a1', 0),
('38b1', 0),
('39a1', 0)]
```

There is one case – 990h3 – when the optimal curve isn't labeled with a 1:

```
sage: [e.cremona_label() for e in cremona_optimal_curves([990])]
['990a1', '990b1', '990c1', '990d1', '990e1', '990f1', '990g1', '990h3', '990i1', '990j1', '990k
```

integral_points_with_bounded_mw_coeffs(*E, mw_base, N*)

Returns the set of integers x which are x-coordinates of points on the curve E which are linear combinations of the generators (basis and torsion points) with coefficients bounded by N.

38.8 Tables of elliptic curves of given rank

The default database of curves contains the following data:

Rank	Number of curves	Maximal conductor
0	30427	9999
1	31871	9999
2	2388	9999
3	836	119888
4	1	234446
5	1	19047851
6	1	5187563742
7	1	382623908456
8	1	457532830151317

AUTHOR: - William Stein (2007-10-07): initial version

See also the functions cremona_curves() and cremona_optimal_curves() which enable easy looping through the Cremona elliptic curve database.

class EllipticCurves()

rank(*rank, tors=0, n=10, labels=False*)

Return a list of at most n non-isogenous curves with given rank and torsion order.

INPUT:

- `rank` (int) – the desired rank
- `tors` (int, default 0) – the desired torsion order (ignored if 0)
- `n` (int, default 10) – the maximum number of curves returned.
- `labels` (bool, default False) – if True, return Cremona labels instead of curves.

OUTPUT:

(list) A list at most n of elliptic curves of required rank.

EXAMPLES:

```
sage: elliptic_curves.rank(n=5, rank=3, tors=2, labels=True)
['59450i1', '59450i2', '61376c1', '61376c2', '65481c1']

sage: elliptic_curves.rank(n=5, rank=0, tors=5, labels=True)
['11a1', '11a3', '38b1', '50b1', '50b2']
```

```
sage: elliptic_curves.rank(n=5, rank=1, tors=7, labels=True)
['574i1', '4730k1', '6378c1']

sage: e = elliptic_curves.rank(6)[0]; e.ainvs(), e.conductor()
([1, 1, 0, -2582, 48720], 5187563742)
sage: e = elliptic_curves.rank(7)[0]; e.ainvs(), e.conductor()
([0, 0, 0, -10012, 346900], 382623908456)
sage: e = elliptic_curves.rank(8)[0]; e.ainvs(), e.conductor()
([0, 0, 1, -23737, 960366], 457532830151317)
```

38.9 Elliptic curves over number fields.

EXAMPLES:

```
sage: k.<i> = NumberField(x^2+1)
sage: E = EllipticCurve([i,2])
sage: E.j_invariant()
-23328/365*i + 864/365
sage: E.simon_two_descent()
(1, 1, [(2*i : -2*i + 2 : 1)])
sage: P = E([2*i,-2*i+2])
sage: P+P
(15/32*i + 3/4 : 139/256*i + 339/256 : 1)
```

class **EllipticCurve_number_field**(*x*, *y=None*)

Elliptic curve over a number field.

EXAMPLES:

```
sage: K.<i>=NumberField(x^2+1)
sage: EllipticCurve([i, i - 1, i + 1, 24*i + 15, 14*i + 35])
Elliptic Curve defined by y^2 + i*x*y + (i+1)*y = x^3 + (i-1)*x^2 + (24*i+15)*x + (14*i+35) over
```

conductor()

Returns the conductor of this elliptic curve as a fractional ideal of the base field.

OUTPUT:

(fractional ideal) The conductor of the curve.

EXAMPLES:

```
sage: K.<i>=NumberField(x^2+1)
sage: EllipticCurve([i, i - 1, i + 1, 24*i + 15, 14*i + 35]).conductor()
Fractional ideal (21*i - 3)
sage: K.<a>=NumberField(x^2-x+3)
sage: EllipticCurve([1 + a , -1 + a , 1 + a , -11 + a , 5 -9*a  ]).conductor()
Fractional ideal (-6*a)
```

A not so well known curve with everywhere good reduction:

```
sage: K.<a>=NumberField(x^2-38)
sage: E=EllipticCurve([0,0,0, 217968148569327655682438l0*a - 134364590724198567128296995, 12
sage: E.conductor()
Fractional ideal (1)
```

global_integral_model()

Return a model of self which is integral at all primes.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2+1)
sage: E = EllipticCurve([i/5,i/5,i/5,i/5,i/5])
sage: P1,P2 = K.primes_above(5)
sage: E.global_integral_model()
Elliptic Curve defined by y^2 + (-i)*x*y + (-25*i)*y = x^3 + 5*i*x^2 + 125*i*x + 3125*i over
```

global_minimal_model(*proof=None*)

Returns a model of self that is integral, minimal at all primes.

Note: This is only implemented for class number 1. In general, such a model may or may not exist.

INPUT:

- `proof` – whether to only use provably correct methods (default controlled by global proof module). Note that the proof module is number_field, not elliptic_curves, since the functions that actually need the flag are in number fields.

OUTPUT:

A global integral and minimal model.

EXAMPLES:

```
sage: K.<a> = NumberField(x^2-38)
sage: E = EllipticCurve([0,0,0, 21796814856932765568243810*a - 13436459072419856712829695,
sage: E.global_minimal_model()
Elliptic Curve defined by y^2 + a*x*y + (a+1)*y = x^3 + (a+1)*x^2 + (3682585202005220468063
```

has_additive_reduction(P)

Return True if this elliptic curve has (bad) additive reduction at the prime P.

INPUT:

- `P` – a prime ideal of the base field of self, or a field element generating such an ideal.

OUTPUT:

(bool) True if the curve has additive reduction at P, else False.

EXAMPLES:

```
sage: E=EllipticCurve('27a1')
sage: [(p,E.has_additive_reduction(p)) for p in prime_range(15)]
[(2, False), (3, True), (5, False), (7, False), (11, False), (13, False)]

sage: K.<a>=NumberField(x^3-2)
sage: P17a, P17b = [P for P,e in K.factor(17)]
sage: E = EllipticCurve([0,0,0,0,2*a+1])
sage: [(p,E.has_additive_reduction(p)) for p in [P17a,P17b]]
[(Fractional ideal (4*a^2 - 2*a + 1), False),
(Fractional ideal (2*a + 1), True)]
```

has_bad_reduction(P)

Return True if this elliptic curve has bad reduction at the prime P.

INPUT:

- `P` – a prime ideal of the base field of self, or a field element generating such an ideal.

OUTPUT:

(bool) True if the curve has bad reduction at P, else False.

Note: This requires determining a local integral minimal model; we do not just check that the discriminant of the current model has valuation zero.

EXAMPLES:

```
sage: E=EllipticCurve('14a1')
sage: [(p,E.has_bad_reduction(p)) for p in prime_range(15)]
```

```
[(2, True), (3, False), (5, False), (7, True), (11, False), (13, False)]

sage: K.<a>=NumberField(x^3-2)
sage: P17a, P17b = [P for P,e in K.factor(17)]
sage: E = EllipticCurve([0,0,0,0,2*a+1])
sage: [(p,E.has_bad_reduction(p)) for p in [P17a,P17b]]
[(Fractional ideal (4*a^2 - 2*a + 1), False),
(Fractional ideal (2*a + 1), True)]
```

has_good_reduction(*P*)

Return True if this elliptic curve has good reduction at the prime P.

INPUT:

•P – a prime ideal of the base field of self, or a field element generating such an ideal.

OUTPUT:

(bool) – True if the curve has good reduction at P, else False.

Note: This requires determining a local integral minimal model; we do not just check that the discriminant of the current model has valuation zero.

EXAMPLES:

```
sage: E=EllipticCurve('14a1')
sage: [(p,E.has_good_reduction(p)) for p in prime_range(15)]
[(2, False), (3, True), (5, True), (7, False), (11, True), (13, True)]

sage: K.<a>=NumberField(x^3-2)
sage: P17a, P17b = [P for P,e in K.factor(17)]
sage: E = EllipticCurve([0,0,0,0,2*a+1])
sage: [(p,E.has_good_reduction(p)) for p in [P17a,P17b]]
[(Fractional ideal (4*a^2 - 2*a + 1), True),
(Fractional ideal (2*a + 1), False)]
```

has_multiplicative_reduction(*P*)

Return True if this elliptic curve has (bad) multiplicative reduction at the prime P.

Note: See also has_split_multiplicative_reduction() and has_nonsplit_multiplicative_reduction().

INPUT:

•**P – a prime ideal of the base field of self, or a field** element generating such an ideal.

OUTPUT:

(bool) True if the curve has multiplicative reduction at P, else False.

EXAMPLES:

```
sage: E=EllipticCurve('14a1')
sage: [(p,E.has_multiplicative_reduction(p)) for p in prime_range(15)]
[(2, True), (3, False), (5, False), (7, True), (11, False), (13, False)]

sage: K.<a>=NumberField(x^3-2)
sage: P17a, P17b = [P for P,e in K.factor(17)]
sage: E = EllipticCurve([0,0,0,0,2*a+1])
sage: [(p,E.has_multiplicative_reduction(p)) for p in [P17a,P17b]]
[(Fractional ideal (4*a^2 - 2*a + 1), False), (Fractional ideal (2*a + 1), False)]
```

has_nonsplit_multiplicative_reduction(*P*)

Return True if this elliptic curve has (bad) non-split multiplicative reduction at the prime P.

INPUT:

•P – a prime ideal of the base field of self, or a field element generating such an ideal.

OUTPUT:

(bool) True if the curve has non-split multiplicative reduction at P, else False.

EXAMPLES:

```
sage: E=EllipticCurve('14a1')
sage: [(p,E.has_nonsplit_multiplicative_reduction(p)) for p in prime_range(15)]
[(2, True), (3, False), (5, False), (7, False), (11, False), (13, False)]

sage: K.<a>=NumberField(x^3-2)
sage: P17a, P17b = [P for P,e in K.factor(17)]
sage: E = EllipticCurve([0,0,0,0,2*a+1])
sage: [(p,E.has_nonsplit_multiplicative_reduction(p)) for p in [P17a,P17b]]
[(Fractional ideal (4*a^2 - 2*a + 1), False), (Fractional ideal (2*a + 1), False)]
```

has_split_multiplicative_reduction(*P*)

Return True if this elliptic curve has (bad) split multiplicative reduction at the prime P.

INPUT:

- P – a prime ideal of the base field of self, or a field element generating such an ideal.

OUTPUT:

(bool) True if the curve has split multiplicative reduction at P, else False.

EXAMPLES:

```
sage: E=EllipticCurve('14a1')
sage: [(p,E.has_split_multiplicative_reduction(p)) for p in prime_range(15)]
[(2, False), (3, False), (5, False), (7, True), (11, False), (13, False)]

sage: K.<a>=NumberField(x^3-2)
sage: P17a, P17b = [P for P,e in K.factor(17)]
sage: E = EllipticCurve([0,0,0,0,2*a+1])
sage: [(p,E.has_split_multiplicative_reduction(p)) for p in [P17a,P17b]]
[(Fractional ideal (4*a^2 - 2*a + 1), False), (Fractional ideal (2*a + 1), False)]
```

integral_model()

Return a model of self which is integral at all primes.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2+1)
sage: E = EllipticCurve([i/5,i/5,i/5,i/5,i/5])
sage: P1,P2 = K.primes_above(5)
sage: E.global_integral_model()
Elliptic Curve defined by y^2 + (-i)*x*y + (-25*i)*y = x^3 + 5*i*x^2 + 125*i*x + 3125*i over
```

is_global_integral_model()

Return true iff self is integral at all primes.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2+1)
sage: E = EllipticCurve([i/5,i/5,i/5,i/5,i/5])
sage: P1,P2 = K.primes_above(5)
sage: Emin = E.global_integral_model()
sage: Emin.is_global_integral_model()
True
```

is_local_integral_model(**P*)

Tests if self is integral at the prime ideal P, or at all the primes if P is a list or tuple.

INPUT:

- *P – a prime ideal, or a list or tuple of primes.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2+1)
sage: P1,P2 = K.primes_above(5)
sage: E = EllipticCurve([i/5,i/5,i/5,i/5,i/5])
sage: E.is_local_integral_model(P1,P2)
False
sage: Emin = E.local_integral_model(P1,P2)
sage: Emin.is_local_integral_model(P1,P2)
True
```

kodaira_symbol(*P, proof=None*)

Returns the Kodaira Symbol of this elliptic curve at the prime P.

INPUT:

- `P` – either None or a prime ideal of the base field of self.
- `proof` – whether to only use provably correct methods (default controlled by global proof module). Note that the proof module is number_field, not elliptic_curves, since the functions that actually need the flag are in number fields.

OUTPUT:

(string) The Kodaira Symbol of the curve at P.

EXAMPLES:

```
sage: K.<a>=NumberField(x^2-5)
sage: E=EllipticCurve([20, 225, 750, 625*a + 6875, 31250*a + 46875])
sage: bad_primes = E.discriminant().support(); bad_primes
[Fractional ideal (7/2*a - 81/2),
Fractional ideal (a + 52),
Fractional ideal (-a),
Fractional ideal (2)]
sage: [E.kodaira_symbol(P) for P in bad_primes]
[I1, I1, I0, II]
sage: K.<a> = QuadraticField(-11)
sage: E = EllipticCurve('11a1').change_ring(K)
sage: [E.kodaira_symbol(P) for P in K(11).support()]
[I10]
```

local_data(*P=None, proof=None*)

Local data for this elliptic curve at the prime P.

INPUT:

- `P` – either None or a prime ideal of the base field of self.
- `proof` – whether to only use provably correct methods (default controlled by global proof module). Note that the proof module is number_field, not elliptic_curves, since the functions that actually need the flag are in number fields.

OUTPUT:

If P is specified, returns the `EllipticCurveLocalData` object associated to the prime P for this curve. Otherwise, returns a list of such objects, one for each prime P in the support of the discriminant of this model.

Note: The model is not required to be integral on input.

For principal P, a generator is used as a uniformizer, and integrality or minimality at other primes is not affected. For non-principal P, the minimal model returned will preserve integrality at other primes, but not minimality.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2+1)
sage: E = EllipticCurve([1 + i, 0, 1, 0, 0])
```

```
sage: E.local_data()
[Local data at Fractional ideal (-3*i - 2):
Reduction type: bad split multiplicative
Local minimal model: Elliptic Curve defined by y^2 + (i+1)*x*y + y = x^3 over Number Field i
Minimal discriminant valuation: 2
Conductor exponent: 1
Kodaira Symbol: I2
Tamagawa Number: 2, Local data at Fractional ideal (2*i + 1):
Reduction type: bad non-split multiplicative
Local minimal model: Elliptic Curve defined by y^2 + (i+1)*x*y + y = x^3 over Number Field i
Minimal discriminant valuation: 1
Conductor exponent: 1
Kodaira Symbol: I1
Tamagawa Number: 1]
sage: E.local_data(K.ideal(3))
Local data at Fractional ideal (3):
Reduction type: good
Local minimal model: Elliptic Curve defined by y^2 + (i+1)*x*y + y = x^3 over Number Field i
Minimal discriminant valuation: 0
Conductor exponent: 0
Kodaira Symbol: I0
Tamagawa Number: 1
```

An example raised in #3897:

```
sage: E = EllipticCurve([1,1])
sage: E.local_data(3)
Local data at Principal ideal (3) of Integer Ring:
Reduction type: good
Local minimal model: Elliptic Curve defined by y^2 = x^3 + x + 1 over Rational Field
Minimal discriminant valuation: 0
Conductor exponent: 0
Kodaira Symbol: I0
Tamagawa Number: 1
```

local_information(*P=None, proof=None*)

code{local_information} has been renamed code{local_data} and is being deprecated.

local_integral_model(**P*)

Return a model of self which is integral at the prime ideal P.

Note: The integrality at other primes is not affected, even if P is non-principal.

INPUT:

- `*P` – a prime ideal, or a list or tuple of primes.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2+1)
sage: P1,P2 = K.primes_above(5)
sage: E = EllipticCurve([i/5,i/5,i/5,i/5,i/5])
sage: E.local_integral_model((P1,P2))
Elliptic Curve defined by y^2 + (-i)*x*y + (-25*i)*y = x^3 + 5*i*x^2 + 125*i*x + 3125*i over
```

local_minimal_model(*P, proof=None*)

Returns a model which is integral at all primes and minimal at P.

INPUT:

- `P` – either None or a prime ideal of the base field of self.
- `proof` – whether to only use provably correct methods (default controlled by global proof module). Note that the proof module is number_field, not elliptic_curves, since the functions that actually need the flag are in number fields.

OUTPUT:

A model of the curve which is minimal (and integral) at P.

Note: The model is not required to be integral on input.

For principal P, a generator is used as a uniformizer, and integrality or minimality at other primes is not affected. For non-principal P, the minimal model returned will preserve integrality at other primes, but not minimality.

EXAMPLES:

```
sage: K.<a>=NumberField(x^2-5)
sage: E=EllipticCurve([20, 225, 750, 625*a + 6875, 31250*a + 46875])
sage: P=K.ideal(a)
sage: E.local_minimal_model(P).ainvs()
[0, 1, 0, a - 33, -2*a + 64]
```

period_lattice(*embedding*)

Returns the period lattice of the elliptic curve for the given embedding of its base field.

INPUT:

- `embedding` - an embedding of the base number field into $\mathbf{R}$ or $\mathbf{C}$.

Note: The precision of the embedding is ignored: we only use the given embedding to determine which embedding into `QQbar` to use. Once the lattice has been initialized, periods can be computed to arbitrary precision.

EXAMPLES:

First define a field with two real embeddings:

```
sage: K.<a> = NumberField(x^3-2)
sage: E=EllipticCurve([0,0,0,a,2])
sage: embs=K.embeddings(CC); len(embs)
3
```

For each embedding we have a different period lattice:

```
sage: E.period_lattice(embs[0])
Period lattice associated to Elliptic Curve defined by y^2 = x^3 + a*x + 2 over Number Field
From: Number Field in a with defining polynomial x^3 - 2
To:   Algebraic Field
Defn: a |--> -0.6299605249474365? - 1.091123635971722?*I

sage: E.period_lattice(embs[1])
Period lattice associated to Elliptic Curve defined by y^2 = x^3 + a*x + 2 over Number Field
From: Number Field in a with defining polynomial x^3 - 2
To:   Algebraic Field
Defn: a |--> -0.6299605249474365? + 1.091123635971722?*I

sage: E.period_lattice(embs[2])
Period lattice associated to Elliptic Curve defined by y^2 = x^3 + a*x + 2 over Number Field
From: Number Field in a with defining polynomial x^3 - 2
To:   Algebraic Field
Defn: a |--> 1.259921049894873?
```

Although the original embeddings have only the default precision, we can obtain the basis with higher precision later:

```
sage: L=E.period_lattice(embs[0])
sage: L.basis()
(1.86405007647981 - 0.903761485143226*I, -0.149344633143919 - 2.06619546272945*I)

sage: L.basis(prec=100)
(1.8640500764798108425920506200 - 0.90376148514322594749786960975*I, -0.14934463314391922099
```

reduction(*place*)

Return the reduction of the elliptic curve at a place of good reduction.

INPUT:

- `place` – a prime ideal in the base field of the curve

OUTPUT:

An elliptic curve over a finite field, the residue field of the place.

EXAMPLES:

```
sage: K.<i> = QuadraticField(-1)
sage: EK = EllipticCurve([0,0,0,i,i+3])
sage: v = K.fractional_ideal(2*i+3)
sage: EK.reduction(v)
Elliptic Curve defined by y^2  = x^3 + 5*x + 8 over Residue field of Fractional ideal (2*i +
sage: EK.reduction(K.ideal(1+i))
...
AttributeError: The curve must have good reduction at the place.
sage: EK.reduction(K.ideal(2))
...
AttributeError: The ideal must be prime.
```

simon_two_descent(*verbose=0, lim1=5, lim3=50, limtriv=10, maxprob=20, limbigprime=30*)

Computes lower and upper bounds on the rank of the Mordell-Weil group, and a list of independent points.

INPUT:

- `verbose` – 0, 1, 2, or 3 (default: 0), the verbosity level
- `lim1` – (default: 5) limit on trivial points on quartics
- `lim3` – (default: 50) limit on points on ELS quartics
- `limtriv` – (default: 10) limit on trivial points on elliptic curve
- `maxprob` – (default: 20)
- `limbigprime` – (default: 30) to distinguish between small and large prime numbers. Use probabilistic tests for large primes. If 0, don't use probabilistic tests.

OUTPUT:

`(lower, upper, list)` where `lower` is a lower bound on the rank, `upper` is an upper bound (the 2-Selmer rank) and `list` is a list of independent points on the Weierstrass model. The length of `list` is equal to either `lower`, or `lower-1`, since when `lower` is less than `upper` and of different parity, the value of `lower` is increased by 1.

Note: For non-quadratic number fields, this code does return, but it takes a long time.

IMPLEMENTATION:

Uses Denis Simon's GP/PARI scripts from url{http://www.math.unicaen.fr/~simon/}.

EXAMPLES:

```
sage: K.<a> = NumberField(x^2 + 23, 'a')
sage: E = EllipticCurve(K, '37')
sage: E == loads(dumps(E))
True
sage: E.simon_two_descent()

```

A curve with 2-torsion:

```
sage: K.<a> = NumberField(x^2 + 7, 'a')
sage: E = EllipticCurve(K, '15a')
sage: v = E.simon_two_descent(); v  # long time (about 10 seconds), points can vary
(1, 3, [...])
```

tamagawa_exponent(*P*, *proof=None*)

Returns the Tamagawa index of this elliptic curve at the prime P.

INPUT:

- `P` – either None or a prime ideal of the base field of self.
- `proof` – whether to only use provably correct methods (default controlled by global proof module). Note that the proof module is number_field, not elliptic_curves, since the functions that actually need the flag are in number fields.

OUTPUT:

(positive integer) The Tamagawa index of the curve at P.

EXAMPLES:

```
sage: K.<a>=NumberField(x^2-5)
sage: E=EllipticCurve([20, 225, 750, 625*a + 6875, 31250*a + 46875])
sage: [E.tamagawa_exponent(P) for P in E.discriminant().support()]
[1, 1, 1, 1]
sage: K.<a> = QuadraticField(-11)
sage: E = EllipticCurve('11a1').change_ring(K)
sage: [E.tamagawa_exponent(P) for P in K(11).support()]
[10]
```

tamagawa_number(*P*, *proof=None*)

Returns the Tamagawa number of this elliptic curve at the prime P.

INPUT:

- `P` – either None or a prime ideal of the base field of self.

- `proof` – whether to only use provably correct methods (default controlled by global proof module). Note that the proof module is number_field, not elliptic_curves, since the functions that actually need the flag are in number fields.

OUTPUT:

(positive integer) The Tamagawa number of the curve at P.

EXAMPLES:

```
sage: K.<a>=NumberField(x^2-5)
sage: E=EllipticCurve([20, 225, 750, 625*a + 6875, 31250*a + 46875])
sage: [E.tamagawa_number(P) for P in E.discriminant().support()]
[1, 1, 1, 1]
sage: K.<a> = QuadraticField(-11)
sage: E = EllipticCurve('11a1').change_ring(K)
sage: [E.tamagawa_number(P) for P in K(11).support()]
[10]
```

torsion_order()

Returns the order of the torsion subgroup of this elliptic curve.

OUTPUT:

(integer) the order of the torsion subgroup of this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve('11a1')
sage: K.<t> = NumberField(x^4 + x^3 + 11*x^2 + 41*x + 101)
sage: EK = E.base_extend(K)
sage: EK.torsion_order()
25

sage: E = EllipticCurve('15a1')
sage: K.<t> = NumberField(x^2 + 2*x + 10)
sage: EK = E.base_extend(K)
sage: EK.torsion_order()
16

sage: E = EllipticCurve('19a1')
sage: K.<t> = NumberField(x^9-3*x^8-4*x^7+16*x^6-3*x^5-21*x^4+5*x^3+7*x^2-7*x+1)
sage: EK = E.base_extend(K)
sage: EK.torsion_order()
9

sage: K.<i> = QuadraticField(-1)
sage: EK = EllipticCurve([0,0,0,i,i+3])
sage: EK.torsion_order()
1
```

torsion_points()

Returns a list of the torsion points of this elliptic curve.

OUTPUT:

(list) A sorted list of the torsion points.

EXAMPLES:

```
sage: E = EllipticCurve('11a1')
sage: E.torsion_points()
[(0 : 1 : 0), (5 : -6 : 1), (5 : 5 : 1), (16 : -61 : 1), (16 : 60 : 1)]
sage: K.<t> = NumberField(x^4 + x^3 + 11*x^2 + 41*x + 101)
sage: EK = E.base_extend(K)
sage: EK.torsion_points()
```

```
[(t : 1/11*t^3 + 6/11*t^2 + 19/11*t + 48/11 : 1),
(1/11*t^3 - 5/11*t^2 + 19/11*t - 40/11 : -6/11*t^3 - 3/11*t^2 - 26/11*t - 321/11 : 1),
(1/11*t^3 - 5/11*t^2 + 19/11*t - 40/11 : 6/11*t^3 + 3/11*t^2 + 26/11*t + 310/11 : 1),
(t : -1/11*t^3 - 6/11*t^2 - 19/11*t - 59/11 : 1),
(16 : 60 : 1),
(-3/55*t^3 - 7/55*t^2 - 2/55*t - 133/55 : 6/55*t^3 + 3/55*t^2 + 25/11*t + 156/55 : 1),

(1 : 0 : 1),
(0 : i : 1),
(-2 : 3*i : 1),
(0 : 1 : 0)]
```

torsion_subgroup()

Returns the torsion subgroup of this elliptic curve.

OUTPUT:

(`EllipticCurveTorsionSubgroup`) The `EllipticCurveTorsionSubgroup` associated to this elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve('11a1')
sage: K.<t>=NumberField(x^4 + x^3 + 11*x^2 + 41*x + 101)
sage: EK=E.base_extend(K)
sage: tor = EK.torsion_subgroup()
sage: tor
Torsion Subgroup isomorphic to Multiplicative Abelian Group isomorphic to C5 x C5 associated
sage: tor.gens()
((16 : 60 : 1), (t : 1/11*t^3 + 6/11*t^2 + 19/11*t + 48/11 : 1))

sage: E = EllipticCurve('15a1')

38.10 Elliptic curves over finite fields

AUTHORS:

- William Stein (2005): Initial version
- Robert Bradshaw et al....
- John Cremona (2008-02): Point counting and group structure for non-prime fields, Frobenius endomorphism and order, elliptic logs

class **`EllipticCurve_finite_field`**(*x, y=None*)

Elliptic curve over a finite field.

`abelian_group`(*debug=False*)

Returns the abelian group structure of the group of points on this elliptic curve.

> **Warning:** The algorithm is definitely *not* intended for use with *large* finite fields! The factorization of the orders of elements must be feasible. Also, baby-step-giant-step methods are used which have space and time requirements which are $O(\sqrt{q})$.

Also, the algorithm uses random points on the curve and hence the generators are likely to differ from one run to another; but the group is cached so the generators will not change in any one run of Sage.

Note: This function applies to elliptic curves over arbitrary finite fields. The related function abelian_group_prime_field() uses the pari script, for prime fields only; it is now obsolete

INPUT:

•`debug` - (default: False): if True, print debugging messages

OUTPUT:

•an abelian group

•tuple of images of each of the generators of the abelian group as points on this curve

AUTHORS:

•John Cremona

EXAMPLES:

```
sage: E=EllipticCurve(GF(11),[2,5])
sage: E.abelian_group()
(Multiplicative Abelian Group isomorphic to C10, ...

sage: E=EllipticCurve(GF(41),[2,5])
sage: E.abelian_group()
(Multiplicative Abelian Group isomorphic to C22 x C2, ...

sage: F.<a>=GF(3^6,'a')
sage: E=EllipticCurve([a^4 + a^3 + 2*a^2 + 2*a, 2*a^5 + 2*a^3 + 2*a^2 + 1])
sage: E.abelian_group()
(Multiplicative Abelian Group isomorphic to C26 x C26, ...

sage: F.<a>=GF(101^3,'a')
sage: E=EllipticCurve([2*a^2 + 48*a + 27, 89*a^2 + 76*a + 24])
sage: E.abelian_group()
(Multiplicative Abelian Group isomorphic to C1031352, ...
```

The group can be trivial:

```
sage: E=EllipticCurve(GF(2),[0,0,1,1,1])
sage: E.abelian_group()
(Trivial Abelian Group, ())
```

Of course, there are plenty of points if we extend the field:

```
sage: E.cardinality(extension_degree=100)
1267650600228231653296516890625
```

This tests the patch for trac #3111, using 10 primes randomly selected:

```
sage: E = EllipticCurve('389a')
sage: for p in [5927, 2297, 1571, 1709, 3851, 127, 3253, 5783, 3499, 4817]:
...       G = E.change_ring(GF(p)).abelian_group()
sage: for p in prime_range(10000):            #long time (~20s)
...       if p != 389:
...           G=E.change_ring(GF(p)).abelian_group()
```

This tests that the bug reported in trac #3926 has been fixed:

```
sage: K.<i> = QuadraticField(-1)
sage: OK = K.ring_of_integers()
sage: P=K.factor(10007)[0][0]
sage: OKmodP = OK.residue_field(P)
sage: E = EllipticCurve([0,0,0,i,i+3])
sage: Emod = E.change_ring(OKmodP); Emod
Elliptic Curve defined by y^2  = x^3 + ibar*x + (ibar+3) over Residue field in ibar of Fract
```

```
sage: Emod.abelian_group() #random generators
(Multiplicative Abelian Group isomorphic to C50067594 x C2,
((3152*ibar + 7679 : 7330*ibar + 7913 : 1), (8466*ibar + 1770 : 0 : 1)))
```

cardinality(*algorithm='heuristic', extension_degree=1*)

Return the number of points on this elliptic curve over an extension field (default: the base field).

INPUT:

- `algorithm` - string (default: 'heuristic'), used only for point counting over prime fields
  - `'heuristic'` - use a heuristic to choose between pari, bsgs and sea.
  - `'pari'` - use the baby step giant step method as implemented in PARI via the C-library function ellap.
  - `'sea'` - use sea.gp as implemented in PARI by Christophe Doche and Sylvain Duquesne. ('sea' stands for 'Schoof-Elkies-Atkin'.)
  - `bsgs` - use the baby step giant step method as implemented in Sage, with the Cremona - Sutherland version of Mestre's trick.
  - `all` - (over prime fields only) compute cardinality with all of pari, sea and bsgs; return result if they agree or raise a RuntimeError if they do not.
- `early_abort` - bool (default: False); this is used only by sea. if True, stop early if a small factor of the order is found.
- `extension_degree` - int (default: 1); if the base field is $k = GF(p^n)$ and extension_degree=d, returns the cardinality of $E(GF(p^{nd}))$.

OUTPUT: an integer

The cardinality is cached.

Over prime fields, one of the above algorithms is used. Over non-prime fields, the serious point counting is done on a standard curve with the same j-invariant over the field GF(p)(j), then lifted to the base_field, and finally account is taken of twists.

For j=0 and j=1728 special formulas are used instead.

EXAMPLES:

```
sage: EllipticCurve(GF(4,'a'),[1,2,3,4,5]).cardinality()
8
sage: k.<a> = GF(3^3)
sage: l = [a^2 + 1, 2*a^2 + 2*a + 1, a^2 + a + 1, 2, 2*a]
sage: EllipticCurve(k,l).cardinality()
29

sage: l = [1, 1, 0, 2, 0]
sage: EllipticCurve(k,l).cardinality()
38
```

An even bigger extension (which we check against Magma):

```
sage: EllipticCurve(GF(3^100,'a'),[1,2,3,4,5]).cardinality()
515377520732011331036459693969645888996929981504
sage: magma.eval("Order(EllipticCurve([GF(3^100)|1,2,3,4,5]))")     # optional - magma
'515377520732011331036459693969645888996929981504'

sage: EllipticCurve(GF(10007),[1,2,3,4,5]).cardinality()
10076
sage: EllipticCurve(GF(10007),[1,2,3,4,5]).cardinality(algorithm='sea')
10076
sage: EllipticCurve(GF(10007),[1,2,3,4,5]).cardinality(algorithm='pari')
10076
sage: EllipticCurve(GF(next_prime(10**20)),[1,2,3,4,5]).cardinality(algorithm='sea')
100000000011093199520
```

The cardinality is cached:

```
sage: E = EllipticCurve(GF(3^100,'a'),[1,2,3,4,5])
sage: E.cardinality() is E.cardinality()
True
sage: E=EllipticCurve(GF(11^2,'a'),[3,3])
sage: E.cardinality()
128
sage: EllipticCurve(GF(11^100,'a'),[3,3]).cardinality()
137806123398222701841183371720896367762643312000384671846835266941791510341065565176497846500
```

cardinality_bsgs(*verbose=False*)

Return the cardinality of self over the base field. Will be called by user function cardinality only when necessary, i.e. when the j_invariant is not in the prime field.
ALGORITHM: A variant of "Mestre's trick" extended to all finite fields by Cremona and Sutherland, 2008.
Note:

1. The Mestre-Schoof-Cremona-Sutherland algorithm may fail for a small finite number of curves over F_q for q at most 49, so for $q < 50$ we use an exhaustive count.
2. Quadratic twists are not implemented in characteristic 2 when $j = 0 (= 1728)$; but this case is treated separately.

EXAMPLES:

```
sage: p=next_prime(10^3)
sage: E=EllipticCurve(GF(p),[3,4])
sage: E.cardinality_bsgs()
1020
sage: E=EllipticCurve(GF(3^4,'a'),[1,1])
sage: E.cardinality_bsgs()
64
sage: F.<a>=GF(101^3,'a')
sage: E=EllipticCurve([2*a^2 + 48*a + 27, 89*a^2 + 76*a + 24])
sage: E.cardinality_bsgs()
1031352
```

cardinality_exhaustive()

Return the cardinality of self over the base field. Simply adds up the number of points with each x-coordinate: only used for small field sizes!

EXAMPLES:

```
sage: p=next_prime(10^3)
sage: E=EllipticCurve(GF(p),[3,4])
sage: E.cardinality_exhaustive()
1020
sage: E=EllipticCurve(GF(3^4,'a'),[1,1])
sage: E.cardinality_exhaustive()
64
```

cardinality_pari()

Return the cardinality of self over the (prime) base field using pari.

The result is not cached.

EXAMPLES:

```
sage: p=next_prime(10^3)
sage: E=EllipticCurve(GF(p),[3,4])
sage: E.cardinality_pari()
1020
sage: K=GF(next_prime(10^6))
```

```
sage: E=EllipticCurve(K,[1,0,0,1,1])
sage: E.cardinality_pari()
999945
```

TESTS:

```
sage: K.<a>=GF(3^20)
sage: E=EllipticCurve(K,[1,0,0,1,a])
sage: E.cardinality_pari()
...
ValueError: cardinality_pari() only works over prime fields.
sage: E.cardinality()
3486794310
```

cardinality_sea(*early_abort=False*)

Return the cardinality of self over the (prime) base field using sea.

INPUT:

- `early_abort` - bool (default: False). if True, an early abort technique is used and the computation is interrupted as soon as a small divisor of the order is detected. The function then returns 0. This is useful for ruling out curves whose cardinality is divisible by a small prime.

The result is not cached.

EXAMPLES:

```
sage: p=next_prime(10^3)
sage: E=EllipticCurve(GF(p),[3,4])
sage: E.cardinality_sea()
1020
sage: K=GF(next_prime(10^6))
sage: E=EllipticCurve(K,[1,0,0,1,1])
sage: E.cardinality_sea()
999945
```

TESTS:

```
sage: K.<a>=GF(3^20)
sage: E=EllipticCurve(K,[1,0,0,1,a])
sage: E.cardinality_sea()
...
ValueError: cardinality_sea() only works over prime fields.
sage: E.cardinality()
3486794310
```

frobenius()

Return the frobenius of self as an element of a quadratic order

Note: This computes the curve cardinality, which may be time-consuming.

Frobenius is only determined up to conjugacy.

EXAMPLES:

```
sage: E=EllipticCurve(GF(11),[3,3])
sage: E.frobenius()
phi
sage: E.frobenius().minpoly()
x^2 - 4*x + 11
```

For some supersingular curves, Frobenius is in Z:

```
sage: E=EllipticCurve(GF(25,'a'),[0,0,0,0,1])
sage: E.frobenius()
-5
```

frobenius_order()

Return the quadratic order Z[phi] where phi is the Frobenius endomorphism of the elliptic curve

Note: This computes the curve cardinality, which may be time-consuming.

EXAMPLES:

```
sage: E=EllipticCurve(GF(11),[3,3])
sage: E.frobenius_order()
Order in Number Field in phi with defining polynomial x^2 - 4*x + 11
```

For some supersingular curves, Frobenius is in Z and the Frobenius order is Z:

```
sage: E=EllipticCurve(GF(25,'a'),[0,0,0,0,1])
sage: R=E.frobenius_order()
sage: R
Order in Number Field in phi with defining polynomial x + 5
sage: R.degree()
1
```

frobenius_polynomial()

Return the characteristic polynomial of Frobenius.

The Frobenius endomorphism of the elliptic curve has quadratic characteristic polynomial. In most cases this is irreducible and defines an imaginary quadratic order; for some supersingular curves, Frobenius is an integer a and the polynomial is $(x-a)^2$.

Note: This computes the curve cardinality, which may be time-consuming.

EXAMPLES:

```
sage: E=EllipticCurve(GF(11),[3,3])
sage: E.frobenius_polynomial()
x^2 - 4*x + 11
```

For some supersingular curves, Frobenius is in Z and the polynomial is a square:

```
sage: E=EllipticCurve(GF(25,'a'),[0,0,0,0,1])
sage: E.frobenius_polynomial().factor()
(x + 5)^2
```

gens()

Returns a tuple of length up to 2 of points which generate the abelian group of points on this elliptic curve. See abelian_group() for limitations.

The algorithm uses random points on the curve, and hence the generators are likely to differ from one run to another; but they are cached so will be consistent in any one run of Sage.

AUTHORS:

- John Cremona

EXAMPLES:

```
sage: E=EllipticCurve(GF(11),[2,5]) # random output
sage: E.gens()
((0 : 4 : 1),)
sage: EllipticCurve(GF(41),[2,5]).gens() # random output
((21 : 1 : 1), (8 : 0 : 1))
sage: F.<a>=GF(3^6,'a')
sage: E=EllipticCurve([a,a+1])
sage: pts=E.gens()
sage: len(pts)
1
sage: pts[0].order()==E.cardinality()
True
```

order(*algorithm='heuristic', extension_degree=1*)

Return the number of points on this elliptic curve over an extension field (default: the base field).

INPUT:

- `algorithm` - string (default: 'heuristic'), used only for point counting over prime fields
  - `'heuristic'` - use a heuristic to choose between pari, bsgs and sea.
  - `'pari'` - use the baby step giant step method as implemented in PARI via the C-library function ellap.
  - `'sea'` - use sea.gp as implemented in PARI by Christophe Doche and Sylvain Duquesne. ('sea' stands for 'Schoof-Elkies-Atkin'.)
  - `bsgs` - use the baby step giant step method as implemented in Sage, with the Cremona - Sutherland version of Mestre's trick.
  - `all` - (over prime fields only) compute cardinality with all of pari, sea and bsgs; return result if they agree or raise a RuntimeError if they do not.
- `early_abort` - bool (default: False); this is used only by sea. if True, stop early if a small factor of the order is found.
- `extension_degree` - int (default: 1); if the base field is $k = GF(p^n)$ and extension_degree=d, returns the cardinality of $E(GF(p^{nd}))$.

OUTPUT: an integer

The cardinality is cached.

Over prime fields, one of the above algorithms is used. Over non-prime fields, the serious point counting is done on a standard curve with the same j-invariant over the field GF(p)(j), then lifted to the base_field, and finally account is taken of twists.

For j=0 and j=1728 special formulas are used instead.

EXAMPLES:

```
sage: EllipticCurve(GF(4,'a'),[1,2,3,4,5]).cardinality()
8
sage: k.<a> = GF(3^3)
sage: l = [a^2 + 1, 2*a^2 + 2*a + 1, a^2 + a + 1, 2, 2*a]
sage: EllipticCurve(k,l).cardinality()
29

sage: l = [1, 1, 0, 2, 0]
sage: EllipticCurve(k,l).cardinality()
38
```

An even bigger extension (which we check against Magma):

```
sage: EllipticCurve(GF(3^100,'a'),[1,2,3,4,5]).cardinality()
515377520732011331036459693969645888996929981504
sage: magma.eval("Order(EllipticCurve([GF(3^100)|1,2,3,4,5]))")     # optional - magma
'515377520732011331036459693969645888996929981504'

sage: EllipticCurve(GF(10007),[1,2,3,4,5]).cardinality()
10076
sage: EllipticCurve(GF(10007),[1,2,3,4,5]).cardinality(algorithm='sea')
10076
sage: EllipticCurve(GF(10007),[1,2,3,4,5]).cardinality(algorithm='pari')
10076
sage: EllipticCurve(GF(next_prime(10**20)),[1,2,3,4,5]).cardinality(algorithm='sea')
100000000011093199520
```

The cardinality is cached:

```
sage: E = EllipticCurve(GF(3^100,'a'),[1,2,3,4,5])
sage: E.cardinality() is E.cardinality()
```

```
True
sage: E=EllipticCurve(GF(11^2,'a'),[3,3])
sage: E.cardinality()
128
sage: EllipticCurve(GF(11^100,'a'),[3,3]).cardinality()
137806123398222701841183371720896367762643312000384671846835266941791510341065565176497846500
```

plot(**args, **kwds*)

Draw a graph of this elliptic curve over a prime finite field.

INPUT:

- `*args, **kwds` - all other options are passed to the circle graphing primitive.

EXAMPLES:

```
sage: E = EllipticCurve(FiniteField(17), [0,1])
sage: P = plot(E, rgbcolor=(0,0,1))
```

points()

All the points on this elliptic curve. The list of points is cached so subsequent calls are free.

EXAMPLES:

```
sage: p = 5
sage: F = GF(p)
sage: E = EllipticCurve(F, [1, 3])
sage: a_sub_p = E.change_ring(QQ).ap(p); a_sub_p
2

sage: len(E.points())
4
sage: p + 1 - a_sub_p
4
sage: E.points()
[(0 : 1 : 0), (1 : 0 : 1), (4 : 1 : 1), (4 : 4 : 1)]

sage: K = GF(p**2,'a')
sage: E = E.change_ring(K)
sage: len(E.points())
32
sage: (p + 1)**2 - a_sub_p**2
32
sage: w = E.points(); w
[(0 : 1 : 0), (0 : 2*a + 4 : 1), (0 : 3*a + 1 : 1), (1 : 0 : 1), (2 : 2*a + 4 : 1), (2 : 3*a
```

Note that the returned list is an immutable sorted Sequence:

```
sage: w[0] = 9
...
ValueError: object is immutable; please change a copy instead.
```

random_element()

Returns a random point on this elliptic curve.

Returns the point at infinity with probability $1/(q+1)$ where the base field has cardinality q.

EXAMPLES:

```
sage: k = GF(next_prime(7^5))
sage: E = EllipticCurve(k,[2,4])
sage: P = E.random_element(); P
(751 : 6230 : 1)
sage: type(P)
```

```
<class 'sage.schemes.elliptic_curves.ell_point.EllipticCurvePoint_finite_field'>
sage: P in E
True

sage: k.<a> = GF(7^5)
sage: E = EllipticCurve(k,[2,4])
sage: P = E.random_element(); P
(a^4 + a + 5 : 6*a^4 + 3*a^3 + 2*a^2 + 4 : 1)
sage: type(P)
<class 'sage.schemes.elliptic_curves.ell_point.EllipticCurvePoint_finite_field'>
sage: P in E
True

sage: k.<a> = GF(2^5)
sage: E = EllipticCurve(k,[a^2,a,1,a+1,1])
sage: P = E.random_element(); P
(a^4 : 0 : 1)
sage: type(P)
<class 'sage.schemes.elliptic_curves.ell_point.EllipticCurvePoint_finite_field'>
sage: P in E
True
```

random_point()

Returns a random point on this elliptic curve.

Returns the point at infinity with probability $1/(q+1)$ where the base field has cardinality q.

EXAMPLES:

```
sage: k = GF(next_prime(7^5))
sage: E = EllipticCurve(k,[2,4])
sage: P = E.random_element(); P
(751 : 6230 : 1)
sage: type(P)
<class 'sage.schemes.elliptic_curves.ell_point.EllipticCurvePoint_finite_field'>
sage: P in E
True

sage: k.<a> = GF(7^5)
sage: E = EllipticCurve(k,[2,4])
sage: P = E.random_element(); P
(a^4 + a + 5 : 6*a^4 + 3*a^3 + 2*a^2 + 4 : 1)
sage: type(P)
<class 'sage.schemes.elliptic_curves.ell_point.EllipticCurvePoint_finite_field'>
sage: P in E
True

sage: k.<a> = GF(2^5)
sage: E = EllipticCurve(k,[a^2,a,1,a+1,1])
sage: P = E.random_element(); P
(a^4 : 0 : 1)
sage: type(P)
<class 'sage.schemes.elliptic_curves.ell_point.EllipticCurvePoint_finite_field'>
sage: P in E
True
```

trace_of_frobenius()

Return the trace of Frobenius acting on this elliptic curve.

Note: This computes the curve cardinality, which may be time-consuming.

EXAMPLES:

```
sage: E=EllipticCurve(GF(101),[2,3])
sage: E.trace_of_frobenius()
6
sage: E=EllipticCurve(GF(11^5,'a'),[2,5])
sage: E.trace_of_frobenius()
802
```

The following shows that the issue from trac #2849 is fixed:

```
sage: E=EllipticCurve(GF(3^5,'a'),[-1,-1])
sage: E.trace_of_frobenius()
-27
```

38.11 Points on elliptic curves

The base class `EllipticCurvePoint_field`, derived from `AdditiveGroupElement`, provides support for points on elliptic curves defined over general fields. The derived classes `EllipticCurvePoint_number_field` and `EllipticCurvePoint_finite_field` provide further support for point on curves defined over number fields (including the rational field $\mathbf{Q}$) and over finite fields. Although there is no special class for points over $\mathbf{Q}$, there is currently greater functionality implemented over $\mathbf{Q}$ than over other number fields.

The class `EllipticCurvePoint`, which is based on `SchemeMorphism_projective_coordinates_ring`, currently has little extra functionality.

EXAMPLES:

An example over $\mathbf{Q}$:

```
sage: E = EllipticCurve('389a1')
sage: P = E(-1,1); P
(-1 : 1 : 1)
sage: Q = E(0,-1); Q
(0 : -1 : 1)
sage: P+Q
(4 : 8 : 1)
sage: P-Q
(1 : 0 : 1)
sage: 3*P-5*Q
(328/361 : -2800/6859 : 1)
```

An example over a number field:

```
sage: K.<i> = QuadraticField(-1)
sage: E = EllipticCurve(K,[1,0,0,0,-1])
sage: P = E(0,i); P
(0 : i : 1)
sage: P.order()
+Infinity
sage: 101*P-100*P==P
True
```

An example over a finite field:

```
sage: K.<a> = GF(101^3)
sage: E = EllipticCurve(K,[1,0,0,0,-1])
sage: P = E(40*a^2 + 69*a + 84 , 58*a^2 + 73*a + 45)
```

```
sage: P.order()
1032210
sage: E.cardinality()
1032210
```

Arithmetic with a point over an extension of a finite field:

```
sage: k.<a> = GF(5^2)
sage: E = EllipticCurve(k,[1,0]); E
Elliptic Curve defined by y^2 = x^3 + x over Finite Field in a of size 5^2
sage: P = E([a,2*a+4])
sage: 5*P
(2*a + 3 : 2*a : 1)
sage: P*5
(2*a + 3 : 2*a : 1)
sage: P + P + P + P + P
(2*a + 3 : 2*a : 1)
```

```
sage: F = Zmod(3)
sage: E = EllipticCurve(F,[1,0]);
sage: P = E([2,1])
sage: import sys
sage: n = sys.maxint
sage: P*(n+1)-P*n == P
True
```

AUTHORS:

- William Stein (2005) – Initial version
- Robert Bradshaw et al....
- **John Cremona (Feb 2008) – Point counting and group structure for** non-prime fields, Frobenius endomorphism and order, elliptic logs
- John Cremona (Aug 2008) – Introduced `EllipticCurvePoint_number_field` class
- Tobias Nagel, Michael Mardaus, John Cremona (Dec 2008) – p-adic elliptic logarithm over $\mathbf{Q}$
- David Hansen (Jan 2009) – Added `weil_pairing` function to `EllipticCurvePoint_finite_field` class

class `EllipticCurvePoint` (*X, v, check=True*)
A point on an elliptic curve.

class `EllipticCurvePoint_field` (*curve, v, check=True*)
A point on an elliptic curve over a field. The point has coordinates in the base field.

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: E([0,0])
(0 : 0 : 1)
sage: E(0,0)                # brackets are optional
(0 : 0 : 1)
sage: E([GF(5)(0), 0])      # entries are coerced
(0 : 0 : 1)
```

```
sage: E(0.000, 0)
(0 : 0 : 1)

sage: E(1,0,0)
...
TypeError: Coordinates [1, 0, 0] do not define a point on
Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field

sage: E = EllipticCurve([0,0,1,-1,0])
sage: S = E(QQ); S
Abelian group of points on Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field

sage: K.<i>=NumberField(x^2+1)
sage: E=EllipticCurve(K,[0,1,0,-160,308])
sage: P=E(26,-120)
sage: Q=E(2+12*i,-36+48*i)
sage: P.order() == Q.order() == 4
True
sage: 2*P==2*Q
False

sage: K.<t>=FractionField(PolynomialRing(QQ,'t'))
sage: E=EllipticCurve([0,0,0,0,t^2])
sage: P=E(0,t)
sage: P,2*P,3*P
((0 : t : 1), (0 : -t : 1), (0 : 1 : 0))
```

TESTS:

```
sage: loads(S.dumps()) == S
True
sage: E = EllipticCurve('37a')
sage: P = E(0,0); P
(0 : 0 : 1)
sage: loads(P.dumps()) == P
True
sage: T = 100*P
sage: loads(T.dumps()) == T
True
```

Test pickling an elliptic curve that has known points on it:

```
sage: e = EllipticCurve([0, 0, 1, -1, 0]); g = e.gens(); loads(dumps(e)) == e
True
```

codomain()

Return the codomain of this point, which is the curve it is on. Synonymous with curve() which is perhaps more intuitive.

EXAMPLES:

```
sage: E=EllipticCurve(QQ,[1,1])
sage: P=E(0,1)
sage: P.domain()
Spectrum of Rational Field
sage: K.<a>=NumberField(x^2-3,'a')
sage: P=E.base_extend(K)(1,a)
sage: P.codomain()
```

```
Elliptic Curve defined by y^2 = x^3 + x + 1 over Number Field in a with defining polynomial
sage: P.codomain() == P.curve()
True
```

curve()

Return the curve that this point is on.

EXAMPLES:

```
sage: E = EllipticCurve('389a')
sage: P = E([-1,1])
sage: P.curve()
Elliptic Curve defined by y^2 + y = x^3 + x^2 - 2*x over Rational Field
```

division_points(*m, poly_only=False*)

Return a list of all points Q such that $mQ = P$ where P = self.

Only points on the elliptic curve containing self and defined over the base field are included.

INPUT:

- m – a positive integer
- poly_only – bool (default: False); if True return polynomial whose roots give all possible x-coordinates of m-th roots of self.

OUTPUT:

(list) – a (possibly empty) list of solutions Q to $mQ = P$, where P = self.

EXAMPLES:

We find the five 5-torsion points on an elliptic curve:

```
sage: E = EllipticCurve('11a'); E
Elliptic Curve defined by y^2 + y = x^3 - x^2 - 10*x - 20 over Rational Field
sage: P = E(0); P
(0 : 1 : 0)
sage: P.division_points(5)
[(0 : 1 : 0), (5 : -6 : 1), (5 : 5 : 1), (16 : -61 : 1), (16 : 60 : 1)]
```

Note above that 0 is included since [5]*0 = 0.

We create a curve of rank 1 with no torsion and do a consistency check:

```
sage: E = EllipticCurve('11a').quadratic_twist(-7)
sage: Q = E([44,-270])
sage: (4*Q).division_points(4)
[(44 : -270 : 1)]
```

We create a curve over a non-prime finite field with group of order 18:

```
sage: k.<a> = GF(25)
sage: E = EllipticCurve(k, [1,2+a,3,4*a,2])
sage: P = E([3,3*a+4])
sage: factor(E.order())
2 * 3^2
sage: P.order()
9
```

We find the 1-division points as a consistency check – there is just one, of course:

```
sage: P.division_points(1)
[(3 : 3*a + 4 : 1)]
```

The point P has order coprime to 2 but divisible by 3, so:

```
sage: P.division_points(2)
[(2*a + 1 : 3*a + 4 : 1), (3*a + 1 : a : 1)]
```

We check that each of the 2-division points works as claimed:

```
sage: [2*Q for Q in P.division_points(2)]
[(3 : 3*a + 4 : 1), (3 : 3*a + 4 : 1)]
```

Some other checks:

```
sage: P.division_points(3)
[]
sage: P.division_points(4)
[(0 : 3*a + 2 : 1), (1 : 0 : 1)]
sage: P.division_points(5)
[(1 : 1 : 1)]
```

An example over a number field (see trac #3383):

```
sage: E = EllipticCurve('19a1')
sage: K.<t> = NumberField(x^9-3*x^8-4*x^7+16*x^6-3*x^5-21*x^4+5*x^3+7*x^2-7*x+1)
sage: EK = E.base_extend(K)
sage: E(0).division_points(3)
[(0 : 1 : 0), (5 : -10 : 1), (5 : 9 : 1)]
sage: EK(0).division_points(3)
[(0 : 1 : 0), (5 : 9 : 1), (5 : -10 : 1)]
sage: E(0).division_points(9)
[(0 : 1 : 0), (5 : -10 : 1), (5 : 9 : 1)]
sage: EK(0).division_points(9)
[(0 : 1 : 0), (5 : 9 : 1), (5 : -10 : 1), (-150/121*t^8 + 414/121*t^7 + 1481/242*t^6 - 2382/
```

domain()

Return the domain of this point, which is $Spec(F)$ where F is the field of definition.

EXAMPLES:

```
sage: E=EllipticCurve(QQ,[1,1])
sage: P=E(0,1)
sage: P.domain()
Spectrum of Rational Field
sage: K.<a>=NumberField(x^2-3,'a')
sage: P=E.base_extend(K)(1,a)
sage: P.domain()
Spectrum of Number Field in a with defining polynomial x^2 - 3
```

has_finite_order()

Return True if this point has finite additive order as an element of the group of points on this curve.

For fields other than number fields and finite fields, this is NotImplemented unless self.is_zero().

EXAMPLES:

```
sage: K.<t>=FractionField(PolynomialRing(QQ,'t'))
sage: E=EllipticCurve([0,0,0,-t^2,0])
sage: P = E(0)
sage: P.has_finite_order()
True
sage: P=E(t,0)
sage: P.has_finite_order()
...
NotImplementedError: Computation of order of a point not implemented over general fields.
sage: (2*P).is_zero()
True
```

has_infinite_order()

Return True if this point has infinite additive order as an element of the group of points on this curve.

For fields other than number fields and finite fields, this is NotImplemented unless self.is_zero().

EXAMPLES:

```
sage: K.<t>=FractionField(PolynomialRing(QQ,'t'))
sage: E=EllipticCurve([0,0,0,-t^2,0])
sage: P = E(0)
sage: P.has_infinite_order()
False
sage: P=E(t,0)
sage: P.has_infinite_order()
...
NotImplementedError: Computation of order of a point not implemented over general fields.
sage: (2*P).is_zero()
True
```

is_divisible_by(*m*)

Return True if there exists a point Q defined over the same field as self such that mQ == self.

INPUT:

- m – a positive integer.

OUTPUT:

(bool) – True if there is a solution, else False.

EXAMPLES:

```
sage: E = EllipticCurve('389a')
sage: Q = 5*E(0,0); Q
(-2739/1444 : -77033/54872 : 1)
sage: Q.is_divisible_by(4)
False
sage: Q.is_divisible_by(5)
True
```

is_finite_order()

Return True if this point has finite additive order as an element of the group of points on this curve.

For fields other than number fields and finite fields, this is NotImplemented unless self.is_zero().

EXAMPLES:

```
sage: K.<t>=FractionField(PolynomialRing(QQ,'t'))
sage: E=EllipticCurve([0,0,0,-t^2,0])
sage: P = E(0)
sage: P.has_finite_order()
True
sage: P=E(t,0)
sage: P.has_finite_order()
...
NotImplementedError: Computation of order of a point not implemented over general fields.
sage: (2*P).is_zero()
True
```

order()

Return the order of this point on the elliptic curve.

If the point is zero, returns 1, otherwise raise a NotImplementedError.

For curves over number fields and finite fields, see below.

EXAMPLE:

```
sage: K.<t>=FractionField(PolynomialRing(QQ,'t'))
sage: E=EllipticCurve([0,0,0,-t^2,0])
sage: P=E(t,0)
sage: P.order()
...
```

```
NotImplementedError: Computation of order of a point not implemented over general fields.
sage: E(0).order() == 1
True
```

plot(***args*)

Plot this point on an elliptic curve.

INPUT:

- `**args` – all arguments get passed directly onto the point plotting function.

EXAMPLES:

```
sage: E = EllipticCurve('389a')
sage: P = E([-1,1])
sage: P.plot(pointsize=30, rgbcolor=(1,0,0))
```

scheme()

Return the scheme of this point, i.e., the curve it is on. This is synonymous with curve() which is perhaps more intuitive.

EXAMPLES:

```
sage: E=EllipticCurve(QQ,[1,1])
sage: P=E(0,1)
sage: P.scheme()
Elliptic Curve defined by y^2 = x^3 + x + 1 over Rational Field
sage: P.scheme() == P.curve()
True
sage: K.<a>=NumberField(x^2-3,'a')
sage: P=E.base_extend(K)(1,a)
sage: P.scheme()
Elliptic Curve defined by y^2 = x^3 + x + 1 over Number Field in a with defining polynomial
```

weil_pairing(*Q*, *n*)

Compute the Weil pairing of self and Q using Miller's algorithm.

INPUT:

- Q – a point on self.curve().
- n – an integer n such that $nP = nQ = (0 : 1 : 0)$ where P = self.

OUTPUT:

An n'th root of unity in the base field self.curve().base_field()

EXAMPLES:

```
sage: F.<a>=GF(2^5)
sage: E=EllipticCurve(F,[0,0,1,1,1])
sage: P = E(a^4 + 1, a^3)
sage: Fx.<b>=GF(2^(4*5))
sage: Ex=EllipticCurve(Fx,[0,0,1,1,1])
sage: phi=Hom(F,Fx)(F.gen().minpoly().roots(Fx)[0][0])
sage: Px=Ex(phi(P.xy()[0]),phi(P.xy()[1]))
sage: O = Ex(0)
sage: Qx = Ex(b^19 + b^18 + b^16 + b^12 + b^10 + b^9 + b^8 + b^5 + b^3 + 1, b^18 + b^13 + b^
sage: Px.weil_pairing(Qx,41) == b^19 + b^15 + b^9 + b^8 + b^6 + b^4 + b^3 + b^2 + 1
True
sage: Px.weil_pairing(17*Px,41) == Fx(1)
True
sage: Px.weil_pairing(O,41) == Fx(1)
True
```

An error is raised if either point is not n-torsion:

```
sage: Px.weil_pairing(O,40)
...
ValueError: points must both be n-torsion
```

A larger example (see trac #4964):

```
sage: P,Q = EllipticCurve(GF(19^4,'a'),[-1,0]).gens()
sage: P.order(), Q.order()
(360, 360)
sage: z = P.weil_pairing(Q,360)
sage: z.multiplicative_order()
360
```

An example over a number field:

```
sage: P,Q = EllipticCurve('11a1').change_ring(CyclotomicField(5)).torsion_subgroup().gens()
sage: (P.order(),Q.order())
(5, 5)
sage: P.weil_pairing(Q,5)
zeta5^2
sage: Q.weil_pairing(P,5)
zeta5^3
```

ALGORITHM:

Implemented using Proposition 8 in [Mil04]. The value 1 is returned for linearly dependent input points. This condition is caught via a DivisionByZeroError, since the use of a discrete logarithm test for linear dependence, is much to slow for large n.

REFERENCES:

[Mil04] Victor S. Miller, "The Weil pairing, and its efficient calculation", J. Cryptol., 17(4):235-261, 2004

AUTHOR:

- David Hansen (2009-01-25)

xy()

Return the x and y coordinates of this point, as a 2-tuple. If this is the point at infinity a ZeroDivisionError is raised.

EXAMPLES:

```
sage: E = EllipticCurve('389a')
sage: P = E([-1,1])
sage: P.xy()
(-1, 1)
sage: Q = E(0); Q
(0 : 1 : 0)
sage: Q.xy()
...
ZeroDivisionError: Rational division by zero
```

class EllipticCurvePoint_finite_field(*curve, v, check=True*)

Class for elliptic curve points over finite fields.

discrete_log(*Q, ord=None*)

Returns discrete log of Q with respect to P =self.

INPUT:

- Q (point) – another point on the same curve as self.
- ord (integer or None (default)) – the order of self.

OUTPUT:

(integer) – The discrete log of Q with respect to P, which is an integer m with $0 \leq m < o(P)$ such that $mP = Q$, if one exists. A ValueError is raised if there is no solution.

Note: The order of self is computed if not supplied.

AUTHOR:

•John Cremona. Adapted to use generic functions 2008-04-05.

EXAMPLE:

```
sage: F=GF(3^6,'a')
sage: a=F.gen()
sage: E= EllipticCurve([0,1,1,a,a])
sage: E.cardinality()
762
sage: A,G=E.abelian_group() ## set since this E is cyclic
sage: P=G[0]
sage: Q=400*P
sage: P.discrete_log(Q)
400
```

order()

Return the order of this point on the elliptic curve.

ALGORITHM:

Use generic functions from `sage.groups.generic`. If the group order is known, use `order_from_multiple()`, otherwise use `order_from_bounds()` with the Hasse bounds for the base field. In the latter case, we might find that we have a generator for the group, in which case it is cached.

We do not cause the group order to be calculated when not known, since this function is used in determining the group order via computation of several random points and their orders.

AUTHOR:

•John Cremona, 2008-02-10, adapted 2008-04-05 to use generic functions.

EXAMPLES:

```
sage: k.<a> = GF(5^5)
sage: E = EllipticCurve(k,[2,4]); E
Elliptic Curve defined by y^2 = x^3 + 2*x + 4 over Finite Field in a of size 5^5
sage: P = E(3*a^4 + 3*a , 2*a + 1 )
sage: P.order()
3227
sage: Q = E(0,2)
sage: Q.order()
7
```

In the next example, the cardinality of E will be computed (using SEA) and cached:

```
sage: p=next_prime(2^150)
sage: E=EllipticCurve(GF(p),[1,1])
sage: P=E(831623307675610677632782670796608848711856078, 42295786042873366706573292533588638
sage: P.order()
1427247692705959881058262545272474300628281448
sage: P.order()==E.cardinality()
True
```

class **EllipticCurvePoint_number_field**(*curve, v, check=True*)

A point on an elliptic curve over a number field.

Most of the functionality is derived from the parent class `EllipticCurvePoint_field`. In addition we have support for the order of a point, and heights (currently only implemented over $\mathbf{Q}$).

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: E([0,0])
(0 : 0 : 1)
sage: E(0,0)                # brackets are optional
(0 : 0 : 1)
sage: E([GF(5)(0), 0])      # entries are coerced
(0 : 0 : 1)

sage: E(0.000, 0)
(0 : 0 : 1)

sage: E(1,0,0)
...
TypeError: Coordinates [1, 0, 0] do not define a point on
Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field

sage: E = EllipticCurve([0,0,1,-1,0])
sage: S = E(QQ); S
Abelian group of points on Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field
```

TESTS:

```
sage: loads(S.dumps()) == S
True
sage: P = E(0,0); P
(0 : 0 : 1)
sage: loads(P.dumps()) == P
True
sage: T = 100*P
sage: loads(T.dumps()) == T
True
```

Test pickling an elliptic curve that has known points on it:

```
sage: e = EllipticCurve([0, 0, 1, -1, 0]); g = e.gens(); loads(dumps(e)) == e
True
```

elliptic_logarithm(*embedding=None, precision=100, algorithm='pari'*)

Returns the elliptic logarithm of this elliptic curve point.

An embedding of the base field into $\mathbf{R}$ (with arbitrary precision) may be given; otherwise the first real embedding is used (with the specified precision), if there are any; otherwise a NotImplementedError is raised, since we have not yet implemented the complex elliptic logarithm.

INPUT:

- `embedding`: an embedding of the base field into RR
- `precision`: a positive integer (default 100) setting the number of bits of precision for the computation
- `algorithm`: either 'pari' (default) to use Pari's `ellpointtoz{}`, or 'sage' for a native implementation (currently not very accurate)

ALGORITHM:

See [Co2] Cohen H., A Course in Computational Algebraic Number Theory GTM 138, Springer 1996.

AUTHORS:

- Michael Mardaus (2008-07),
- Tobias Nagel (2008-07) – original version from [Co2].
- John Cremona (2008-07) – revision following eclib code.

EXAMPLES:

```
sage: E = EllipticCurve('389a')
sage: E.discriminant() > 0
True
sage: P = E([-1,1])
sage: P.is_on_identity_component ()
False
sage: P.elliptic_logarithm (precision=96)
0.47934825019021931612953301 01 + 0.985868850775824102211203849...*I
sage: Q=E([3,5])
sage: Q.is_on_identity_component()
True
sage: Q.elliptic_logarithm (precision=96)
1.9311282715425594424885852 20
```

An example with negative discriminant, and a torsion point:

```
sage: E = EllipticCurve('11a1')
sage: E.discriminant() < 0
True
sage: P = E([16,-61])
sage: P.elliptic_logarithm(precision=70)
0.25384186085591068434
sage: E.period_lattice().real_period(prec=70) / P.elliptic_logarithm(precision=70)
5.0000000000000000000
```

A larger example. The default algorithm uses Pari and makes sure the result has the requested precision:

```
sage: E = EllipticCurve([1, 0, 1, -85357462, 303528987048]) #18074g1
sage: P = E([4458713781401/835903744, -64466909836503771/24167649046528, 1])
sage: P.elliptic_logarithm()  # 100 bits
0.27656204014107061464076203097
```

However, the native algorithm 'sage' has trouble with precision in this example:

```
sage: P.elliptic_logarithm(algorithm='sage')  # 100 bits
0.2765620401410710087007...
```

This shows that the bug reported at #4901 has been fixed:

```
sage: E = EllipticCurve("4390c2")
sage: P = E(683762969925/44944,-565388972095220019/9528128)
sage: P.elliptic_logarithm()
0.00025638725886520225353198932529
sage: P.elliptic_logarithm(precision=64)
0.0002563872588652022 54
sage: P.elliptic_logarithm(precision=65)
0.00025638725886520225 35
sage: P.elliptic_logarithm(precision=128)
0.00025638725886520225353198932528666427412
sage: P.elliptic_logarithm(precision=129)
0.00025638725886520225353198932528666427412
sage: P.elliptic_logarithm(precision=256)
0.00025638725886520225353198932528666427411683880083463700150051421280096109363 73
sage: P.elliptic_logarithm(precision=257)
0.00025638725886520225353198932528666427411683880083463700150051421280096109363730
```

has_finite_order()

Return True iff this point has finite order on the elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([0,0,1,-1,0])
sage: P = E([0,0]); P
(0 : 0 : 1)
sage: P.has_finite_order()
False

sage: E = EllipticCurve([0,1])
sage: P = E([-1,0])
sage: P.has_finite_order()
True
```

has_good_reduction(*P=None*)

Returns True iff this point has good reduction modulo a prime.

INPUT:

- P – a prime of the base_field of the point's curve, or None (default)

OUTPUT:

(bool) If a prime P of the base field is specified, returns True iff the point has good reduction at P; otherwise, return true if the point has god reduction at all primes in the support of the discriminant of this model.

EXAMPLES:

```
sage: E = EllipticCurve('990e1')
sage: P = E.gen(0); P
(15 : 51 : 1)
sage: [E.has_good_reduction(p) for p in [2,3,5,7]]
[False, False, False, True]
sage: [P.has_good_reduction(p) for p in [2,3,5,7]]
[True, False, True, True]
sage: [E.tamagawa_exponent(p) for p in [2,3,5,7]]
[2, 2, 1, 1]
sage: [(2*P).has_good_reduction(p) for p in [2,3,5,7]]
[True, True, True, True]
sage: P.has_good_reduction()
False
sage: (2*P).has_good_reduction()
True
sage: (3*P).has_good_reduction()
False

sage: K.<i> = NumberField(x^2+1)
sage: E = EllipticCurve(K,[0,1,0,-160,308])
sage: P = E(26,-120)
sage: E.discriminant().support()
[Fractional ideal (i + 1),
Fractional ideal (-i - 2),
Fractional ideal (2*i + 1),
Fractional ideal (3)]
sage: [E.tamagawa_exponent(p) for p in E.discriminant().support()]
[1, 4, 4, 4]
sage: P.has_good_reduction()
False
sage: (2*P).has_good_reduction()
False
sage: (4*P).has_good_reduction()
True
```

has_infinite_order()

Return True iff this point has infinite order on the elliptic curve.

EXAMPLES:

```
sage: E = EllipticCurve([0,0,1,-1,0])
sage: P = E([0,0]); P
(0 : 0 : 1)
sage: P.has_infinite_order()
True

sage: E = EllipticCurve([0,1])
sage: P = E([-1,0])
sage: P.has_infinite_order()
False
```

height (*precision=None*)

The Neron-Tate canonical height of the point.

Currently only implemented for curves defined over $\mathbf{Q}$ (using pari); and for points of finite order.

INPUT:

- `self` – a point on a curve over $\mathbf{Q}$
- `precision` – (int or None (default)): the precision in bits of the result (default real precision if None)

OUTPUT:

The rational number 0, or a nonzero real field element

EXAMPLES:

```
sage: E = EllipticCurve('11a'); E
Elliptic Curve defined by y^2 + y = x^3 - x^2 - 10*x - 20 over Rational Field
sage: P = E([5,5]); P
(5 : 5 : 1)
sage: P.height()
0
sage: Q = 5*P
sage: Q.height()
0

sage: E = EllipticCurve('37a'); E
Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field
sage: P = E([0,0])
sage: P.height()
0.0511114082399688
sage: P.order()
+Infinity
sage: E.regulator()       # slightly random output
0.051111408239968840

sage: E = EllipticCurve('4602a1'); E
Elliptic Curve defined by y^2 + x*y  = x^3 + x^2 - 37746035*x - 89296920339 over Rational Fi
sage: x = 77985922458974949246858229195945103471590
sage: y = 19575260230015313702261379022151675961965157108920263594545223
sage: d = 2254020761884782243
sage: E([ x / d^2,  y / d^3 ]).height()
86.7406561381275

sage: E = EllipticCurve([17, -60, -120, 0, 0]); E
Elliptic Curve defined by y^2 + 17*x*y - 120*y = x^3 - 60*x^2 over Rational Field
sage: E([30, -90]).height()
0
```

```
sage: E = EllipticCurve('389a1'); E
Elliptic Curve defined by y^2 + y = x^3 + x^2 - 2*x over Rational Field
sage: [P,Q] = [E(-1,1),E(0,-1)]
sage: P.height(precision=100)
0.68666708330558658572355210295
sage: (3*Q).height(precision=100)/Q.height(precision=100)
9.0000000000000000000000000000
sage: _.parent()
Real Field with 100 bits of precision
```

An example to show that the bug at #5252 is fixed:

```
sage: E = EllipticCurve([1, -1, 1, -20637587012466263707737269 78, 32838647793306133075103747
sage: P = E([-30987785091199, 258909576181697016447])
sage: P.height()
25.8603170675462
sage: P.height(precision=100)
25.860317067546190743868840741
sage: P.height(precision=250)
25.860317067546190743868840740735110323098872903844416215577171041783572513
sage: P.height(precision=500)
25.860317067546190743868840740735110323098872903844416215577171041783572512955113057088981 32
```

Unfortunately, canonical height is not yet implemented in general:

```
sage: E = EllipticCurve('5077a1').change_ring(QuadraticField(-3,'a'))
sage: P = E([-2,3,1])
sage: P.height()
...
NotImplementedError: canonical height not yet implemented over general number fields.
```

is_on_identity_component(*embedding=None*)

Returns True iff this point is on the identity component of its curve with respect to a given (real or complex) embedding.

INPUT:

- `self` – a point on a curve over any ordered field (e.g. $\mathbf{Q}$)
- `embedding` – an embedding from the base_field of the point's curve into $\mathbf{R}$ or $\mathbf{C}$; if None (the default) it uses the first embedding of the base_field into $\mathbf{R}$ if any, else the first embedding into $\mathbf{C}$.

OUTPUT:

(bool) – True iff the point is on the identity component of the curve. (If the point is zero then the result is True.)

EXAMPLES:

For $K = \mathbf{Q}$ there is no need to specify an embedding:

```
sage: E=EllipticCurve('5077a1')
sage: [E.lift_x(x).is_on_identity_component() for x in range(-3,5)]
[False, False, False, False, False, True, True, True]
```

An example over a field with two real embeddings:

```
sage: L.<a> = QuadraticField(2)
sage: E=EllipticCurve(L,[0,1,0,a,a])
sage: P=E(-1,0)
sage: [P.is_on_identity_component(e) for e in L.embeddings(RR)]
[False, True]
```

We can check this as follows:

```
sage: [e(E.discriminant())>0 for e in L.embeddings(RR)]
[True, False]
sage: e = L.embeddings(RR)[0]
sage: E1 = EllipticCurve(RR,[e(ai) for ai in E.ainvs()])
sage: e1,e2,e3 = E1.two_division_polynomial().roots(RR,multiplicities=False)
sage: e1 < e2 < e3 and e(P[0]) < e3
True
```

order()

Return the order of this point on the elliptic curve.

If the point has infinite order, returns +Infinity. For curves defined over $\mathbf{Q}$, we call pari; over other number fields we implement the function here.

EXAMPLES:

```
sage: E = EllipticCurve([0,0,1,-1,0])
sage: P = E([0,0]); P
(0 : 0 : 1)
sage: P.order()
+Infinity

sage: E = EllipticCurve([0,1])
sage: P = E([-1,0])
sage: P.order()
2
```

padic_elliptic_logarithm(*p, absprec=20*)

Computes the p-adic elliptic logarithm of this point.

INPUT:

`p` - integer: a prime `absprec` - integer (default: 20): the initial p-adic absolute precision of the computation

OUTPUT:

The p-adic elliptic logarithm of self, with precision `absprec`.

AUTHORS:

- Tobias Nagel
- Michael Mardaus
- John Cremona

ALGORITHM:

For points in the formal group (i.e. not integral at p) we take the `log()` function from the formal groups module and evaluate it at $-x/y$. Otherwise we first multiply the point to get into the formal group, and divide the result afterwards.

TODO:

See comments at trac #4805. Currently the absolute precision of the result may be less than the given value of absprec, and error-handling is imperfect.

EXAMPLES:

```
sage: E = EllipticCurve([0,1,1,-2,0])
sage: E(0).padic_elliptic_logarithm(3)
0
sage: P = E(0,0)
sage: P.padic_elliptic_logarithm(3)
2 + 2*3 + 3^3 + 2*3^7 + 3^8 + 3^9 + 3^11 + 3^15 + 2*3^17 + 3^18 + O(3^19)
sage: P.padic_elliptic_logarithm(3).lift()
660257522
sage: P = E(-11/9,28/27)
```

```
sage: [(2*P).padic_elliptic_logarithm(p)/P.padic_elliptic_logarithm(p) for p in prime_range(
[2 + O(2^19), 2 + O(3^20), 2 + O(5^19), 2 + O(7^19), 2 + O(11^19), 2 + O(13^19), 2 + O(17^19
sage: [(3*P).padic_elliptic_logarithm(p)/P.padic_elliptic_logarithm(p) for p in prime_range(
[1 + 2 + O(2^19), 3 + 3^20 + O(3^21), 3 + O(5^19), 3 + O(7^19), 3 + O(11^19)]
sage: [(5*P).padic_elliptic_logarithm(p)/P.padic_elliptic_logarithm(p) for p in prime_range(
[1 + 2^2 + O(2^19), 2 + 3 + O(3^20), 5 + O(5^19), 5 + O(7^19), 5 + O(11^19)]
```

An example which arose during reviewing #4741:

```
sage: E = EllipticCurve('794a1')
sage: P = E(-1,2)
sage: P.padic_elliptic_logarithm(2) # default precision=20
2^4 + 2^5 + 2^6 + 2^8 + 2^9 + 2^13 + 2^14 + 2^15 + O(2^16)
sage: P.padic_elliptic_logarithm(2, absprec=30)
2^4 + 2^5 + 2^6 + 2^8 + 2^9 + 2^13 + 2^14 + 2^15 + 2^22 + 2^23 + 2^24 + O(2^26)
sage: P.padic_elliptic_logarithm(2, absprec=40)
2^4 + 2^5 + 2^6 + 2^8 + 2^9 + 2^13 + 2^14 + 2^15 + 2^22 + 2^23 + 2^24 + 2^28 + 2^29 + 2^31 +
```

38.12 Torsion subgroups of elliptic curves over number fields (including $\mathbb{Q}$).

AUTHORS:

- Nick Alexander: original implementation over **Q**
- Chris Wuthrich: original implementation over number fields
- **John Cremona: rewrote p-primary part to use division** polynomials, added some features, unified Number Field and **Q** code.

class **EllipticCurveTorsionSubgroup**(*E, algorithm=None*)

The torsion subgroup of an elliptic curve over a number field.

EXAMPLES:

Examples over **Q**:

```
sage: E = EllipticCurve([-4, 0]); E
Elliptic Curve defined by y^2  = x^3 - 4*x over Rational Field
sage: G = E.torsion_subgroup(); G
Torsion Subgroup isomorphic to Multiplicative Abelian Group isomorphic to C2 x C2 associated to
sage: G.order()
4
sage: G.gen(0)
(2 : 0 : 1)
sage: G.gen(1)
(0 : 0 : 1)
sage: G.ngens()
2
```

```
sage: E = EllipticCurve([17, -120, -60, 0, 0]); E
Elliptic Curve defined by y^2 + 17*x*y - 60*y = x^3 - 120*x^2 over Rational Field
sage: G = E.torsion_subgroup(); G
Torsion Subgroup isomorphic to Trivial Abelian Group associated to the Elliptic Curve defined by
sage: G.gens()
()
```

```
sage: e = EllipticCurve([0, 330761566545336520666609946884,0,\
347897536144342179642120321790729023127716119338758604800,\
114112815436927429551902303280680424778815462104985764887003237028585178135281666400000])
sage: e.torsion_order()
16
```

Constructing points from the torsion subgroup (which is an abstract abelian group):

```
sage: E = EllipticCurve('14a1')
sage: T = E.torsion_subgroup()
sage: [E(t) for t in T]
[(0 : 1 : 0),
(9 : 23 : 1),
(2 : 2 : 1),
(1 : -1 : 1),
(2 : -5 : 1),
(9 : -33 : 1)]
```

An example where the torsion subgroup is not cyclic:

```
sage: E = EllipticCurve([0,0,0,-49,0])
sage: T = E.torsion_subgroup()
sage: [E(t) for t in T]
[(0 : 1 : 0), (0 : 0 : 1), (7 : 0 : 1), (-7 : 0 : 1)]
```

An example where the torsion subgroup is trivial:

```
sage: E = EllipticCurve('37a1')
sage: T = E.torsion_subgroup()
sage: T
Torsion Subgroup isomorphic to Trivial Abelian Group associated to the Elliptic Curve defined by
sage: [E(t) for t in T]
[(0 : 1 : 0)]
```

Examples over other Number Fields:

```
sage: E=EllipticCurve('11a1')
sage: K.<i>=NumberField(x^2+1)
sage: EK=E.change_ring(K)
sage: from sage.schemes.elliptic_curves.ell_torsion import EllipticCurveTorsionSubgroup
sage: EllipticCurveTorsionSubgroup(EK)
Torsion Subgroup isomorphic to Multiplicative Abelian Group isomorphic to C5 associated to the E
```

Note: this class is normally constructed indirectly as follows:

```
sage: T = EK.torsion_subgroup(); T
Torsion Subgroup isomorphic to Multiplicative Abelian Group isomorphic to C5 associated to the E
sage: type(T)
<class 'sage.schemes.elliptic_curves.ell_torsion.EllipticCurveTorsionSubgroup'>
```

AUTHORS:

- Nick Alexamder - initial implementation over $\mathbf{Q}$.
- Chris Wuthrich - initial implementation over number fields.
- John Cremona - additional features and unification.

curve()
Return the curve of this torsion subgroup.
EXAMPLES:

```
sage: E=EllipticCurve('11a1')
sage: K.<i>=NumberField(x^2+1)
sage: EK=E.change_ring(K)
sage: T = EK.torsion_subgroup()
sage: T.curve() is EK
True
```

gen(*i=0*)
Return the i'th torsion generator.
EXAMPLES:

```
sage: E=EllipticCurve('11a1')
sage: K.<i>=NumberField(x^2+1)
sage: EK=E.change_ring(K)
sage: T = EK.torsion_subgroup()
sage: T.gen()
(16 : 60 : 1)
```

ngens()
Return the number of torsion generators.
EXAMPLES:

```
sage: E=EllipticCurve('11a1')
sage: K.<i>=NumberField(x^2+1)
sage: EK=E.change_ring(K)
sage: T = EK.torsion_subgroup()
sage: T.ngens()
1
```

points()
Return a list of all the points in this torsion subgroup. The list is cached.
EXAMPLES:

```
sage: K.<i>=NumberField(x^2 + 1)
sage: E = EllipticCurve(K,[0,0,0,1,0])
sage: tor = E.torsion_subgroup()
sage: tor.points()
[(i : 0 : 1), (0 : 0 : 1), (-i : 0 : 1), (0 : 1 : 0)]
```

38.13 Local data for elliptic curves over number fields (including $\mathbb{Q}$) at primes.

AUTHORS:

- John Cremona: First version 2008-09-21 (refactoring code from `ell_number_field.py` and `ell_rational_field.py`)

class EllipticCurveLocalData(*E, P, proof=None, algorithm='pari'*)
The class for the local reduction data of an elliptic curve.

Currently supported are elliptic curves defined over $\mathbf{Q}$, and elliptic curves defined over a number field, at an arbitrary prime or prime ideal.

bad_reduction_type()

Return the type of bad reduction of this reduction data.

OUTPUT:

(int or None):

- +1 for split multiplicative reduction
- -1 for non-split multiplicative reduction
- 0 for additive reduction
- None for good reduction

EXAMPLES:

```
sage: E=EllipticCurve('14a1')
sage: [(p,E.local_data(p).bad_reduction_type()) for p in prime_range(15)]
[(2, -1), (3, None), (5, None), (7, 1), (11, None), (13, None)]

sage: K.<a>=NumberField(x^3-2)
sage: P17a, P17b = [P for P,e in K.factor(17)]
sage: E = EllipticCurve([0,0,0,0,2*a+1])
sage: [(p,E.local_data(p).bad_reduction_type()) for p in [P17a,P17b]]
[(Fractional ideal (4*a^2 - 2*a + 1), None), (Fractional ideal (2*a + 1), 0)]
```

conductor_valuation()

Return the valuation of the conductor from this local reduction data.

EXAMPLES:

```
sage: from sage.schemes.elliptic_curves.ell_local_data import EllipticCurveLocalData
sage: E = EllipticCurve([0,0,0,0,64]); E
Elliptic Curve defined by y^2 = x^3 + 64 over Rational Field
sage: data = EllipticCurveLocalData(E,2)
sage: data.conductor_valuation()
2
```

has_additive_reduction()

Return True if there is additive reduction.

EXAMPLES:

```
sage: E = EllipticCurve('27a1')
sage: [(p,E.local_data(p).has_additive_reduction()) for p in prime_range(15)]
[(2, False), (3, True), (5, False), (7, False), (11, False), (13, False)]

sage: K.<a> = NumberField(x^3-2)
sage: P17a, P17b = [P for P,e in K.factor(17)]
sage: E = EllipticCurve([0,0,0,0,2*a+1])
sage: [(p,E.local_data(p).has_additive_reduction()) for p in [P17a,P17b]]
[(Fractional ideal (4*a^2 - 2*a + 1), False),
(Fractional ideal (2*a + 1), True)]
```

has_bad_reduction()

Return True if there is bad reduction.

EXAMPLES:

```
sage: E = EllipticCurve('14a1')
sage: [(p,E.local_data(p).has_bad_reduction()) for p in prime_range(15)]
[(2, True), (3, False), (5, False), (7, True), (11, False), (13, False)]

sage: K.<a> = NumberField(x^3-2)
sage: P17a, P17b = [P for P,e in K.factor(17)]
sage: E = EllipticCurve([0,0,0,0,2*a+1])
```

```
sage: [(p,E.local_data(p).has_bad_reduction()) for p in [P17a,P17b]]
[(Fractional ideal (4*a^2 - 2*a + 1), False),
(Fractional ideal (2*a + 1), True)]
```

has_good_reduction()

Return True if there is good reduction.

EXAMPLES:

```
sage: E = EllipticCurve('14a1')
sage: [(p,E.local_data(p).has_good_reduction()) for p in prime_range(15)]
[(2, False), (3, True), (5, True), (7, False), (11, True), (13, True)]

sage: K.<a> = NumberField(x^3-2)
sage: P17a, P17b = [P for P,e in K.factor(17)]
sage: E = EllipticCurve([0,0,0,0,2*a+1])
sage: [(p,E.local_data(p).has_good_reduction()) for p in [P17a,P17b]]
[(Fractional ideal (4*a^2 - 2*a + 1), True),
(Fractional ideal (2*a + 1), False)]
```

has_multiplicative_reduction()

Return True if there is multiplicative reduction.

Note: See also `has_split_multiplicative_reduction()` and `has_nonsplit_multiplicative_reduction()`.

EXAMPLES:

```
sage: E = EllipticCurve('14a1')
sage: [(p,E.local_data(p).has_multiplicative_reduction()) for p in prime_range(15)]
[(2, True), (3, False), (5, False), (7, True), (11, False), (13, False)]

sage: K.<a> = NumberField(x^3-2)
sage: P17a, P17b = [P for P,e in K.factor(17)]
sage: E = EllipticCurve([0,0,0,0,2*a+1])
sage: [(p,E.local_data(p).has_multiplicative_reduction()) for p in [P17a,P17b]]
[(Fractional ideal (4*a^2 - 2*a + 1), False), (Fractional ideal (2*a + 1), False)]
```

has_nonsplit_multiplicative_reduction()

Return True if there is non-split multiplicative reduction.

EXAMPLES:

```
sage: E = EllipticCurve('14a1')
sage: [(p,E.local_data(p).has_nonsplit_multiplicative_reduction()) for p in prime_range(15)]
[(2, True), (3, False), (5, False), (7, False), (11, False), (13, False)]

sage: K.<a> = NumberField(x^3-2)
sage: P17a, P17b = [P for P,e in K.factor(17)]
sage: E = EllipticCurve([0,0,0,0,2*a+1])
sage: [(p,E.local_data(p).has_nonsplit_multiplicative_reduction()) for p in [P17a,P17b]]
[(Fractional ideal (4*a^2 - 2*a + 1), False), (Fractional ideal (2*a + 1), False)]
```

has_split_multiplicative_reduction()

Return True if there is split multiplicative reduction.

EXAMPLES:

```
sage: E = EllipticCurve('14a1')
sage: [(p,E.local_data(p).has_split_multiplicative_reduction()) for p in prime_range(15)]
[(2, False), (3, False), (5, False), (7, True), (11, False), (13, False)]
```

```
sage: K.<a> = NumberField(x^3-2)
sage: P17a, P17b = [P for P,e in K.factor(17)]
sage: E = EllipticCurve([0,0,0,0,2*a+1])
sage: [(p,E.local_data(p).has_split_multiplicative_reduction()) for p in [P17a,P17b]]
[(Fractional ideal (4*a^2 - 2*a + 1), False),
(Fractional ideal (2*a + 1), False)]
```

kodaira_symbol()

Return the Kodaira symbol from this local reduction data.

EXAMPLES:

```
sage: from sage.schemes.elliptic_curves.ell_local_data import EllipticCurveLocalData
sage: E = EllipticCurve([0,0,0,0,64]); E
Elliptic Curve defined by y^2 = x^3 + 64 over Rational Field
sage: data = EllipticCurveLocalData(E,2)
sage: data.kodaira_symbol()
IV
```

minimal_model()

Return the (local) minimal model from this local reduction data.

EXAMPLES:

```
sage: from sage.schemes.elliptic_curves.ell_local_data import EllipticCurveLocalData
sage: E = EllipticCurve([0,0,0,0,64]); E
Elliptic Curve defined by y^2  = x^3 + 64 over Rational Field
sage: data = EllipticCurveLocalData(E,2)
sage: data.minimal_model()
Elliptic Curve defined by y^2 = x^3 + 1 over Rational Field
sage: data.minimal_model() == E.local_minimal_model(2)
True
```

prime()

Return the prime ideal associated with this local reduction data.

EXAMPLES:

```
sage: from sage.schemes.elliptic_curves.ell_local_data import EllipticCurveLocalData
sage: E = EllipticCurve([0,0,0,0,64]); E
Elliptic Curve defined by y^2 = x^3 + 64 over Rational Field
sage: data = EllipticCurveLocalData(E,2)
sage: data.prime()
Principal ideal (2) of Integer Ring
```

tamagawa_exponent()

Return the Tamagawa index from this local reduction data.

This is the exponent of $E(K_v)/E^0(K_v)$; in most cases it is the same as the Tamagawa index.

EXAMPLES:

```
sage: from sage.schemes.elliptic_curves.ell_local_data import EllipticCurveLocalData
sage: E = EllipticCurve('816a1')
sage: data = EllipticCurveLocalData(E,2)
sage: data.kodaira_symbol()
I2*
sage: data.tamagawa_number()
4
sage: data.tamagawa_exponent()
2

sage: E = EllipticCurve('200c4')
```

```
sage: data = EllipticCurveLocalData(E,5)
sage: data.kodaira_symbol()
I4*
sage: data.tamagawa_number()
4
sage: data.tamagawa_exponent()
2
```

tamagawa_number()

Return the Tamagawa number from this local reduction data.

This is the index $[E(K_v) : E^0(K_v)]$.

EXAMPLES:

```
sage: from sage.schemes.elliptic_curves.ell_local_data import EllipticCurveLocalData
sage: E = EllipticCurve([0,0,0,0,64]); E
Elliptic Curve defined by y^2 = x^3 + 64 over Rational Field
sage: data = EllipticCurveLocalData(E,2)
sage: data.tamagawa_number()
3
```

check_prime(*K*, *P*)

Function to check that P determines a prime of K, and return that ideal.

INPUT:

- K – a number field (including $\mathbf{Q}$).
- P – an element of K or a (fractional) ideal of K.

OUTPUT:

- If K is $\mathbf{Q}$: the prime integer equal to or which generates P.
- If K is not $\mathbf{Q}$‘: the prime ideal equal to or generated by P.

Note: If P is not a prime and does not generate a prime, a TypeError is raised.

EXAMPLES:

```
sage: from sage.schemes.elliptic_curves.ell_local_data import check_prime
sage: check_prime(QQ,3)
3
sage: check_prime(QQ,ZZ.ideal(31))
31
sage: K.<a>=NumberField(x^2-5)
sage: check_prime(K,a)
Fractional ideal (a)
sage: check_prime(K,a+1)
Fractional ideal (a + 1)
sage: [check_prime(K,P) for P in K.primes_above(31)]
[Fractional ideal (-5/2*a - 1/2), Fractional ideal (-5/2*a + 1/2)]
```

38.14 Kodaira symbols.

Kodaira symbols encode the type of reduction of an elliptic curve at a (finite) place.

The standard notation for Kodaira Symbols is as a string which is one of I_m, II, III, IV, I_m^*, II*, III*, IV*, where m denotes a non-negative integer. These have been encoded by single integers by different people. For convenience we give here the conversion table between strings, the eclib coding and the pari encoding.

Kodaira Symbol	Eclib coding	Pari Coding
I_0	0	1
I_0^*	1	-1
I_m $(m > 0)$	$10m$	$m + 4$
I_m^* $(m > 0)$	$10m + 1$	$-(m + 4)$
II	2	2
III	3	3
IV	4	4
II^*	7	-2
III^*	6	-3
IV^*	5	-4

AUTHORS:

- David Roe <roed@math.harvard.edu>
- John Cremona

KodairaSymbol(*symbol*)

Returns the specified Kodaira symbol.

INPUT:

- `symbol` (string or integer) – Either a string of the form "I0", "I1", ..., "In", "II", "III", "IV", "I0*", "I1*", ..., "In*", "II*", "III*", or "IV*", or an integer encoding a Kodaira symbol using Pari's conventions.

OUTPUT:

(KodairaSymbol) The corresponding Kodaira symbol.

EXAMPLES:

```
sage: KS = KodairaSymbol
sage: [KS(n) for n in range(1,10)]
[I0, II, III, IV, I1, I2, I3, I4, I5]
sage: [KS(-n) for n in range(1,10)]
[I0*, II*, III*, IV*, I1*, I2*, I3*, I4*, I5*]
sage: all([KS(str(KS(n)))==KS(n) for n in range(-10,10) if n!=0])
True
```

class **KodairaSymbol_class**(*symbol*)

Class to hold a Kodaira symbol of an elliptic curve over a p-adic local field.

Users should use the `KodairaSymbol()` function to construct Kodaira Symbols rather than use the class constructor directly.

38.15 Isomorphisms between Weierstrass models of elliptic curves

AUTHORS:

- Robert Bradshaw (2007): initial version
- John Cremona (Jan 2008): isomorphisms, automorphisms and twists in all characteristics

class **WeierstrassIsomorphism**(*E=None, urst=None, F=None*)

Class representing a Weierstrass isomorphism between two elliptic curves.

class baseWI (*u=1, r=0, s=0, t=0*)

This class implements the basic arithmetic of isomorphisms between Weierstrass models of elliptic curves. These are specified by lists of the form $[u, r, s, t]$ (with $u \neq 0$) which specifies a transformation $(x, y) \mapsto (x', y')$ where

$$(x, y) = (u^2x' + r, u^3y' + su^2x' + t).$$

INPUT:

- `u, r, s, t` (default (1,0,0,0)) – standard parameters of an isomorphism between Weierstrass models.

EXAMPLES:

```
sage: from sage.schemes.elliptic_curves.weierstrass_morphism import *
sage: baseWI()
(1, 0, 0, 0)
sage: baseWI(2,3,4,5)
(2, 3, 4, 5)
sage: R.<u,r,s,t>=QQ[]; baseWI(u,r,s,t)
(u, r, s, t)
```

is_identity()

Returns True if this is the identity isomorphism.

EXAMPLES:

```
sage: from sage.schemes.elliptic_curves.weierstrass_morphism import *
sage: w=baseWI(); w.is_identity()
True
sage: w=baseWI(2,3,4,5); w.is_identity()
False
```

tuple()

Returns the parameters u, r, s, t as a tuple.

EXAMPLES:

```
sage: from sage.schemes.elliptic_curves.weierstrass_morphism import *
sage: u,r,s,t=baseWI(2,3,4,5).tuple()
sage: w=baseWI(2,3,4,5)
sage: u,r,s,t=w.tuple()
sage: u
2
```

isomorphisms (*E, F, JustOne=False*)

Returns one or all isomorphisms between two elliptic curves.

INPUT:

- `E, F` (EllipticCurve) – Two elliptic curves.
- `JustOne` (bool) If True, returns one isomorphism, or None if the curves are not isomorphic. If False, returns a (possibly empty) list of isomorphisms.

OUTPUT:

Either None, or a 4-tuple (u, r, s, t) representing an isomorphism, or a list of these.

Note: This function is not intended for users, who should use the interface provided by `ell_generic`.

EXAMPLES:

```
sage: from sage.schemes.elliptic_curves.weierstrass_morphism import *
sage: isomorphisms(EllipticCurve_from_j(0),EllipticCurve('27a3'))
[(-1, 0, 0, -1), (1, 0, 0, 0)]
sage: isomorphisms(EllipticCurve_from_j(0),EllipticCurve('27a3'),JustOne=True)
(1, 0, 0, 0)
sage: isomorphisms(EllipticCurve_from_j(0),EllipticCurve('27a1'))
[]
sage: isomorphisms(EllipticCurve_from_j(0),EllipticCurve('27a1'),JustOne=True)
```

38.16 Period lattices of elliptic curves and related functions.

Let E be an elliptic curve defined over a number field K (including $\mathbf{Q}$). We attach a period lattice (a discrete rank 2 subgroup of $\mathbf{C}$) to each embedding of K into $\mathbf{C}$.

In the case of real embeddings, the lattice is stable under complex conjugation and is called a real lattice. These have two types: rectangular, (the real curve has two connected components and positive discriminant) or non-rectangular (one connected component, negative discriminant).

The periods are computed to arbitrary precision using the AGM (Gauss's Arithmetic-Geometric Mean).

EXAMPLES:

```
sage: K.<a> = NumberField(x^3-2)
sage: E = EllipticCurve([0,1,0,a,a])
```

First we try a real embedding:

```
sage: emb = K.embeddings(RealField())[0]
sage: L = E.period_lattice(emb); L
Period lattice associated to Elliptic Curve defined by y^2 = x^3 + x^2 + a*x + a over Number Field in
From: Number Field in a with defining polynomial x^3 - 2
To:   Algebraic Real Field
Defn: a |--> 1.259921049894873?
```

The first basis period is real:

```
sage: L.basis()
(3.81452977217855, 1.90726488608927 + 1.34047785962440*I)
sage: L.is_real()
True
```

For a basis ω_1, ω_2 normalised so that ω_1/ω_2 is in the fundamental region of the upper half-plane, use the function `normalised_basis()` instead:

```
sage: L.normalised_basis()
(1.90726488608927 - 1.34047785962440*I, -1.90726488608927 - 1.34047785962440*I)
```

Next a complex embedding:

```
sage: emb = K.embeddings(ComplexField())[0]
sage: L = E.period_lattice(emb); L
Period lattice associated to Elliptic Curve defined by y^2 = x^3 + x^2 + a*x + a over Number Field in
From: Number Field in a with defining polynomial x^3 - 2
```

```
To:   Algebraic Field
Defn: a |--> -0.6299605249474365? - 1.091123635971722?*I
```

In this case, the basis ω_1, ω_2 is always normalised so that $\tau = \omega_1/\omega_2$ is in the fundamental region in the upper half plane:

```
sage: w1,w2 = L.basis(); w1,w2
(-1.37588604166076 - 2.58560946624443*I, -2.10339907847356 + 0.428378776460622*I)
sage: L.is_real()
False
sage: tau = w1/w2; tau
0.387694505032876 + 1.30821088214407*I
sage: L.normalised_basis()
(-1.37588604166076 - 2.58560946624443*I, -2.10339907847356 + 0.428378776460622*I)
```

AUTHORS:

- ?: initial version.
- John Cremona:
  - Adapted to handle real embeddings of number fields, September 2008.
  - Added basis_matrix function, November 2008
  - Added support for complex embeddings, May 2009.

class **PeriodLattice**(*base_ring, rank, degree, sparse=False*)

The class for the period lattice of an algebraic variety.

class **PeriodLattice_ell**(*E, embedding=None*)

The class for the period lattice of an elliptic curve.

Currently supported are elliptic curves defined over $\mathbf{Q}$, and elliptic curves defined over a number field with a real or complex embedding, where the lattice constructed depends on that embedding.

basis(*prec=None, algorithm='sage'*)

Return a basis for this period lattice as a 2-tuple.

INPUT:

- `prec` (default: `None`) – precision in bits (default precision if `None`).
- `algorithm` (string, default 'sage') – choice of implementation (for real ambeddings only) between 'sage' (native Sage implementation) or 'pari' (use the pari library: only available for real embeddings).

OUTPUT:

(tuple of Complex) (ω_1, ω_2) where the lattice is $\mathbf{Z}\omega_1 + \mathbf{Z}\omega_2$. If the lattice is real then ω_1 is real and positive, $\Im(\omega_2) > 0$ and $\Re(\omega_1/\omega_2)$ is either 0 (for rectangular lattices) or $\frac{1}{2}$ (for non-rectangular lattices). Otherwise, ω_1/ω_2 is in the fundamental region of the upper half-plane. If the latter normalisation is required for real lattices, use the function `normalised_basis()` instead.

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: E.period_lattice().basis()
(2.99345864623196, 2.45138938198679*I)
```

This shows that the issue reported at trac #3954 is fixed:

```
sage: E = EllipticCurve('37a')
sage: b1 = E.period_lattice().basis(prec=30)
sage: b2 = E.period_lattice().basis(prec=30)
```

```
sage: b1 == b2
True
```

This shows that the issue reported at trac #4064 is fixed:

```
sage: E = EllipticCurve('37a')
sage: E.period_lattice().basis(prec=30)[0].parent()
Real Field with 30 bits of precision
sage: E.period_lattice().basis(prec=100)[0].parent()
Real Field with 100 bits of precision

sage: K.<a> = NumberField(x^3-2)
sage: emb = K.embeddings(RealField())[0]
sage: E = EllipticCurve([0,1,0,a,a])
sage: L = E.period_lattice(emb)
sage: L.basis(64)
(3.81452977217854509, 1.90726488608927254 + 1.34047785962440202*I)

sage: emb = K.embeddings(ComplexField())[0]
sage: L = E.period_lattice(emb)
sage: w1,w2 = L.basis(); w1,w2
(-1.37588604166076 - 2.58560946624443*I, -2.10339907847356 + 0.428378776460622*I)
sage: L.is_real()
False
sage: tau = w1/w2; tau
0.387694505032876 + 1.30821088214407*I
```

basis_matrix(*prec=None, normalised=False*)

Return the basis matrix of this period lattice.

INPUT:

- prec (int or None''(default)) - real precision in bits (default real precision if ''None).
- normalised (bool, default None) – if True and the embedding is real, use the normalised basis (see normalised_basis()) instead of the default.

OUTPUT:

A 2x2 real matrix whose rows are the lattice basis vectors, after identifying $\mathbf{C}$ with $\mathbf{R}^2$.

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: E.period_lattice().basis_matrix()
[ 2.99345864623196 0.000000000000000]
[0.000000000000000  2.45138938198679]

sage: K.<a> = NumberField(x^3-2)
sage: emb = K.embeddings(RealField())[0]
sage: E = EllipticCurve([0,1,0,a,a])
sage: L = E.period_lattice(emb)
sage: L.basis_matrix(64)
[ 3.81452977217854509 0.000000000000000000]
[ 1.90726488608927254  1.34047785962440202]
```

See #4388:

```
sage: L = EllipticCurve('11a1').period_lattice()
sage: L.basis_matrix()
[ 1.26920930427955 0.000000000000000]
[0.634604652139775  1.45881661693850]
sage: L.basis_matrix(normalised=True)
```

```
[0.634604652139775 -1.45881661693850]
[-1.26920930427955 0.000000000000000]

sage: L = EllipticCurve('389a1').period_lattice()
sage: L.basis_matrix()
[ 2.49021256085505 0.000000000000000]
[0.000000000000000  1.97173770155165]
sage: L.basis_matrix(normalised=True)
[ 2.49021256085505 0.000000000000000]
[0.000000000000000 -1.97173770155165]
```

complex_area(*prec=None*)

Return the area of a fundamental domain for the period lattice of the elliptic curve.

INPUT:

- prec (int or None''(default)) - real precision in bits (default real precision if ''None).

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: E.period_lattice().complex_area()
7.33813274078958

sage: K.<a> = NumberField(x^3-2)
sage: embs = K.embeddings(ComplexField())
sage: E = EllipticCurve([0,1,0,a,a])
sage: [E.period_lattice(emb).is_real() for emb in K.embeddings(CC)]
[False, False, True]
sage: [E.period_lattice(emb).complex_area() for emb in embs]
[6.02796894766694, 6.02796894766694, 5.11329270448346]
```

is_real()

Return True if this period lattice is real.

EXAMPLES:

```
sage: f = EllipticCurve('11a')
sage: f.period_lattice().is_real()
True

sage: K.<i> = QuadraticField(-1)
sage: E = EllipticCurve(K,[0,0,0,i,2*i])
sage: emb = K.embeddings(ComplexField())[0]
sage: L = E.period_lattice(emb)
sage: L.is_real()
False

sage: K.<a> = NumberField(x^3-2)
sage: E = EllipticCurve([0,1,0,a,a])
sage: [E.period_lattice(emb).is_real() for emb in K.embeddings(CC)]
[False, False, True]
```

ALGORITHM:

The lattice is real if it is associated to a real embedding; such lattices are stable under conjugation.

is_rectangular()

Return True if this period lattice is rectangular.

Note: Only defined for real lattices; a RuntimeError is raised for non-real lattices.

EXAMPLES:

```
sage: f = EllipticCurve('11a')
sage: f.period_lattice().basis()
(1.26920930427955, 0.634604652139775 + 1.45881661693850*I)
sage: f.period_lattice().is_rectangular()
False

sage: f = EllipticCurve('37b')
sage: f.period_lattice().basis()
(1.08852159290423, 1.76761067023379*I)
sage: f.period_lattice().is_rectangular()
True
```

ALGORITHM:

The period lattice is rectangular precisely if the discriminant of the Weierstrass equation is positive, or equivalently if the number of real components is 2.

normalised_basis (*prec=None, algorithm='sage'*)

Return a normalised basis for this period lattice as a 2-tuple.

INPUT:

- `prec` (default: `None`) – precision in bits (default precision if `None`).
- `algorithm` (string, default 'sage') – choice of implementation (for real ambeddings only) between 'sage' (native Sage implementation) or 'pari' (use the pari library: only available for real embeddings).

OUTPUT:

(tuple of Complex) (ω_1, ω_2) where the lattice has the form $\mathbf{Z}\omega_1 + \mathbf{Z}\omega_2$. The basis is normalised so that ω_1/ω_2 is in the fundamental region of the upper half-plane. For an alternative normalisation for real lattices (with the first period real), use the function basis() instead.

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: E.period_lattice().normalised_basis()
(2.99345864623196, -2.45138938198679*I)

sage: K.<a> = NumberField(x^3-2)
sage: emb = K.embeddings(RealField())[0]
sage: E = EllipticCurve([0,1,0,a,a])
sage: L = E.period_lattice(emb)
sage: L.normalised_basis(64)
(1.90726488608927254 - 1.34047785962440202*I, -1.90726488608927254 - 1.34047785962440202*I)

sage: emb = K.embeddings(ComplexField())[0]
sage: L = E.period_lattice(emb)
sage: w1,w2 = L.normalised_basis(); w1,w2
(-1.37588604166076 - 2.58560946624443*I, -2.10339907847356 + 0.428378776460622*I)
sage: L.is_real()
False
sage: tau = w1/w2; tau
0.387694505032876 + 1.30821088214407*I
```

omega (*prec=None*)

Returns the real or complex volume of this period lattice.

INPUT:

- `prec` (int or `None``(default)) - real precision in bits (default real precision if ``None`)

OUTPUT:

(real) For real lattices, this is the real period times the number of connected components. For non-real lattices it is the complex area.

Note: If the curve is defined over **Q** and is given by a *minimal* Weierstrass equation, then this is the correct period in the BSD conjecture, i.e., it is the least real period * 2 when the period lattice is rectangular. More generally the product of this quantity over all embeddings appears in the generalised BSD formula.

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: E.period_lattice().omega()
5.98691729246392
```

This is not a minimal model:

```
sage: E = EllipticCurve([0,-432*6^2])
sage: E.period_lattice().omega()
0.486109385710056
```

If you were to plug the above omega into the BSD conjecture, you would get nonsense. The following works though:

```
sage: F = E.minimal_model()
sage: F.period_lattice().omega()
0.972218771420113

sage: K.<a> = NumberField(x^3-2)
sage: emb = K.embeddings(RealField())[0]
sage: E = EllipticCurve([0,1,0,a,a])
sage: L = E.period_lattice(emb)
sage: L.omega(64)
3.81452977217854509
```

A complex example (taken from J.E.Cremona and E.Whitley, *Periods of cusp forms and elliptic curves over imaginary quadratic fields*, Mathematics of Computation 62 No. 205 (1994), 407-429):

```
sage: K.<i> = QuadraticField(-1)
sage: E = EllipticCurve([0,1-i,i,-i,0])
sage: L = E.period_lattice(K.embeddings(CC)[0])
sage: L.omega()
8.80694160502647
```

real_period(*prec=None*)

Returns the real period of this period lattice.

INPUT:

- `prec` (int or `None` (default)) – real precision in bits (default real precision if `None`)

Note: Only defined for real lattices; a RuntimeError is raised for non-real lattices.

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: E.period_lattice().real_period()
2.99345864623196

sage: K.<a> = NumberField(x^3-2)
sage: emb = K.embeddings(RealField())[0]
sage: E = EllipticCurve([0,1,0,a,a])
sage: L = E.period_lattice(emb)
sage: L.real_period(64)
3.81452977217854509
```

sigma(*z, prec=None, flag=0*)

Returns the value of the Weierstrass sigma function for this elliptic curve period lattice.

INPUT:

- `z` – a complex number

- **prec (default: None) – real precision in bits** (default real precision if None).
- flag –
  0: (default) ???;
  1: computes an arbitrary determination of log(sigma(z))
  2, 3: same using the product expansion instead of theta series. ???

Note: The reason for the ???'s above, is that the PARI documentation for ellsigma is very vague. Also this is only implemented for curves defined over $\mathbf{Q}$.

TODO:

This function does not use any of the PeriodLattice functions and so should be moved to ell_rational_field.

EXAMPLES:

```
sage: EllipticCurve('389a1').period_lattice().sigma(CC(2,1))
2.60912163570108 - 0.200865080824587*I
```

normalise_periods(*w1, w2*)

Normalise the period basis (w_1, w_2) so that w_1/w_2 is in the fundamental region.

INPUT:

- w1, w2 (complex) – two complex numbers with non-real ratio

OUTPUT:

(tuple) $((\omega_1', \omega_2'), [a, b, c, d])$ where a, b, c, d are integers such that

- $ad - bc = \pm 1$;
- $(\omega_1', \omega_2') = (a\omega_1 + b\omega_2, c\omega_1 + d\omega_2)$;
- $\tau = \omega_1'/\omega_2'$ is in the upper half plane;
- $|\tau| \geq 1$ and $|\Re(\tau)| \leq \frac{1}{2}$.

EXAMPLES:

```
sage: from sage.schemes.elliptic_curves.period_lattice import reduce_tau, normalise_periods
sage: w1 = CC(1.234, 3.456)
sage: w2 = CC(1.234, 3.456000001)
sage: w1/w2    # in lower half plane!
0.999999999743367 - 9.16334785827644e-11*I
sage: w1w2, abcd = normalise_periods(w1,w2)
sage: a,b,c,d = abcd
sage: w1w2 == (a*w1+b*w2, c*w1+d*w2)
True
sage: w1w2[0]/w1w2[1]
1.23400010389203e9*I
sage: a*d-b*c # note change of orientation
-1
```

reduce_tau(*tau*)

Transform a point in the upper half plane to the fundamental region.

INPUT:

- tau (complex) – a complex number with positive imaginary part

OUTPUT:

(tuple) $(\tau', [a, b, c, d])$ where a, b, c, d are integers such that

- $ad - bc = 1$;
- $\tau' = (a\tau + b)/(c\tau + d)$;

- $|\tau'| \geq 1$;
- $|\Re(\tau')| \leq \frac{1}{2}$.

EXAMPLES:

```
sage: from sage.schemes.elliptic_curves.period_lattice import reduce_tau
sage: reduce_tau(CC(1.23,3.45))
(0.230000000000000 + 3.45000000000000*I, [1, -1, 0, 1])
sage: reduce_tau(CC(1.23,0.0345))
(-0.463960069171512 + 1.35591888067914*I, [-5, 6, 4, -5])
sage: reduce_tau(CC(1.23,0.0000345))
(0.130000000001761 + 2.89855072463768*I, [13, -16, 100, -123])
```

38.17 Formal groups of elliptic curves.

AUTHORS:

- William Stein: original implementations
- David Harvey: improved asymptotics of some methods
- Nick Alexander: separation from ell_generic.py, bugfixes and docstrings

class **EllipticCurveFormalGroup**(*E*)

The formal group associated to an elliptic curve.

curve()

The elliptic curve this formal group is associated to.

EXAMPLES:

```
sage: E = EllipticCurve("37a")
sage: F = E.formal_group()
sage: F.curve()
Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field
```

differential(*prec=20*)

Returns the power series $f(t) = 1 + \cdots$ such that $f(t)dt$ is the usual invariant differential $dx/(2y + a_1x + a_3)$.

INPUT:

- `prec` - nonnegative integer (default 20), answer will be returned $O(t^{\text{prec}})$

OUTPUT: a power series with given precision

DETAILS: Return the formal series

$$f(t) = 1 + a_1 t + ({a_1}^2 + a_2)t^2 + \cdots$$

to precision $O(t^{prec})$ of page 113 of [Silverman AEC1].

The result is cached, and a cached version is returned if possible.

Warning: The resulting series will have precision prec, but its parent PowerSeriesRing will have default precision 20 (or whatever the default default is).

EXAMPLES:

```
sage: EllipticCurve([-1, 1/4]).formal_group().differential(15)
 1 - 2*t^4 + 3/4*t^6 + 6*t^8 - 5*t^10 - 305/16*t^12 + 105/4*t^14 + O(t^15)
sage: EllipticCurve(Integers(53), [-1, 1/4]).formal_group().differential(15)
 1 + 51*t^4 + 14*t^6 + 6*t^8 + 48*t^10 + 24*t^12 + 13*t^14 + O(t^15)
```

AUTHOR:

•David Harvey (2006-09-10): factored out of log

group_law (*prec=10*)

The formal group law.

INPUT:

•`prec` - integer (default 10)

OUTPUT: a power series with given precision in ZZ[[ZZ[['t1']],'t2']]

DETAILS: Return the formal power series

$$F(t_1, t_2) = t_1 + t_2 - a_1 t_1 t_2 - \cdots$$

to precision $O(t^{prec})$ of page 115 of [Silverman AEC1].

The result is cached, and a cached version is returned if possible.

Warning: The resulting power series will have precision prec, but its parent PowerSeriesRing will have default precision 20 (or whatever the default default is).

AUTHORS:

•Nick Alexander: minor fixes, docstring

EXAMPLES:

```
sage: e = EllipticCurve([1, 2])
sage: F = e.formal_group().group_law(5); F
 t1 + O(t1^5) + (1 - 2*t1^4 + O(t1^5))*t2 + (-4*t1^3 + O(t1^5))*t2^2 + (-4*t1^2 - 30*t1^4 +
sage: i = e.formal_group().inverse(5)
sage: Fx = F.base_extend(F.base_ring().base_extend(i.parent()))
sage: Fx (i.parent().gen()) (i)
 O(t^5)
```

Let's ensure caching with changed precision is working:

```
sage: e.formal_group().group_law(4)
 t1 + O(t1^4) + (1 + O(t1^4))*t2 + (-4*t1^3 + O(t1^4))*t2^2 + (-4*t1^2 + O(t1^4))*t2^3 + O(t
```

inverse (*prec=20*)

The formal group inverse law i(t), which satisfies F(t, i(t)) = 0.

INPUT:

•`prec` - integer (default 20)

OUTPUT: a power series with given precision

DETAILS: Return the formal power series

$$i(t) = -t + a_1 t^2 + \cdots$$

to precision $O(t^{prec})$ of page 114 of [Silverman AEC1].

The result is cached, and a cached version is returned if possible.

Warning: The resulting power series will have precision prec, but its parent PowerSeriesRing will have default precision 20 (or whatever the default default is).

EXAMPLES:

```
sage: e = EllipticCurve([1, 2])
sage: F = e.formal_group().group_law(5)
sage: i = e.formal_group().inverse(5)
sage: Fx = F.base_extend(F.base_ring().base_extend(i.parent()))
sage: Fx (i) (i.parent().gen())
O(t^5)
```

log (*prec=20*)

Returns the power series $f(t) = t + \cdots$ which is an isomorphism to the additive formal group.

Generally this only makes sense in characteristic zero, although the terms before t^p may work in characteristic p.

INPUT:

- `prec` - nonnegative integer (default 20)

OUTPUT: a power series with given precision

EXAMPLES:

```
sage: EllipticCurve([-1, 1/4]).formal_group().log(15)
 t - 2/5*t^5 + 3/28*t^7 + 2/3*t^9 - 5/11*t^11 - 305/208*t^13 + O(t^15)
```

AUTHORS:

- David Harvey (2006-09-10): rewrote to use differential

mult_by_n (*n, prec=10*)

The formal 'multiplication by n' endomorphism $[n]$.

INPUT:

- `prec` - integer (default 10)

OUTPUT: a power series with given precision

DETAILS: Return the formal power series

$$[n](t) = nt + \cdots$$

to precision $O(t^{prec})$ of Proposition 2.3 of [Silverman AEC1].

Warning: The resulting power series will have precision prec, but its parent PowerSeriesRing will have default precision 20 (or whatever the default default is).

AUTHORS:

- Nick Alexander: minor fixes, docstring
- David Harvey (2007-03): faster algorithm for char 0 field case

EXAMPLES:

```
sage: e = EllipticCurve([1, 2, 3, 4, 6])
sage: e.formal_group().mult_by_n(0, 5)
 O(t^5)
sage: e.formal_group().mult_by_n(1, 5)
 t + O(t^5)
```

We verify an identity of low degree:

```
sage: none = e.formal_group().mult_by_n(-1, 5)
sage: two = e.formal_group().mult_by_n(2, 5)
sage: ntwo = e.formal_group().mult_by_n(-2, 5)
sage: ntwo - none(two)
 O(t^5)
sage: ntwo - two(none)
 O(t^5)
```

It's quite fast:

```
sage: E = EllipticCurve("37a"); F = E.formal_group()
sage: F.mult_by_n(100, 20)
100*t - 49999950*t^4 + 3999999960*t^5 + 14285614285800*t^7 - 2999989920000150*t^8 + 13333332
```

sigma (*prec=10*)

EXAMPLE:

```
sage: E = EllipticCurve('14a')
sage: F = E.formal_group()
sage: F.sigma(5)
t + 1/2*t^2 + (1/2*c + 1/3)*t^3 + (3/4*c + 3/4)*t^4 + O(t^5)
```

w (*prec=20*)

The formal group power series w.

INPUT:

•`prec` - integer (default 20)

OUTPUT: a power series with given precision

DETAILS: Return the formal power series

$$w(t) = t^3 + a_1 t^4 + (a_2 + a_1^2)t^5 + \cdots$$

to precision $O(t^{prec})$ of Proposition IV.1.1 of [Silverman AEC1]. This is the formal expansion of $w = -1/y$ about the formal parameter $t = -x/y$ at
$infty$.

The result is cached, and a cached version is returned if possible.

Warning: The resulting power series will have precision prec, but its parent PowerSeriesRing will have default precision 20 (or whatever the default default is).

ALGORITHM: Uses Newton's method to solve the elliptic curve equation at the origin. Complexity is roughly $O(M(n))$ where n is the precision and $M(n)$ is the time required to multiply polynomials of length n over the coefficient ring of E.

AUTHOR:

•David Harvey (2006-09-09): modified to use Newton's method instead of a recurrence formula.

EXAMPLES:

```
sage: e = EllipticCurve([0, 0, 1, -1, 0])
sage: e.formal_group().w(10)
 t^3 + t^6 - t^7 + 2*t^9 + O(t^10)
```

Check that caching works:

```
sage: e = EllipticCurve([3, 2, -4, -2, 5])
sage: e.formal_group().w(20)
 t^3 + 3*t^4 + 11*t^5 + 35*t^6 + 101*t^7 + 237*t^8 + 312*t^9 - 949*t^10 - 10389*t^11 - 57087
sage: e.formal_group().w(7)
 t^3 + 3*t^4 + 11*t^5 + 35*t^6 + O(t^7)
sage: e.formal_group().w(35)
 t^3 + 3*t^4 + 11*t^5 + 35*t^6 + 101*t^7 + 237*t^8 + 312*t^9 - 949*t^10 - 10389*t^11 - 57087
```

x (*prec=20*)

Return the formal series $x(t) = t/w(t)$ in terms of the local parameter $t = -x/y$ at infinity.

INPUT:

•`prec` - integer (default 20)

OUTPUT: a Laurent series with given precision
DETAILS: Return the formal series

$$x(t) = t^{-2} - a_1 t^{-1} - a_2 - a_3 t - \cdots$$

to precision $O(t^{prec})$ of page 113 of [Silverman AEC1].

Warning: The resulting series will have precision prec, but its parent PowerSeriesRing will have default precision 20 (or whatever the default default is).

EXAMPLES:

```
sage: EllipticCurve([0, 0, 1, -1, 0]).formal_group().x(10)
 t^-2 - t + t^2 - t^4 + 2*t^5 - t^6 - 2*t^7 + 6*t^8 - 6*t^9 + O(t^10)
```

y (*prec=20*)
Return the formal series $y(t) = -1/w(t)$ in terms of the local parameter $t = -x/y$ at infinity.
INPUT:

•`prec` - integer (default 20)

OUTPUT: a Laurent series with given precision
DETAILS: Return the formal series

$$y(t) = -t^{-3} + a_1 t^{-2} + a_2 t + a_3 + \cdots$$

to precision $O(t^{prec})$ of page 113 of [Silverman AEC1].
The result is cached, and a cached version is returned if possible.

Warning: The resulting series will have precision prec, but its parent PowerSeriesRing will have default precision 20 (or whatever the default default is).

EXAMPLES:

```
sage: EllipticCurve([0, 0, 1, -1, 0]).formal_group().y(10)
 -t^-3 + 1 - t + t^3 - 2*t^4 + t^5 + 2*t^6 - 6*t^7 + 6*t^8 + 3*t^9 + O(t^10)
```

38.18 Tate's parametrisation of p-adic curves with multiplicative reduction

Let E be an elliptic curve defined over the p-adic numbers $\mathbf{Q}_p$. Suppose that E has multiplicative reduction, i.e. that the j-invariant of E has negative valuation, say n. Then there exists a parameter q in $\mathbf{Z}_p$ of valuation n such that the points of E defined over the algebraic closure $\bar{\mathbf{Q}}_p$ are in bijection with $\bar{\mathbf{Q}}_p^\times / q^{\mathbf{Z}}$. More precisely there exists the series $s_4(q)$ and $s_6(q)$ such that the $y^2 + xy = x^3 + s_4(q)x + s_6(q)$ curve is isomorphic to E over $\bar{\mathbf{Q}}_p$ (or over $\mathbf{Q}_p$ if the reduction is *split* multiplicative). There is p-adic analytic map from $\bar{\mathbf{Q}}_p^\times$ to this curve with kernel $q^{\mathbf{Z}}$. Points of good reduction correspond to points of valuation 0 in $\bar{\mathbf{Q}}_p^\times$. See chapter V of [Sil2] for more details.

class TateCurve (*E, p*)

Tate's p-adic uniformisation of an elliptic curve with multiplicative reduction.

Note: Some of the methods of this Tate curve only work when the reduction is split multiplicative over $\mathbf{Q}_p$.

EXAMPLES:

```
sage: e = EllipticCurve('130a1')
sage: eq = e.tate_curve(5); eq
5-adic Tate curve associated to the Elliptic Curve defined by y^2 + x*y + y = x^3 - 33*x + 68 ov
sage: eq == loads(dumps(eq))
True
```

REFERENCES :

•[Sil2] Silverman Joseph, Advanced Topics in the Arithmetic of Elliptic Curves, GTM 151, Springer 1994.

E2 (*prec=20*)

Returns the value of the p-adic Eisenstein series of weight 2 evaluated on the elliptic curve having split multiplicative reduction.

INPUT:

•`prec` - the p-adic precision, default is 20.

EXAMPLES:

```
sage: eq = EllipticCurve('130a1').tate_curve(5)
sage: eq.E2(prec=10)
4 + 2*5^2 + 2*5^3 + 5^4 + 2*5^5 + 5^7 + 5^8 + 2*5^9 + O(5^10)
```

L_invariant (*prec=20*)

Returns the *mysterious* $\mathcal{L}$-invariant associated to an elliptic curve with split multiplicative reduction. One instance where this constant appears is in the exceptional case of the p-adic Birch and Swinnerton-Dyer conjecture as formulated in [MTT]. See [Col] for a detailed discussion.

INPUT:

•`prec` - the p-adic precision, default is 20.

REFERENCES:

•[MTT] B. Mazur, J. Tate, and J. Teitelbaum, On p-adic analogues of the conjectures of Birch and Swinnerton-Dyer, Inventiones mathematicae 84, (1986), 1-48.

•[Col] Pierre Colmez, Invariant $\mathcal{L}$ et derivees de valeurs propores de Frobenius, preprint, 2004.

EXAMPLES:

```
sage: eq = EllipticCurve('130a1').tate_curve(5)
sage: eq.L_invariant(prec=10)
5^3 + 4*5^4 + 2*5^5 + 2*5^6 + 2*5^7 + 3*5^8 + 5^9 + O(5^10)
```

curve (*prec=20*)

Returns the p-adic elliptic curve of the form $y^2 + xy = x^3 + s_4x + s_6$. This curve with split multiplicative reduction is isomorphic to the given curve over the algebraic closure of $\mathbf{Q}_p$.

INPUT:

•`prec` - the p-adic precision, default is 20.

EXAMPLES:

```
sage: eq = EllipticCurve('130a1').tate_curve(5)
sage: eq.curve(prec=5)
Elliptic Curve defined by y^2 + (1+O(5^5))*x*y  = x^3 +
(2*5^4+5^5+2*5^6+5^7+3*5^8+O(5^9))*x + (2*5^3+5^4+2*5^5+5^7+O(5^8)) over 5-adic
Field with capped relative precision 5
```

is_split()

Returns True if the given elliptic curve has split multiplicative reduction.

EXAMPLES:

```
sage: eq = EllipticCurve('130a1').tate_curve(5)
sage: eq.is_split()
True

sage: eq = EllipticCurve('37a1').tate_curve(37)
sage: eq.is_split()
False
```

lift(*P, prec=20*)

Given a point P in the formal group of the elliptic curve E with split multiplicative reduction, this produces an element u in $\mathbf{Q}_p^\times$ mapped to the point P by the Tate parametrisation. The algorithm return the unique such element in $1 + p\mathbf{Z}_p$.

INPUT:

- `P` - a point on the elliptic curve.
- `prec` - the p-adic precision, default is 20.

EXAMPLES:

```
sage: e = EllipticCurve('130a1')
sage: eq = e.tate_curve(5)
sage: P = e([-6,10])
sage: l = eq.lift(12*P, prec=10); l
1 + 4*5 + 5^3 + 5^4 + 4*5^5 + 5^6 + 5^7 + 4*5^8 + 5^9 + O(5^10)
```

Now we map the lift l back and check that it is indeed right.:

```
sage: eq.parametrisation_onto_original_curve(l)
(4*5^-2 + 2*5^-1 + 4*5 + 3*5^3 + 5^4 + 2*5^5 + 4*5^6 + O(5^7) : 2*5^-3 + 5^-1 + 4 + 4*5 + 5^
sage: e5 = e.change_ring(Qp(5,9))
sage: e5(12*P)
(4*5^-2 + 2*5^-1 + 4*5 + 3*5^3 + 5^4 + 2*5^5 + 4*5^6 + O(5^7) : 2*5^-3 + 5^-1 + 4 + 4*5 + 5^
```

original_curve()

Returns the elliptic curve the Tate curve was constructed from.

EXAMPLES:

```
sage: eq = EllipticCurve('130a1').tate_curve(5)
sage: eq.original_curve()
Elliptic Curve defined by y^2 + x*y + y = x^3 - 33*x + 68 over Rational Field
```

padic_height(*prec=20*)

Returns the canonical p-adic height function on the original curve.

INPUT:

- `prec` - the p-adic precision, default is 20.

OUTPUT:

- A function that can be evaluated on rational points of E.

EXAMPLES:

```
sage: e = EllipticCurve('130a1')
sage: eq = e.tate_curve(5)
sage: h = eq.padic_height(prec=10)
sage: P=e.gens()[0]
sage: h(P)
2*5^-1 + 1 + 2*5 + 2*5^2 + 3*5^3 + 3*5^6 + 5^7 + O(5^8)
```

Check that it is a quadratic function:

```
sage: h(3*P)-3^2*h(P)
O(5^8)
```

padic_regulator (*prec=20*)

Computes the canonical p-adic regulator on the extended Mordell-Weil group as in [MTT] (with the correction of [Wer] and sign convention in [SW].) The p-adic Birch and Swinnerton-Dyer conjecture predicts that this value appears in the formula for the leading term of the p-adic L-function.

INPUT:

•`prec` - the p-adic precision, default is 20.

REFERENCES:

•[MTT] B. Mazur, J. Tate, and J. Teitelbaum, On p-adic analogues of the conjectures of Birch and Swinnerton-Dyer, Inventiones mathematicae 84, (1986), 1-48.

•[Wer] Annette Werner, Local heights on abelian varieties and rigid analytic unifomization, Doc. Math. 3 (1998), 301-319.

•[SW] William Stein and Christian Wuthrich, Computations About Tate-Shafarevich Groups using Iwasawa theory, preprint 2009.

EXAMPLES:

```
sage: eq = EllipticCurve('130a1').tate_curve(5)
sage: eq.padic_regulator()
2*5^-1 + 1 + 2*5 + 2*5^2 + 3*5^3 + 3*5^6 + 5^7 + 3*5^9 + 3*5^10 + 3*5^12 + 4*5^13 + 3*5^15 +
```

parameter (*prec=20*)

Returns the Tate parameter q such that the curve is isomorphic over the algebraic closure of $\mathbf{Q}_p$ to the curve $\mathbf{Q}_p^\times/q^{\mathbf{Z}}$.

INPUT:

•`prec` - the p-adic precision, default is 20.

EXAMPLES:

```
sage: eq = EllipticCurve('130a1').tate_curve(5)
sage: eq.parameter(prec=5)
3*5^3 + 3*5^4 + 2*5^5 + 2*5^6 + 3*5^7 + O(5^8)
```

parametrisation_onto_original_curve (*u, prec=20*)

Given an element u in $\mathbf{Q}_p^\times$, this computes its image on the original curve under the p-adic uniformisation of E.

INPUT:

•`u` - a non-zero p-adic number.

•`prec` - the p-adic precision, default is 20.

EXAMPLES:

```
sage: eq = EllipticCurve('130a1').tate_curve(5)
sage: eq.parametrisation_onto_original_curve(1+5+5^2+O(5^10))
(4*5^-2 + 4*5^-1 + 4 + 2*5^3 + 3*5^4 + 2*5^6 + O(5^7) :
3*5^-3 + 5^-2 + 4*5^-1 + 1 + 4*5 + 5^2 + 3*5^5 + O(5^6) : 1 + O(5^20))
```

Here is how one gets a 4-torsion point on E over $\mathbf{Q}_5$:

```
sage: R = Qp(5,10)
sage: i = R(-1).sqrt()
sage: T = eq.parametrisation_onto_original_curve(i); T
(2 + 3*5 + 4*5^2 + 2*5^3 + 5^4 + 4*5^5 + 2*5^7 + 5^8 + 5^9 + O(5^10) :
3*5 + 5^2 + 5^4 + 3*5^5 + 3*5^7 + 2*5^8 + 4*5^9 + O(5^10) : 1 + O(5^20))
sage: 4*T
(0 : 1 + O(5^20) : 0)
```

parametrisation_onto_tate_curve(*u, prec=20*)

Given an element u in $\mathbf{Q}_p^\times$, this computes its image on the Tate curve under the p-adic uniformisation of E.

INPUT:

- `u` - a non-zero p-adic number.
- `prec` - the p-adic precision, default is 20.

EXAMPLES:

```
sage: eq = EllipticCurve('130a1').tate_curve(5)
sage: eq.parametrisation_onto_tate_curve(1+5+5^2+O(5^10))
(5^-2 + 4*5^-1 + 1 + 2*5 + 3*5^2 + 2*5^5 + 3*5^6 + O(5^7) :
4*5^-3 + 2*5^-1 + 4 + 2*5 + 3*5^4 + 2*5^5 + O(5^6) : 1 + O(5^20))
```

prime()

Returns the residual characteristic p.

EXAMPLES:

```
sage: eq = EllipticCurve('130a1').tate_curve(5)
sage: eq.original_curve()
Elliptic Curve defined by y^2 + x*y + y = x^3 - 33*x + 68 over Rational Field
sage: eq.prime()
5
```

38.19 Computation of Frobenius matrix on Monsky-Washnitzer cohomology.

The most interesting functions to be exported here are matrix_of_frobenius() and adjusted_prec().

Currently this code is limited to the case $p \geq 5$ (no $GF(p^n)$ for $n > 1$), and only handles the elliptic curve case (not more general hyperelliptic curves).

REFERENCES:

AUTHORS:

- David Harvey and Robert Bradshaw: initial code developed at the 2006 MSRI graduate workshop, working with Jennifer Balakrishnan and Liang Xiao
- David Harvey (2006-08): cleaned up, rewrote some chunks, lots more documentation, added Newton iteration method, added more complete 'trace trick', integrated better into Sage.
- David Harvey (2007-02): added algorithm with sqrt(p) complexity (removed in May 2007 due to better C++ implementation)
- Robert Bradshaw (2007-03): keep track of exact form in reduction algorithms
- Robert Bradshaw (2007-04): generalization to hyperelliptic curves

class MonskyWashnitzerDifferential(*parent, val=0, offset=0*)

Represents an element of the form F dx/2y

coeff()
This is a one-dimensional module over the base ring, generated by dx/2y. Return A where $Adx/2y = self$.

coeffs(*R=None*)

coleman_integral(*P, Q*)

extract_pow_y(*k*)
Really the power of y in A where self = A dx/2y.

integrate(*P, Q*)

max_pow_y()
Really the maximum power of y in A where self = A dx/2y.

min_pow_y()
Really the minimum power of y in A where self = A dx/2y.

reduce()
Use homology relations to find a and f such that $self = a + df$ where a is given in terms of the $x^i dx/2y$.

reduce_fast(*even_degree_only=False*)
Use homology relations to find a and f such that $self = a + df$ where a is given in terms of the $x^i dx/2y$.
EXAMPLES:

```
sage: R.<x> = QQ['x']
sage: E = HyperellipticCurve(x^3-4*x+4)
sage: x, y = E.monsky_washnitzer_gens()
sage: x.diff().reduce_fast()
(x, (0, 0))
sage: y.diff().reduce_fast()
(y*1, (0, 0))
sage: (y^-1).diff().reduce_fast()
((y^-1)*1, (0, 0))
sage: (y^-11).diff().reduce_fast()
((y^-11)*1, (0, 0))
sage: (x*y^2).diff().reduce_fast()
(y^2*x, (0, 0))
```

reduce_neg_y()
Use homology relations to eliminate negative powers of y.

reduce_neg_y_fast(*even_degree_only=False*)
Use homology relations to eliminate negative powers of y.
EXAMPLES:

```
sage: R.<x> = QQ['x']
sage: E = HyperellipticCurve(x^5-3*x+1)
sage: x, y = E.monsky_washnitzer_gens()
sage: (y^-1).diff().reduce_neg_y_fast()
((y^-1)*1, 0 dx/2y)
sage: (y^-5*x^2+y^-1*x).diff().reduce_neg_y_fast()
((y^-1)*x + (y^-5)*x^2, 0 dx/2y)
```

It leaves non-negative powers of y alone:

```
sage: y.diff()
((-3)*1 + 5*x^4) dx/2y
sage: y.diff().reduce_neg_y_fast()
(0, ((-3)*1 + 5*x^4) dx/2y)
```

reduce_neg_y_faster(*even_degree_only=False*)
Use homology relations to eliminate negative powers of y.

reduce_pos_y()
Use homology relations to eliminate positive powers of y.

reduce_pos_y_fast(*even_degree_only=False*)
Use homology relations to eliminate positive powers of y.
EXAMPLES:

```
sage: R.<x> = QQ['x']
sage: E = HyperellipticCurve(x^3-4*x+4)
sage: x, y = E.monsky_washnitzer_gens()
sage: y.diff().reduce_pos_y_fast()
(y*1, 0 dx/2y)
sage: (y^2).diff().reduce_pos_y_fast()
(y^2*1, 0 dx/2y)
sage: (y^2*x).diff().reduce_pos_y_fast()
(y^2*x, 0 dx/2y)
sage: (y^92*x).diff().reduce_pos_y_fast()
(y^92*x, 0 dx/2y)
sage: w = (y^3 + x).diff()
sage: w += w.parent()(x)
sage: w.reduce_pos_y_fast()
(y^3*1 + x, x dx/2y)
```

MonskyWashnitzerDifferentialRing(*base_ring*)

class **MonskyWashnitzerDifferentialRing_class**(*base_ring*)

Q()

base_extend(*R*)

change_ring(*R*)

degree()

frob_Q(*p*)

frob_basis_elements(*prec, p*)

frob_invariant_differential(*prec, p*)

$$F_p(dx/y) = px^{p-1}y(F_py)^{-1}dx/y = px^{p-1}y^{1-p}(1+pEy^{-2p})^{-1/2}dx/y = px^{p-1}y^{1-p}(F_pQy^{-p})^{-1/2}dx/y$$

Use Newton's method to calculate the square root.

helper_matrix()
We use this to solve for the linear combination of x^iy^j needed to clear all terms with y^{j-1}.

invariant_differential()

x_to_p(*p*)

class **SpecialCubicQuotientRing**(*Q, laurent_series=False*)
Specialised class for representing the quotient ring $R[x,T]/(T-x^3-ax-b)$, where R is an arbitrary commutative base ring (in which 2 and 3 are invertible), a and b are elements of that ring.

Polynomials are represented internally in the form $p_0+p_1x+p_2x^2$ where the p_i are polynomials in T. Multiplication of polynomials always reduces high powers of x (i.e. beyond x^2) to powers of T.

Hopefully this ring is faster than a general quotient ring because it uses the special structure of this ring to speed multiplication (which is the dominant operation in the frobenius matrix calculation). I haven't actually tested this theory though...

TODO: - Eventually we will want to run this in characteristic 3, so we need to: (a) Allow Q(x) to contain an x^2 term, and (b) Remove the requirement that 3 be invertible. Currently this is used in the Toom-Cook algorithm to speed multiplication.

EXAMPLES:

```
sage: B.<t> = PolynomialRing(Integers(125))
sage: R = monsky_washnitzer.SpecialCubicQuotientRing(t^3 - t + B(1/4))
sage: R
SpecialCubicQuotientRing over Ring of integers modulo 125 with polynomial T = x^3 + 124*x + 94
```

Get generators:

```
sage: x, T = R.gens()
sage: x
(0) + (1)*x + (0)*x^2
sage: T
(T) + (0)*x + (0)*x^2
```

Coercions:

```
sage: R(7)
(7) + (0)*x + (0)*x^2
```

Create elements directly from polynomials:

```
sage: A, z = R.poly_ring().objgen()
sage: A
Univariate Polynomial Ring in T over Ring of integers modulo 125
sage: R.create_element(z^2, z+1, 3)
(T^2) + (T + 1)*x + (3)*x^2
```

Some arithmetic:

```
sage: x^3
(T + 31) + (1)*x + (0)*x^2
sage: 3 * x**15 * T**2 + x - T
(3*T^7 + 90*T^6 + 110*T^5 + 20*T^4 + 58*T^3 + 26*T^2 + 124*T) + (15*T^6 + 110*T^5 + 35*T^4 + 63*
```

Retrieve coefficients (output is zero-padded):

```
sage: x^10
(3*T^2 + 61*T + 8) + (T^3 + 93*T^2 + 12*T + 40)*x + (3*T^2 + 61*T + 9)*x^2
sage: (x^10).coeffs()
[[8, 61, 3, 0], [40, 12, 93, 1], [9, 61, 3, 0]]
```

TODO: write an example checking multiplication of these polynomials against Sage's ordinary quotient ring arithmetic. I can't seem to get the quotient ring stuff happening right now...

create_element (*p0, p1, p2, check=True*)

Creates the element $p_0 + p_1 * x + p_2 * x^2$, where pi's are polynomials in T.

INPUT:

- `p0, p1, p2` - coefficients; must be coercable into poly_ring()
- `check` - bool (default True): whether to carry out coercion

EXAMPLES:

```
sage: B.<t> = PolynomialRing(Integers(125))
sage: R = monsky_washnitzer.SpecialCubicQuotientRing(t^3 - t + B(1/4))
sage: A, z = R.poly_ring().objgen()
sage: R.create_element(z^2, z+1, 3)
(T^2) + (T + 1)*x + (3)*x^2
```

gens()
Return a list [x, T] where x and T are the generators of the ring (as element *of this ring*).
Note: I have no idea if this is compatible with the usual Sage 'gens' interface.
EXAMPLES:

```
sage: B.<t> = PolynomialRing(Integers(125))
sage: R = monsky_washnitzer.SpecialCubicQuotientRing(t^3 - t + B(1/4))
sage: x, T = R.gens()
sage: x
(0) + (1)*x + (0)*x^2
sage: T
(T) + (0)*x + (0)*x^2
```

poly_ring()
Return the underlying polynomial ring in T.
EXAMPLES:

```
sage: B.<t> = PolynomialRing(Integers(125))
sage: R = monsky_washnitzer.SpecialCubicQuotientRing(t^3 - t + B(1/4))
sage: R.poly_ring()
Univariate Polynomial Ring in T over Ring of integers modulo 125
```

class **SpecialCubicQuotientRingElement**(*parent, p0, p1, p2, check=True*)
An element of a SpecialCubicQuotientRing.

coeffs()
Returns list of three lists of coefficients, corresponding to the x^0, x^1, x^2 coefficients. The lists are zero padded to the same length. The list entries belong to the base ring.
EXAMPLES:

```
sage: B.<t> = PolynomialRing(Integers(125))
sage: R = monsky_washnitzer.SpecialCubicQuotientRing(t^3 - t + B(1/4))
sage: p = R.create_element(t, t^2 - 2, 3)
sage: p.coeffs()
[[0, 1, 0], [123, 0, 1], [3, 0, 0]]
```

scalar_multiply(*scalar*)
Multiplies this element by a scalar, i.e. just multiply each coefficient of x^j by the scalar.
INPUT:

- `scalar` - either an element of base_ring, or an element of poly_ring.

EXAMPLES:

```
sage: B.<t> = PolynomialRing(Integers(125))
sage: R = monsky_washnitzer.SpecialCubicQuotientRing(t^3 - t + B(1/4))
sage: x, T = R.gens()
sage: f = R.create_element(2, t, t^2 - 3)
sage: f
(2) + (T)*x + (T^2 + 122)*x^2
sage: f.scalar_multiply(2)
(4) + (2*T)*x + (2*T^2 + 119)*x^2
sage: f.scalar_multiply(t)
(2*T) + (T^2)*x + (T^3 + 122*T)*x^2
```

shift(*n*)
Returns this element multiplied by T^n.
EXAMPLES:

```
sage: B.<t> = PolynomialRing(Integers(125))
sage: R = monsky_washnitzer.SpecialCubicQuotientRing(t^3 - t + B(1/4))
sage: f = R.create_element(2, t, t^2 - 3)
sage: f
(2) + (T)*x + (T^2 + 122)*x^2
sage: f.shift(1)
(2*T) + (T^2)*x + (T^3 + 122*T)*x^2
sage: f.shift(2)
(2*T^2) + (T^3)*x + (T^4 + 122*T^2)*x^2
```

square()

EXAMPLES:

```
sage: B.<t> = PolynomialRing(Integers(125))
sage: R = monsky_washnitzer.SpecialCubicQuotientRing(t^3 - t + B(1/4))
sage: x, T = R.gens()

sage: f = R.create_element(1 + 2*t + 3*t^2, 4 + 7*t + 9*t^2, 3 + 5*t + 11*t^2)
sage: f.square()
(73*T^5 + 16*T^4 + 38*T^3 + 39*T^2 + 70*T + 120) + (121*T^5 + 113*T^4 + 73*T^3 + 8*T^2 + 51*
```

class SpecialHyperellipticQuotientElement(*parent, val=0, offset=0, check=True*)

change_ring(*R*)

coeffs(*R=None*)

diff()

extract_pow_y(*k*)

max_pow_y()

min_pow_y()

truncate_neg(*n*)

SpecialHyperellipticQuotientRing(**args*)

class SpecialHyperellipticQuotientRing_class(*Q, R=None, invert_y=True*)

Q()

base_extend(*R*)

change_ring(*R*)

curve()

degree()

gens()

is_field()

monomial(*i, j, b=None*)

Returns $by^j x^i$, computed quickly.

monomial_diff_coeffs(*i, j*)

The key here is that the formula for $d(x^i y^j)$ is messy in terms of i, but varies nicely with j.

$$d(x^i y^j) = y^{j-1}(2ix^{i-1}y^2 + j(A_i(x) + B_i(x)y^2))\frac{dx}{2y}$$

Where A, B have degree at most $n-1$ for each i. Pre-compute A_i, B_i for each i the "hard" way, and the rest are easy.

monomial_diff_coeffs_matrices()

monsky_washnitzer()

prime()

x()

y()

adjusted_prec(*p, prec*)

Computes how much precision is required in matrix_of_frobenius to get an answer correct to prec p-adic digits.

The issue is that the algorithm used in matrix_of_frobenius sometimes performs divisions by p, so precision is lost during the algorithm.

The estimate returned by this function is based on Kedlaya's result (Lemmas 2 and 3 of "Counting Points on Hyperelliptic Curves..."), which implies that if we start with M p-adic digits, the total precision loss is at most $1 + \lfloor \log_p(2M-3) \rfloor$ p-adic digits. (This estimate is somewhat less than the amount you would expect by naively counting the number of divisions by p.)

INPUT:

- `p` - a prime = 5
- `prec` - integer, desired output precision, = 1

OUTPUT: adjusted precision (usually slightly more than prec)

frobenius_expansion_by_newton(*Q, p, M*)

Computes the action of Frobenius on dx/y and on xdx/y, using Newton's method (as suggested in Kedlaya's paper).

(This function does *not* yet use the cohomology relations - that happens afterwards in the "reduction" step.)

More specifically, it finds F_0 and F_1 in the quotient ring $R[x,T]/(T - Q(x))$, such that

$$F(dx/y) = T^{-r} F0 dx/y, \text{ and } F(xdx/y) = T^{-r} F1 dx/y$$

where

$$r = ((2M-3)p - 1)/2.$$

(Here T is $y^2 = z^{-2}$, and R is the coefficient ring of Q.)

F_0 and F_1 are computed in the SpecialCubicQuotientRing associated to Q, so all powers of x^j for $j \geq 3$ are reduced to powers of T.

INPUT:

- `Q` - cubic polynomial of the form $Q(x) = x^3 + ax + b$, whose coefficient ring is a $Z/(p^M)Z$-algebra
- `p` - residue characteristic of the p-adic field
- `M` - p-adic precision of the coefficient ring (this will be used to determine the number of Newton iterations)

OUTPUT:

- `F0, F1` - elements of SpecialCubicQuotientRing(Q), as described above
- `r` - non-negative integer, as described above

frobenius_expansion_by_series(*Q, p, M*)

Computes the action of Frobenius on dx/y and on x dx/y, using a series expansion.

(This function computes the same thing as frobenius_expansion_by_newton(), using a different method. Theoretically the Newton method should be asymptotically faster, when the precision gets large. However, in practice, this functions seems to be marginally faster for moderate precision, so I'm keeping it here until I figure out exactly why it's faster.)

(This function does *not* yet use the cohomology relations - that happens afterwards in the "reduction" step.)

More specifically, it finds F0 and F1 in the quotient ring $R[x,T]/(T - Q(x))$, such that $F(dx/y) = T^{-r}F0dx/y$, and $F(xdx/y) = T^{-r}F1dx/y$ where $r = ((2M-3)p-1)/2$. (Here T is $y^2 = z^{-2}$, and R is the coefficient ring of Q.)

F_0 and F_1 are computed in the SpecialCubicQuotientRing associated to Q, so all powers of x^j for $j \geq 3$ are reduced to powers of T.

It uses the sum

$$F0 = \sum_{k=0}^{M-2} \binom{-1/2}{k} px^{p-1}E^k T^{(M-2-k)p}$$

and

$$F1 = x^p F0,$$
$$where`E = Q(x^p) - Q(x)^p`.$$

INPUT:

- `Q` - cubic polynomial of the form $Q(x) = x^3 + ax + b$, whose coefficient ring is a $\mathbf{Z}/(p^M)\mathbf{Z}$ -algebra
- `p` - residue characteristic of the p-adic field
- `M` - p-adic precision of the coefficient ring (this will be used to determine the number of terms in the series)

OUTPUT:

- `F0, F1` - elements of SpecialCubicQuotientRing(Q), as described above
- `r` - non-negative integer, as described above

helper_matrix(*Q*)

Computes the (constant) matrix used to calculate the linear combinations of the $d(x^i y^j)$ needed to eliminate the negative powers of y in the cohomology (i.e. in reduce_negative()).

INPUT:

- `Q` - cubic polynomial

lift(*x*)

Tries to call x.lift(), presumably from the p-adics to ZZ.

If this fails, it assumes the input is a power series, and tries to lift it to a power series over QQ.

This function is just a very kludgy solution to the problem of trying to make the reduction code (below) work over both Zp and Zp[[t]].

matrix_of_frobenius(*Q, p, M, trace=None, compute_exact_forms=False*)

Computes the matrix of Frobenius on Monsky-Washnitzer cohomology, with respect to the basis $(dx/y, xdx/y)$.

INPUT:

- `Q` - cubic polynomial $Q(x) = x^3 + ax + b$ defining an elliptic curve E by $y^2 = Q(x)$. The coefficient ring of Q should be a $\mathbf{Z}/(p^M)\mathbf{Z}$-algebra in which the matrix of frobenius will be constructed.
- `p` - prime = 5 for which E has good reduction
- `M` - integer = 2; p -adic precision of the coefficient ring
- `trace` - (optional) the trace of the matrix, if known in advance. This is easy to compute because it's just the a_p of the curve. If the trace is supplied, matrix_of_frobenius will use it to speed the computation (i.e. we know the determinant is p, so we have two conditions, so really only column of the matrix needs to be computed. It's actually a little more complicated than that, but that's the basic idea.) If trace=None,

then both columns will be computed independently, and you can get a strong indication of correctness by verifying the trace afterwards.

Warning: THE RESULT WILL NOT NECESSARILY BE CORRECT TO M p-ADIC DIGITS. If you want prec digits of precision, you need to use the function adjusted_prec(), and then you need to reduce the answer mod p^{prec} at the end.

OUTPUT: 2x2 matrix of frobenius on Monsky-Washnitzer cohomology, with entries in the coefficient ring of Q.

EXAMPLES: A simple example:

```
sage: p = 5
sage: prec = 3
sage: M = monsky_washnitzer.adjusted_prec(p, prec)
sage: M
5
sage: R.<x> = PolynomialRing(Integers(p**M))
sage: A = monsky_washnitzer.matrix_of_frobenius(x^3 - x + R(1/4), p, M)
sage: A
[3090  187]
[2945  408]
```

But the result is only accurate to prec digits:

```
sage: B = A.change_ring(Integers(p**prec))
sage: B
[90 62]
[70 33]
```

Check trace (123 = -2 mod 125) and determinant:

```
sage: B.det()
5
sage: B.trace()
123
sage: EllipticCurve([-1, 1/4]).ap(5)
-2
```

Try using the trace to speed up the calculation:

```
sage: A = monsky_washnitzer.matrix_of_frobenius(x^3 - x + R(1/4),
...                                             p, M, -2)
sage: A
[2715  187]
[1445  408]
```

Hmmm... it looks different, but that's because the trace of our first answer was only -2 modulo 5^3, not -2 modulo 5^5. So the right answer is:

```
sage: A.change_ring(Integers(p**prec))
     [90 62]
     [70 33]
```

Check it works with only one digit of precision:

```
sage: p = 5
sage: prec = 1
sage: M = monsky_washnitzer.adjusted_prec(p, prec)
sage: R.<x> = PolynomialRing(Integers(p**M))
sage: A = monsky_washnitzer.matrix_of_frobenius(x^3 - x + R(1/4), p, M)
sage: A.change_ring(Integers(p))
[0 2]
[0 3]
```

Here's an example that's particularly badly conditioned for using the trace trick:

```
sage: p = 11
sage: prec = 3
sage: M = monsky_washnitzer.adjusted_prec(p, prec)
sage: R.<x> = PolynomialRing(Integers(p**M))
sage: A = monsky_washnitzer.matrix_of_frobenius(x^3 + 7*x + 8, p, M)
sage: A.change_ring(Integers(p**prec))
[1144  176]
[ 847  185]
```

The problem here is that the top-right entry is divisible by 11, and the bottom-left entry is divisible by 11^2. So when you apply the trace trick, neither $F(dx/y)$ nor $F(xdx/y)$ is enough to compute the whole matrix to the desired precision, even if you try increasing the target precision by one. Nevertheless, `matrix_of_frobenius` knows how to get the right answer by evaluating $F((x+1)dx/y)$ instead:

```
sage: A = monsky_washnitzer.matrix_of_frobenius(x^3 + 7*x + 8, p, M, -2)
sage: A.change_ring(Integers(p**prec))
[1144  176]
[ 847  185]
```

The running time is about `O(p*prec**2)` (times some logarithmic factors), so it's feasible to run on fairly large primes, or precision (or both?!?!):

```
sage: p = 10007
sage: prec = 2
sage: M = monsky_washnitzer.adjusted_prec(p, prec)
sage: R.<x> = PolynomialRing(Integers(p**M))
sage: A = monsky_washnitzer.matrix_of_frobenius(            # long time
...                               x^3 - x + R(1/4), p, M)   # long time
sage: B = A.change_ring(Integers(p**prec)); B               # long time
[74311982 57996908]
[95877067 25828133]
sage: B.det()                                               # long time
10007
sage: B.trace()                                             # long time
66
sage: EllipticCurve([-1, 1/4]).ap(10007)                    # long time
66
```

```
sage: p = 5
sage: prec = 300
sage: M = monsky_washnitzer.adjusted_prec(p, prec)
sage: R.<x> = PolynomialRing(Integers(p**M))
sage: A = monsky_washnitzer.matrix_of_frobenius(            # long time
...                               x^3 - x + R(1/4), p, M)   # long time
sage: B = A.change_ring(Integers(p**prec))                  # long time
sage: B.det()                                               # long time
```

```
5
sage: -B.trace()                                                    # long time
2
sage: EllipticCurve([-1, 1/4]).ap(5)                                # long time
-2
```

Let's check consistency of the results for a range of precisions:

```
sage: p = 5
sage: max_prec = 60
sage: M = monsky_washnitzer.adjusted_prec(p, max_prec)
sage: R.<x> = PolynomialRing(Integers(p**M))
sage: A = monsky_washnitzer.matrix_of_frobenius(x^3 - x + R(1/4), p, M)          # long time
sage: A = A.change_ring(Integers(p**max_prec))                      # long time
sage: result = []                                                   # long time
sage: for prec in range(1, max_prec):                               # long time
...       M = monsky_washnitzer.adjusted_prec(p, prec)              # long time
...       R.<x> = PolynomialRing(Integers(p^M),'x')                 # long time
...       B = monsky_washnitzer.matrix_of_frobenius(                # long time
...                           x^3 - x + R(1/4), p, M)               # long time
...       B = B.change_ring(Integers(p**prec))                      # long time
...       result.append(B == A.change_ring(                         # long time
...                                   Integers(p**prec)))           # long time
sage: result == [True] * (max_prec - 1)                             # long time
True
```

The remaining examples discuss what happens when you take the coefficient ring to be a power series ring; i.e. in effect you're looking at a family of curves.

The code does in fact work...

```
sage: p = 11
sage: prec = 3
sage: M = monsky_washnitzer.adjusted_prec(p, prec)
sage: S.<t> = PowerSeriesRing(Integers(p**M), default_prec=4)
sage: a = 7 + t + 3*t^2
sage: b = 8 - 6*t + 17*t^2
sage: R.<x> = PolynomialRing(S)
sage: Q = x**3 + a*x + b
sage: A = monsky_washnitzer.matrix_of_frobenius(Q, p, M)     # long time
sage: B = A.change_ring(PowerSeriesRing(Integers(p**prec), 't', default_prec=4))        # long t
sage: B                                                             # long time
[1144 + 264*t + 841*t^2 + 1025*t^3 + O(t^4)  176 + 1052*t + 216*t^2 + 523*t^3 + O(t^4)]
[   847 + 668*t + 81*t^2 + 424*t^3 + O(t^4)   185 + 341*t + 171*t^2 + 642*t^3 + O(t^4)]
```

The trace trick should work for power series rings too, even in the badly- conditioned case. Unfortunately I don't know how to compute the trace in advance, so I'm not sure exactly how this would help. Also, I suspect the running time will be dominated by the expansion, so the trace trick won't really speed things up anyway. Another problem is that the determinant is not always p:

```
sage: B.det()                                                       # long time
11 + 484*t^2 + 451*t^3 + O(t^4)
```

However, it appears that the determinant always has the property that if you substitute t - 11t, you do get the constant series p (mod p**prec). Similarly for the trace. And since the parameter only really makes sense when it's divisible by p anyway, perhaps this isn't a problem after all.

matrix_of_frobenius_hyperelliptic(*Q, p=None, prec=None, M=None*)

reduce_all(*Q, p, coeffs, offset, compute_exact_form=False*)

Applies cohomology relations to reduce all terms to a linear combination of dx/y and xdx/y.

INPUT:

- `Q` - cubic polynomial
- `coeffs` - list of length 3 lists. The i^{th} list [a, b, c] represents $y^{2(i-offset)}(a + bx + cx^2)dx/y$.
- `offset` - nonnegative integer

OUTPUT:

- `A, B` - pair such that the input differential is cohomologous to (A + Bx) dx/y.

Note: The algorithm operates in-place, so the data in coeffs is destroyed.

EXAMPLE:

```
sage: R.<x> = Integers(5^3)['x']
sage: Q = x^3 - x + R(1/4)
sage: coeffs = [[1, 2, 3], [4, 5, 6], [7, 8, 9]]
sage: coeffs = [[R.base_ring()(a) for a in row] for row in coeffs]
sage: monsky_washnitzer.reduce_all(Q, 5, coeffs, 1)
 (21, 106)
```

reduce_negative(*Q, p, coeffs, offset, exact_form=None*)

Applies cohomology relations to incorporate negative powers of y into the y^0 term.

INPUT:

- `p` - prime
- `Q` - cubic polynomial
- `coeffs` - list of length 3 lists. The i^{th} list [a, b, c] represents $y^{2(i-offset)}(a + bx + cx^2)dx/y$.
- `offset` - nonnegative integer

OUTPUT: The reduction is performed in-place. The output is placed in coeffs[offset]. Note that coeffs[i] will be meaningless for i offset after this function is finished.

EXAMPLE:

```
sage: R.<x> = Integers(5^3)['x']
sage: Q = x^3 - x + R(1/4)
sage: coeffs = [[10, 15, 20], [1, 2, 3], [4, 5, 6], [7, 8, 9]]
sage: coeffs = [[R.base_ring()(a) for a in row] for row in coeffs]
sage: monsky_washnitzer.reduce_negative(Q, 5, coeffs, 3)
sage: coeffs[3]
 [28, 52, 9]

sage: R.<x> = Integers(7^3)['x']
sage: Q = x^3 - x + R(1/4)
sage: coeffs = [[7, 14, 21], [1, 2, 3], [4, 5, 6], [7, 8, 9]]
sage: coeffs = [[R.base_ring()(a) for a in row] for row in coeffs]
sage: monsky_washnitzer.reduce_negative(Q, 7, coeffs, 3)
sage: coeffs[3]
 [245, 332, 9]
```

reduce_positive(*Q, p, coeffs, offset, exact_form=None*)

Applies cohomology relations to incorporate positive powers of y into the y^0 term.

INPUT:

- `Q` - cubic polynomial
- `coeffs` - list of length 3 lists. The i^{th} list [a, b, c] represents $y^{2(i-offset)}(a+bx+cx^2)dx/y$.
- `offset` - nonnegative integer

OUTPUT: The reduction is performed in-place. The output is placed in coeffs[offset]. Note that coeffs[i] will be meaningless for i offset after this function is finished.

EXAMPLE:

```
sage: R.<x> = Integers(5^3)['x']
sage: Q = x^3 - x + R(1/4)

sage: coeffs = [[1, 2, 3], [10, 15, 20]]
sage: coeffs = [[R.base_ring()(a) for a in row] for row in coeffs]
sage: monsky_washnitzer.reduce_positive(Q, 5, coeffs, 0)
sage: coeffs[0]
 [16, 102, 88]

sage: coeffs = [[9, 8, 7], [10, 15, 20]]
sage: coeffs = [[R.base_ring()(a) for a in row] for row in coeffs]
sage: monsky_washnitzer.reduce_positive(Q, 5, coeffs, 0)
sage: coeffs[0]
 [24, 108, 92]
```

reduce_zero(*Q, coeffs, offset, exact_form=None*)

Applies cohomology relation to incorporate x^2y^0 term into x^0y^0 and x^1y^0 terms.

INPUT:

- `Q` - cubic polynomial
- `coeffs` - list of length 3 lists. The i^{th} list [a, b, c] represents $y^{2(i-offset)}(a+bx+cx^2)dx/y$.
- `offset` - nonnegative integer

OUTPUT: The reduction is performed in-place. The output is placed in coeffs[offset]. This method completely ignores coeffs[i] for i != offset.

EXAMPLE:

```
sage: R.<x> = Integers(5^3)['x']
sage: Q = x^3 - x + R(1/4)
sage: coeffs = [[1, 2, 3], [4, 5, 6], [7, 8, 9]]
sage: coeffs = [[R.base_ring()(a) for a in row] for row in coeffs]
sage: monsky_washnitzer.reduce_zero(Q, coeffs, 1)
sage: coeffs[1]
 [6, 5, 0]
```

transpose_list(*input*)

INPUT:

- `input` - a list of lists, each list of the same length

OUTPUT:

- `output` - a list of lists such that output[i][j] = input[j][i]

EXAMPLES:

```
sage: from sage.schemes.elliptic_curves.monsky_washnitzer import transpose_list
sage: L = [[1, 2], [3, 4], [5, 6]]
sage: transpose_list(L)
[[1, 3, 5], [2, 4, 6]]
```

38.20 p-adic L-functions of elliptic curves

To an elliptic curve E over the rational numbers and a prime p, one can associate a p-adic L-function; at least if E does not have additive reduction at p. This function is defined by interpolation of L-values of E at twists. Through the main conjecture of Iwasawa theory it should also be equal to a characteristic series of a certain Selmer group.

If E is ordinary, then it is an element of $\mathbf{Z}_p[\![T]\!]$ and according to the p-adic version of the Birch and Swinnerton-Dyer conjecture [MTT], the order of vanishing at $T = 0$ is just the rank of $E(\mathbf{Q})$ or this rank plus one if the reduction at p is split multiplicative.

If E is supersingular, the series will have coefficients in a quadratic extension of $\mathbf{Z}_p$. We have also implemented the p-adic L-series as formulated by Perrin-Riou [BP], which has coefficients in the Dieudonne $D_pE = H^1_{dR}(E/\mathbf{Q}_p)$ module of E. There is a different description by Pollack [Po] which is not available here.

See [SW] for more details.

class pAdicLseries (*E, p, use_eclib=False, normalize='L_ratio'*)

The p-adic L-series of an elliptic curve.

EXAMPLES: An ordinary example:

```
sage: e = EllipticCurve('389a')
sage: L = e.padic_lseries(5)
sage: L.series(0)
...
ValueError: n (=0) must be a positive integer
sage: L.series(1)
O(T^1)
sage: L.series(2)
```

```
O(5^4) + O(5)*T + (4 + O(5))*T^2 + (2 + O(5))*T^3 + (3 + O(5))*T^4 + O(T^5)
sage: L.series(3, prec=10)
O(5^5) + O(5^2)*T + (4 + 4*5 + O(5^2))*T^2 + (2 + 4*5 + O(5^2))*T^3 + (3 + O(5^2))*T^4 + (1 + O(
sage: L.series(2,quadratic_twist=-3)
2 + 4*5 + 4*5^2 + O(5^4) + O(5)*T + (1 + O(5))*T^2 + (4 + O(5))*T^3 + O(5)*T^4 + O(T^5)
```

A prime p such that E[p] is reducible:

```
sage: L = EllipticCurve('11a').padic_lseries(5)
sage: L.series(1)
5 + O(5^2) + O(T)
sage: L.series(2)
5 + 4*5^2 + O(5^3) + O(5^0)*T + O(5^0)*T^2 + O(5^0)*T^3 + O(5^0)*T^4 + O(T^5)
sage: L.series(3)
5 + 4*5^2 + 4*5^3 + O(5^4) + O(5)*T + O(5)*T^2 + O(5)*T^3 + O(5)*T^4 + O(T^5)
```

the load-dumps test:

```
sage: lp = EllipticCurve('11a').padic_lseries(5)
sage: lp == loads(dumps(lp))
True
```

alpha (*prec=20*)

Return a p-adic root α of the polynomial $x^2 - a_p x + p$ with $ord_p(\alpha) < 1$. In the ordinary case this is just the unit root.

INPUT: - `prec` - positive integer, the p-adic precision of the root.

EXAMPLES: Consider the elliptic curve 37a:

```
sage: E = EllipticCurve('37a')
```

An ordinary prime:

```
sage: L = E.padic_lseries(5)
sage: alpha = L.alpha(10); alpha
3 + 2*5 + 4*5^2 + 2*5^3 + 5^4 + 4*5^5 + 2*5^7 + 5^8 + 5^9 + O(5^10)
sage: alpha^2 - E.ap(5)*alpha + 5
O(5^10)
```

A supersingular prime:

```
sage: L = E.padic_lseries(3)
sage: alpha = L.alpha(10); alpha
(1 + O(3^10))*alpha
sage: alpha^2 - E.ap(3)*alpha + 3
(O(3^10))*alpha^2 + (O(3^11))*alpha + (O(3^11))
```

A reducible prime:

```
sage: L = EllipticCurve('11a').padic_lseries(5)
sage: L.alpha(5)
1 + 4*5 + 3*5^2 + 2*5^3 + 4*5^4 + O(5^5)
```

elliptic_curve()

Return the elliptic curve to which this p-adic L-series is associated.

EXAMPLES:

```
sage: L = EllipticCurve('11a').padic_lseries(5)
sage: L.elliptic_curve()
Elliptic Curve defined by y^2 + y = x^3 - x^2 - 10*x - 20 over Rational Field
```

measure (*a, n, prec, quadratic_twist=1*)

Return the measure on $\mathbf{Z}_p^\times$ defined by

$$\mu_{E,\alpha}^+(a+p^n\mathbf{Z}_p) = \frac{1}{\alpha^n}\left[\frac{a}{p^n}\right]^+ - \frac{1}{\alpha^{n+1}}\left[\frac{a}{p^{n-1}}\right]^+$$

where $[\cdot]^+$ is the modular symbol. This is used to define this p-adic L-function (at least when the reduction is good).

The optional argument `quadratic_twist` replaces E by the twist in the above formula, but the twisted modular symbol is computed using a sum over modular symbols of E rather then finding the modular symbols for the twist.

Note that the normalisation is not correct at this stage: use `_quotient_of periods` and `_quotient_of periods_to_twist` to correct.

Note also that this function does not check if the condition on the `quadratic_twist=D` is satisfied. So the result will only be correct if for each prime ℓ dividing D, we have $ord_\ell(N) <= ord_\ell(D)$, where N is the conductor of the curve.

INPUT:

- `a` - an integer
- `n` - a non-negative integer
- `prec` - an integer
- `quadratic_twist` (default = 1) - a fundamental discriminant of a quadratic field, should be coprime to the conductor of E

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: L = E.padic_lseries(5)
sage: L.measure(1,2, prec=9)
2 + 3*5 + 4*5^3 + 2*5^4 + 3*5^5 + 3*5^6 + 4*5^7 + 4*5^8 + O(5^9)
sage: L.measure(1,2, quadratic_twist=8,prec=15)
O(5^15)
sage: L.measure(1,2, quadratic_twist=-4,prec=15)
4 + 4*5 + 4*5^2 + 3*5^3 + 2*5^4 + 5^5 + 3*5^6 + 5^8 + 2*5^9 + 3*5^12 + 2*5^13 + 4*5^14 + O(5

sage: E = EllipticCurve('11a1')
sage: a = E.quadratic_twist(-3).padic_lseries(5).measure(1,2,prec=15)
sage: b = E.padic_lseries(5).measure(1,2, quadratic_twist=-3,prec=15)
sage: a == b/E.padic_lseries(5)._quotient_of_periods_to_twist(-3)
True
```

modular_symbol (*r, sign=1, quadratic_twist=1*)

Return the modular symbol evaluated at r. This is used to compute this p-adic L-series.

Note that the normalisation is not correct at this stage: use `_quotient_of periods_to_twist` to correct.

Note also that this function does not check if the condition on the quadratic_twist=D is satisfied. So the result will only be correct if for each prime ℓ dividing D, we have $ord_{\ell(N)} <= ord_\ell(D)$, where N is the conductor of the curve.

INPUT:

- `r` - a cusp given as either a rational number or oo
- `sign` - +1 (default) or -1 (only implemented without twists)
- `quadratic_twist` - a fundamental discriminant of a quardratic field or +1 (default)

EXAMPLES:

```
sage: E = EllipticCurve('11a1')
sage: lp = E.padic_lseries(5)
sage: [lp.modular_symbol(r) for r in [0,1/5,oo,1/11]]
```

```
[1/5, 6/5, 0, 0]
sage: [lp.modular_symbol(r,sign=-1) for r in [0,1/3,oo,1/7]]
[0, 1, 0, -1]
sage: [lp.modular_symbol(r,quadratic_twist=-20) for r in [0,1/5,oo,1/11]]
[2, 2, 0, 1]

sage: lpt = E.quadratic_twist(-3).padic_lseries(5)
sage: et = E.padic_lseries(5)._quotient_of_periods_to_twist(-3)
sage: lpt.modular_symbol(0) == lp.modular_symbol(0,quadratic_twist=-3)/et
True
```

order_of_vanishing()

Return the order of vanishing of this p-adic L-series.

The output of this function is provably correct, due to a theorem of Kato [Ka]. This function will terminate if and only if the Mazur-Tate-Teitelbaum analogue [MTT] of the BSD conjecture about the rank of the curve is true and the subgroup of elements of p-power order in the Shafarevich-Tate group of this curve is finite. I.e. if this function terminates (with no errors!), then you may conclude that the p-adic BSD rank conjecture is true and that the p-part of Sha is finite.

NOTE: currently p must be a prime of good ordinary reduction.

REFERENCES:

- [MTT] B. Mazur, J. Tate, and J. Teitelbaum, On p-adic analogues of the conjectures of Birch and Swinnerton-Dyer, Inventiones mathematicae 84, (1986), 1-48.
- [Ka] Kayuza Kato, p-adic Hodge theory and values of zeta functions of modular forms, Cohomologies p-adiques et applications arithmetiques III, Asterisque vol 295, SMF, Paris, 2004.

EXAMPLES:

```
sage: L = EllipticCurve('11a').padic_lseries(3)
sage: L.order_of_vanishing()
0
sage: L = EllipticCurve('11a').padic_lseries(5)
sage: L.order_of_vanishing()
0
sage: L = EllipticCurve('37a').padic_lseries(5)
sage: L.order_of_vanishing()
1
sage: L = EllipticCurve('43a').padic_lseries(3)
sage: L.order_of_vanishing()
1
sage: L = EllipticCurve('37b').padic_lseries(3)
sage: L.order_of_vanishing()
0
```

We verify that Sha(E)(p) is finite for p=3,5,7 for the first curve of rank 2:

```
sage: e = EllipticCurve('389a')
sage: for p in primes(3,10):
...       print p, e.padic_lseries(p).order_of_vanishing()
3 2
5 2
7 2
```

prime()

Returns the prime p as in 'p-adic L-function'.

EXAMPLES:

```
sage: L = EllipticCurve('11a').padic_lseries(5)
sage: L.prime()
5
```

teichmuller(*prec*)

Return Teichmuller lifts to the given precision.

INPUT:

•`prec` - a positive integer.

OUTPUT:

•a list of p-adic numbers, the cached Teichmuller lifts

EXAMPLES:

```
sage: L = EllipticCurve('11a').padic_lseries(7)
sage: L.teichmuller(1)
[0, 1, 2, 3, 4, 5, 6]
sage: L.teichmuller(2)
[0, 1, 30, 31, 18, 19, 48]
```

class pAdicLseriesOrdinary(*E, p, use_eclib=False, normalize='L_ratio'*)

is_ordinary()

Return True if the elliptic that this L-function is attached to is ordinary.

EXAMPLES:

```
sage: L = EllipticCurve('11a').padic_lseries(5)
sage: L.is_ordinary()
True
```

is_supersingular()

Return True if the elliptic that this L function is attached to is supersingular.

EXAMPLES:

```
sage: L = EllipticCurve('11a').padic_lseries(5)
sage: L.is_supersingular()
False
```

power_series(*n=2, quadratic_twist=1, prec=5*)

Returns the n-th approximation to the p-adic L-series as a power series in T (corresponding to $\gamma - 1$ with $\gamma = 1 + p$ as a generator of $1 + p\mathbf{Z}_p$). Each coefficient is a p-adic number whose precision is provably correct.

Here the normalization of the p-adic L-series is chosen such that $L_p(E, 1) = (1 - 1/\alpha)^2 L(E, 1)/\Omega_E$ where α is the unit root of the characteristic polynomial of Frobenius on $T_p E$ and Ω_E is the Neron period of E.

INPUT:

•`n` - (default: 2) a positive integer

•`quadratic_twist` - (default: +1) a fundamental discriminant of a qudratic field, coprime to the conductor of the curve

•`prec` - (default: 5) maximal number of terms of the series to compute; to compute as many as possible just give a very large number for `prec`; the result will still be correct.

ALIAS: power_series is identical to series.

EXAMPLES: We compute some p-adic L-functions associated to the elliptic curve 11a:

```
sage: E = EllipticCurve('11a')
sage: p = 3
sage: E.is_ordinary(p)
True
sage: L = E.padic_lseries(p)
sage: L.series(3)
2 + 3 + 3^2 + 2*3^3 + O(3^5) + (1 + 3 + O(3^2))*T + (1 + 2*3 + O(3^2))*T^2 + O(3)*T^3 + (2*3
```

Another example at a prime of bad reduction, where the p-adic L-function has an extra 0 (compared to the non p-adic L-function):

```
sage: E = EllipticCurve('11a')
sage: p = 11
sage: E.is_ordinary(p)
True
sage: L = E.padic_lseries(p)
sage: L.series(2)
O(11^4) + (10 + O(11))*T + (6 + O(11))*T^2 + (2 + O(11))*T^3 + (5 + O(11))*T^4 + O(T^5)
```

We compute a p-adic L-function that vanishes to order 2:

```
sage: E = EllipticCurve('389a')
sage: p = 3
sage: E.is_ordinary(p)
True
sage: L = E.padic_lseries(p)
sage: L.series(1)
O(T^1)
sage: L.series(2)
O(3^4) + O(3)*T + (2 + O(3))*T^2 + O(T^3)
sage: L.series(3)
O(3^5) + O(3^2)*T + (2 + 2*3 + O(3^2))*T^2 + (2 + O(3))*T^3 + (1 + 3 + O(3^2))*T^4 + O(T^5)
```

Checks if the precision can be changed (trac 5846):

```
sage: L.series(3,prec=4)
O(3^5) + O(3^2)*T + (2 + 2*3 + O(3^2))*T^2 + (2 + O(3))*T^3 + O(T^4)
sage: L.series(3,prec=6)
O(3^5) + O(3^2)*T + (2 + 2*3 + O(3^2))*T^2 + (2 + O(3))*T^3 + (1 + 3 + O(3^2))*T^4 + (1 + O(
```

Rather than computing the p-adic L-function for the curve '15523a1', one can compute it as a quadratic_twist:

```
sage: E = EllipticCurve('43a1')
sage: lp = E.padic_lseries(3)
sage: lp.series(2,quadratic_twist=-19)
2 + 2*3 + 2*3^2 + O(3^4) + (1 + O(3))*T + (1 + O(3))*T^2 + O(T^3)
sage: E.quadratic_twist(-19).label()    #optional --- conductor is greater than 10000
'15523a1'
```

This proves that the rank of '15523a1' is zero, even if `mwrank` can not determine this.

series (*n=2, quadratic_twist=1, prec=5*)

Returns the n-th approximation to the p-adic L-series as a power series in T (corresponding to $\gamma - 1$ with $\gamma = 1 + p$ as a generator of $1 + p\mathbf{Z}_p$). Each coefficient is a p-adic number whose precision is provably correct.

Here the normalization of the p-adic L-series is chosen such that $L_p(E,1) = (1 - 1/\alpha)^2 L(E,1)/\Omega_E$ where α is the unit root of the characteristic polynomial of Frobenius on T_pE and Ω_E is the Neron period of E.

INPUT:

- `n` - (default: 2) a positive integer
- `quadratic_twist` - (default: +1) a fundamental discriminant of a qudratic field, coprime to the conductor of the curve
- `prec` - (default: 5) maximal number of terms of the series to compute; to compute as many as possible just give a very large number for `prec`; the result will still be correct.

ALIAS: power_series is identical to series.

EXAMPLES: We compute some p-adic L-functions associated to the elliptic curve 11a:

```
sage: E = EllipticCurve('11a')
sage: p = 3
sage: E.is_ordinary(p)
True
sage: L = E.padic_lseries(p)
sage: L.series(3)
2 + 3 + 3^2 + 2*3^3 + O(3^5) + (1 + 3 + O(3^2))*T + (1 + 2*3 + O(3^2))*T^2 + O(3)*T^3 + (2*3
```

Another example at a prime of bad reduction, where the p-adic L-function has an extra 0 (compared to the non p-adic L-function):

```
sage: E = EllipticCurve('11a')
sage: p = 11
sage: E.is_ordinary(p)
True
sage: L = E.padic_lseries(p)
sage: L.series(2)
O(11^4) + (10 + O(11))*T + (6 + O(11))*T^2 + (2 + O(11))*T^3 + (5 + O(11))*T^4 + O(T^5)
```

We compute a p-adic L-function that vanishes to order 2:

```
sage: E = EllipticCurve('389a')
sage: p = 3
sage: E.is_ordinary(p)
True
sage: L = E.padic_lseries(p)
sage: L.series(1)
O(T^1)
sage: L.series(2)
O(3^4) + O(3)*T + (2 + O(3))*T^2 + O(T^3)
sage: L.series(3)
O(3^5) + O(3^2)*T + (2 + 2*3 + O(3^2))*T^2 + (2 + O(3))*T^3 + (1 + 3 + O(3^2))*T^4 + O(T^5)
```

Checks if the precision can be changed (trac 5846):

```
sage: L.series(3,prec=4)
O(3^5) + O(3^2)*T + (2 + 2*3 + O(3^2))*T^2 + (2 + O(3))*T^3 + O(T^4)
sage: L.series(3,prec=6)
O(3^5) + O(3^2)*T + (2 + 2*3 + O(3^2))*T^2 + (2 + O(3))*T^3 + (1 + 3 + O(3^2))*T^4 + (1 + O(
```

Rather than computing the p-adic L-function for the curve '15523a1', one can compute it as a quadratic_twist:

```
sage: E = EllipticCurve('43a1')
sage: lp = E.padic_lseries(3)
sage: lp.series(2,quadratic_twist=-19)
2 + 2*3 + 2*3^2 + O(3^4) + (1 + O(3))*T + (1 + O(3))*T^2 + O(T^3)
sage: E.quadratic_twist(-19).label()    #optional --- conductor is greater than 10000
'15523a1'
```

This proves that the rank of '15523a1' is zero, even if `mwrank` can not determine this.

class pAdicLseriesSupersingular(*E, p, use_eclib=False, normalize='L_ratio'*)

Dp_valued_height(*prec=20*)

Returns the canonical p-adic height with values in the Dieudonne module $D_p(E)$. It is defined to be

$$h_\eta \cdot \omega - h_\omega \cdot \eta$$

where h_η is made out of the sigma function of Bernardi and h_ω is log_E^2. The answer `v` is given as `v[1]*omega + v[2]*eta`. The coordinates of `v` are dependent of the Weierstrass equation.

EXAMPLES:

```
sage: E = EllipticCurve('53a')
sage: L = E.padic_lseries(5)
sage: h = L.Dp_valued_height(7)
sage: h(E.gens()[0])
(3*5 + 5^2 + 2*5^3 + 3*5^4 + 4*5^5 + 5^6 + 5^7 + O(5^8), 5^2 + 4*5^4 + 2*5^7 + 3*5^8 + O(5^9
```

Dp_valued_regulator (*prec=20, v1=0, v2=0*)

Returns the canonical p-adic regulator with values in the Dieudonne module $D_p(E)$ as defined by Perrin-Riou using the p-adic height with values in $D_p(E)$. The result is written in the basis ω, $\varphi(\omega)$, and hence the coordinates of the result are independent of the chosen Weierstrass equation.

NOTE: The definition here is corrected with repect to Perrin-Riou's article [PR]. See [SW].

- [SW] William Stein and Christian Wuthrich, Computations About Tate-Shafarevich Groups using Iwasawa theory, preprint 2009.

EXAMPLES:

```
sage: E = EllipticCurve('43a')
sage: L = E.padic_lseries(7)
sage: L.Dp_valued_regulator(7)
(5*7 + 6*7^2 + 4*7^3 + 4*7^4 + 7^5 + 4*7^7 + O(7^8), 4*7^2 + 2*7^3 + 3*7^4 + 7^5 + 6*7^6 + 4
```

Dp_valued_series (*n=3, quadratic_twist=1, prec=5*)

Returns a vector of two components which are p-adic power series. The answer v is such that

$$(1-\varphi)^{-2}\cdot L_p(E,T) = \mathtt{v[1]}\cdot\omega + \mathtt{v[2]}\cdot\varphi(\omega)$$

as an element of the Dieudonne module $D_p(E) = H^1_{dR}(E/\mathbf{Q}_p)$ where ω is the invariant differential and φ is the Frobenius on $D_p(E)$. According to the p-adic Birch and Swinnerton-Dyer conjecture [BP] this function has a zero of order rank of $E(\mathbf{Q})$ and it's leading term is contains the order of the Tate-Shafarevich group, the Tamagawa numbers, the order of the torsion subgroup and the D_p-valued p-adic regulator.

INPUT:

- `n` - (default: 3) a positive integer
- `prec` - (default: 5) a positive integer

REFERENCE:

- [BP] Dominique Bernardi and Bernadette Perrin-Riou, Variante p-adique de la conjecture de Birch et Swinnerton-Dyer (le cas supersingulier), C. R. Acad. Sci. Paris, Ser I. Math, 317 (1993), no 3, 227-232.

EXAMPLES:

```
sage: E = EllipticCurve('14a')
sage: L = E.padic_lseries(5)
sage: L.Dp_valued_series(4)
(1 + 4*5 + 4*5^3 + O(5^4) + (4 + O(5))*T + (1 + O(5))*T^2 + (4 + O(5))*T^3 + (2 + O(5))*T^4
```

bernardi_sigma_function (*prec=20*)

Return the p-adic sigma function of Bernardi in terms of $z = log(t)$. This is the same as `padic_sigma` with `E2 = 0`.

EXAMPLES:

```
sage: E = EllipticCurve('14a')
sage: L = E.padic_lseries(5)
sage: L.bernardi_sigma_function(5) # Todo: some sort of consistency check!?
z + 1/24*z^3 + 29/384*z^5 - 8399/322560*z^7 - 291743/92897280*z^9 - 4364831/5225472*z^10 + 2
```

frobenius (*prec=20, method='mw'*)

This returns a geometric Frobenius φ on the Diedonne module $D_p(E)$ with respect to the basis ω, the invariant differential, and $\eta = x\omega$. It satisfies $\varphi^2 - a_p/p\,\varphi + 1/p = 0$.

INPUT:

- `prec` - (default: 20) a positive integer
- `method` - either 'mw' (default) for Monsky-Washintzer or 'approx' for the method described by Bernardi and Perrin-Riou (much slower)

EXAMPLES:

```
sage: E = EllipticCurve('14a')
sage: L = E.padic_lseries(5)
sage: phi = L.frobenius(5)
sage: phi
[                   2 + 5^2 + 5^4 + O(5^5)     3*5^-1 + 3 + 5 + 4*5^2 + 5^3 + O(5^4)]
[      3 + 3*5^2 + 4*5^3 + 3*5^4 + O(5^5) 3 + 4*5 + 3*5^2 + 4*5^3 + 3*5^4 + O(5^5)]
sage: -phi^2
[5^-1 + O(5^4)         O(5^4)]
[       O(5^5) 5^-1 + O(5^4)]
```

is_ordinary()

is_supersingular()

power_series (*n=3, quadratic_twist=1, prec=5*)

Return the n-th approximation to the p-adic L-series as a power series in T (corresponding to $\gamma - 1$ with $\gamma = 1 + p$ as a generator of $1 + p\mathbf{Z}_p$). Each coefficient is an element of a quadratic extension of the p-adic number whose precision is probably correct.

Here the normalization of the p-adic L-series is chosen such that $L_p(E,1) = (1 - 1/\alpha)^2 L(E,1)/\Omega_E$ where α is the unit root of the characteristic polynomial of Frobenius on T_pE and Ω_E is the Neron period of E.

INPUT:

- `n` - (default: 3) a positive integer
- `prec` - (default: 5) maxima number of terms of the series to compute; to compute as many as possible just give a very large number for prec; the result will still be correct.

ALIAS: power_series is identical to series.

EXAMPLES: A superingular example, where we must compute to higher precision to see anything:

```
sage: e = EllipticCurve('37a')
sage: L = e.padic_lseries(3); L
3-adic L-series of Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field
sage: L.series(2)
O(T^3)
sage: L.series(4)          # takes a long time (several seconds)
(O(3))*alpha + (O(3^2)) + ((O(3^-1))*alpha + (2*3^-1 + O(3^0)))*T + ((O(3^-1))*alpha + (2*3^
sage: L.alpha(2).parent()
Univariate Quotient Polynomial Ring in alpha over 3-adic Field with capped
relative precision 2 with modulus (1 + O(3^2))*x^2 + (3 + O(3^3))*x + (3 + O(3^3))
```

series (*n=3, quadratic_twist=1, prec=5*)

Return the n-th approximation to the p-adic L-series as a power series in T (corresponding to $\gamma - 1$ with $\gamma = 1 + p$ as a generator of $1 + p\mathbf{Z}_p$). Each coefficient is an element of a quadratic extension of the p-adic number whose precision is probably correct.

Here the normalization of the p-adic L-series is chosen such that $L_p(E,1) = (1 - 1/\alpha)^2 L(E,1)/\Omega_E$ where α is the unit root of the characteristic polynomial of Frobenius on T_pE and Ω_E is the Neron period of E.

INPUT:

- n - (default: 3) a positive integer
- prec - (default: 5) maxima number of terms of the series to compute; to compute as many as possible just give a very large number for prec; the result will still be correct.

ALIAS: power_series is identical to series.

EXAMPLES: A superingular example, where we must compute to higher precision to see anything:

```
sage: e = EllipticCurve('37a')
sage: L = e.padic_lseries(3); L
3-adic L-series of Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field
sage: L.series(2)
O(T^3)
sage: L.series(4)          # takes a long time (several seconds)
(O(3))*alpha + (O(3^2)) + ((O(3^-1))*alpha + (2*3^-1 + O(3^0)))*T + ((O(3^-1))*alpha + (2*3^
sage: L.alpha(2).parent()
Univariate Quotient Polynomial Ring in alpha over 3-adic Field with capped
relative precision 2 with modulus (1 + O(3^2))*x^2 + (3 + O(3^3))*x + (3 + O(3^3))
```

38.21 Modular symbols

To an elliptic curves E over the rational numbers one can associate a space - or better two spaces - of modular symbols of level N, equal to the conductor of E; because E is known to be modular.

There are two implementations of modular symbols, one within sage and the other as part of Cremona's eclib. One can choose here which one is used.

The normalisation of our modular symbols attached to E can be chosen, too. For instance one can make it depended on E rather than on its isogeny class. This is useful for p-adic L-functions.

For more details on modular symbols consult the following

class ModularSymbol()

A modular symbol attached to an elliptic curve, which is the map $\mathbf{Q} \to \mathbf{Q}$ obtained by sending r to the normalized symmetrized (or anti-symmetrized) integral from r to ∞.

This is as defined in [MTT], but normalized to depend on the curve and not only its isogeny class as in [SW].

See the documentation of E.modular_symbol() in Elliptic curves over the rational numbers for help.

REFERENCES:

- [MTT] B. Mazur, J. Tate, and J. Teitelbaum, On p-adic analogues of the conjectures of Birch and Swinnerton-Dyer, Inventiones mathematicae 84, (1986), 1-48.

- [SW] William Stein and Christian Wuthrich, Computations About Tate-Shafarevich Groups using Iwasawa theory, preprint 2009.

base_ring()

Return the base ring for this modular symbol.

EXAMPLES:

```
sage: m = EllipticCurve('11a1').modular_symbol()
sage: m.base_ring()
Rational Field
```

elliptic_curve()

Return the elliptic curve of this modular symbol.

EXAMPLES:

```
sage: m = EllipticCurve('11a1').modular_symbol()
sage: m.elliptic_curve()
Elliptic Curve defined by y^2 + y = x^3 - x^2 - 10*x - 20 over Rational Field
```

sign()

Return the sign of this elliptic curve modular symbol.

EXAMPLES:

```
sage: m = EllipticCurve('11a1').modular_symbol()
sage: m.sign()
1
sage: m = EllipticCurve('11a1').modular_symbol(sign=-1)
sage: m.sign()
-1
```

class ModularSymbolECLIB(*E, sign, normalize='L_ratio'*)

class ModularSymbolSage(*E, sign, normalize='L_ratio'*)

modular_symbol_space(*E, sign, base_ring, bound=None*)

Creates the space of modular symbols of a given sign over a give base_ring, attached to the isogeny class of elliptic curves.

INPUT:

- `E` - an elliptic curve over $\mathbf{Q}$
- `sign` - integer, -1, 0, or 1
- `base_ring` - ring
- `bound` - (default: None) maximum number of Hecke operators to use to cut out modular symbols factor. If None, use enough to provably get the correct answer.

OUTPUT: a space of modular symbols

EXAMPLES:

```
sage: import sage.schemes.elliptic_curves.ell_modular_symbols
sage: E=EllipticCurve('11a1')
sage: M=sage.schemes.elliptic_curves.ell_modular_symbols.modular_symbol_space(E,-1,GF(37))
sage: M
Modular Symbols space of dimension 1 for Gamma_0(11) of weight 2 with sign -1 over Finite Field
```

38.22 Tate-Shafarevich group

If E is an elliptic curve over a global field K, the Shafarevich-Tate group is the subgroup of elements in $H^1(K, E)$ which map to zero under every global-to-local restriction map $H^1(K, E) \to H^1(K_v, E)$, one for each place v of K. It is known to be a torsion group and the m-torsion is finite for all $m > 1$. It is conjectured to be a finite.

AUTHORS:

- who started this ?
- chris wuthrich (04/09) - reformat docstrings.

class Sha (E)

The Shafarevich-Tate group associated to an elliptic curve.

If E is an elliptic curve over a global field K, the Shafarevich-Tate group is the subgroup of elements in $H^1(K, E)$ which map to zero under every global-to-local restriction map $H^1(K, E) \to H^1(K_v, E)$, one for each place v of K.

EXAMPLES:

```
sage: E = EllipticCurve('389a')
sage: E.sha()
Shafarevich-Tate group for the Elliptic Curve defined by y^2 + y = x^3 + x^2 - 2*x over Rational
```

an (*use_database=False*)

Returns the Birch and Swinnerton-Dyer conjectural order of Sha as a provably corret integer, unless the analytic rank is > 1, in which case this function returns a numerical value.

INPUT: `use_database` – bool (default: False); if True, try to use any databases installed to lookup the analytic order of Sha, if possible. The order of Sha is computed if it can't be looked up.

This result is proved correct if the order of vanishing is 0 and the Manin constant is <= 2.

If the optional parameter `use_database` is True (default: False), this function returns the analytic order of Sha as listed in Cremona's tables, if this curve appears in Cremona's tables.

EXAMPLES:

```
sage: E = EllipticCurve([0, -1, 1, -10, -20])    # 11A  = X_0(11)
sage: E.sha().an()
1
sage: E = EllipticCurve([0, -1, 1, 0, 0])        # X_1(11)
sage: E.sha().an()
1

sage: EllipticCurve('14a4').sha().an()
1
sage: EllipticCurve('14a4').sha().an(use_database=True)    # will be faster if you have large
1
```

The smallest conductor curve with nontrivial Sha:

```
sage: E = EllipticCurve([1,1,1,-352,-2689])      # 66b3
sage: E.sha().an()
4
```

The four optimal quotients with nontrivial Sha and conductor <= 1000:

```
sage: E = EllipticCurve([0, -1, 1, -929, -10595])        # 571A
sage: E.sha().an()
4
sage: E = EllipticCurve([1, 1, 0, -1154, -15345])        # 681B
```

```
sage: E.sha().an()
9
sage: E = EllipticCurve([0, -1, 0, -900, -10098])        # 960D
sage: E.sha().an()
4
sage: E = EllipticCurve([0, 1, 0, -20, -42])             # 960N
sage: E.sha().an()
4
```

The smallest conductor curve of rank > 1:

```
sage: E = EllipticCurve([0, 1, 1, -2, 0])        # 389A (rank 2)
sage: E.sha().an()
1.00000000000000
```

The following are examples that require computation of the Mordell-Weil group and regulator:

```
sage: E = EllipticCurve([0, 0, 1, -1, 0])                      # 37A  (rank 1)
sage: E.sha().an()
1

sage: E = EllipticCurve("1610f3")
sage: E.sha().an()
4
```

In this case the input curve is not minimal, and if this function didn't transform it to be minimal, it would give nonsense:

```
sage: E = EllipticCurve([0,-432*6^2])
sage: E.sha().an()
1
```

an_numerical (*prec=None, use_database=True, proof=None*)

Return the numerical analytic order of Sha, which is a floating point number in all cases.

INPUT:

- `prec` - integer (default: 53) bits precision – used for the L-series computation, period, regulator, etc.
- `use_database` - whether the rank and generators should be looked up in the database if possible. Default is True
- `proof` - bool or None (default: None, see proof.[tab] or sage.structure.proof) proof option passed onto regulator and rank computation.

Note: See also the an() command, which will return a provably correct integer when the rank is 0 or 1.

Warning: If the curve's generators are not known, computing them may be very time-consuming. Also, computation of the L-series derivative will be time-consuming for large rank and large conductor, and the computation time for this may increase substantially at greater precision. However, use of very low precision less than about 10 can cause the underlying pari library functions to fail.

EXAMPLES:

```
sage: EllipticCurve('11a').sha().an_numerical()
1.00000000000000
sage: EllipticCurve('37a').sha().an_numerical() # long time
1.00000000000000
sage: EllipticCurve('389a').sha().an_numerical() # long time
1.00000000000000
sage: EllipticCurve('66b3').sha().an_numerical()
4.00000000000000
sage: EllipticCurve('5077a').sha().an_numerical() # long time
1.00000000000000
```

A rank 4 curve:

```
sage: EllipticCurve([1, -1, 0, -79, 289]).sha().an_numerical()    # long time
1.00000000000000
```

A rank 5 curve:

```
sage: EllipticCurve([0, 0, 1, -79, 342]).sha().an_numerical(prec=10, proof=False) # long tim
1.0
```

See trac #1115

```
sage: sha=EllipticCurve('37a1').sha()
sage: [sha.an_numerical(prec) for prec in xrange(40,100,10)] # long time
[1.0000000000,
1.0000000000000,
1.0000000000000000,
1.00000000000000000000,
1.000000000000000000000000,
1.0000000000000000000000000000]
```

an_padic(*p, prec=0, use_twists=True*)

Returns the conjectural order of Sha(E), according to the p-adic analogue of the Birch and Swinnerton-Dyer conjecture as formulated in [MTT] and [BP].

REFERENCES:

- [MTT] B. Mazur, J. Tate, and J. Teitelbaum, On p-adic analogues of the conjectures of Birch and Swinnerton-Dyer, Inventiones mathematicae 84, (1986), 1-48.
- [BP] Dominique Bernardi and Bernadette Perrin-Riou, Variante p-adique de la conjecture de Birch et Swinnerton-Dyer (le cas supersingulier), C. R. Acad. Sci. Paris, Ser I. Math, 317 (1993), no 3, 227-232.
- [SW] William Stein and Christian Wuthrich, Computations About Tate-Shafarevich Groups using Iwasawa theory, preprint 2009.

INPUT:

- `p` - a prime > 3
- `prec` (optional) - the precision used in the computation of the p-adic L-Series
- `use_twists` (default = True) - If true the algorithm may change use a quadratic twist with minimal conductor to do the modular symbol computations rather than using the modular symbols of the curve itself. If False it forces the computation using the modular symbols of the curve itself.

OUTPUT: p-adic number - that conjecturally equals $Sha(E)(p)$.

If prec is set to zero (default) then the precision is set so that at least the first p-adic digit of conjectural $Sha(E)(p)$ is determined.

EXAMPLES: Good ordinary examples:

```
sage: EllipticCurve('11a1').sha().an_padic(5)  #rank 0
1 + O(5^2)
sage: EllipticCurve('43a1').sha().an_padic(5)  #rank 1
1 + O(5)
sage: EllipticCurve('389a1').sha().an_padic(5,4) #rank 2   (long time)
1 + O(5^3)
sage: EllipticCurve('858k2').sha().an_padic(7)  #rank 0, non trivial sha  (long time)
7^2 + O(7^3)
sage: EllipticCurve('300b2').sha().an_padic(3)  # an example with 9 elements in sha
3^2 + O(3^3)
sage: EllipticCurve('300b2').sha().an_padic(7)
2 + 7 + O(7^4)
```

Exceptional cases:

```
sage: EllipticCurve('11a1').sha().an_padic(11) #rank 0
1 + O(11)
```

The output has the correct sign

```
sage: EllipticCurve('123a1').sha().an_padic(41) #rank 1    (long time)
1 + O(41)
sage: EllipticCurve('817a1').sha().an_padic(43) #rank 2    (long time)
1 + O(43)
```

Supersingular cases:

```
sage: EllipticCurve('34a1').sha().an_padic(5) # rank 0     (long time)
1 + O(5^3)
sage: EllipticCurve('43a1').sha().an_padic(7) # rank 1    (very long time -- nearly a minute
1 + O(7)
sage: EllipticCurve('1483a1').sha().an_padic(5) # rank 2   (long time)
1 + O(5)
```

Cases that use a twist to a lower conductor

```
sage: EllipticCurve('99a1').sha().an_padic(5)
1 + O(5)
sage: EllipticCurve('240d3').sha().an_padic(5)  # sha has 4 elements here
4 + O(5)
sage: EllipticCurve('448c5').sha().an_padic(7,prec=4)  # long time
2 + 7 + O(7^3)
```

bound()

Compute a provably correct bound on the order of the Shafarevich-Tate group of this curve. The bound is a either False (no bound) or a list B of primes such that any divisor of Sha is in this list.

EXAMPLES:

```
sage: EllipticCurve('37a').sha().bound()
([2], 1)
```

bound_kato()

Returns a list p of primes such that the theorems of Kato's [Ka] and others (e.g., as explained in a paper/thesis of Grigor Grigorov [Gri]) imply that if p divides the order of Sha(E) then p is in the list.

If $L(E,1) = 0$, then this function gives no information, so it returns False.

THEOREM (Kato): Suppose $p \geq 5$ is a prime so the p-adic representation $\rho_{E,p}$ is surjective and $L(E,1) \neq 0$. Then $ord_p(\#Sha(E))$ divides $ord_p(L(E,1)/\Omega_E)$.

EXAMPLES:

```
sage: E = EllipticCurve([0, -1, 1, -10, -20])    # 11A  = X_0(11)
sage: E.sha().bound_kato()
[2, 3, 5]
sage: E = EllipticCurve([0, -1, 1, 0, 0])        # X_1(11)
sage: E.sha().bound_kato()
[2, 3, 5]
sage: E = EllipticCurve([1,1,1,-352,-2689])      # 66B3
sage: E.sha().bound_kato()
[2, 3]
```

For the following curve one really has that 25 divides the order of Sha (by Grigorov-Stein paper [GS]):

```
sage: E = EllipticCurve([1, -1, 0, -332311, -73733731])    # 1058D1
sage: E.sha().bound_kato()                  # long time (about 1 second)
[2, 3, 5]
sage: E.non_surjective()                # long time (about 1 second)
[]
```

For this one, Sha is divisible by 7:

```
sage: E = EllipticCurve([0, 0, 0, -4062871, -3152083138])    # 3364C1
sage: E.sha().bound_kato()                  # long time (< 10 seconds)
[2, 3, 7]
```

No information about curves of rank > 0:

```
sage: E = EllipticCurve([0, 0, 1, -1, 0])        # 37A  (rank 1)
sage: E.sha().bound_kato()
False
```

bound_kolyvagin(*D=0, regulator=None, ignore_nonsurj_hypothesis=False*)

Given a fundamental discriminant $D \neq -3, -4$ that satisfies the Heegner hypothesis for E, return a list of primes so that Kolyvagin's theorem (as in Gross's paper) implies that any prime divisor of Sha is in this list.

INPUT:

- `D` - (optional) a fundamental discriminant < -4 that satisfies the Heegner hypothesis for E; if not given, use the first such D
- `regulator` – (optional) regulator of $E(K)$; if not given, will be computed (which could take a long time)
- `ignore_nonsurj_hypothesis` (optional: default False) – If True, then gives the bound coming from Heegner point index, but without any hypothesis on surjectivity of the mod-p representation.

OUTPUT:

- list - a list of primes such that if p divides Sha(E/K), then p is in this list, unless E/K has complex multiplication or analytic rank greater than 2 (in which case we return 0).
- index - the odd part of the index of the Heegner point in the full group of K-rational points on E. (If E has CM, returns 0.)

REMARKS:

1. We do not have to assume that the Manin constant is 1 (or a power of 2). If the Manin constant were divisible by a prime, that prime would get included in the list of bad primes.
2. We assume the Gross-Zagier theorem is True under the hypothesis that $gcd(N, D) = 1$, instead of the stronger hypothesis $gcd(2 \cdot N, D) = 1$ that is in the original Gross-Zagier paper. That Gross-Zagier is true when $gcd(N, D) = 1$ is"well-known" to the experts, but doesn't seem to written up well in the literature.
3. Correctness of the computation is guaranteed using interval arithmetic, under the assumption that the regulator, square root, and period lattice are computed to precision at least 10^{-10}, i.e., they are correct up to addition or a real number with absolute value less than 10^{-10}.

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: E.sha().bound_kolyvagin()
([2], 1)
sage: E = EllipticCurve('141a')
sage: E.sha().an()
1
sage: E.sha().bound_kolyvagin()
([2, 7], 49)
```

We get no information the curve has rank 2.:

```
sage: E = EllipticCurve('389a')
sage: E.sha().bound_kolyvagin()
(0, 0)
sage: E = EllipticCurve('681b')
sage: E.sha().an()
9
sage: E.sha().bound_kolyvagin()
([2, 3], 9)
```

p_primary_bound(*p*)

Returns a provable upper bound for the order of $Sha(E)(p)$. In particular, if this algorithm does not fail, then it proves that the p-primary part of Sha is finite.

INPUT: p – a prime > 3

OUTPUT: integer – power of p that bounds $Sha(E)(p)$ from above

The result is a proven upper bound on the order of $Sha(E)(p)$. So in particular it proves it finiteness even if the rank of the curve is larger than 1. Note also that this bound is sharp if one assumes the main conjecture of Iwasawa theory of elliptic curves (and this is known in certain cases).

EXAMPLES:

```
sage: e = EllipticCurve('11a3')
sage: e.sha().p_primary_bound(5)
0
sage: e.sha().p_primary_bound(7)
0
sage: e.sha().p_primary_bound(11)
0
sage: e.sha().p_primary_bound(13)
0

sage: e = EllipticCurve('389a1')
sage: e.sha().p_primary_bound(5)
0
sage: e.sha().p_primary_bound(7)
0
sage: e.sha().p_primary_bound(11)
0
sage: e.sha().p_primary_bound(13)
0

sage: e = EllipticCurve('858k2')
sage: e.sha().p_primary_bound(3)           # long time
0
sage: e.sha().p_primary_bound(7)           # long time
2
```

two_selmer_bound()

This returns a lower bound on the $\mathbb{F}_2$-dimension of the 2-torsion part of Sha, provided we can determine the rank of E. But it is not the best possible bound.

TO DO: This should be rewritten, to give the exact order of Sha[2], or if we can not find sufficently many points it should give a lower bound.

EXAMPLE:

```
sage: sh = EllipticCurve('571a1').sha()
sage: sh.two_selmer_bound()
2
sage: sh.an()
```

```
4

sage: sh = EllipticCurve('66a1').sha()
sage: sh.two_selmer_bound()
0
sage: sh.an()
1

sage: sh = EllipticCurve('960d1').sha()
sage: sh.two_selmer_bound()
0
sage: sh.an()
4
```

38.23 Miscellaneous p-adic functions

p-adic functions from ell_rational_field.py, moved here to reduce crowding in that file.

matrix_of_frobenius (*self, p, prec=20, check=False, check_hypotheses=True, algorithm='auto'*)
See the parameters and documentation for padic_E2.

padic_E2 (*self, p, prec=20, check=False, check_hypotheses=True, algorithm='auto'*)
Returns the value of the p-adic modular form $E2$ for (E, ω) where ω is the usual invariant differential $dx/(2y + a_1x + a_3)$.

INPUT:

- `p` - prime (= 5) for which E is good and ordinary
- `prec` - (relative) p-adic precision (= 1) for result
- `check` - boolean, whether to perform a consistency check. This will slow down the computation by a constant factor 2. (The consistency check is to compute the whole matrix of frobenius on Monsky-Washnitzer cohomology, and verify that its trace is correct to the specified precision. Otherwise, the trace is used to compute one column from the other one (possibly after a change of basis).)
- `check_hypotheses` - boolean, whether to check that this is a curve for which the p-adic sigma function makes sense
- `algorithm` - one of "standard", "sqrtp", or "auto". This selects which version of Kedlaya's algorithm is used. The "standard" one is the one described in Kedlaya's paper. The "sqrtp" one has better performance for large p, but only works when $p > 6N$ (N = prec). The "auto" option selects "sqrtp" whenever possible.

  Note that if the "sqrtp" algorithm is used, a consistency check will automatically be applied, regardless of the setting of the "check" flag.

OUTPUT: p-adic number to precision prec

Note: If the discriminant of the curve has nonzero valuation at p, then the result will not be returned mod p^{prec}, but it still *will* have prec *digits* of precision.

TODO: - Once we have a better implementation of the "standard" algorithm, the algorithm selection strategy for "auto" needs to be revisited.

AUTHORS:

- David Harvey (2006-09-01): partly based on code written by Robert Bradshaw at the MSRI 2006 modular forms workshop

ACKNOWLEDGMENT: - discussion with Eyal Goren that led to the trace trick.

EXAMPLES: Here is the example discussed in the paper "Computation of p-adic Heights and Log Convergence" (Mazur, Stein, Tate):

```
sage: EllipticCurve([-1, 1/4]).padic_E2(5)
2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + 4*5^10 + 2*5^11 + 2*5^12 + 2*5^14 + 3*5^15
```

Let's try to higher precision (this is the same answer the MAGMA implementation gives):

```
sage: EllipticCurve([-1, 1/4]).padic_E2(5, 100)
2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + 4*5^10 + 2*5^11 + 2*5^12 + 2*5^14 + 3*5^15
```

Check it works at low precision too:

```
sage: EllipticCurve([-1, 1/4]).padic_E2(5, 1)
2 + O(5)
sage: EllipticCurve([-1, 1/4]).padic_E2(5, 2)
2 + 4*5 + O(5^2)
sage: EllipticCurve([-1, 1/4]).padic_E2(5, 3)
2 + 4*5 + O(5^3)
```

TODO: With the old(-er), i.e., = sage-2.4 p-adics we got $5 + O(5^2)$ as output, i.e., relative precision 1, but with the newer p-adics we get relative precision 0 and absolute precision 1.

```
sage: EllipticCurve([1, 1, 1, 1, 1]).padic_E2(5, 1)
O(5)
```

Check it works for different models of the same curve (37a), even when the discriminant changes by a power of p (note that E2 depends on the differential too, which is why it gets scaled in some of the examples below):

```
sage: X1 = EllipticCurve([-1, 1/4])
sage: X1.j_invariant(), X1.discriminant()
 (110592/37, 37)
sage: X1.padic_E2(5, 10)
 2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + O(5^10)

sage: X2 = EllipticCurve([0, 0, 1, -1, 0])
sage: X2.j_invariant(), X2.discriminant()
 (110592/37, 37)
sage: X2.padic_E2(5, 10)
 2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + O(5^10)

sage: X3 = EllipticCurve([-1*(2**4), 1/4*(2**6)])
sage: X3.j_invariant(), X3.discriminant() / 2**12
 (110592/37, 37)
sage: 2**(-2) * X3.padic_E2(5, 10)
 2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + O(5^10)

sage: X4 = EllipticCurve([-1*(7**4), 1/4*(7**6)])
sage: X4.j_invariant(), X4.discriminant() / 7**12
 (110592/37, 37)
sage: 7**(-2) * X4.padic_E2(5, 10)
 2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + O(5^10)
```

```
sage: X5 = EllipticCurve([-1*(5**4), 1/4*(5**6)])
sage: X5.j_invariant(), X5.discriminant() / 5**12
 (110592/37, 37)
sage: 5**(-2) * X5.padic_E2(5, 10)
 2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + O(5^10)

sage: X6 = EllipticCurve([-1/(5**4), 1/4/(5**6)])
sage: X6.j_invariant(), X6.discriminant() * 5**12
 (110592/37, 37)
sage: 5**2 * X6.padic_E2(5, 10)
 2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + O(5^10)
```

Test check=True vs check=False:

```
sage: EllipticCurve([-1, 1/4]).padic_E2(5, 1, check=False)
2 + O(5)
sage: EllipticCurve([-1, 1/4]).padic_E2(5, 1, check=True)
2 + O(5)
sage: EllipticCurve([-1, 1/4]).padic_E2(5, 30, check=False)
2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + 4*5^10 + 2*5^11 + 2*5^12 + 2*5^14 + 3*5^15
sage: EllipticCurve([-1, 1/4]).padic_E2(5, 30, check=True)
2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + 5^8 + 3*5^9 + 4*5^10 + 2*5^11 + 2*5^12 + 2*5^14 + 3*5^15
```

Here's one using the $p^{1/2}$ algorithm:

```
sage: EllipticCurve([-1, 1/4]).padic_E2(3001, 3, algorithm="sqrtp")
1907 + 2819*3001 + 1124*3001^2 + O(3001^3)
```

padic_height (*self, p, prec=20, sigma=None, check_hypotheses=True*)

Computes the cyclotomic p-adic height.

The equation of the curve must be minimal at p.

INPUT:

- `p` - prime = 5 for which the curve has semi-stable reduction
- `prec` - integer = 1, desired precision of result
- `sigma` - precomputed value of sigma. If not supplied, this function will call padic_sigma to compute it.
- `check_hypotheses` - boolean, whether to check that this is a curve for which the p-adic height makes sense

OUTPUT: A function that accepts two parameters:

- a Q-rational point on the curve whose height should be computed
- optional boolean flag 'check': if False, it skips some input checking, and returns the p-adic height of that point to the desired precision.
- The normalization (sign and a factor 1/2 with respect to some other normalizations that appear in the literature) is chosen in such a way as to make the p-adic Birch Swinnerton-Dyer conjecture hold as stated in [Mazur-Tate-Teitelbaum].

AUTHORS:

- Jennifer Balakrishnan: original code developed at the 2006 MSRI graduate workshop on modular forms
- David Harvey (2006-09-13): integrated into Sage, optimised to speed up repeated evaluations of the returned height function, addressed some thorny precision questions
- David Harvey (2006-09-30): rewrote to use division polynomials for computing denominator of nP.

•David Harvey (2007-02): cleaned up according to algorithms in "Efficient Computation of p-adic Heights"

•Chris Wuthrich (2007-05): added supersingular and multiplicative heights

EXAMPLES:

```
sage: E = EllipticCurve("37a")
sage: P = E.gens()[0]
sage: h = E.padic_height(5, 10)
sage: h(P)
5 + 5^2 + 5^3 + 3*5^6 + 4*5^7 + 5^9 + O(5^10)
```

An anomalous case:

```
sage: h = E.padic_height(53, 10)
sage: h(P)
26*53^-1 + 30 + 20*53 + 47*53^2 + 10*53^3 + 32*53^4 + 9*53^5 + 22*53^6 + 35*53^7 + 30*53^8 + 17*
```

Boundary case:

```
sage: E.padic_height(5, 3)(P)
5 + 5^2 + O(5^3)
```

A case that works the division polynomial code a little harder:

```
sage: E.padic_height(5, 10)(5*P)
5^3 + 5^4 + 5^5 + 3*5^8 + 4*5^9 + O(5^10)
```

Check that answers agree over a range of precisions:

```
sage: max_prec = 30    # make sure we get past p^2    # long time
sage: full = E.padic_height(5, max_prec)(P)           # long time
sage: for prec in range(1, max_prec):                 # long time
...       assert E.padic_height(5, prec)(P) == full   # long time
```

A supersingular prime for a curve:

```
sage: E = EllipticCurve('37a')
sage: E.is_supersingular(3)
True
sage: h = E.padic_height(3, 5)
sage: h(E.gens()[0])
(3 + 3^3 + O(3^6), 2*3^2 + 3^3 + 3^4 + 3^5 + 2*3^6 + O(3^7))
sage: E.padic_regulator(5)
5 + 5^2 + 5^3 + 3*5^6 + 4*5^7 + 5^9 + 5^10 + 3*5^11 + 3*5^12 + 5^13 + 4*5^14 + 5^15 + 2*5^16 + 5
sage: E.padic_regulator(3, 5)
(3 + 2*3^2 + 3^3 + O(3^4), 3^2 + 2*3^3 + 3^4 + O(3^5))
```

A torsion point in both the good and supersingular cases:

```
sage: E = EllipticCurve('11a')
sage: P = E.torsion_subgroup().gens()[0]; P
(5 : 5 : 1)
sage: h = E.padic_height(19, 5)
sage: h(P)
0
sage: h = E.padic_height(5, 5)
sage: h(P)
0
```

The result is not dependend on the model for the curve: sage: E = EllipticCurve([0,0,0,0,2^12*17]) sage: Em = E.minimal_model() sage: P = E.gens()[0] sage: Pm = Em.gens()[0] sage: h = E.padic_height(7) sage: hm = Em.padic_height(7) sage: h(P) == hm(Pm) True

padic_height_pairing_matrix(*self, p, prec=20, height=None, check_hypotheses=True*)

Computes the cyclotomic p-adic height pairing matrix of this curve with respect to the basis self.gens() for the Mordell-Weil group for a given odd prime p of good ordinary reduction.

INPUT:

- `p` - prime = 5
- `prec` - answer will be returned modulo p^{prec}
- `height` - precomputed height function. If not supplied, this function will call padic_height to compute it.
- `check_hypotheses` - boolean, whether to check that this is a curve for which the p-adic height makes sense

OUTPUT: The p-adic cyclotomic height pairing matrix of this curve to the given precision.

TODO: - remove restriction that curve must be in minimal weierstrass form. This is currently required for E.gens().

AUTHORS:

- David Harvey, Liang Xiao, Robert Bradshaw, Jennifer Balakrishnan: original implementation at the 2006 MSRI graduate workshop on modular forms
- David Harvey (2006-09-13): cleaned up and integrated into Sage, removed some redundant height computations

EXAMPLES:

```
sage: E = EllipticCurve("37a")
sage: E.padic_height_pairing_matrix(5, 10)
[5 + 5^2 + 5^3 + 3*5^6 + 4*5^7 + 5^9 + O(5^10)]
```

A rank two example:

```
sage: e =EllipticCurve('389a')
sage: e._set_gens([e(-1, 1), e(1,0)])  # avoid platform dependent gens
sage: e.padic_height_pairing_matrix(5,10)
[                      3*5 + 2*5^2 + 5^4 + 5^5 + 5^7 + 4*5^9 + O(5^10) 5 + 4*5^2 + 5^3 + 2*5^4 +
[5 + 4*5^2 + 5^3 + 2*5^4 + 3*5^5 + 4*5^6 + 5^7 + 5^8 + 2*5^9 + O(5^10)                           4
```

An anomalous rank 3 example:

```
sage: e = EllipticCurve("5077a")
sage: e._set_gens([e(-1,3), e(2,0), e(4,6)])
sage: e.padic_height_pairing_matrix(5,4)
[4 + 3*5 + 4*5^2 + 4*5^3 + O(5^4)       4 + 4*5^2 + 2*5^3 + O(5^4)       3*5 + 4*5^2 + 5^3 + O(5
[      4 + 4*5^2 + 2*5^3 + O(5^4)   3 + 4*5 + 3*5^2 + 5^3 + O(5^4)               2 + 4*5 + O(5
[      3*5 + 4*5^2 + 5^3 + O(5^4)                 2 + 4*5 + O(5^4)     1 + 3*5 + 5^2 + 5^3 + O(5
```

padic_height_via_multiply(*self, p, prec=20, E2=None, check_hypotheses=True*)

Computes the cyclotomic p-adic height.

The equation of the curve must be minimal at p.

INPUT:

- `p` - prime = 5 for which the curve has good ordinary reduction

- `prec` - integer = 2, desired precision of result
- `E2` - precomputed value of E2. If not supplied, this function will call padic_E2 to compute it. The value supplied must be correct mod $p^(prec - 2)$ (or slightly higher in the anomalous case; see the code for details).
- `check_hypotheses` - boolean, whether to check that this is a curve for which the p-adic height makes sense

OUTPUT: A function that accepts two parameters:

- a Q-rational point on the curve whose height should be computed
- optional boolean flag 'check': if False, it skips some input checking, and returns the p-adic height of that point to the desired precision.
- The normalization (sign and a factor 1/2 with respect to some other normalizations that appear in the literature) is chosen in such a way as to make the p-adic Birch Swinnerton-Dyer conjecture hold as stated in [Mazur-Tate-Teitelbaum].

AUTHORS:

- David Harvey (2008-01): based on the padic_height() function, using the algorithm of"Computing p-adic heights via point multiplication"

EXAMPLES:

```
sage: E = EllipticCurve("37a")
sage: P = E.gens()[0]
sage: h = E.padic_height_via_multiply(5, 10)
sage: h(P)
5 + 5^2 + 5^3 + 3*5^6 + 4*5^7 + 5^9 + O(5^10)
```

An anomalous case:

```
sage: h = E.padic_height_via_multiply(53, 10)
sage: h(P)
26*53^-1 + 30 + 20*53 + 47*53^2 + 10*53^3 + 32*53^4 + 9*53^5 + 22*53^6 + 35*53^7 + 30*53^8 + 17*
```

Supply the value of E2 manually:

```
sage: E2 = E.padic_E2(5, 8)
sage: E2
2 + 4*5 + 2*5^3 + 5^4 + 3*5^5 + 2*5^6 + O(5^8)
sage: h = E.padic_height_via_multiply(5, 10, E2=E2)
sage: h(P)
5 + 5^2 + 5^3 + 3*5^6 + 4*5^7 + 5^9 + O(5^10)
```

Boundary case:

```
sage: E.padic_height_via_multiply(5, 3)(P)
5 + 5^2 + O(5^3)
```

Check that answers agree over a range of precisions:

```
sage: max_prec = 30    # make sure we get past p^2    # long time
sage: full = E.padic_height(5, max_prec)(P)           # long time
sage: for prec in range(2, max_prec):                 # long time
...       assert E.padic_height_via_multiply(5, prec)(P) == full   # long time
```

padic_lseries(*self, p, normalize='L_ratio', use_eclib=False*)

Return the p-adic L-series of self at p, which is an object whose approx method computes approximation to the true p-adic L-series to any desired precision.

INPUT:

- p - prime
- use_eclib - bool (default:False); whether or not to use John Cremona's eclib for the computation of modular symbols
- normalize - 'L_ratio' (default), 'period' or 'none'; this is describes the way the modular symbols are normalized. See modular_symbol for more details.

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: L = E.padic_lseries(5); L
5-adic L-series of Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field
sage: type(L)
<class 'sage.schemes.elliptic_curves.padic_lseries.pAdicLseriesOrdinary'>
```

We compute the 3-adic L-series of two curves of rank 0 and in each case verify the interpolation property for their leading coefficient (i.e., value at 0):

```
sage: e = EllipticCurve('11a')
sage: ms = e.modular_symbol()
sage: [ms(1/11), ms(1/3), ms(0), ms(oo)]
[0, -3/10, 1/5, 0]
sage: ms(0)
1/5
sage: L = e.padic_lseries(3)
sage: P = L.series(5)
sage: P(0)
2 + 3 + 3^2 + 2*3^3 + 2*3^5 + 3^6 + O(3^7)
sage: alpha = L.alpha(9); alpha
2 + 3^2 + 2*3^3 + 2*3^4 + 2*3^6 + 3^8 + O(3^9)
sage: R.<x> = QQ[]
sage: f = x^2 - e.ap(3)*x + 3
sage: f(alpha)
O(3^9)
sage: r = e.lseries().L_ratio(); r
1/5
sage: (1 - alpha^(-1))^2 * r
2 + 3 + 3^2 + 2*3^3 + 2*3^5 + 3^6 + 3^7 + O(3^9)
sage: P(0)
2 + 3 + 3^2 + 2*3^3 + 2*3^5 + 3^6 + O(3^7)
```

Next consider the curve 37b:

```
sage: e = EllipticCurve('37b')
sage: L = e.padic_lseries(3)
sage: P = L.series(5)
sage: alpha = L.alpha(9); alpha
1 + 2*3 + 3^2 + 2*3^5 + 2*3^7 + 3^8 + O(3^9)
sage: r = e.lseries().L_ratio(); r
1/3
sage: (1 - alpha^(-1))^2 * r
3 + 3^2 + 2*3^4 + 2*3^5 + 2*3^6 + 3^7 + O(3^9)
sage: P(0)
3 + 3^2 + 2*3^4 + 2*3^5 + O(3^6)
```

We can use eclib to compute the L-series:

```
sage: e = EllipticCurve('11a')
sage: L = e.padic_lseries(3,use_eclib=True)
sage: L.series(5,prec=10)
1 + 2*3^3 + 3^6 + O(3^7) + (2 + 2*3 + 3^2 + O(3^4))*T + (2 + 3 + 3^2 + 2*3^3 + O(3^4))*T^2 + (2*
```

padic_regulator(*self, p, prec=20, height=None, check_hypotheses=True*)

Computes the cyclotomic p-adic regulator of this curve.

INPUT:

- p - prime = 5
- prec - answer will be returned modulo p^{prec}
- height - precomputed height function. If not supplied, this function will call padic_height to compute it.
- check_hypotheses - boolean, whether to check that this is a curve for which the p-adic height makes sense

OUTPUT: The p-adic cyclotomic regulator of this curve, to the requested precision.

If the rank is 0, we output 1.

TODO: - remove restriction that curve must be in minimal weierstrass form. This is currently required for E.gens().

AUTHORS:

- Liang Xiao: original implementation at the 2006 MSRI graduate workshop on modular forms
- David Harvey (2006-09-13): cleaned up and integrated into Sage, removed some redundant height computations
- Chris Wuthrich (2007-05-22): added multiplicative and supersingular cases
- David Harvey (2007-09-20): fixed some precision loss that was occurring

EXAMPLES:

```
sage: E = EllipticCurve("37a")
sage: E.padic_regulator(5, 10)
5 + 5^2 + 5^3 + 3*5^6 + 4*5^7 + 5^9 + O(5^10)
```

An anomalous case:

```
sage: E.padic_regulator(53, 10)
26*53^-1 + 30 + 20*53 + 47*53^2 + 10*53^3 + 32*53^4 + 9*53^5 + 22*53^6 + 35*53^7 + 30*53^8 + O(5
```

An anomalous case where the precision drops some:

```
sage: E = EllipticCurve("5077a")
sage: E.padic_regulator(5, 10)
5 + 5^2 + 4*5^3 + 2*5^4 + 2*5^5 + 2*5^6 + 4*5^7 + 2*5^8 + 5^9 + O(5^10)
```

Check that answers agree over a range of precisions:

```
sage: max_prec = 30    # make sure we get past p^2    # long time
sage: full = E.padic_regulator(5, max_prec)           # long time
sage: for prec in range(1, max_prec):                 # long time
...       assert E.padic_regulator(5, prec) == full   # long time
```

A case where the generator belongs to the formal group already (trac #3632):

```
sage: E = EllipticCurve([37,0])
sage: E.padic_regulator(5,10)
2*5^2 + 2*5^3 + 5^4 + 5^5 + 4*5^6 + 3*5^8 + 4*5^9 + O(5^10)
```

The result is not dependend on the model for the curve:

```
sage: E = EllipticCurve([0,0,0,0,2^12*17])
sage: Em = E.minimal_model()
sage: E.padic_regulator(7) == Em.padic_regulator(7)
True
```

padic_sigma(*self, p, N=20, E2=None, check=False, check_hypotheses=True*)

Computes the p-adic sigma function with respect to the standard invariant differential $dx/(2y + a_1x + a_3)$, as defined by Mazur and Tate, as a power series in the usual uniformiser t at the origin.

The equation of the curve must be minimal at p.

INPUT:

- `p` - prime = 5 for which the curve has good ordinary reduction
- `N` - integer = 1, indicates precision of result; see OUTPUT section for description
- `E2` - precomputed value of E2. If not supplied, this function will call padic_E2 to compute it. The value supplied must be correct mod p^{N-2}.
- `check` - boolean, whether to perform a consistency check (i.e. verify that the computed sigma satisfies the defining
- `differential equation` - note that this does NOT guarantee correctness of all the returned digits, but it comes pretty close :-))
- `check_hypotheses` - boolean, whether to check that this is a curve for which the p-adic sigma function makes sense

OUTPUT: A power series $t + \cdots$ with coefficients in $\mathbf{Z}_p$.

The output series will be truncated at $O(t^{N+1})$, and the coefficient of t^n for $n \geq 1$ will be correct to precision $O(p^{N-n+1})$.

In practice this means the following. If $t_0 = p^k u$, where u is a p-adic unit with at least N digits of precision, and $k \geq 1$, then the returned series may be used to compute $\sigma(t_0)$ correctly modulo p^{N+k} (i.e. with N correct p-adic digits).

ALGORITHM: Described in "Efficient Computation of p-adic Heights" (David Harvey), which is basically an optimised version of the algorithm from "p-adic Heights and Log Convergence" (Mazur, Stein, Tate).

Running time is soft-$O(N^2 \log p)$, plus whatever time is necessary to compute E_2.

AUTHORS:

- David Harvey (2006-09-12)
- David Harvey (2007-02): rewrote

EXAMPLES:

```
sage: EllipticCurve([-1, 1/4]).padic_sigma(5, 10)
O(5^11) + (1 + O(5^10))*t + O(5^9)*t^2 + (3 + 2*5^2 + 3*5^3 + 3*5^6 + 4*5^7 + O(5^8))*t^3 + O(5^
```

Run it with a consistency check:

```
sage: EllipticCurve("37a").padic_sigma(5, 10, check=True)
O(5^11) + (1 + O(5^10))*t + O(5^9)*t^2 + (3 + 2*5^2 + 3*5^3 + 3*5^6 + 4*5^7 + O(5^8))*t^3 + (3 +
```

Boundary cases:

```
sage: EllipticCurve([1, 1, 1, 1, 1]).padic_sigma(5, 1)
 (1 + O(5))*t + O(t^2)
sage: EllipticCurve([1, 1, 1, 1, 1]).padic_sigma(5, 2)
 (1 + O(5^2))*t + (3 + O(5))*t^2 + O(t^3)
```

Supply your very own value of E2:

```
sage: X = EllipticCurve("37a")
sage: my_E2 = X.padic_E2(5, 8)
sage: my_E2 = my_E2 + 5**5    # oops!!!
sage: X.padic_sigma(5, 10, E2=my_E2)
O(5^11) + (1 + O(5^10))*t + O(5^9)*t^2 + (3 + 2*5^2 + 3*5^3 + 4*5^5 + 2*5^6 + 3*5^7 + O(5^8))*t^
```

Check that sigma is "weight 1".

```
sage: f = EllipticCurve([-1, 3]).padic_sigma(5, 10)
sage: g = EllipticCurve([-1*(2**4), 3*(2**6)]).padic_sigma(5, 10)
sage: t = f.parent().gen()
sage: f(2*t)/2
(1 + O(5^10))*t + (4 + 3*5 + 3*5^2 + 3*5^3 + 4*5^4 + 4*5^5 + 3*5^6 + 5^7 + O(5^8))*t^3 + (3 + 3*
sage: g
O(5^11) + (1 + O(5^10))*t + O(5^9)*t^2 + (4 + 3*5 + 3*5^2 + 3*5^3 + 4*5^4 + 4*5^5 + 3*5^6 + 5^7
sage: f(2*t)/2 -g
O(t^11)
```

Test that it returns consistent results over a range of precision:

```
sage: max_N = 30   # get up to at least p^2          # long time
sage: E = EllipticCurve([1, 1, 1, 1, 1])             # long time
sage: p = 5                                          # long time
sage: E2 = E.padic_E2(5, max_N)                      # long time
sage: max_sigma = E.padic_sigma(p, max_N, E2=E2)     # long time
sage: for N in range(3, max_N):                      # long time
...       sigma = E.padic_sigma(p, N, E2=E2)         # long time
...       assert sigma == max_sigma
```

padic_sigma_truncated(*self, p, N=20, lamb=0, E2=None, check_hypotheses=True*)

Computes the p-adic sigma function with respect to the standard invariant differential $dx/(2y + a_1x + a_3)$, as defined by Mazur and Tate, as a power series in the usual uniformiser t at the origin.

The equation of the curve must be minimal at p.

This function differs from padic_sigma() in the precision profile of the returned power series; see OUTPUT below.

INPUT:

- `p` - prime = 5 for which the curve has good ordinary reduction
- `N` - integer = 2, indicates precision of result; see OUTPUT section for description
- `lamb` - integer = 0, see OUTPUT section for description
- `E2` - precomputed value of E2. If not supplied, this function will call padic_E2 to compute it. The value supplied must be correct mod p^{N-2}.
- `check_hypotheses` - boolean, whether to check that this is a curve for which the p-adic sigma function makes sense

OUTPUT: A power series $t + \cdots$ with coefficients in $\mathbf{Z}_p$.

The coefficient of t^j for $j \geq 1$ will be correct to precision $O(p^{N-2+(3-j)(lamb+1)})$.

ALGORITHM: Described in "Efficient Computation of p-adic Heights" (David Harvey, to appear in LMS JCM), which is basically an optimised version of the algorithm from "p-adic Heights and Log Convergence" (Mazur, Stein, Tate), and "Computing p-adic heights via point multiplication" (David Harvey, still draft form).

Running time is soft-$O(N^2\lambda^{-1}\log p)$, plus whatever time is necessary to compute E_2.

AUTHOR:

- David Harvey (2008-01): wrote based on previous padic_sigma function

EXAMPLES:

```
sage: E = EllipticCurve([-1, 1/4])
sage: E.padic_sigma_truncated(5, 10)
O(5^11) + (1 + O(5^10))*t + O(5^9)*t^2 + (3 + 2*5^2 + 3*5^3 + 3*5^6 + 4*5^7 + O(5^8))*t^3 + O(5^
```

Note the precision of the t^3 coefficient depends only on N, not on lamb:

```
sage: E.padic_sigma_truncated(5, 10, lamb=2)
O(5^17) + (1 + O(5^14))*t + O(5^11)*t^2 + (3 + 2*5^2 + 3*5^3 + 3*5^6 + 4*5^7 + O(5^8))*t^3 + O(5
```

Compare against plain padic_sigma() function over a dense range of N and lamb

```
sage: E = EllipticCurve([1, 2, 3, 4, 7])                              # long time
sage: E2 = E.padic_E2(5, 50)                                          # long time
sage: for N in range(2, 10):                                          # long time
...       for lamb in range(10):                                      # long time
...           correct = E.padic_sigma(5, N + 3*lamb, E2=E2)           # long time
...           compare = E.padic_sigma_truncated(5, N=N, lamb=lamb, E2=E2)    # long time
...           assert compare == correct                               # long time
```

CHAPTER

THIRTYNINE

HYPERELLIPTIC CURVES

39.1 Hyperelliptic curve constructor

HyperellipticCurve (*f, h=None, names=None, PP=None*)

Returns the hyperelliptic curve $y^2 + hy = f$, for univariate polynomials h and f. If h is not given, then it defaults to 0.

INPUT:

- `f` - univariate polynomial
- `h` - optional univariate polynomial

EXAMPLES: A curve with and without the h term:

```
sage: R.<x> = QQ[]
sage: HyperellipticCurve(x^5 + x + 1)
Hyperelliptic Curve over Rational Field defined by y^2 = x^5 + x + 1
sage: HyperellipticCurve(x^19 + x + 1, x-2)
Hyperelliptic Curve over Rational Field defined by y^2 + (x - 2)*y = x^19 + x + 1
```

A curve over a non-prime finite field:

```
sage: k.<a> = GF(9); R.<x> = k[]
sage: HyperellipticCurve(x^3 + x - 1, x+a)
Hyperelliptic Curve over Finite Field in a of size 3^2 defined by y^2 + (x + a)*y = x^3 + x + 2
```

Here's one where we change the names of the vars in the homogeneous polynomial:

```
sage: k.<a> = GF(9); R.<x> = k[]
sage: HyperellipticCurve(x^3 + x - 1, x+a, names=['X','Y'])
Hyperelliptic Curve over Finite Field in a of size 3^2 defined by Y^2 + (X + a)*Y = X^3 + X + 2
```

39.2 Hyperelliptic curves over a finite field

EXAMPLES:

```
sage: K.<a> = GF(9, 'a')
sage: x = polygen(K)
sage: C = HyperellipticCurve(x^7 - x^5 - 2, x^2 + a)
sage: C._points_fast_sqrt()
[(0 : 1 : 0), (2*a : 2*a + 2 : 1), (2*a : 2*a : 1), (a + 1 : a : 1), (a + 1 : a + 1 : 1), (2 : a + 1
```

class HyperellipticCurve_finite_field(*PP, f, h=None, names=None, genus=None*)

frobenius_polynomial()

Charpoly of frobenius, as an element of ZZ[x].

TESTS:: sage: R.<t> = PolynomialRing(GF(37)) sage: H = HyperellipticCurve(t^5 + t + 2) sage: H.frobenius_polynomial() x^4 + x^3 - 52*x^2 + 37*x + 1369

A quadratic twist: sage: H = HyperellipticCurve(2*t^5 + 2*t + 4) sage: H.frobenius_polynomial() x^4 - x^3 - 52*x^2 - 37*x + 1369

points()

All the points on this hyperelliptic curve.

EXAMPLES:

```
sage: x = polygen(GF(7))
sage: C = HyperellipticCurve(x^7 - x^2 - 1)
sage: C.points()
[(0 : 1 : 0), (2 : 5 : 1), (2 : 2 : 1), (3 : 0 : 1), (4 : 6 : 1), (4 : 1 : 1), (5 : 0 : 1),

sage: x = polygen(GF(121, 'a'))
sage: C = HyperellipticCurve(x^5 + x - 1, x^2 + 2)
sage: len(C.points())
122
```

39.3 Hyperelliptic curves over a general ring

EXAMPLE:

```
sage: P.<x> = GF(5)[]
sage: f = x^5 - 3*x^4 - 2*x^3 + 6*x^2 + 3*x - 1
sage: C = HyperellipticCurve(f); C
Hyperelliptic Curve over Finite Field of size 5 defined by y^2 = x^5 + 2*x^4 + 3*x^3 + x^2 + 3*x + 4
```

EXAMPLE:

```
sage: P.<x> = QQ[]
sage: f = 4*x^5 - 30*x^3 + 45*x - 22
sage: C = HyperellipticCurve(f); C
Hyperelliptic Curve over Rational Field defined by y^2 = 4*x^5 - 30*x^3 + 45*x - 22
sage: C.genus()
2

sage: D = C.affine_patch(0)
sage: D.defining_polynomials()[0].parent()
Multivariate Polynomial Ring in x0, x1 over Rational Field
```

class HyperellipticCurve_generic(*PP, f, h=None, names=None, genus=None*)

change_ring(*R*)

genus()

has_odd_degree_model()

Return True if an odd degree model of self exists over the field of definition; False otherwise.

Use `odd_degree_model` to calculate an odd degree model.

EXAMPLES:: sage: x = QQ['x'].0 sage: HyperellipticCurve(x^5 + x).has_odd_degree_model() True sage: HyperellipticCurve(x^6 + x).has_odd_degree_model() True sage: HyperellipticCurve(x^6 + x + 1).has_odd_degree_model() False

hyperelliptic_polynomials(*K=None, var='x'*)

EXAMPLES:

```
sage: R.<x> = QQ[]; C = HyperellipticCurve(x^3 + x - 1, x^3/5); C
Hyperelliptic Curve over Rational Field defined by y^2 + 1/5*x^3*y = x^3 + x - 1
sage: C.hyperelliptic_polynomials()
(x^3 + x - 1, 1/5*x^3)
```

jacobian()

lift_x(*x, all=False*)

monsky_washnitzer_gens()

odd_degree_model()

Return an odd degree model of self, or raise ValueError if one does not exist over the field of definition.

EXAMPLES:

```
sage: x = QQ['x'].gen()
sage: H = HyperellipticCurve((x^2 + 2)*(x^2 + 3)*(x^2 + 5)); H
Hyperelliptic Curve over Rational Field defined by y^2 = x^6 + 10*x^4 + 31*x^2 + 30
sage: H.odd_degree_model()
...
ValueError: No odd degree model exists over field of definition

sage: K2 = QuadraticField(-2, 'a')
sage: Hp2 = H.change_ring(K2).odd_degree_model(); Hp2
Hyperelliptic Curve over Number Field in a with defining polynomial x^2 + 2 defined by y^2 =

sage: K3 = QuadraticField(-3, 'b')
sage: Hp3 = H.change_ring(QuadraticField(-3, 'b')).odd_degree_model(); Hp3
Hyperelliptic Curve over Number Field in b with defining polynomial x^2 + 3 defined by y^2 =

Of course, Hp2 and Hp3 are isomorphic over the composite
extension.  One consequence of this is that odd degree models
reduced over "different" fields should have the same number of
points on their reductions.  43 and 67 split completely in the
compositum, so when we reduce we find:

sage: P2 = K2.factor(43)[0][0]
sage: P3 = K3.factor(43)[0][0]
sage: Hp2.change_ring(K2.residue_field(P2)).frobenius_polynomial()
x^4 - 16*x^3 + 134*x^2 - 688*x + 1849
sage: Hp3.change_ring(K3.residue_field(P3)).frobenius_polynomial()

(1)
sage: # Moreover the following relation holds in the 5-torsion subgroup:
sage: Q2 + Q4 == 2*Q1
```

```
True
```

dimension()

Return the dimension of this Jacobian.

OUTPUT: Integer

EXAMPLES:

```
sage: k.<a> = GF(9); R.<x> = k[]
sage: HyperellipticCurve(x^3 + x - 1, x+a).jacobian().dimension()
1
sage: g = HyperellipticCurve(x^6 + x - 1, x+a).jacobian().dimension(); g
2
sage: type(g)
<type 'sage.rings.integer.Integer'>
```

point(*mumford, check=True*)

39.7 Rational point sets on a Jacobian

EXAMPLES:

```
sage: x = QQ['x'].0
sage: f = x^5 + x + 1
sage: C = HyperellipticCurve(f); C
Hyperelliptic Curve over Rational Field defined by y^2 = x^5 + x + 1
sage: C(QQ)
Set of Rational Points of Hyperelliptic Curve over Rational Field defined by y^2 = x^5 + x + 1
sage: P = C([0,1,1])
sage: J = C.jacobian(); J
Jacobian of Hyperelliptic Curve over Rational Field defined by y^2 = x^5 + x + 1
sage: Q = J(QQ)(P); Q
(x, y - 1)
sage: Q + Q
(x^2, y - 1/2*x - 1)
sage: Q*3
(x^2 - 1/64*x + 1/8, y + 255/512*x + 65/64)
```

class JacobianHomset_divisor_classes(*X, S*)

base_extend(*R*)

curve()

value_ring()

Returns S for a homset X(T) where T = Spec(S).

39.8 Jacobian 'morphism' as a class in the Picard group.

This module implements the group operation in the Picard group of a hyperelliptic curve, represented as divisors in Mumford representation, using Cantor's algorithm.

A divisor on the hyperelliptic curve $y^2+yh(x) = f(x)$ is stored in Mumford representation, that is, as two polynomials $u(x)$ and $v(x)$ such that:

- $u(x)$ is monic,
- $u(x)$ divides $f(x) - h(x)v(x) - v(x)^2$,
- $deg(v(x)) < deg(u(x)) \leq g$.

REFERENCES:

A readable introduction to divisors, the Picard group, Mumford representation, and Cantor's algorithm:

- J. Scholten, F. Vercauteren. An Introduction to Elliptic and Hyperelliptic Curve Cryptography and the NTRU Cryptosystem. To appear in B. Preneel (Ed.) State of the Art in Applied Cryptography - COSIC '03, Lecture Notes in Computer Science, Springer 2004.

A standard reference in the field of cryptography:

- R. Avanzi, H. Cohen, C. Doche, G. Frey, T. Lange, K. Nguyen, and F. Vercauteren, Handbook of Elliptic and Hyperelliptic Curve Cryptography. CRC Press, 2005.

EXAMPLES: The following curve is the reduction of a curve whose Jacobian has complex multiplication.

```
sage: x = GF(37)['x'].gen()
sage: H = HyperellipticCurve(x^5 + 12*x^4 + 13*x^3 + 15*x^2 + 33*x); H
Hyperelliptic Curve over Finite Field of size 37 defined by y^2 = x^5 + 12*x^4 + 13*x^3 + 15*x^2 + 33
```

At this time, Jacobians of hyperelliptic curves are handled differently than elliptic curves:

```
sage: J = H.jacobian(); J
Jacobian of Hyperelliptic Curve over Finite Field of size 37 defined by y^2 = x^5 + 12*x^4 + 13*x^3 +
sage: J = J(J.base_ring()); J
Set of points of Jacobian of Hyperelliptic Curve over Finite Field of size 37 defined by y^2 = x^5 +
```

Points on the Jacobian are represented by Mumford's polynomials. First we find a couple of points on the curve:

```
sage: P1 = H.lift_x(2); P1
(2 : 11 : 1)
sage: Q1 = H.lift_x(10); Q1
(10 : 18 : 1)
```

Observe that 2 and 10 are the roots of the polynomials in x, respectively:

```
sage: P = J(P1); P
(x + 35, y + 26)
sage: Q = J(Q1); Q
(x + 27, y + 19)

sage: P + Q
(x^2 + 25*x + 20, y + 13*x)
sage: (x^2 + 25*x + 20).roots(multiplicities=False)
[10, 2]
```

Frobenius satisfies

$$x^4 + 12 * x^3 + 78 * x^2 + 444 * x + 1369$$

on the Jacobian of this reduction and the order of the Jacobian is $N = 1904$.

```
sage: 1904*P
(1)
sage: 34*P == 0
True
sage: 35*P == P
True
sage: 33*P == -P
True

sage: Q*1904
(1)
sage: Q*238 == 0
True
sage: Q*239 == Q
True
sage: Q*237 == -Q
True
```

class JacobianMorphism_divisor_class_field(*parent, polys, check=True*)

An element of a Jacobian defined over a field, i.e. in $J(K) = \mathrm{Pic}^0_K(C)$.

scheme()

Return the scheme this morphism maps to; or, where this divisor lives.

> **Warning:** Although a pointset is defined over a specific field, the scheme returned may be over a different (usually smaller) field. The example below demonstrates this: the pointset is determined over a number field of absolute degree 2 but the scheme returned is defined over the rationals.

EXAMPLES:

```
sage: x = QQ['x'].gen()
sage: f = x^5 + x
sage: H = HyperellipticCurve(f)
sage: F.<a> = NumberField(x^2 - 2, 'a')
sage: J = H.jacobian()(F); J
Set of points of Jacobian of Hyperelliptic Curve over Rational Field defined by y^2 = x^5 +

sage: P = J(H.lift_x(F(1)))
sage: P.scheme()
Jacobian of Hyperelliptic Curve over Rational Field defined by y^2 = x^5 + x
```

cantor_composition(*D1, D2, f, h, genus*)

EXAMPLES:

```
sage: F.<a> = GF(7^2, 'a')
sage: x = F['x'].gen()
sage: f = x^7 + x^2 + a
sage: H = HyperellipticCurve(f, 2*x); H
Hyperelliptic Curve over Finite Field in a of size 7^2 defined by y^2 + 2*x*y = x^7 + x^2 + a
sage: J = H.jacobian()(F); J
Set of points of Jacobian of Hyperelliptic Curve over Finite Field in a of size 7^2 defined by y

sage: Q = J(H.lift_x(F(1))); Q
(x + 6, y + 2*a + 2)
sage: 10*Q # indirect doctest
(x^3 + (3*a + 1)*x^2 + (2*a + 5)*x + a + 5, y + (4*a + 5)*x^2 + (a + 1)*x + 6*a + 3)
```

```
sage: 7*8297*Q
(1)

sage: Q = J(H.lift_x(F(a+1))); Q
(x + 6*a + 6, y + 2)
sage: 7*8297*Q # indirect doctest
(1)
```

cantor_composition_simple (*D1, D2, f, genus*)

Given D_1 and D_2 two reduced Mumford divisors on the Jacobian of the curve $y^2 = f(x)$, computes a representative $D_1 + D_2$.

Warning: The representative computed is NOT reduced! Use `cantor_reduction_simple()` to reduce it.

EXAMPLES:

```
sage: x = QQ['x'].gen()
sage: f = x^5 + x
sage: H = HyperellipticCurve(f); H
Hyperelliptic Curve over Rational Field defined by y^2 = x^5 + x

sage: F.<a> = NumberField(x^2 - 2, 'a')
sage: J = H.jacobian()(F); J
Set of points of Jacobian of Hyperelliptic Curve over Rational Field defined by y^2 = x^5 + x de

sage: P = J(H.lift_x(F(1))); P
(x - 1, y - a)
sage: Q = J(H.lift_x(F(0))); Q
(x, y)
sage: 2*P + 2*Q # indirect doctest
(x^2 - 2*x + 1, y - 3/2*a*x + 1/2*a)
sage: 2*(P + Q) # indirect doctest
(x^2 - 2*x + 1, y - 3/2*a*x + 1/2*a)
sage: 3*P # indirect doctest
(x^2 - 25/32*x + 49/32, y - 45/256*a*x - 315/256*a)
```

cantor_reduction (*a, b, f, h, genus*)

Return the unique reduced divisor linearly equivalent to (a, b) on the curve $y^2 + yh(x) = f(x)$.

See the docstring of `sage.schemes.hyperelliptic_curves.jacobian_morphism` for information about divisors, linear equivalence, and reduction.

EXAMPLES:

```
sage: x = QQ['x'].gen()
sage: f = x^5 - x
sage: H = HyperellipticCurve(f, x); H
Hyperelliptic Curve over Rational Field defined by y^2 + x*y = x^5 - x
sage: J = H.jacobian()(QQ); J
Set of points of Jacobian of Hyperelliptic Curve over Rational Field defined by y^2 + x*y = x^5
```

The following point is 2-torsion:

```
sage: Q = J(H.lift_x(0)); Q
(x, y)
sage: 2*Q # indirect doctest
(1)
```

The next point is not 2-torsion:

```
sage: P = J(H.lift_x(-1)); P
(x + 1, y - 1)
sage: 2 * J(H.lift_x(-1)) # indirect doctest
(x^2 + 2*x + 1, y - 3*x - 4)
sage: 3 * J(H.lift_x(-1)) # indirect doctest
(x^2 - 487*x - 324, y - 10754*x - 7146)
```

cantor_reduction_simple(*a, b, f, genus*)

Return the unique reduced divisor linearly equivalent to (a, b) on the curve $y^2 = f(x)$.

See the docstring of sage.schemes.hyperelliptic_curves.jacobian_morphism for information about divisors, linear equivalence, and reduction.

EXAMPLES:

```
sage: x = QQ['x'].gen()
sage: f = x^5 - x
sage: H = HyperellipticCurve(f); H
Hyperelliptic Curve over Rational Field defined by y^2 = x^5 - x
sage: J = H.jacobian()(QQ); J
Set of points of Jacobian of Hyperelliptic Curve over Rational Field defined by y^2 = x^5 - x de
```

The following point is 2-torsion:

```
sage: P = J(H.lift_x(-1)); P
(x + 1, y)
sage: 2 * P # indirect doctest
(1)
```

39.9 Conductor and Reduction Types for Genus 2 Curves

AUTHORS:

- Qing Liu and Henri Cohen (1994-1998): wrote genus2reduction C program
- William Stein (2006-03-05): wrote Sage interface to genus2reduction

ACKNOWLEDGMENT: (From Liu's website:) Many thanks to Henri Cohen who started writing this program. After this program is available, many people pointed out to me (mathematical as well as programming) bugs : B. Poonen, E. Schaefer, C. Stahlke, M. Stoll, F. Villegas. So thanks to all of them. Thanks also go to Ph. Depouilly who help me to compile the program.

Also Liu has given me explicit permission to include genus2reduction with Sage and for people to modify the C source code however they want.

class Genus2reduction()

Conductor and Reduction Types for Genus 2 Curves.

Use `R = genus2reduction(Q, P)` to obtain reduction information about the Jacobian of the projective smooth curve defined by $y^2 + Q(x)y = P(x)$. Type `R?` for further documentation and a description of how to interpret the local reduction data.

EXAMPLES:

```
sage: x = QQ['x'].0
sage: R = genus2reduction(x^3 - 2*x^2 - 2*x + 1, -5*x^5)
sage: R.conductor
1416875
sage: factor(R.conductor)
5^4 * 2267
```

This means that only the odd part of the conductor is known.

```
sage: R.prime_to_2_conductor_only
True
```

The discriminant is always minimal away from 2, but possibly not at 2.

```
sage: factor(R.minimal_disc)
2^3 * 5^5 * 2267
```

Printing R summarizes all the information computed about the curve

```
sage: R
Reduction data about this proper smooth genus 2 curve:
    y^2 + (x^3 - 2*x^2 - 2*x + 1)*y = -5*x^5
A Minimal Equation (away from 2):
    y^2 = x^6 - 240*x^4 - 2550*x^3 - 11400*x^2 - 24100*x - 19855
Minimal Discriminant (away from 2):  56675000
Conductor (away from 2): 1416875
Local Data:
    p=2
    (potential) stable reduction:  (II), j=1
    p=5
    (potential) stable reduction:  (I)
    reduction at p: [V] page 156, (3), f=4
    p=2267
    (potential) stable reduction:  (II), j=432
    reduction at p: [I{1-0-0}] page 170, (1), f=1
```

Here are some examples of curves with modular Jacobians:

```
sage: R = genus2reduction(x^3 + x + 1, -2*x^5 - 3*x^2 + 2*x - 2)
sage: factor(R.conductor)
23^2
sage: factor(genus2reduction(x^3 + 1, -x^5 - 3*x^4 + 2*x^2 + 2*x - 2).conductor)
29^2
sage: factor(genus2reduction(x^3 + x + 1, x^5 + 2*x^4 + 2*x^3 + x^2 - x - 1).conductor)
5^6
```

EXAMPLE:

```
sage: genus2reduction(0, x^6 + 3*x^3 + 63)
Reduction data about this proper smooth genus 2 curve:
        y^2 = x^6 + 3*x^3 + 63
A Minimal Equation (away from 2):
        y^2 = x^6 + 3*x^3 + 63
Minimal Discriminant (away from 2):  10628388316852992
```

```
Conductor (away from 2): 2893401
Local Data:
        p=2
        (potential) stable reduction:  (V), j1+j2=0, j1*j2=0
        p=3
        (potential) stable reduction:  (I)
        reduction at p: [III{9}] page 184, (3)^2, f=10
        p=7
        (potential) stable reduction:  (V), j1+j2=0, j1*j2=0
        reduction at p: [I{0}-II-0] page 159, (1), f=2
```

In the above example, Liu remarks that in fact at $p = 2$, the reduction is [II-II-0] page 163, (1), $f = 8$. So the conductor of J(C) is actually $2 \cdot 2893401 = 5786802$.

A MODULAR CURVE:

Consider the modular curve $X_1(13)$ defined by an equation

$$y^2 + (x^3 - x^2 - 1)y = x^2 - x.$$

We have:

```
sage: genus2reduction(x^3-x^2-1, x^2 - x)
Reduction data about this proper smooth genus 2 curve:
        y^2 + (x^3 - x^2 - 1)*y = x^2 - x
A Minimal Equation (away from 2):
        y^2 = x^6 + 58*x^5 + 1401*x^4 + 18038*x^3 + 130546*x^2 + 503516*x + 808561
Minimal Discriminant (away from 2):  169
Conductor: 169
Local Data:
        p=13
        (potential) stable reduction:  (V), j1+j2=0, j1*j2=0
        reduction at p: [I{0}-II-0] page 159, (1), f=2
```

So the curve has good reduction at 2. At $p = 13$, the stable reduction is union of two elliptic curves, and both of them have 0 as modular invariant. The reduction at 13 is of type [I_0-II-0] (see Namikawa-Ueno, page 159). It is an elliptic curve with a cusp. The group of connected components of the Neron model of $J(C)$ is trivial, and the exponent of the conductor of $J(C)$ at 13 is $f = 2$. The conductor of $J(C)$ is 13^2. (Note: It is a theorem of Conrad-Edixhoven-Stein that the component group of $J(X_1(p))$ is trivial for all primes p.)

console()

raw(*Q*, *P*)

Return the raw output of running the `genus2reduction` program on the hyperelliptic curve $y^2 + Q(x)y = P(x)$ as a string.

INPUT:

- `Q` - something coercible to a univariate polynomial over Q.
- `P` - something coercible to a univariate polynomial over Q.

OUTPUT:

- `string` - raw output
- `Q` - what Q was actually input to auxiliary genus2reduction program
- `P` - what P was actually input to auxiliary genus2reduction program

EXAMPLES:

```
sage: x = QQ['x'].0
sage: print genus2reduction.raw(x^3 - 2*x^2 - 2*x + 1, -5*x^5)[0]
a minimal equation over Z[1/2] is :
```

```
y^2 = x^6-240*x^4-2550*x^3-11400*x^2-24100*x-19855
<BLANKLINE>
factorization of the minimal (away from 2) discriminant :
[2,3;5,5;2267,1]
<BLANKLINE>
p=2
(potential) stable reduction :  (II), j=1
p=5
(potential) stable reduction :  (I)
reduction at p : [V] page 156, (3), f=4
p=2267
(potential) stable reduction :  (II), j=432
reduction at p : [I{1-0-0}] page 170, (1), f=1
<BLANKLINE>
the prime to 2 part of the conductor is 1416875
in factorized form : [2,0;5,4;2267,1]
```

Verify that we fix trac 5573:

```
sage: genus2reduction(x^3 + x^2 + x,-2*x^5 + 3*x^4 - x^3 - x^2 - 6*x - 2)
Reduction data about this proper smooth genus 2 curve:
y^2 + (x^3 + x^2 + x)*y = -2*x^5 + 3*x^4 - x^3 - x^2 - 6*x - 2
...
```

class Genus2reduction_expect (*server=None, server_tmpdir=None, logfile=None*)

class ReductionData (*raw, P, Q, minimal_equation, minimal_disc, local_data, conductor, prime_to_2_conductor_only*)

Reduction data for a genus 2 curve.

How to read `local_data` attribute, i.e., if this class is R, then the following is the meaning of `R.local_data[p]`.

For each prime number p dividing the discriminant of $y^2 + Q(x)y = P(x)$, there are two lines.

The first line contains information about the stable reduction after field extension. Here are the meanings of the symbols of stable reduction :

(I) The stable reduction is smooth (i.e. the curve has potentially good reduction).

(II) The stable reduction is an elliptic curve E with an ordinary double point. j mod p is the modular invariant of E.

(III) The stable reduction is a projective line with two ordinary double points.

(IV) The stable reduction is two projective lines crossing transversally at three points.

(V) The stable reduction is the union of two elliptic curves E_1 and E_2 intersecting transversally at one point. Let j_1, j_2 be their modular invariants, then $j_1 + j_2$ and $j_1 j_2$ are computed (they are numbers mod p).

(VI) The stable reduction is the union of an elliptic curve E and a projective line which has an ordinary double point. These two components intersect transversally at one point. j mod p is the modular invariant of E.

(VII) The stable reduction is as above, but the two components are both singular.

In the cases (I) and (V), the Jacobian $J(C)$ has potentially good reduction. In the cases (III), (IV) and (VII), $J(C)$ has potentially multiplicative reduction. In the two remaining cases, the (potential) semi-abelian reduction of $J(C)$ is extension of an elliptic curve (with modular invariant j mod p) by a torus.

The second line contains three data concerning the reduction at p without any field extension.

1. The first symbol describes the REDUCTION AT p of C. We use the symbols of Namikawa-Ueno for the type of the reduction (Namikawa, Ueno:"The complete classification of fibers in pencils of curves of genus two", Manuscripta Math., vol. 9, (1973), pages 143-186.) The reduction symbol is followed by the corresponding page number (or just an indiction) in the above article. The lower index is printed by ,

for instance, [I2-II-5] means [I_2-II-5]. Note that if K and K' are Kodaira symbols for singular fibers of elliptic curves, [K-K'-m] and [K'-K-m] are the same type. Finally, [K-K'-1] (not the same as [K-K'-1]) is [K'-K-alpha] in the notation of Namikawa-Ueno. The figure [2I_0-m] in Namikawa-Ueno, page 159 must be denoted by [2I_0-(m+1)].

2. The second datum is the GROUP OF CONNECTED COMPONENTS (over an ALGEBRAIC CLOSURE (!) of $\mathbf{F}_p$) of the Neron model of J(C). The symbol (n) means the cyclic group with n elements. When n=0, (0) is the trivial group (1). `Hn` is isomorphic to (2)x(2) if n is even and to (4) otherwise.

   Note - The set of rational points of Φ can be computed using Theorem 1.17 in S. Bosch and Q. Liu "Rational points of the group of components of a Neron model", Manuscripta Math. 98 (1999), 275-293.

3. Finally, f is the exponent of the conductor of $J(C)$ at p.

Warning: Be careful regarding the formula:

$$\text{valuation of the naive minimal discriminant} = f + n - 1 + 11c(X).$$

(Q. Liu : "Conducteur et discriminant minimal de courbes de genre 2", Compositio Math. 94 (1994) 51-79, Theoreme 2) is valid only if the residual field is algebraically closed as stated in the paper. So this equality does not hold in general over $\mathbf{Q}_p$. The fact is that the minimal discriminant may change after unramified extension. One can show however that, at worst, the change will stabilize after a quadratic unramified extension (Q. Liu : "Modeles entiers de courbes hyperelliptiques sur un corps de valuation discrete", Trans. AMS 348 (1996), 4577-4610, Section 7.2, Proposition 4).

CHAPTER

FORTY

CODING THEORY

40.1 Linear Codes

VERSION: 1.1

Let F be a finite field (we denote the finite field with q elements by $\mathbf{F}_q$). A subspace of F^n (with the standard basis) is called a linear code of length n. If its dimension is denoted k then we typically store a basis of C as a $k \times n$ matrix (the rows are the basis vectors) called the generator matrix of C. The rows of the parity check matrix of C are a basis for the code,

$$C^* = \{v \in GF(q)^n \mid v \cdot c = 0, \ for\ all\ c \in C\},$$

called the dual space of C.

If $F = \mathbf{F}_2$ then C is called a binary code. If $F = \mathbf{F}_q$ then C is called a q-ary code. The elements of a code C are called codewords.

The symmetric group S_n acts on F^n by permuting coordinates. If an element $p \in S_n$ sends a code C of length n to itself (in other words, every codeword of C is sent to some other codeword of C) then p is called a permutation automorphism of C. The (permutation) automorphism group is denoted $Aut(C)$.

This file contains

1. LinearCode class definition; LinearCodeFromVectorspace conversion function,
2. The spectrum (weight distribution), covering_radius, minimum distance programs (calling Steve Linton's or CJ Tjhal's C programs), characteristic_function, and several implementations of the Duursma zeta function (sd_zeta_polynomial, zeta_polynomial, zeta_function, chinen_polynomial, for example),
3. interface with best_known_linear_code_www (interface with codetables.de since A. Brouwer's online tables have been disabled), bounds_minimum_distance which call tables in GUAVA (updated May 2006) created by Cen Tjhai instead of the online internet tables,
4. gen_mat, list, check_mat, decode, dual_code, extended_code, shortened, punctured, genus, binomial_moment, and divisor methods for LinearCode,
5. Boolean-valued functions such as "==", is_self_dual, is_self_orthogonal, is_subcode, is_permutation_automorphism, is_permutation_equivalent (which interfaces with Robert Miller's partition refinement code),
6. permutation methods: automorphism_group_binary_code, is_permutation_automorphism, (permutation_automorphism_group is deprecated), permuted_code, standard_form, module_composition_factors,
7. design-theoretic methods: assmus_mattson_designs (implementing Assmus-Mattson Theorem),

8. code constructions, such as HammingCode and ToricCode, are in a separate `code_constructions.py` module; in the separate `guava.py` module, you will find constructions, such as RandomLinearCodeGuava and BinaryReedMullerCode, wrapped from the corresponding GUAVA codes.

EXAMPLES:

```
sage: MS = MatrixSpace(GF(2),4,7)
sage: G = MS([[1,1,1,0,0,0,0], [1,0,0,1,1,0,0], [0,1,0,1,0,1,0], [1,1,0,1,0,0,1]])
sage: C = LinearCode(G)
sage: C.basis()
[(1, 1, 1, 0, 0, 0, 0),
 (1, 0, 0, 1, 1, 0, 0),
 (0, 1, 0, 1, 0, 1, 0),
 (1, 1, 0, 1, 0, 0, 1)]
sage: c = C.basis()[1]
sage: c in C
True
sage: c.nonzero_positions()
[0, 3, 4]
sage: c.support()
[0, 3, 4]
sage: c.parent()
Vector space of dimension 7 over Finite Field of size 2
```

To be added:

1. More wrappers
2. GRS codes and special decoders.
3. P^1 Goppa codes and group actions on P^1 RR space codes.

- David Joyner (2005-11-22, 2006-12-03): initial version
- William Stein (2006-01-23): Inclusion in Sage
- David Joyner (2006-01-30, 2006-04): small fixes
- David Joyner (2006-07): added documentation, group-theoretical methods, ToricCode
- David Joyner (2006-08): hopeful latex fixes to documentation, added list and __iter__ methods to LinearCode and examples, added hamming_weight function, fixed random method to return a vector, TrivialCode, fixed subtle bug in dual_code, added galois_closure method, fixed mysterious bug in permutation_automorphism_group (GAP was over-using "G" somehow?)
- David Joyner (2006-08): hopeful latex fixes to documentation, added CyclicCode, best_known_linear_code, bounds_minimum_distance, assmus_mattson_designs (implementing Assmus-Mattson Theorem).
- David Joyner (2006-09): modified decode syntax, fixed bug in is_galois_closed, added LinearCode_from_vectorspace, extended_code, zeta_function

- Nick Alexander (2006-12-10): factor GUAVA code to guava.py
- David Joyner (2007-05): added methods punctured, shortened, divisor, characteristic_polynomial, binomial_moment, support for LinearCode. Completely rewritten zeta_function (old version is now zeta_function2) and a new function, LinearCodeFromVectorSpace.
- David Joyner (2007-11): added zeta_polynomial, weight_enumerator, chinen_polynomial; improved best_known_code; made some pythonic revisions; added is_equivalent (for binary codes)
- David Joyner (2008-01): fixed bug in decode reported by Harald Schilly, (with Mike Hansen) added some doctests.
- David Joyner (2008-02): translated standard_form, dual_code to Python.
- David Joyner (2008-03): translated punctured, shortened, extended_code, random (and renamed random to random_element), deleted zeta_function2, zeta_function3, added wrapper automorphism_group_binary_code to Robert Miller's code), added direct_sum_code, is_subcode, is_self_dual, is_self_orthogonal, redundancy_matrix, did some alphabetical reorganizing to make the file more readable. Fixed a bug in permutation_automorphism_group which caused it to crash.
- David Joyner (2008-03): fixed bugs in spectrum and zeta_polynomial (which misbehaved over non-prime base rings.
- David Joyner (2008-10): use CJ Tjhal's MinimumWeight if char = 2 or 3 for min_dist; add is_permutation_equivalent and improve permutation_automorphism_group using an interface with Robert Miller's code; added interface with Leon's code for the spectrum method.
- David Joyner (2009-02): added native decoding methods (see module_decoder.py)

TESTS:

```
sage: MS = MatrixSpace(GF(2),4,7)
sage: G  = MS([[1,1,1,0,0,0,0], [1,0,0,1,1,0,0], [0,1,0,1,0,1,0], [1,1,0,1,0,0,1]])
sage: C  = LinearCode(G)
sage: C == loads(dumps(C))
True
```

class **LinearCode**(*gen_mat*)

A class for linear codes over a finite field or finite ring. Each instance is a linear code determined by a generator matrix G (i.e., a k x n matrix of (full) rank k, $k \leq n$ over a finite field F.

INPUT:

- G - a generator matrix over F. (G can be defined over a finite ring but the matrices over that ring must have certain attributes, such as"rank".)

OUTPUT: The linear code of length n over F having G as a generator matrix.

EXAMPLES:

```
sage: MS = MatrixSpace(GF(2),4,7)
sage: G  = MS([[1,1,1,0,0,0,0], [1,0,0,1,1,0,0], [0,1,0,1,0,1,0], [1,1,0,1,0,0,1]])
sage: C  = LinearCode(G)
sage: C
Linear code of length 7, dimension 4 over Finite Field of size 2
sage: C.base_ring()
Finite Field of size 2
sage: C.dimension()
4
sage: C.length()
```

```
7
sage: C.minimum_distance()
3
sage: C.spectrum()
[1, 0, 0, 7, 7, 0, 0, 1]
sage: C.weight_distribution()
[1, 0, 0, 7, 7, 0, 0, 1]
sage: MS = MatrixSpace(GF(5),4,7)
sage: G  = MS([[1,1,1,0,0,0,0], [1,0,0,1,1,0,0], [0,1,0,1,0,1,0], [1,1,0,1,0,0,1]])
sage: C  = LinearCode(G)
sage: C
Linear code of length 7, dimension 4 over Finite Field of size 5
```

AUTHORS:

- David Joyner (11-2005)

ambient_space()

assmus_mattson_designs(*t, mode=None*)

Assmus and Mattson Theorem (section 8.4, page 303 of [HP]): Let $A_0, A_1, ..., A_n$ be the weights of the codewords in a binary linear $[n, k, d]$ code C, and let $A_0^*, A_1^*, ..., A_n^*$ be the weights of the codewords in its dual $[n, n-k, d^*]$ code C^*. Fix a t, $0 < t < d$, and let

$$s = |\{i \mid A_i^* \neq 0, 0 < i \leq n - t\}|.$$

Assume $s \leq d - t$.

1. If $A_i \neq 0$ and $d \leq i \leq n$ then $C_i = \{c \in C \mid wt(c) = i\}$ holds a simple t-design.
2. If $A_i^* \neq 0$ and $d* \leq i \leq n - t$ then $C_i^* = \{c \in C^* \mid wt(c) = i\}$ holds a simple t-design.

A block design is a pair (X, B), where X is a non-empty finite set of $v > 0$ elements called points, and B is a non-empty finite multiset of size b whose elements are called blocks, such that each block is a non-empty finite multiset of k points. A design without repeated blocks is called a simple block design. If every subset of points of size t is contained in exactly λ blocks the block design is called a $t - (v, k, \lambda)$ design (or simply a t-design when the parameters are not specified). When $\lambda = 1$ then the block design is called a $S(t, k, v)$ Steiner system.

In the Assmus and Mattson Theorem (1), X is the set $\{1, 2, ..., n\}$ of coordinate locations and $B = \{supp(c) \mid c \in C_i\}$ is the set of supports of the codewords of C of weight i. Therefore, the parameters of the t-design for C_i are

```
t =       given
v =       n
k =       i   (k not to be confused with dim(C))
b =       Ai
lambda = b*binomial(k,t)/binomial(v,t)  (by Theorem 8.1.6,
                                          p 294, in [HP])
```

Setting the mode="verbose" option prints out the values of the parameters.

The first example below means that the binary [24,12,8]-code C has the property that the (support of the) codewords of weight 8 (resp, 12, 16) form a 5-design. Similarly for its dual code C^* (of course $C = C^*$ in this case, so this info is extraneous). The test fails to produce 6-designs (ie, the hypotheses of the theorem fail to hold, not that the 6-designs definitely don't exist). The command assmus_mattson_designs(C,5,mode="verbose") returns the same value but prints out more detailed information.

The second example below illustrates the blocks of the 5-(24, 8, 1) design (ie, the S(5,8,24) Steiner system).

EXAMPLES:

```
sage: C = ExtendedBinaryGolayCode()              #  example 1
sage: C.assmus_mattson_designs(5)
['weights from C: ',
[8, 12, 16, 24],
'designs from C: ',
[[5, (24, 8, 1)], [5, (24, 12, 48)], [5, (24, 16, 78)], [5, (24, 24, 1)]],
'weights from C*: ',
[8, 12, 16],
'designs from C*: ',
[[5, (24, 8, 1)], [5, (24, 12, 48)], [5, (24, 16, 78)]]]
sage: C.assmus_mattson_designs(6)
0
sage: X = range(24)                              #  example 2
sage: blocks = [c.support() for c in C if hamming_weight(c)==8]; len(blocks)  # long time co
759
```

REFERENCE:

•[HP] W. C. Huffman and V. Pless, Fundamentals of ECC, Cambridge Univ. Press, 2003.

automorphism_group_binary_code()

This only applies to linear binary codes and returns its (permutation) automorphism group. In other words, if the code C has length n then it returns the subgroup of the symmetric group S_n:

$$\{g \in S_n \mid g(c) \in C, \forall c \in C\},$$

where S_n acts on $GF(2)^n$ by permuting coordinates.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: G = C.automorphism_group_binary_code(); G
Permutation Group with generators [(3,4)(5,6), (3,5)(4,6), (2,3)(5,7), (1,2)(5,6)]
sage: G.order()
168
```

basis()

binomial_moment(i)

Returns the i-th binomial moment of the $[n, k, d]_q$-code C:

$$B_i(C) = \sum_{S,|S|=i} \frac{q^{k_S} - 1}{q - 1}$$

where k_S is the dimension of the shortened code C_{J-S}, $J = [1, 2, ..., n]$. (The normalized binomial moment is $b_i(C) = \binom{(}{n}, d + i)^{-1} B_{d+i}(C)$.) In other words, C_{J-S} is the isomorphic to the subcode of C of codewords supported on S.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: C.binomial_moment(2)
0
sage: C.binomial_moment(3)     # long time
0
sage: C.binomial_moment(4)     # long time
35
```

,. warning:

```
This is slow.
```

•I. Duursma, "Combinatorics of the two-variable zeta function", Finite fields and applications, 109-136, Lecture Notes in Comput. Sci., 2948, Springer, Berlin, 2004.

characteristic()

characteristic_polynomial()

Returns the characteristic polynomial of a linear code, as defined in van Lint's text [vL].

EXAMPLES:

```
sage: C = ExtendedBinaryGolayCode()
sage: C.characteristic_polynomial()
-4/3*x^3 + 64*x^2 - 2816/3*x + 4096
```

REFERENCES:

•van Lint, Introduction to coding theory, 3rd ed., Springer-Verlag GTM, 86, 1999.

check_mat()

Returns the check matrix of self.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: Cperp = C.dual_code()
sage: C; Cperp
Linear code of length 7, dimension 4 over Finite Field of size 2
Linear code of length 7, dimension 3 over Finite Field of size 2
sage: C.gen_mat()
[1 0 0 1 0 1 0]
[0 1 0 1 0 1 1]
[0 0 1 1 0 0 1]
[0 0 0 0 1 1 1]
sage: C.check_mat()
[1 0 0 1 1 0 1]
[0 1 0 1 0 1 1]
[0 0 1 1 1 1 0]
sage: Cperp.check_mat()
[1 0 0 1 0 1 0]
[0 1 0 1 0 1 1]
[0 0 1 1 0 0 1]
[0 0 0 0 1 1 1]
sage: Cperp.gen_mat()
[1 0 0 1 1 0 1]
[0 1 0 1 0 1 1]
[0 0 1 1 1 1 0]
```

chinen_polynomial()

Returns the Chinen zeta polynomial of the code.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: C.chinen_polynomial()       # long time
1/5*(2*sqrt(2)*t^3 + 2*sqrt(2)*t^2 + 2*t^2 + sqrt(2)*t + 2*t + 1)/(sqrt(2) + 1)
sage: C = TernaryGolayCode()
sage: C.chinen_polynomial()       # long time
1/7*(3*sqrt(3)*t^3 + 3*sqrt(3)*t^2 + 3*t^2 + sqrt(3)*t + 3*t + 1)/(sqrt(3) + 1)
```

This last output agrees with the corresponding example given in Chinen's paper below.

REFERENCES:

•Chinen, K. "An abundance of invariant polynomials satisfying the Riemann hypothesis", April 2007 preprint.

covering_radius()

Wraps Guava's CoveringRadius command.

The covering radius of a linear code C is the smallest number r with the property that each element v of the ambient vector space of C has at most a distance r to the code C. So for each vector v there must be an element c of C with $d(v, c) \leq r$. A binary linear code with reasonable small covering radius is often referred to as a covering code.

For example, if C is a perfect code, the covering radius is equal to t, the number of errors the code can correct, where d = 2t+1, with d the minimum distance of C

EXAMPLES:

```
sage: C = HammingCode(5,GF(2))
sage: C.covering_radius()
1
```

decode(*right, method='syndrome'*)

Decodes a received vector v (=right) to an element c in the code C (=self). Optional methods are "guava", "nearest neighbor" or "syndrome". The method="guava" wraps GUAVA's Decodeword (Hamming codes have a special decoding algorithm; otherwise, syndrome decoding is used). The default is "syndrome".

INPUT:

- v - must be a vector of length = length(C)

OUTPUT: The codeword c in C closest to v.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: MS = MatrixSpace(GF(2),1,7)
sage: F = GF(2); a = F.gen()
sage: v1 = [a,a,F(0),a,a,F(0),a]
sage: C.decode(v1)
(1, 0, 0, 1, 1, 0, 1)
sage: C.decode(v1,method="nearest neighbor")
(1, 0, 0, 1, 1, 0, 1)
sage: C.decode(v1,method="guava")
(1, 0, 0, 1, 1, 0, 1)
sage: v2 = matrix([[a,a,F(0),a,a,F(0),a]])
sage: C.decode(v2)
(1, 0, 0, 1, 1, 0, 1)
sage: v3 = vector([a,a,F(0),a,a,F(0),a])
sage: c = C.decode(v3); c
(1, 0, 0, 1, 1, 0, 1)
sage: c in C
True
sage: C = HammingCode(2,GF(5))
sage: v = vector(GF(5),[1,0,0,2,1,0])
sage: C.decode(v)
(2, 0, 0, 2, 1, 0)
sage: F = GF(4,"a")
sage: C = HammingCode(2,F)
sage: v = vector(F, [1,0,0,a,1])
sage: C.decode(v)
(1, 0, 0, 1, 1)
sage: C.decode(v, method="nearest neighbor")
(1, 0, 0, 1, 1)
sage: C.decode(v, method="guava")
(1, 0, 0, 1, 1)
```

Does not work for very long codes since the syndrome table grows too large.

dimension()

direct_sum(*other*)

C1, C2 must be linear codes defined over the same base ring. Returns the (usual vector space) direct sum of the codes.

EXAMPLES:

```
sage: C1 = HammingCode(3,GF(2))
sage: C2 = C1.direct_sum(C1); C2
Linear code of length 14, dimension 8 over Finite Field of size 2
sage: C3 = C1.direct_sum(C2); C3
Linear code of length 21, dimension 12 over Finite Field of size 2
```

divisor()

Returns the divisor of a code (the divisor is the smallest integer $d_0 > 0$ such that each $A_i > 0$ iff i is divisible by d_0).

EXAMPLES:

```
sage: C = ExtendedBinaryGolayCode()
sage: C.divisor()   # Type II self-dual
4
sage: C = QuadraticResidueCodeEvenPair(17,GF(2))[0]
sage: C.divisor()
2
```

dual_code()

This computes the dual code Cd of the code C,

$$Cd = \{v \in V \mid v \cdot c = 0, \ \forall c \in C\}.$$

Does not call GAP.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: C.dual_code()
Linear code of length 7, dimension 3 over Finite Field of size 2
sage: C = HammingCode(3,GF(4,'a'))
sage: C.dual_code()
Linear code of length 21, dimension 3 over Finite Field in a of size 2^2
```

extended_code()

If self is a linear code of length n defined over F then this returns the code of length n+1 where the last digit c_n satisfies the check condition $c_0 + ... + c_n = 0$. If self is an $[n, k, d]$ binary code then the extended code $C^\vee$ is an $[n + 1, k, d^\vee]$ code, where $d^=d$ (if d is even) and $d^\vee = d + 1$ (if d is odd).

EXAMPLES:

```
sage: C = HammingCode(3,GF(4,'a'))
sage: C
Linear code of length 21, dimension 18 over Finite Field in a of size 2^2
sage: Cx = C.extended_code()
sage: Cx
Linear code of length 22, dimension 18 over Finite Field in a of size 2^2
```

galois_closure(*F0*)

If self is a linear code defined over F and F_0 is a subfield with Galois group $G = Gal(F/F_0)$ then this returns the G-module C^- containing C.

EXAMPLES:

```
sage: C = HammingCode(3,GF(4,'a'))
sage: Cc = C.galois_closure(GF(2))
sage: C; Cc
```

```
Linear code of length 21, dimension 18 over Finite Field in a of size 2^2
Linear code of length 21, dimension 20 over Finite Field in a of size 2^2
sage: c = C.basis()[1]
sage: V = VectorSpace(GF(4,'a'),21)
sage: c2 = V([x^2 for x in c.list()])
sage: c2 in C
False
sage: c2 in Cc
True
```

gen_mat()

Returns the generator matrix of the code.

EXAMPLES:

```
sage: C1 = HammingCode(3,GF(2))
sage: C1.gen_mat()
[1 0 0 1 0 1 0]
[0 1 0 1 0 1 1]
[0 0 1 1 0 0 1]
[0 0 0 0 1 1 1]
sage: C2 = HammingCode(2,GF(4,"a"))
sage: C2.gen_mat()
[    1     0     0     1     1]
[    0     1     0     1 a + 1]
[    0     0     1     1     a]
```

gens()

genus()

Returns the "Duursma genus" of the code, $\gamma_C = n + 1 - k - d$.

EXAMPLES:

```
sage: C1 = HammingCode(3,GF(2)); C1
Linear code of length 7, dimension 4 over Finite Field of size 2
sage: C1.genus()
1
sage: C2 = HammingCode(2,GF(4,"a")); C2
Linear code of length 5, dimension 3 over Finite Field in a of size 2^2
sage: C2.genus()
0
```

Since all Hamming codes have minimum distance 3, these computations agree with the definition, n+1-k-d.

is_galois_closed()

Checks if C is equal to its Galois closure.

is_permutation_automorphism(g)

Returns 1 if g is an element of S_n (n = length of self) and if g is an automorphism of self.

EXAMPLES:

```
sage: C = HammingCode(3,GF(3))
sage: g = SymmetricGroup(13).random_element()
sage: C.is_permutation_automorphism(g)
0
sage: MS = MatrixSpace(GF(2),4,8)
sage: G  = MS([[1,0,0,0,1,1,1,0],[0,1,1,1,0,0,0,0],[0,0,0,0,0,0,0,1],[0,0,0,0,0,1,0,0]])
sage: C  = LinearCode(G)
sage: S8 = SymmetricGroup(8)
sage: g = S8("(2,3)")
sage: C.is_permutation_automorphism(g)
```

```
1
sage: g = S8("(1,2,3,4)")
sage: C.is_permutation_automorphism(g)
0
```

is_permutation_equivalent(*other, method=None*)

Returns true if self and other are permutation equivalent codes and false otherwise. The method="verbose" option also returns a permutation (if true) sending self to other. Uses Robert Miller's double coset partition refinement work.

EXAMPLES:

```
sage: P.<x> = PolynomialRing(GF(2),"x")
sage: g = x^3+x+1
sage: C1 = CyclicCodeFromGeneratingPolynomial(7,g); C1
Linear code of length 7, dimension 4 over Finite Field of size 2
sage: C2 = HammingCode(3,GF(2)); C2
Linear code of length 7, dimension 4 over Finite Field of size 2
sage: C1.is_permutation_equivalent(C2)
True
sage: C1.is_permutation_equivalent(C2,method="verbose")
(True, (4,6,5,7))
sage: C1 = RandomLinearCode(10,5,GF(2))
sage: C2 = RandomLinearCode(10,5,GF(3))
sage: C1.is_permutation_equivalent(C2)
False
```

is_self_dual()

A code C is self-dual if C == C.dual_code() is True.

Returns True if the code is self-dual (in the usual Hamming inner product) and False otherwise.

EXAMPLES:

```
sage: C = ExtendedBinaryGolayCode()
sage: C.is_self_dual()
True
sage: C = HammingCode(3,GF(2))
sage: C.is_self_dual()
False
```

is_self_orthogonal(*C*)

A code C is self-orthogonal if C is a subcode of C.dual_code().

Returns True if the code is self-dual (in the usual Hamming inner product) and False otherwise.

EXAMPLES:

```
sage: C = ExtendedBinaryGolayCode()
sage: C.is_self_orthogonal()
True
sage: C = HammingCode(3,GF(2))
sage: C.is_self_orthogonal()
False
sage: C = QuasiQuadraticResidueCode(11)
sage: C.is_self_orthogonal()
True
```

is_subcode(*other*)

Returns true if the first is a subcode of the second.

EXAMPLES:

```
sage: C1 = HammingCode(3,GF(2))
sage: G1 = C1.gen_mat()
sage: G2 = G1.matrix_from_rows([0,1,2])
sage: C2 = LinearCode(G2)
sage: C2.is_subcode(C1)
True
sage: C1.is_subcode(C2)
False
sage: C3 = C1.extended_code()
sage: C1.is_subcode(C3)
False
sage: C4 = C1.punctured([1])
sage: C4.is_subcode(C1)
False
sage: C5 = C1.shortened([1])
sage: C5.is_subcode(C1)
False
sage: C1 = HammingCode(3,GF(9,"z"))
sage: G1 = C1.gen_mat()
sage: G2 = G1.matrix_from_rows([0,1,2])
sage: C2 = LinearCode(G2)
sage: C2.is_subcode(C1)
True
```

length()

list()

Return list of all elements of this linear code.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: Clist = C.list()
sage: Clist[5]; Clist[5] in C
(1, 0, 1, 0, 0, 1, 1)
True
```

minimum_distance()

If q is not 2 or 3 then this uses a GAP kernel function (in C) written by Steve Linton. If q is 2 or 3 then this uses a very fast program written in C written by CJ Tjhal (this is much faster, except in some small examples).

EXAMPLES:

```
sage: MS = MatrixSpace(GF(3),4,7)
sage: G = MS([[1,1,1,0,0,0,0], [1,0,0,1,1,0,0], [0,1,0,1,0,1,0], [1,1,0,1,0,0,1]])
sage: C = LinearCode(G)
sage: C.minimum_distance()
3
sage: C = HammingCode(2,GF(4,"a")); C
Linear code of length 5, dimension 3 over Finite Field in a of size 2^2
sage: C.minimum_distance()
3
```

module_composition_factors(*gp*)

Prints the GAP record of the Meataxe composition factors module in Meataxe notation.

EXAMPLES:

```
sage: MS = MatrixSpace(GF(2),4,8)
sage: G  = MS([[1,0,0,0,1,1,1,0],[0,1,1,1,0,0,0,0],[0,0,0,0,0,0,0,1],[0,0,0,0,0,1,0,0]])
sage: C  = LinearCode(G)
```

```
sage: gp = C.automorphism_group_binary_code()
```

Now type "C.module_composition_factors(gp)" to get the record printed.

permutation_automorphism_group(*method='partition'*)

If C is an $[n, k, d]$ code over F, this function computes the subgroup $Aut(C) \subset S_n$ of all permutation automorphisms of C. The binary case always uses the (default) partition refinement method of Robert Miller.

Options: If method="gap" then GAP's MatrixAutomorphism function (written by Thomas Breuer) is used. The implementation combines an idea of mine with an improvement suggested by Cary Huffman. If method="gap+verbose" then code-theoretic data is printed out at several stages of the computation. If method="partition" then the (default) partition refinement method of Robert Miller is used.

EXAMPLES:

```
sage: MS = MatrixSpace(GF(2),4,8)
sage: G  = MS([[1,0,0,0,1,1,1,0],[0,1,1,1,0,0,0,0],[0,0,0,0,0,0,0,1],[0,0,0,0,0,1,0,0]])
sage: C  = LinearCode(G)
sage: C
Linear code of length 8, dimension 4 over Finite Field of size 2
sage: G = C.permutation_automorphism_group()
sage: G.order()
144
```

A less easy example involves showing that the permutation automorphism group of the extended ternary Golay code is the Mathieu group M_{11}.

```
sage: C = ExtendedTernaryGolayCode()
sage: M11 = MathieuGroup(11)
sage: M11.order()
7920
sage: G = C.permutation_automorphism_group()  # this should take < 5 seconds
sage: G.is_isomorphic(M11)                    # this should take < 5 seconds
True
```

In the binary case, uses sage.coding.binary_code:

```
sage: C = ExtendedBinaryGolayCode()
sage: G = C.permutation_automorphism_group()
sage: G.order()
244823040
```

In the non-binary case:

```
sage: C = HammingCode(2,GF(3)); C
Linear code of length 4, dimension 2 over Finite Field of size 3
sage: C.permutation_automorphism_group(method="partition")
Permutation Group with generators [(1,2,3)]
sage: C = HammingCode(2,GF(4,"z")); C
Linear code of length 5, dimension 3 over Finite Field in z of size 2^2
sage: C.permutation_automorphism_group(method="partition")
Permutation Group with generators [(1,2)(3,4), (1,3)(2,4)]
sage: C.permutation_automorphism_group(method="gap")
Permutation Group with generators [(1,2)(3,4), (1,3)(2,4)]
sage: C = TernaryGolayCode()
sage: C.permutation_automorphism_group(method="gap")
Permutation Group with generators [(3,4)(5,7)(6,9)(8,11), (3,5,8)(4,11,7)(6,9,10), (2,3)(4,6
```

However, the option `method="gap+verbose"`, will print out

Minimum distance: 5 Weight distribution: [1, 0, 0, 0, 0, 132, 132, 0, 330, 110, 0, 24]

Using the 132 codewords of weight 5 Supergroup size: 39916800

in addition to the output of C.permutation_automorphism_group(method="gap").

permuted_code(p)

Returns the permuted code - the code C which is equivalent to self via the column permutation p.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: G = C.automorphism_group_binary_code(); G
Permutation Group with generators [(3,4)(5,6), (3,5)(4,6), (2,3)(5,7), (1,2)(5,6)]
sage: g = G("(2,3)(5,7)")
sage: Cg = C.permuted_code(g)
sage: Cg
Linear code of length 7, dimension 4 over Finite Field of size 2
sage: C == Cg
True
```

punctured(L)

Returns the code punctured at the positions L, $L \subset \{1, 2, ..., n\}$. If C is a code of length n in GF(q) then the code C^L obtained from C by puncturing at the positions in L is the code of length n-L consisting of codewords of C which have their $i - th$ coordinate deleted if $i \in L$ and left alone if $i \notin L$:

$$C^L = \{(c_{i_1}, ..., c_{i_N}) \mid (c_1, ..., c_n) \in C\},$$

where $\{1, 2, ..., n\} - T = \{i_1, ..., i_N\}$. In particular, if $L = \{j\}$ then C^L is simply the code obtained from C by deleting the $j - th$ coordinate of each codeword. The code C^L is called the punctured code at L. The dimension of C^L can decrease if $|L| > d - 1$.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: C.punctured([1,2])
Linear code of length 5, dimension 4 over Finite Field of size 2
```

random_element()

Returns a random codeword.

EXAMPLES:

```
sage: C = HammingCode(3,GF(4,'a'))
sage: Cc = C.galois_closure(GF(2))
sage: c = C.gen_mat()[1]
sage: V = VectorSpace(GF(4,'a'),21)
sage: c2 = V([x^2 for x in c.list()])
sage: c2 in C
False
sage: c2 in Cc
True
```

redundancy_matrix(C)

If C is a linear [n,k,d] code then this function returns a kx(n-k) matrix A such that G = (I,A) generates a code (in standard form) equiv to C. If C is already in standard form and G = (I,A) is its gen mat then this function simply returns that A.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: C.gen_mat()
[1 0 0 1 0 1 0]
[0 1 0 1 0 1 1]
[0 0 1 1 0 0 1]
[0 0 0 0 1 1 1]
sage: C.redundancy_matrix()
[1 1 0]
[1 1 1]
```

```
[1 0 1]
[0 1 1]
sage: C.standard_form()[0].gen_mat()
[1 0 0 0 1 1 0]
[0 1 0 0 1 1 1]
[0 0 1 0 1 0 1]
[0 0 0 1 0 1 1]
sage: C = HammingCode(2,GF(3))
sage: C.gen_mat()
[1 0 2 2]
[0 1 2 1]
sage: C.redundancy_matrix()
[2 2]
[2 1]
```

sd_duursma_data(*C, i*)

INPUT: The formally s.d. code C and the type number (1,2,3,4) (does not check if C is actually sd)

RETURN: The data v,m as in Duursama [D]

EXAMPLES:

REFERENCES:

- [D] I. Duursma, "Extremal weight enumerators and ultraspherical polynomials"

sd_duursma_q(*C, i, d0*)

INPUT:

- `C` - an sd code (does not check if C is actually an sd code),
- `i` - the type number, one of 1,2,3,4,
- `d0` - and the divisor d0 (the smallest integer d00 such that each A_i0 iff i is divisible by d0).

RETURN: The coefficients $q_0, q_1, ...$, of $q(T)$ as in Duursama [D].

EXAMPLES:

REFERENCES:

- [D] I. Duursma, "Extremal weight enumerators and ultraspherical polynomials"

sd_zeta_polynomial(*C, typ=1*)

Returns the Duursma zeta function of a self-dual code using the construction in [D].

INPUT:

- `typ` - type of the s.d. code; one of 1,2,3, or 4.

EXAMPLES:

```
sage: C1 = HammingCode(3,GF(2))
sage: C2 = C1.extended_code(); C2
Linear code of length 8, dimension 4 over Finite Field of size 2
sage: C2.is_self_dual()
True
sage: C2.sd_zeta_polynomial()
2/5*T^2 + 2/5*T + 1/5
sage: C2.zeta_polynomial()
2/5*T^2 + 2/5*T + 1/5
sage: P = C2.sd_zeta_polynomial(); P(1)
1
sage: F.<z> = GF(4,"z")
sage: MS = MatrixSpace(F, 3, 6)
sage: G = MS([[1,0,0,1,z,z],[0,1,0,z,1,z],[0,0,1,z,z,1]])
sage: C = LinearCode(G)  # the "hexacode"
sage: C.sd_zeta_polynomial(4)
1
```

It is a general fact about Duursma zeta polynomials that P(1) = 1.

REFERENCES:

•[D] I. Duursma, "Extremal weight enumerators and ultraspherical polynomials"

shortened(*L*)

Returns the code shortened at the positions L, $L \subset \{1, 2, ..., n\}$. Consider the subcode $C(L)$ consisting of all codewords $c \in C$ which satisfy $c_i = 0$ for all $i \in L$. The punctured code $C(L)^L$ is called the shortened code on L and is denoted C_L. The code constructed is actually only isomorphic to the shortened code defined in this way.

By Theorem 1.5.7 in [HP], C_L is $((C^\perp)^L)^\perp$. This is used in the construction below.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: C.shortened([1,2])
Linear code of length 5, dimension 2 over Finite Field of size 2
```

spectrum(*method=None*)

The default method (gap) uses a GAP kernel function (in C) written by Steve Linton.

METHOD:

•`None` - defaults to gap except in the binary case

•`gap` - uses the GAP function

•`leon` - uses Jeffrey Leon's software via Guava

•`binary` - uses Sage native Cython code

The optional method (leon) may create a stack smashing error and a traceback but should return the correct answer. It appears to run much faster than the"gap" method in some ("small") examples and much slower than the "gap" method in other ("larger") examples.

EXAMPLES:

```
sage: MS = MatrixSpace(GF(2),4,7)
sage: G = MS([[1,1,1,0,0,0,0],[1,0,0,1,1,0,0],[0,1,0,1,0,1,0],[1,1,0,1,0,0,1]])
sage: C = LinearCode(G)
sage: C.spectrum()
[1, 0, 0, 7, 7, 0, 0, 1]
sage: F.<z> = GF(2^2,"z")
sage: C = HammingCode(2, F); C
Linear code of length 5, dimension 3 over Finite Field in z of size 2^2
sage: C.spectrum()
[1, 0, 0, 30, 15, 18]
sage: C = HammingCode(3,GF(2)); C
Linear code of length 7, dimension 4 over Finite Field of size 2
sage: C.spectrum(method="leon")
[1, 0, 0, 7, 7, 0, 0, 1]
sage: C = HammingCode(3,GF(3)); C
Linear code of length 13, dimension 10 over Finite Field of size 3
sage: C.spectrum() == C.spectrum(method="leon")
True
sage: C = HammingCode(2,GF(5)); C
Linear code of length 6, dimension 4 over Finite Field of size 5
sage: C.spectrum() == C.spectrum(method="leon")
True
sage: C = HammingCode(2,GF(7)); C
Linear code of length 8, dimension 6 over Finite Field of size 7
sage: C.spectrum() == C.spectrum(method="leon")
True
```

standard_form()

An $[n, k]$ linear code with generator matrix G is in standard form is the row-reduced echelon form of G is

(I, A), where I denotes the $k \times k$ identity matrix and A is a $k \times (n-k)$ block. This method returns a pair (C, p) where C is a code permutation equivalent to self and p in S_n (n = length of C) is the permutation sending self to C. This does not call GAP.

Thanks to Frank Luebeck for (the GAP version of) this code.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: C.gen_mat()
[1 0 0 1 0 1 0]
[0 1 0 1 0 1 1]
[0 0 1 1 0 0 1]
[0 0 0 0 1 1 1]
sage: Cs,p = C.standard_form()
sage: p
(4,5)
sage: Cs
Linear code of length 7, dimension 4 over Finite Field of size 2
sage: Cs.gen_mat()
[1 0 0 0 1 1 0]
[0 1 0 0 1 1 1]
[0 0 1 0 1 0 1]
[0 0 0 1 0 1 1]
sage: MS = MatrixSpace(GF(3),3,7)
sage: G = MS([[1,0,0,0,1,1,0],[0,1,0,1,0,1,0],[0,0,0,0,0,0,1]])
sage: C = LinearCode(G)
sage: G; C.standard_form()[0].gen_mat()
[1 0 0 0 1 1 0]
[0 1 0 1 0 1 0]
[0 0 0 0 0 0 1]
[1 0 0 0 1 1 0]
[0 1 0 1 0 1 0]
[0 0 1 0 0 0 0]
sage: C.standard_form()[1]
(3,7)
```

support()

Returns the set of indices j where A_j is nonzero, where spectrum(self) = $[A_0, A_1, ..., A_n]$.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: C.spectrum()
[1, 0, 0, 7, 7, 0, 0, 1]
sage: C.support()
[0, 3, 4, 7]
```

weight_distribution(*method=None*)

The default method (gap) uses a GAP kernel function (in C) written by Steve Linton.

METHOD:

- `None` - defaults to gap except in the binary case
- `gap` - uses the GAP function
- `leon` - uses Jeffrey Leon's software via Guava
- `binary` - uses Sage native Cython code

The optional method (leon) may create a stack smashing error and a traceback but should return the correct answer. It appears to run much faster than the"gap" method in some ("small") examples and much slower than the "gap" method in other ("larger") examples.

EXAMPLES:

```
sage: MS = MatrixSpace(GF(2),4,7)
sage: G = MS([[1,1,1,0,0,0,0],[1,0,0,1,1,0,0],[0,1,0,1,0,1,0],[1,1,0,1,0,0,1]])
sage: C = LinearCode(G)
sage: C.spectrum()
[1, 0, 0, 7, 7, 0, 0, 1]
sage: F.<z> = GF(2^2,"z")
sage: C = HammingCode(2, F); C
Linear code of length 5, dimension 3 over Finite Field in z of size 2^2
sage: C.spectrum()
[1, 0, 0, 30, 15, 18]
sage: C = HammingCode(3,GF(2)); C
Linear code of length 7, dimension 4 over Finite Field of size 2
sage: C.spectrum(method="leon")
[1, 0, 0, 7, 7, 0, 0, 1]
sage: C = HammingCode(3,GF(3)); C
Linear code of length 13, dimension 10 over Finite Field of size 3
sage: C.spectrum() == C.spectrum(method="leon")
True
sage: C = HammingCode(2,GF(5)); C
Linear code of length 6, dimension 4 over Finite Field of size 5
sage: C.spectrum() == C.spectrum(method="leon")
True
sage: C = HammingCode(2,GF(7)); C
Linear code of length 8, dimension 6 over Finite Field of size 7
sage: C.spectrum() == C.spectrum(method="leon")
True
```

weight_enumerator(*names='xy'*)

Returns the weight enumerator of the code.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: C.weight_enumerator()
x^7 + 7*x^4*y^3 + 7*x^3*y^4 + y^7
sage: C.weight_enumerator(names="st")
s^7 + 7*s^4*t^3 + 7*s^3*t^4 + t^7
```

zeta_function(*name='T'*)

Returns the Duursma zeta function of the code.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: C.zeta_function()
(2/5*T^2 + 2/5*T + 1/5)/(2*T^2 - 3*T + 1)
```

zeta_polynomial(*name='T'*)

Returns the Duursma zeta polynomial of the code C.

Assumes `C.minimum_distance()` 1 and minimum_distance $(C^{\perp}) > 1$.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: C.zeta_polynomial()
2/5*T^2 + 2/5*T + 1/5
sage: C = best_known_linear_code(6,3,GF(2))
sage: C.minimum_distance()
3
sage: C.zeta_polynomial()
2/5*T^2 + 2/5*T + 1/5
```

```
sage: C = HammingCode(4,GF(2))
sage: C.zeta_polynomial()
16/429*T^6 + 16/143*T^5 + 80/429*T^4 + 32/143*T^3 + 30/143*T^2 + 2/13*T + 1/13
sage: F.<z> = GF(4,"z")
sage: MS = MatrixSpace(F, 3, 6)
sage: G = MS([[1,0,0,1,z,z],[0,1,0,z,1,z],[0,0,1,z,z,1]])
sage: C = LinearCode(G)  # the "hexacode"
sage: C.zeta_polynomial()
1
```

- I. Duursma, "From weight enumerators to zeta functions", in Discrete Applied Mathematics, vol. 111, no. 1-2, pp. 55-73, 2001.

LinearCodeFromVectorSpace(*self*)

Simply converts a vector subspace V of $GF(q)^n$ into a LinearCode.

best_known_linear_code(*n, k, F*)

best_known_linear_code returns the best known (as of 11 May 2006) linear code of length n, dimension k over field F. The function uses the tables described in bounds_minimum_distance to construct this code.

This does not require an internet connection.

EXAMPLES:

```
sage: best_known_linear_code(10,5,GF(2))     # long time
Linear code of length 10, dimension 5 over Finite Field of size 2
sage: gap.eval("C:=BestKnownLinearCode(10,5,GF(2))")      # long time
'a linear [10,5,4]2..4 shortened code'
```

This means that best possible binary linear code of length 10 and dimension 5 is a code with minimum distance 4 and covering radius somewhere between 2 and 4. Use `minimum_distance_why(10,5,GF(2))` or `print bounds_minimum_distance(10,5,GF(2))` for further details.

best_known_linear_code_www(*n, k, F, verbose=False*)

Explains the construction of the best known linear code over GF(q) with length n and dimension k, courtesy of the www page http://www.codetables.de/.

INPUT:

- `n` - integer, the length of the code
- `k` - integer, the dimension of the code
- `F` - finite field, whose field order must be in [2, 3, 4, 5, 7, 8, 9]
- `verbose` - bool (default=False), print verbose message

OUTPUT:

- `str` - text about why the bounds are as given

EXAMPLES:

```
sage: L = best_known_linear_code_www(72, 36, GF(2)) # requires internet, optional
sage: print L                                       # requires internet, optional
Construction of a linear code
[72,36,15] over GF(2):
[1]:  [73, 36, 16] Cyclic Linear Code over GF(2)
     CyclicCode of length 73 with generating polynomial x^37 + x^36 + x^34 +
x^33 + x^32 + x^27 + x^25 + x^24 + x^22 + x^21 + x^19 + x^18 + x^15 + x^11 +
x^10 + x^8 + x^7 + x^5 + x^3 + 1

bounds_minimum_distance(*n, k, F*)

The function bounds_minimum_distance calculates a lower and upper bound for the minimum distance of an optimal linear code with word length n, dimension k over field F. The function returns a record with the two bounds and an explanation for each bound. The function Display can be used to show the explanations.

The values for the lower and upper bound are obtained from a table constructed by Cen Tjhai for GUAVA, derived from the table of Brouwer. (See http://www.win.tue.nl/ aeb/voorlincod.html or use the Sage function minimum_distance_why for the most recent data.) These tables contain lower and upper bounds for q=2 (n <= 257), 3 (n <= 243), 4 (n <= 256). (Current as of 11 May 2006.) For codes over other fields and for larger word lengths, trivial bounds are used.

This does not require an internet connection. The format of the output is a little non-intuitive. Try print bounds_minimum_distance(10,5,GF(2)) for example.

code2leon(*C*)

Writes a file in Sage's temp directory representing the code C, returning the absolute path to the file. This is the Sage translation of the GuavaToLeon command in Guava's codefun.gi file.

INPUT:

- C - a linear code (over GF(p), p < 11)

OUTPUT:

- Absolute path to the file written.

EXAMPLES:

```
sage: C = HammingCode(3,GF(2)); C
Linear code of length 7, dimension 4 over Finite Field of size 2
sage: file_loc = sage.coding.linear_code.code2leon(C)
sage: f = open(file_loc); print f.read()
LIBRARY code;
code=seq(2,4,7,seq(
1,0,0,1,0,1,0,
0,1,0,1,0,1,1,
0,0,1,1,0,0,1,
0,0,0,0,1,1,1
));
FINISH;
sage: f.close()
```

hamming_weight(*v*)

min_wt_vec_gap(*Gmat, F*)

Uses C programs written by Steve Linton in the kernel of GAP, so is fairly fast.

INPUT: Same as wtdist.

OUTPUT: Returns a minimum weight vector v of the code generated by Gmat ## , the "message" vector m such that m*G = v, and the (minimum) distance, as a triple.

EXAMPLES:

```
sage: Gstr = "Z(2)*[[1,1,1,0,0,0,0], [1,0,0,1,1,0,0], [0,1,0,1,0,1,0], [1,1,0,1,0,0,1]]"
sage: sage.coding.linear_code.min_wt_vec_gap(Gstr,GF(2))
(0, 0, 1, 0, 1, 1, 0)
```

Here Gstr is a generator matrix of the Hamming [7,4,3] binary code.

AUTHORS:

- David Joyner (11-2005)

self_orthogonal_binary_codes(*n, k, b=2, parent=None, BC=None, equal=False, in_test=None*)

Returns a Python iterator which generates a complete set of representatives of all permutation equivalence classes of self-orthogonal binary linear codes of length in [1..n] and dimension in [1..k].

INPUT:

- `n` - maximal length
- `k` - maximal dimension
- `b` - require that the generators all have weight divisible by b (if b=2, all self-orthogonal codes are generated, and if b=4, all doubly even codes are generated). Must be an even positive integer.
- `parent` - default None, used in recursion
- `BC` - default None, used in recursion
- `equal` - default False, if True generates only [n, k] codes
- `in_test` - default None, used in recursion

EXAMPLES: Generate all self-orthogonal codes of length up to 7 and dimension up to 3:

```
sage: for B in self_orthogonal_binary_codes(7,3):
...     print B
...
Linear code of length 2, dimension 1 over Finite Field of size 2
Linear code of length 4, dimension 2 over Finite Field of size 2
Linear code of length 6, dimension 3 over Finite Field of size 2
Linear code of length 4, dimension 1 over Finite Field of size 2
Linear code of length 6, dimension 2 over Finite Field of size 2
Linear code of length 6, dimension 2 over Finite Field of size 2
Linear code of length 7, dimension 3 over Finite Field of size 2
Linear code of length 6, dimension 1 over Finite Field of size 2
```

Generate all doubly-even codes of length up to 7 and dimension up to 3:

```
sage: for B in self_orthogonal_binary_codes(7,3,4):
...     print B; print B.gen_mat()
...
Linear code of length 4, dimension 1 over Finite Field of size 2
[1 1 1 1]
Linear code of length 6, dimension 2 over Finite Field of size 2
[1 1 1 1 0 0]
[0 1 0 1 1 1]
Linear code of length 7, dimension 3 over Finite Field of size 2
[1 0 1 1 0 1 0]
[0 1 0 1 1 1 0]
[0 0 1 0 1 1 1]
```

Generate all doubly-even codes of length up to 7 and dimension up to 2:

```
sage: for B in self_orthogonal_binary_codes(7,2,4):
...    print B; print B.gen_mat()
Linear code of length 4, dimension 1 over Finite Field of size 2
[1 1 1 1]
Linear code of length 6, dimension 2 over Finite Field of size 2
[1 1 1 1 0 0]
[0 1 0 1 1 1]
```

Generate all self-orthogonal codes of length equal to 8 and dimension equal to 4:

```
sage: for B in self_orthogonal_binary_codes(8, 4, equal=True):
...     print B; print B.gen_mat()
Linear code of length 8, dimension 4 over Finite Field of size 2
[1 0 0 1 0 0 0 0]
[0 1 0 0 1 0 0 0]
[0 0 1 0 0 1 0 0]
[0 0 0 0 0 0 1 1]
Linear code of length 8, dimension 4 over Finite Field of size 2
[1 0 0 1 1 0 1 0]
[0 1 0 1 1 1 0 0]
[0 0 1 0 1 1 1 0]
[0 0 0 1 0 1 1 1]
```

Since all the codes will be self-orthogonal, b must be divisible by 2:

```
sage: list(self_orthogonal_binary_codes(8, 4, 1, equal=True))
...
ValueError: b (1) must be a positive even integer.
```

wtdist_gap(*Gmat, F*)

INPUT:

- `Gmat` - a string representing a GAP generator matrix G of a linear code.
- `F` - a (Sage) finite field - the base field of the code.

OUTPUT: Returns the spectrum of the associated code.

EXAMPLES:

```
sage: Gstr = 'Z(2)*[[1,1,1,0,0,0,0], [1,0,0,1,1,0,0], [0,1,0,1,0,1,0], [1,1,0,1,0,0,1]]'
sage: F = GF(2)
sage: sage.coding.linear_code.wtdist_gap(Gstr, F)
[1, 0, 0, 7, 7, 0, 0, 1]
```

Here Gstr is a generator matrix of the Hamming [7,4,3] binary code.

ALGORITHM: Uses C programs written by Steve Linton in the kernel of GAP, so is fairly fast.

40.2 Linear code constructions.

AUTHOR:

- David Joyner (2007-05): initial version

- " (2008-02): added cyclic codes, Hamming codes
- " (2008-03): added BCH code, LinearCodeFromCheckmatrix, ReedSolomonCode, WalshCode, DuadicCodeEvenPair, DuadicCodeOddPair, QR codes (even and odd)
- " (2008-09) fix for bug in BCHCode reported by F. Voloch
- " (2008-10) small docstring changes to WalshCode and walsh_matrix

This file contains constructions of error-correcting codes which are pure Python/Sage and not obtained from wrapping GUAVA functions. The GUAVA wrappers are in guava.py.

Let F be a finite field with q elements. Here's a constructive definition of a cyclic code of length n.

1. Pick a monic polynomial $g(x) \in F[x]$ dividing $x^n - 1$. This is called the generating polynomial of the code.
2. For each polynomial $p(x) \in F[x]$, compute $p(x)g(x) \pmod{x^n - 1}$.'$Denotetheanswerby$'$c_0 + c_1x + ... + c_{n-1}x^{n-1}$.
3. $\mathbf{c} = (c_0, c_1, ..., c_{n-1})$ is a codeword in C. Every codeword in C arises in this way (from some $p(x)$).

The polynomial notation for the code is to call $c_0 + c_1x + ... + c_{n-1}x^{n-1}$ the codeword (instead of $(c_0, c_1, ..., c_{n-1})$). The polynomial $h(x) = (x^n - 1)/g(x)$ is called the check polynomial of C.

Let n be a positive integer relatively prime to q and let α be a primitive n-th root of unity. Each generator polynomial g of a cyclic code C of length n has a factorization of the form

$$g(x) = (x - \alpha^{k_1})...(x - \alpha^{k_r}),$$

where $\{k_1, ..., k_r\} \subset \{0, ..., n - 1\}$. The numbers α^{k_i}, $1 \leq i \leq r$, are called the zeros of the code C. Many families of cyclic codes (such as BCH codes and the quadratic residue codes) are defined using properties of the zeros of C.

- BCHCode - A 'Bose-Chaudhuri-Hockenghem code' (or BCH code for short) is the largest possible cyclic code of length n over field F=GF(q), whose generator polynomial has zeros (which contain the set) $Z = \{a^i \mid i \in C_b \cup ...C_{b+delta-2}\}$, where a is a primitive n^{th} root of unity in the splitting field $GF(q^m)$, b is an integer $0 \leq b \leq n - delta + 1$ and m is the multiplicative order of q modulo n. The default here is $b = 0$ (unlike Guava, which has default $b = 1$). Here C_k are the cyclotomic codes (see `cyclotomic_cosets`).
- BinaryGolayCode, ExtendedBinaryGolayCode, TernaryGolayCode, ExtendedTernaryGolayCode the well-known"extremal" Golay codes, http://en.wikipedia.org/wiki/Golay_code
- cyclic codes - CyclicCodeFromGeneratingPolynomial (= CyclicCode), CyclicCodeFromCheckPolynomial, http://en.wikipedia.org/wiki/Cyclic_code
- DuadicCodeEvenPair, DuadicCodeOddPair: Constructs the "even (resp. odd) pair" of duadic codes associated to the "splitting" S1, S2 of n. This is a special type of cyclic code whose generator is determined by S1, S2. See chapter 6 in [HP].
- HammingCode - the well-known Hamming code, http://en.wikipedia.org/wiki/Hamming_code
- LinearCodeFromCheckMatrix - for specifying the code using the check matrix instead of the generator matrix.
- QuadraticResidueCodeEvenPair, QuadraticResidueCodeOddPair: Quadratic residue codes of a given odd prime length and base ring either don't exist at all or occur as 4-tuples - a pair of "odd-like" codes and a pair of "even-like" codes. If n 2 is prime then (Theorem 6.6.2 in [HP]) a QR code exists over GF(q) iff q is a quadratic residue mod n. Here they are constructed as"even-like" duadic codes associated the splitting (Q,N) mod n, where Q is the set of non-zero quadratic residues and N is the non-residues. QuadraticResidueCode (a special case) and ExtendedQuadraticResidueCode are included as well.

- RandomLinearCode - Repeatedly applies Sage's random_element applied to the ambient MatrixSpace of the generator matrix until a full rank matrix is found.
- ReedSolomonCode - Given a finite field F of order q, let n and k be chosen such that $1 \leq k \leq n \leq q$. Pick n distinct elements of F, denoted $\{x_1, x_2, ..., x_n\}$. Then, the codewords are obtained by evaluating every polynomial in $F[x]$ of degree less than k at each x_i.
- ToricCode - Let P denote a list of lattice points in $\mathbf{Z}^d$ and let T denote a listing of all points in $(F^x)^d$. Put $n = |T|$ and let k denote the dimension of the vector space of functions $V = \mathrm{Span}\{x^e \mid e \in P\}$. The associated toric code C is the evaluation code which is the image of the evaluation map $eval_T : V \to F^n$, where x^e is the multi-index notation.
- WalshCode - a binary linear $[2^m, m, 2^{m-1}]$ code related to Hadamard matrices. http://en.wikipedia.org/wiki/Walsh_code

Please see the docstrings below for further details.

BCHCode (*n, delta, F, b=0*)

A 'Bose-Chaudhuri-Hockenghem code' (or BCH code for short) is the largest possible cyclic code of length n over field F=GF(q), whose generator polynomial has zeros (which contain the set) $Z = \{a^b, a^{b+1}, ..., a^{b+delta-2}\}$, where a is a primitive n^{th} root of unity in the splitting field $GF(q^m)$, b is an integer $0 \leq b \leq n - delta + 1$ and m is the multiplicative order of q modulo n. (The integers $b, ..., b + delta - 2$ typically lie in the range $1, ..., n - 1$.) The integer $delta \geq 1$ is called the "designed distance". The length n of the code and the size q of the base field must be relatively prime. The generator polynomial is equal to the least common multiple of the minimal polynomials of the elements of the set Z above.

Special cases are b=1 (resulting codes are called 'narrow-sense' BCH codes), and $n = q^m - 1$ (known as 'primitive' BCH codes).

It may happen that several values of delta give rise to the same BCH code. The largest one is called the Bose distance of the code. The true minimum distance, d, of the code is greater than or equal to the Bose distance, so $d \geq delta$.

EXAMPLES:

```
sage: FF.<a> = GF(3^2,"a")
sage: x = PolynomialRing(FF,"x").gen()
sage: L = [b.minpoly() for b in [a,a^2,a^3]]; g = LCM(L)
sage: f = x^(8)-1
sage: g.divides(f)
True
sage: C = CyclicCode(8,g); C
Linear code of length 8, dimension 4 over Finite Field of size 3
sage: C.minimum_distance()
4
sage: C = BCHCode(8,3,GF(3),1); C
Linear code of length 8, dimension 4 over Finite Field of size 3
sage: C.minimum_distance()
4
sage: C = BCHCode(8,3,GF(3)); C
Linear code of length 8, dimension 5 over Finite Field of size 3
sage: C.minimum_distance()
3
sage: C = BCHCode(26, 5, GF(5), b=1); C
Linear code of length 26, dimension 10 over Finite Field of size 5
```

•[HP] W. C. Huffman, V. Pless, Fundamentals of Error-Correcting Codes, Cambridge Univ. Press, 2003.

BinaryGolayCode()

BinaryGolayCode() returns a binary Golay code. This is a perfect [23,12,7] code. It is also (equivalent to) a cyclic code, with generator polynomial $g(x) = 1 + x^2 + x^4 + x^5 + x^6 + x^{10} + x^{11}$. Extending it yields the extended Golay code (see ExtendedBinaryGolayCode).

EXAMPLE:

```
sage: C = BinaryGolayCode()
sage: C
Linear code of length 23, dimension 12 over Finite Field of size 2
sage: C.minimum_distance()                # long time
7
```

AUTHORS:

- David Joyner (2007-05)

CyclicCode(*n, g, ignore=True*)

If g is a polynomial over GF(q) which divides $x^n - 1$ then this constructs the code "generated by g" (ie, the code associated with the principle ideal gR in the ring $R = GF(q)[x]/(x^n - 1)$ in the usual way).

The option "ignore" says to ignore the condition that (a) the characteristic of the base field does not divide the length (the usual assumption in the theory of cyclic codes), and (b) g must divide $x^n - 1$. If ignore=True, instead of returning an error, a code generated by $gcd(x^n - 1, g)$ is created.

EXAMPLES:

```
sage: P.<x> = PolynomialRing(GF(3),"x")
sage: g = x-1
sage: C = CyclicCodeFromGeneratingPolynomial(4,g); C
Linear code of length 4, dimension 3 over Finite Field of size 3
sage: P.<x> = PolynomialRing(GF(4,"a"),"x")
sage: g = x^3+1
sage: C = CyclicCodeFromGeneratingPolynomial(9,g); C
Linear code of length 9, dimension 6 over Finite Field in a of size 2^2
sage: P.<x> = PolynomialRing(GF(2),"x")
sage: g = x^3+x+1
sage: C = CyclicCodeFromGeneratingPolynomial(7,g); C
Linear code of length 7, dimension 4 over Finite Field of size 2
sage: C.gen_mat()
[1 1 0 1 0 0 0]
[0 1 1 0 1 0 0]
[0 0 1 1 0 1 0]
[0 0 0 1 1 0 1]
sage: g = x+1
sage: C = CyclicCodeFromGeneratingPolynomial(4,g); C
Linear code of length 4, dimension 3 over Finite Field of size 2
sage: C.gen_mat()
[1 1 0 0]
[0 1 1 0]
[0 0 1 1]
```

On the other hand, CyclicCodeFromPolynomial(4,x) will produce a ValueError including a traceback error message: "x must divide $x^4 - 1$". You will also get a ValueError if you type

```
sage: P.<x> = PolynomialRing(GF(4,"a"),"x")
sage: g = x^2+1
```

followed by CyclicCodeFromGeneratingPolynomial(6,g). You will also get a ValueError if you type

```
sage: P.<x> = PolynomialRing(GF(3),"x")
sage: g = x^2-1
sage: C = CyclicCodeFromGeneratingPolynomial(5,g); C
Linear code of length 5, dimension 4 over Finite Field of size 3
```

followed by C = CyclicCodeFromGeneratingPolynomial(5,g,False), with a traceback message including "x^2+2 must divide x^5-1".

CyclicCodeFromCheckPolynomial (*n, h, ignore=True*)

If h is a polynomial over GF(q) which divides x^n-1 then this constructs the code "generated by $g=(x^n-1)/h$" (ie, the code associated with the principle ideal gR in the ring $R=GF(q)[x]/(x^n-1)$ in the usual way). The option "ignore" says to ignore the condition that the characteristic of the base field does not divide the length (the usual assumption in the theory of cyclic codes).

EXAMPLES:

```
sage: P.<x> = PolynomialRing(GF(3),"x")
sage: C = CyclicCodeFromCheckPolynomial(4,x + 1); C
Linear code of length 4, dimension 1 over Finite Field of size 3
sage: C = CyclicCodeFromCheckPolynomial(4,x^3 + x^2 + x + 1); C
Linear code of length 4, dimension 3 over Finite Field of size 3
sage: C.gen_mat()
[2 1 0 0]
[0 2 1 0]
[0 0 2 1]
```

CyclicCodeFromGeneratingPolynomial (*n, g, ignore=True*)

If g is a polynomial over GF(q) which divides x^n-1 then this constructs the code "generated by g" (ie, the code associated with the principle ideal gR in the ring $R=GF(q)[x]/(x^n-1)$ in the usual way).

The option "ignore" says to ignore the condition that (a) the characteristic of the base field does not divide the length (the usual assumption in the theory of cyclic codes), and (b) g must divide x^n-1. If ignore=True, instead of returning an error, a code generated by $gcd(x^n-1,g)$ is created.

EXAMPLES:

```
sage: P.<x> = PolynomialRing(GF(3),"x")
sage: g = x-1
sage: C = CyclicCodeFromGeneratingPolynomial(4,g); C
Linear code of length 4, dimension 3 over Finite Field of size 3
sage: P.<x> = PolynomialRing(GF(4,"a"),"x")
sage: g = x^3+1
sage: C = CyclicCodeFromGeneratingPolynomial(9,g); C
Linear code of length 9, dimension 6 over Finite Field in a of size 2^2
sage: P.<x> = PolynomialRing(GF(2),"x")
sage: g = x^3+x+1
sage: C = CyclicCodeFromGeneratingPolynomial(7,g); C
Linear code of length 7, dimension 4 over Finite Field of size 2
sage: C.gen_mat()
[1 1 0 1 0 0 0]
[0 1 1 0 1 0 0]
[0 0 1 1 0 1 0]
[0 0 0 1 1 0 1]
sage: g = x+1
sage: C = CyclicCodeFromGeneratingPolynomial(4,g); C
Linear code of length 4, dimension 3 over Finite Field of size 2
sage: C.gen_mat()
[1 1 0 0]
```

```
[0 1 1 0]
[0 0 1 1]
```

On the other hand, CyclicCodeFromPolynomial(4,x) will produce a ValueError including a traceback error message: "x must divide $x^4 - 1$". You will also get a ValueError if you type

```
sage: P.<x> = PolynomialRing(GF(4,"a"),"x")
sage: g = x^2+1
```

followed by CyclicCodeFromGeneratingPolynomial(6,g). You will also get a ValueError if you type

```
sage: P.<x> = PolynomialRing(GF(3),"x")
sage: g = x^2-1
sage: C = CyclicCodeFromGeneratingPolynomial(5,g); C
Linear code of length 5, dimension 4 over Finite Field of size 3
```

followed by C = CyclicCodeFromGeneratingPolynomial(5,g,False), with a traceback message including "x^2+2 must divide $x^5 - 1$".

DuadicCodeEvenPair(*F, S1, S2*)

Constructs the "even pair" of duadic codes associated to the "splitting" (see the docstring for `is_a_splitting` for the definition) S1, S2 of n.

> **Warning:** Maybe the splitting should be associated to a sum of q-cyclotomic cosets mod n, where q is a *prime*.

EXAMPLES:

```
sage: from sage.coding.code_constructions import is_a_splitting
sage: n = 11; q = 3
sage: C = cyclotomic_cosets(q,n); C
[[0], [1, 3, 4, 5, 9], [2, 6, 7, 8, 10]]
sage: S1 = C[1]
sage: S2 = C[2]
sage: is_a_splitting(S1,S2,11)
(True, 2)
sage: DuadicCodeEvenPair(GF(q),S1,S2)
(Linear code of length 11, dimension 5 over Finite Field of size 3,
 Linear code of length 11, dimension 5 over Finite Field of size 3)
```

DuadicCodeOddPair(*F, S1, S2*)

Constructs the "odd pair" of duadic codes associated to the "splitting" S1, S2 of n.

> **Warning:** Maybe the splitting should be associated to a sum of q-cyclotomic cosets mod n, where q is a *prime*.

EXAMPLES:

```
sage: from sage.coding.code_constructions import is_a_splitting
sage: n = 11; q = 3
sage: C = cyclotomic_cosets(q,n); C
[[0], [1, 3, 4, 5, 9], [2, 6, 7, 8, 10]]
sage: S1 = C[1]
sage: S2 = C[2]
sage: is_a_splitting(S1,S2,11)
(True, 2)
sage: DuadicCodeOddPair(GF(q),S1,S2)
```

```
(Linear code of length 11, dimension 6 over Finite Field of size 3,
 Linear code of length 11, dimension 6 over Finite Field of size 3)
```

This is consistent with Theorem 6.1.3 in [HP].

ExtendedBinaryGolayCode()

ExtendedBinaryGolayCode() returns the extended binary Golay code. This is a perfect [24,12,8] code. This code is self-dual.

EXAMPLES:

```
sage: C = ExtendedBinaryGolayCode()
sage: C
Linear code of length 24, dimension 12 over Finite Field of size 2
sage: C.minimum_distance()
8
```

AUTHORS:

- David Joyner (2007-05)

ExtendedQuadraticResidueCode(*n, F*)

The extended quadratic residue code (or XQR code) is obtained from a QR code by adding a check bit to the last coordinate. (These codes have very remarkable properties such as large automorphism groups and duality properties - see [HP], Section 6.6.3-6.6.4.)

INPUT:

- n - an odd prime
- F - a finite prime field F whose order must be a quadratic residue modulo n.

OUTPUT: Returns an extended quadratic residue code.

EXAMPLES:

```
sage: C1 = QuadraticResidueCode(7,GF(2))
sage: C2 = C1.extended_code()
sage: C3 = ExtendedQuadraticResidueCode(7,GF(2)); C3
Linear code of length 8, dimension 4 over Finite Field of size 2
sage: C2 == C3
True
sage: C = ExtendedQuadraticResidueCode(17,GF(2))
sage: C
Linear code of length 18, dimension 9 over Finite Field of size 2
sage: C3 = QuadraticResidueCodeOddPair(7,GF(2))[0]
sage: C3x = C3.extended_code()
sage: C4 = ExtendedQuadraticResidueCode(7,GF(2))
sage: C3x == C4
True
```

AUTHORS:

- David Joyner (07-2006)

ExtendedTernaryGolayCode()

ExtendedTernaryGolayCode returns a ternary Golay code. This is a self-dual perfect [12,6,6] code.

EXAMPLES:

```
sage: C = ExtendedTernaryGolayCode()
sage: C
Linear code of length 12, dimension 6 over Finite Field of size 3
sage: C.minimum_distance()
6
```

AUTHORS:

- David Joyner (11-2005)

HammingCode(*r*, *F*)

Implements the Hamming codes.

The r^{th} Hamming code over $F = GF(q)$ is an $[n, k, d]$ code with length $n = (q^r - 1)/(q - 1)$, dimension $k = (q^r - 1)/(q - 1) - r$ and minimum distance $d = 3$. The parity check matrix of a Hamming code has rows consisting of all nonzero vectors of length r in its columns, modulo a scalar factor so no parallel columns arise. A Hamming code is a single error-correcting code.

INPUT:

- `r` - an integer 2
- `F` - a finite field.

OUTPUT: Returns the r-th q-ary Hamming code.

EXAMPLES:

```
sage: HammingCode(3,GF(2))
Linear code of length 7, dimension 4 over Finite Field of size 2
sage: C = HammingCode(3,GF(3)); C
Linear code of length 13, dimension 10 over Finite Field of size 3
sage: C.minimum_distance()
3
sage: C = HammingCode(3,GF(4,'a')); C
Linear code of length 21, dimension 18 over Finite Field in a of size 2^2
```

LinearCodeFromCheckMatrix(*H*)

A linear [n,k]-code C is uniquely determined by its generator matrix G and check matrix H. We have the following short exact sequence

$$0 \to \mathbf{F}^k \xrightarrow{G} \mathbf{F}^n \xrightarrow{H} \mathbf{F}^{n-k} \to 0.$$

("Short exact" means (a) the arrow G is injective, i.e., G is a full-rank $k \times n$ matrix, (b) the arrow H is surjective, and (c) $\text{image}(G) = \text{kernel}(H)$.)

EXAMPLES:

```
sage: C = HammingCode(3,GF(2))
sage: H = C.check_mat(); H
[1 0 0 1 1 0 1]
[0 1 0 1 0 1 1]
[0 0 1 1 1 1 0]
sage: LinearCodeFromCheckMatrix(H) == C
True
sage: C = HammingCode(2,GF(3))
sage: H = C.check_mat(); H
[1 0 2 2]
[0 1 2 1]
sage: LinearCodeFromCheckMatrix(H) == C
True
```

```
sage: C = RandomLinearCode(10,5,GF(4,"a"))
sage: H = C.check_mat()
sage: LinearCodeFromCheckMatrix(H) == C
True
```

QuadraticResidueCode(*n, F*)

A quadratic residue code (or QR code) is a cyclic code whose generator polynomial is the product of the polynomials $x - \alpha^i$ (α is a primitive n^{th} root of unity; i ranges over the set of quadratic residues modulo n).

See QuadraticResidueCodeEvenPair and QuadraticResidueCodeOddPair for a more general construction.

INPUT:

- n - an odd prime
- F - a finite prime field F whose order must be a quadratic residue modulo n.

OUTPUT: Returns a quadratic residue code.

EXAMPLES:

```
sage: C = QuadraticResidueCode(7,GF(2))
sage: C
Linear code of length 7, dimension 4 over Finite Field of size 2
sage: C = QuadraticResidueCode(17,GF(2))
sage: C
Linear code of length 17, dimension 9 over Finite Field of size 2
sage: C1 = QuadraticResidueCodeOddPair(7,GF(2))[0]
sage: C2 = QuadraticResidueCode(7,GF(2))
sage: C1 == C2
True
sage: C1 = QuadraticResidueCodeOddPair(17,GF(2))[0]
sage: C2 = QuadraticResidueCode(17,GF(2))
sage: C1 == C2
True
```

AUTHORS:

- David Joyner (11-2005)

QuadraticResidueCodeEvenPair(*n, F*)

Quadratic residue codes of a given odd prime length and base ring either don't exist at all or occur as 4-tuples - a pair of "odd-like" codes and a pair of "even-like" codes. If n 2 is prime then (Theorem 6.6.2 in [HP]) a QR code exists over GF(q) iff q is a quadratic residue mod n.

They are constructed as "even-like" duadic codes associated the splitting (Q,N) mod n, where Q is the set of non-zero quadratic residues and N is the non-residues.

EXAMPLES:

```
sage: QuadraticResidueCodeEvenPair(17,GF(13))
(Linear code of length 17, dimension 8 over Finite Field of size 13,
 Linear code of length 17, dimension 8 over Finite Field of size 13)
sage: QuadraticResidueCodeEvenPair(17,GF(2))
(Linear code of length 17, dimension 8 over Finite Field of size 2,
 Linear code of length 17, dimension 8 over Finite Field of size 2)
sage: QuadraticResidueCodeEvenPair(13,GF(9,"z"))
(Linear code of length 13, dimension 6 over Finite Field in z of size 3^2,
 Linear code of length 13, dimension 6 over Finite Field in z of size 3^2)
sage: C1 = QuadraticResidueCodeEvenPair(7,GF(2))[0]
sage: C1.is_self_orthogonal()
True
```

```
sage: C2 = QuadraticResidueCodeEvenPair(7,GF(2))[1]
sage: C2.is_self_orthogonal()
True
sage: C3 = QuadraticResidueCodeOddPair(17,GF(2))[0]
sage: C4 = QuadraticResidueCodeEvenPair(17,GF(2))[1]
sage: C3 == C4.dual_code()
True
```

This is consistent with Theorem 6.6.9 and Exercise 365 in [HP].

QuadraticResidueCodeOddPair(*n, F*)

Quadratic residue codes of a given odd prime length and base ring either don't exist at all or occur as 4-tuples - a pair of "odd-like" codes and a pair of "even-like" codes. If n 2 is prime then (Theorem 6.6.2 in [HP]) a QR code exists over GF(q) iff q is a quadratic residue mod n.

They are constructed as "odd-like" duadic codes associated the splitting (Q,N) mod n, where Q is the set of non-zero quadratic residues and N is the non-residues.

EXAMPLES:

```
sage: QuadraticResidueCodeOddPair(17,GF(13))
(Linear code of length 17, dimension 9 over Finite Field of size 13,
 Linear code of length 17, dimension 9 over Finite Field of size 13)
sage: QuadraticResidueCodeOddPair(17,GF(2))
(Linear code of length 17, dimension 9 over Finite Field of size 2,
 Linear code of length 17, dimension 9 over Finite Field of size 2)
sage: QuadraticResidueCodeOddPair(13,GF(9,"z"))
(Linear code of length 13, dimension 7 over Finite Field in z of size 3^2,
 Linear code of length 13, dimension 7 over Finite Field in z of size 3^2)
sage: C1 = QuadraticResidueCodeOddPair(17,GF(2))[1]
sage: C1x = C1.extended_code()
sage: C2 = QuadraticResidueCodeOddPair(17,GF(2))[0]
sage: C2x = C2.extended_code()
sage: C2x.spectrum(); C1x.spectrum()
[1, 0, 0, 0, 0, 0, 102, 0, 153, 0, 153, 0, 102, 0, 0, 0, 0, 0, 1]
[1, 0, 0, 0, 0, 0, 102, 0, 153, 0, 153, 0, 102, 0, 0, 0, 0, 0, 1]
sage: C2x == C1x.dual_code()
True
sage: C3 = QuadraticResidueCodeOddPair(7,GF(2))[0]
sage: C3x = C3.extended_code()
sage: C3x.spectrum()
[1, 0, 0, 0, 14, 0, 0, 0, 1]
sage: C3x.is_self_dual()
True
```

This is consistent with Theorem 6.6.14 in [HP].

RandomLinearCode(*n, k, F*)

The method used is to first construct a $k \times n$ matrix using Sage's random_element method for the MatrixSpace class. The construction is probabilistic but should only fail extremely rarely.

INPUT: Integers n,k, with nk1, and a finite field F

OUTPUT: Returns a "random" linear code with length n, dimension k over field F.

EXAMPLES:

```
sage: C = RandomLinearCode(30,15,GF(2))
sage: C
Linear code of length 30, dimension 15 over Finite Field of size 2
sage: C = RandomLinearCode(10,5,GF(4,'a'))
```

```
sage: C
Linear code of length 10, dimension 5 over Finite Field in a of size 2^2
```

AUTHORS:

- David Joyner (2007-05)

ReedSolomonCode(*n, k, F, pts=None*)

Given a finite field F of order q, let n and k be chosen such that $1 \leq k \leq n \leq q$. Pick n distinct elements of F, denoted $\{x_1, x_2, ..., x_n\}$. Then, the codewords are obtained by evaluating every polynomial in $F[x]$ of degree less than k at each x_i:

$$C = \{(f(x_1), f(x_2), ..., f(x_n)), f \in F[x], \deg(f) < k\}.$$

C is a $[n, k, n-k+1]$ code. (In particular, C is MDS.)

INPUT: n : the length k : the dimension F : the base ring pts : (optional) list of n points in F (if None then Sage picks n of them in the order given to the elements of F)

EXAMPLES:

```
sage: C = ReedSolomonCode(6,4,GF(7)); C
Linear code of length 6, dimension 4 over Finite Field of size 7
sage: C.minimum_distance()
3
sage: C = ReedSolomonCode(6,4,GF(8,"a")); C
Linear code of length 6, dimension 4 over Finite Field in a of size 2^3
sage: C.minimum_distance()
3
sage: F.<a> = GF(3^2,"a")
sage: pts = [0,1,a,a^2,2*a,2*a+1]
sage: len(Set(pts)) == 6 # to make sure there are no duplicates
True
sage: C = ReedSolomonCode(6,4,F,pts); C
Linear code of length 6, dimension 4 over Finite Field in a of size 3^2
sage: C.minimum_distance()
3
```

TernaryGolayCode()

TernaryGolayCode returns a ternary Golay code. This is a perfect [11,6,5] code. It is also equivalent to a cyclic code, with generator polynomial $g(x) = 2 + x^2 + 2x^3 + x^4 + x^5$.

EXAMPLES:

```
sage: C = TernaryGolayCode()
sage: C
Linear code of length 11, dimension 6 over Finite Field of size 3
sage: C.minimum_distance()
5
```

AUTHORS:

- David Joyner (2007-5)

ToricCode(*P, F*)

Let P denote a list of lattice points in $\mathbf{Z}^d$ and let T denote the set of all points in $(F^x)^d$ (ordered in some fixed way). Put $n = |T|$ and let k denote the dimension of the vector space of functions $V = \mathrm{Span}\{x^e \mid e \in P\}$. The associated toric code C is the evaluation code which is the image of the evaluation map

$$\mathrm{eval}_\mathrm{T} : V \to F^n,$$

where x^e is the multi-index notation ($x = (x_1, ..., x_d)$, $e = (e_1, ..., e_d)$, and $x^e = x_1^{e_1}...x_d^{e_d}$), where $eval_T(f(x)) = (f(t_1), ..., f(t_n))$, and where $T = \{t_1, ..., t_n\}$. This function returns the toric codes discussed in [J].

INPUT:

- `P` - all the integer lattice points in a polytope defining the toric variety.
- `F` - a finite field.

OUTPUT: Returns toric code with length n = , dimension k over field F.

EXAMPLES:

```
sage: C = ToricCode([[0,0],[1,0],[2,0],[0,1],[1,1]],GF(7))
sage: C
Linear code of length 36, dimension 5 over Finite Field of size 7
sage: C.minimum_distance()
24
sage: C = ToricCode([[-2,-2],[-1,-2],[-1,-1],[-1,0],[0,-1],[0,0],[0,1],[1,-1],[1,0]],GF(5))
sage: C
Linear code of length 16, dimension 9 over Finite Field of size 5
sage: C.minimum_distance()
6
sage: C = ToricCode([ [0,0],[1,1],[1,2],[1,3],[1,4],[2,1],[2,2],[2,3],[3,1],[3,2],[4,1]],GF(8,"a
sage: C
Linear code of length 49, dimension 11 over Finite Field in a of size 2^3
```

This is in fact a [49,11,28] code over GF(8). If you type next `C.minimum_distance()` and wait overnight (!), you should get 28.

AUTHOR:

- David Joyner (07-2006)

- [J] D. Joyner, Toric codes over finite fields, Applicable Algebra in Engineering, Communication and Computing, 15, (2004), p. 63-79

TrivialCode(*F, n*)

WalshCode(*m*)

Returns the binary Walsh code of length 2^m. The matrix of codewords correspond to a Hadamard matrix. This is a (constant rate) binary linear $[2^m, m, 2^{m-1}]$ code.

EXAMPLES:

```
sage: C = WalshCode(4); C
Linear code of length 16, dimension 4 over Finite Field of size 2
sage: C = WalshCode(3); C
Linear code of length 8, dimension 3 over Finite Field of size 2
sage: C.spectrum()
[1, 0, 0, 0, 7, 0, 0, 0]
```

REFERENCES:

- http://en.wikipedia.org/wiki/Hadamard_matrix
- http://en.wikipedia.org/wiki/Walsh_code

cyclotomic_cosets(*q, n, t=None*)

INPUT: q,n,t positive integers (or t=None) Some type-checking of inputs is performed.

OUTPUT: q-cyclotomic cosets mod n (or, if t is not None, the q-cyclotomic coset mod n containing t)

Let q, n be relatively print positive integers and let $A = q^{ZZ}$. The group A acts on ZZ/nZZ by multiplication. The orbits of this action are "cyclotomic cosets", or more precisely "q-cyclotomic cosets mod n". Sometimes the smallest element of the coset is called the "coset leader". The algorithm will always return the cosets as sorted lists of lists, so the coset leader will always be the first element in the list.

These cosets arise in the theory of duadic codes and minimal polynomials of finite fields. Fix a primitive element z of $GF(q^k)$. The minimal polynomial of z^s over $GF(q)$ is given by

$$M_s(x) = \prod_{i \in C_s} (x - z^i),$$

where C_s is the q-cyclotomic coset mod n containing s, $n = q^k - 1$.

EXAMPLES:

```
sage: cyclotomic_cosets(2,11)
[[0], [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]]
sage: cyclotomic_cosets(2,15)
[[0], [1, 2, 4, 8], [3, 6, 9, 12], [5, 10], [7, 11, 13, 14]]
sage: cyclotomic_cosets(2,15,5)
[5, 10]
sage: cyclotomic_cosets(3,16)
[[0], [1, 3, 9, 11], [2, 6], [4, 12], [5, 7, 13, 15], [8], [10, 14]]
sage: F.<z> = GF(2^4, "z")
sage: P.<x> = PolynomialRing(F,"x")
sage: a = z^5
sage: a.minimal_polynomial()
x^2 + x + 1
sage: prod([x-z^i for i in [5, 10]])
x^2 + x + 1
sage: cyclotomic_cosets(3,2,0)
[0]
sage: cyclotomic_cosets(3,2,1)
[1]
sage: cyclotomic_cosets(3,2,2)
[0]
```

This last output looks strange but is correct, since the elements of the cosets are in ZZ/nZZ and 2 = 0 in ZZ/2ZZ.

is_a_splitting(*S1, S2, n*)

INPUT: S1, S2 are disjoint sublists partitioning [1, 2, ..., n-1] n1 is an integer

OUTPUT: a, b where a is True or False, depending on whether S1, S2 form a "splitting" of n (ie, if there is a b1 such that b*S1=S2 (point-wise multiplication mod n), and b is a splitting (if a = True) or 0 (if a = False)

Splittings are useful for computing idempotents in the quotient ring $Q = GF(q)[x]/(x^n - 1)$. For

EXAMPLES:

```
sage: from sage.coding.code_constructions import is_a_splitting
sage: n = 11; q = 3
sage: C = cyclotomic_cosets(q,n); C
[[0], [1, 3, 4, 5, 9], [2, 6, 7, 8, 10]]
sage: S1 = C[1]
```

```
sage: S2 = C[2]
sage: is_a_splitting(S1,S2,11)
(True, 2)
sage: F = GF(q)
sage: P.<x> = PolynomialRing(F,"x")
sage: I = Ideal(P,[x^n-1])
sage: Q.<x> = QuotientRing(P,I)
sage: i1 = -sum([x^i for i in S1]); i1
2*x^9 + 2*x^5 + 2*x^4 + 2*x^3 + 2*x
sage: i2 = -sum([x^i for i in S2]); i2
2*x^10 + 2*x^8 + 2*x^7 + 2*x^6 + 2*x^2
sage: i1^2 == i1
True
sage: i2^2 == i2
True
sage: (1-i1)^2 == 1-i1
True
sage: (1-i2)^2 == 1-i2
True
```

We return to dealing with polynomials (rather than elements of quotient rings), so we can construct cyclic codes:

```
sage: P.<x> = PolynomialRing(F,"x")
sage: i1 = -sum([x^i for i in S1])
sage: i2 = -sum([x^i for i in S2])
sage: i1_sqrd = (i1^2).quo_rem(x^n-1)[1]
sage: i1_sqrd  == i1
True
sage: i2_sqrd = (i2^2).quo_rem(x^n-1)[1]
sage: i2_sqrd  == i2
True
sage: C1 = CyclicCodeFromGeneratingPolynomial(n,i1)
sage: C2 = CyclicCodeFromGeneratingPolynomial(n,1-i2)
sage: C1.dual_code() == C2
True
```

This is a special case of Theorem 6.4.3 in [HP].

lift2smallest_field(*a*)

INPUT: a is an element of a finite field GF(q)

OUTPUT: the element b of the smallest subfield F of GF(q) for which F(b)=a.

EXAMPLES:

```
sage: from sage.coding.code_constructions import lift2smallest_field
sage: FF.<z> = GF(3^4,"z")
sage: a = z^10
sage: lift2smallest_field(a)
(2*z + 1, Finite Field in z of size 3^2)
sage: a = z^40
sage: lift2smallest_field(a)
(2, Finite Field of size 3)
```

AUTHORS:

- John Cremona

lift2smallest_field2(*a*)

INPUT: a is an element of a finite field GF(q) OUTPUT: the element b of the smallest subfield F of GF(q) for which F(b)=a.

EXAMPLES:

```
sage: from sage.coding.code_constructions import lift2smallest_field2
sage: FF.<z> = GF(3^4,"z")
sage: a = z^40
sage: lift2smallest_field2(a)
(2, Finite Field of size 3)
sage: FF.<z> = GF(2^4,"z")
sage: a = z^15
sage: lift2smallest_field2(a)
(1, Finite Field of size 2)
```

Warning: Since coercion (the FF(b) step) has a bug in it, this *only works* in the case when you *know* F is a prime field.

AUTHORS:

- David Joyner

permutation_action(*g*, *v*)

Returns permutation of rows g*v. Works on lists, matrices, sequences and vectors (by permuting coordinates). The code requires switching from i to i+1 (and back again) since the SymmetricGroup is, by convention, the symmetric group on the "letters" 1, 2, ..., n (not 0, 1, ..., n-1).

EXAMPLES:

```
sage: V = VectorSpace(GF(3),5)
sage: v = V([0,1,2,0,1])
sage: G = SymmetricGroup(5)
sage: g = G([(1,2,3)])
sage: permutation_action(g,v)
(1, 2, 0, 0, 1)
sage: g = G([()])
sage: permutation_action(g,v)
(0, 1, 2, 0, 1)
sage: g = G([(1,2,3,4,5)])
sage: permutation_action(g,v)
(1, 2, 0, 1, 0)
sage: L = Sequence([1,2,3,4,5])
sage: permutation_action(g,L)
[2, 3, 4, 5, 1]
sage: MS = MatrixSpace(GF(3),3,7)
sage: A = MS([[1,0,0,0,1,1,0],[0,1,0,1,0,1,0],[0,0,0,0,0,0,1]])
sage: S5 = SymmetricGroup(5)
sage: g = S5([(1,2,3)])
sage: A
[1 0 0 0 1 1 0]
[0 1 0 1 0 1 0]
[0 0 0 0 0 0 1]
sage: permutation_action(g,A)
[0 1 0 1 0 1 0]
[0 0 0 0 0 0 1]
[1 0 0 0 1 1 0]
```

It also works on lists and is a "left action":

```
sage: v = [0,1,2,0,1]
sage: G = SymmetricGroup(5)
sage: g = G([(1,2,3)])
sage: gv = permutation_action(g,v); gv
[1, 2, 0, 0, 1]
sage: permutation_action(g,v) == g(v)
True
sage: h = G([(3,4)])
sage: gv = permutation_action(g,v)
sage: hgv = permutation_action(h,gv)
sage: hgv == permutation_action(h*g,v)
True
```

AUTHORS:

- David Joyner, licensed under the GPL v2 or greater.

walsh_matrix(*m0*)

This is the generator matrix of a Walsh code. The matrix of codewords correspond to a Hadamard matrix.

EXAMPLES:

```
sage: walsh_matrix(2)
[0 0 1 1]
[0 1 0 1]
sage: walsh_matrix(3)
[0 0 0 0 1 1 1 1]
[0 0 1 1 0 0 1 1]
[0 1 0 1 0 1 0 1]
sage: C = LinearCode(walsh_matrix(4)); C
Linear code of length 16, dimension 4 over Finite Field of size 2
sage: C.spectrum()
[1, 0, 0, 0, 0, 0, 0, 0, 15, 0, 0, 0, 0, 0, 0, 0, 0]
```

This last code has minimum distance 8.

- http://en.wikipedia.org/wiki/Hadamard_matrix

40.3 Binary self-dual codes

This module implements functions useful for studying binary self-dual codes. The main function is `self_dual_codes_binary`, which is a case-by-case list of entries, each represented by a Python dictionary.

Format of each entry: a Python dictionary with keys "order autgp", "spectrum", "code", "Comment", "Type", where

- "code" - a sd code C of length n, dim n/2, over GF(2)
- "order autgp" - order of the permutation automorphism group of C
- "Type" - the type of C (which can be "I" or "II", in the binary case)
- "spectrum" - the spectrum [A0,A1,...,An]
- "Comment" - possibly an empty string.

Python dictionaries were used since they seemed to be both human-readable and allow others to update the database easiest.

- The following double for loop can be time-consuming but should be run once in awhile for testing purposes. It should only print True and have no trace-back errors:

```
for n in [4,6,8,10,12,14,16,18,20,22]:
     C = self_dual_codes_binary(n); m = len(C.keys())
     for i in range(m):
         C0 = C["%s"%n]["%s"%i]["code"]
         print n, '  ',i, '    ',C["%s"%n]["%s"%i]["spectrum"] == C0.spectrum()
         print C0 == C0.dual_code()
         G = C0.automorphism_group_binary_code()
         print C["%s"%n]["%s"%i]["order autgp"] == G.order()
```

- To check if the "Riemann hypothesis" holds, run the following code:

```
R = PolynomialRing(CC,"T")
T = R.gen()
for n in [4,6,8,10,12,14,16,18,20,22]:
     C = self_dual_codes_binary(n); m = len(C["%s"%n].keys())
     for i in range(m):
         C0 = C["%s"%n]["%s"%i]["code"]
         if C0.minimum_distance()>2:
             f = R(C0.sd_zeta_polynomial())
             print n,i,[z[0].abs() for z in f.roots()]
```

You should get lists of numbers equal to 0.707106781186548.

Here's a rather naive construction of self-dual codes in the binary case:

For even m, let A_m denote the mxm matrix over GF(2) given by adding the all 1's matrix to the identity matrix (in `MatrixSpace(GF(2),m,m)` of course). If M_1, ..., M_r are square matrices, let $diag(M_1, M_2, ..., M_r)$ denote the"block diagonal" matrix with the M_i 's on the diagonal and 0's elsewhere. Let $C(m_1, ..., m_r, s)$ denote the linear code with generator matrix having block form $G = (I, A)$, where $A = diag(A_{m_1}, A_{m_2}, ..., A_{m_r}, I_s)$, for some (even) m_i 's and s, where $m_1 + m_2 + ... + m_r + s = n/2$. Note: Such codes $C(m_1, ..., m_r, s)$ are SD.

SD codes not of this form will be called (for the purpose of documenting the code below) "exceptional". Except when n is "small", most sd codes are exceptional (based on a counting argument and table 9.1 in the Huffman+Pless [HP], page 347).

MS2(n)

matA(n)

matId(n)

self_dual_codes_binary(*n*)

Returns the dictionary of inequivalent sd codes of length n.

For n=4 even, returns the sd codes of a given length, up to (perm) equivalence, the (perm) aut gp, and the type.

The number of inequiv "diagonal" sd binary codes in the database of length n is ("diagonal" is defined by the conjecture above) is the same as the restricted partition number of n, where only integers from the set 1,4,6,8,... are allowed. This is the coeff of x^n in the series expansion $(1-x)^{-1}\prod_{2^\infty(1-x^{2j})^{-1}}$. Typing the command f = (1-x)(-1)*prod([(1-x(2*j))(-1) for j in range(2,18)]) into Sage, we obtain for the coeffs of x^4, x^6, ... [1, 1, 2, 2, 3, 3, 5, 5, 7, 7, 11, 11, 15, 15, 22, 22, 30, 30, 42, 42, 56, 56, 77, 77, 101, 101, 135, 135, 176, 176, 231] These numbers grow too slowly to account for all the sd codes (see Huffman+Pless' Table 9.1, referenced above). In fact, in Table 9.10 of [HP], the number B_n of inequivalent sd binary codes of length n is given:

```
n   2 4 6 8 10 12 14 16 18 20 22 24  26  28  30
B_n 1 1 1 2  2  3  4  7  9 16 25 55 103 261 731
```

According to http://www.research.att.com/~njas/sequences/A003179, the next 2 entries are: 3295, 24147.

EXAMPLES:

```
sage: C = self_dual_codes_binary(10)
sage: C["10"]["0"]["code"] == C["10"]["0"]["code"].dual_code()
True
sage: C["10"]["1"]["code"] == C["10"]["1"]["code"].dual_code()
True
sage: len(C["10"].keys()) # number of inequiv sd codes of length 10
2
sage: C = self_dual_codes_binary(12)
sage: C["12"]["0"]["code"] == C["12"]["0"]["code"].dual_code()
True
sage: C["12"]["1"]["code"] == C["12"]["1"]["code"].dual_code()
True
sage: C["12"]["2"]["code"] == C["12"]["2"]["code"].dual_code()
True
```

40.4 Bounds for Parameters of Codes

AUTHORS:

- David Joyner (2006-07): initial implementation.
- William Stein (2006-07): minor editing of docs and code (fixed bug in elias_bound_asymp)
- David Joyner (2006-07): fixed dimension_upper_bound to return an integer, added example to elias_bound_asymp.

This module provided some upper and lower bounds for the parameters of codes.

Let F be a finite field (we denote the finite field with q elements by $\mathbf{F}_q$). A subset C of $V = F^n$ is called a code of length n. A subspace of V (with the standard basis) is called a linear code of length n. If its dimension is denoted k then we typically store a basis of C as a $k \times n$ matrix (the rows are the basis vectors). If $F = \mathbf{F}_2$ then C is called a binary code. If F has q elements then C is called a q-ary code. The elements of a code C are called codewords. The information rate of C is

$$R = \frac{\log_q |C|}{n},$$

where $|C|$ denotes the number of elements of C. If $\mathbf{v} = (v_1, v_2, ..., v_n)$, $\mathbf{w} = (w_1, w_2, ..., w_n)$ are vectors in $V = F^n$ then we define

$$d(\mathbf{v}, \mathbf{w}) = |\{i \mid 1 \leq i \leq n,\ v_i \neq w_i\}|$$

to be the Hamming distance between $\mathbf{v}$ and $\mathbf{w}$. The function $d : V \times V \to \mathbf{N}$ is called the Hamming metric. The weight of a vector (in the Hamming metric) is $d(\mathbf{v}, \mathbf{0})$. The minimum distance of a linear code is the smallest non-zero weight of a codeword in C. The relatively minimum distance is denoted

$$\delta = d/n.$$

A linear code with length n, dimension k, and minimum distance d is called an $[n, k, d]_q$-code and n, k, d are called its parameters. A (not necessarily linear) code C with length n, size $M = |C|$, and minimum distance d is called an $(n, M, d)_q$-code (using parentheses instead of square brackets). Of course, $k = \log_q(M)$ for linear codes.

What is the "best" code of a given length? Let F be a finite field with q elements. Let $A_q(n, d)$ denote the largest M such that there exists a (n, M, d) code in F^n. Let $B_q(n, d)$ (also denoted $A_q^{lin}(n, d)$) denote the largest k such that there exists a $[n, k, d]$ code in F^n. (Of course, $A_q(n, d) \geq B_q(n, d)$.) Determining $A_q(n, d)$ and $B_q(n, d)$ is one of the main problems in the theory of error-correcting codes.

These quantities related to solving a generalization of the childhood game of "20 questions".

GAME: Player 1 secretly chooses a number from 1 to M (M is large but fixed). Player 2 asks a series of "yes/no questions" in an attempt to determine that number. Player 1 may lie at most e times ($e \geq 0$ is fixed). What is the minimum number of "yes/no questions" Player 2 must ask to (always) be able to correctly determine the number Player 1 chose?

If feedback is not allowed (the only situation considered here), call this minimum number $g(M, e)$.

Lemma: For fixed e and M, $g(M, e)$ is the smallest n such that $A_2(n, 2e + 1) \geq M$.

Thus, solving the solving a generalization of the game of "20 questions" is equivalent to determining $A_2(n, d)$! Using Sage, you can determine the best known estimates for this number in 2 ways:

(1) Indirectly, using minimum_distance_lower_bound(n,k,F) and minimum_distance_upper_bound(n,k,F) (both of which which connect to the internet using Steven Sivek's linear_code_bound(q,n,k)) (2) codesize_upper_bound(n,d,q), dimension_upper_bound(n,d,q), which use GUAVA's UpperBound(n, d, q)

This module implements:

- codesize_upper_bound(n,d,q), for the best known (as of May, 2006) upper bound A(n,d) for the size of a code of length n, minimum distance d over a field of size q.
- dimension_upper_bound(n,d,q), an upper bound $B(n, d) = B_q(n, d)$ for the dimension of a linear code of length n, minimum distance d over a field of size q.
- gilbert_lower_bound(n,q,d), a lower bound for number of elements in the largest code of min distance d in $\mathbf{F}_q^n$.
- gv_info_rate(n,delta,q), $log_q(GLB)/n$, where GLB is the Gilbert lower bound and delta = d/n.
- gv_bound_asymp(delta,q), asymptotic analog of Gilbert lower bound.
- plotkin_upper_bound(n,q,d)
- plotkin_bound_asymp(delta,q), asymptotic analog of Plotkin bound.
- griesmer_upper_bound(n,q,d)
- elias_upper_bound(n,q,d)
- elias_bound_asymp(delta,q), asymptotic analog of Elias bound.
- hamming_upper_bound(n,q,d)

- hamming_bound_asymp(delta,q), asymptotic analog of Hamming bound.
- singleton_upper_bound(n,q,d)
- singleton_bound_asymp(delta,q), asymptotic analog of Singleton bound.
- mrrw1_bound_asymp(delta,q), "first" asymptotic McEliese-Rumsey-Rodemich-Welsh bound for the information rate.

PROBLEM: In this module we shall typically either (a) seek bounds on k, given n, d, q, (b) seek bounds on R, delta, q (assuming n is "infinity").

TODO:

- Johnson bounds for binary codes.
- mrrw2_bound_asymp(delta,q), "second" asymptotic McEliese-Rumsey-Rodemich-Welsh bound for the information rate.

REFERENCES:

- C. Huffman, V. Pless, Fundamentals of error-correcting codes, Cambridge Univ. Press, 2003.

codesize_upper_bound(*n, d, q*)

Returns the best known upper bound $A(n, d) = A_q(n, d)$ for the size of a code of length n, minimum distance d over a field of size q. The function first checks for trivial cases (like d=1 or n=d), and if the value is in the built-in table. Then it calculates the minimum value of the upper bound using the methods of Singleton, Hamming, Johnson, Plotkin and Elias. If the code is binary, $A(n, 2\ell - 1) = A(n + 1, 2\ell)$, so the function takes the minimum of the values obtained from all methods for the parameters $(n, 2\ell - 1)$ and $(n + 1, 2\ell)$.

Wraps GUAVA's UpperBound(n, d, q).

EXAMPLES:

```
sage: codesize_upper_bound(10,3,2)
85
```

dimension_upper_bound(*n, d, q*)

Returns an upper bound $B(n, d) = B_q(n, d)$ for the dimension of a linear code of length n, minimum distance d over a field of size q.

EXAMPLES:

```
sage: dimension_upper_bound(10,3,2)
6
```

elias_bound_asymp(*delta, q*)

Computes the asymptotic Elias bound for the information rate, provided $0 < \delta 1 - 1/q$.

EXAMPLES:

```
sage: elias_bound_asymp(1/4,2)
0.39912396330...
```

elias_upper_bound(*n, q, d*)

Returns the Elias upper bound for number of elements in the largest code of minimum distance d in $\mathbf{F}_q^n$. Wraps GAP's UpperBoundElias.

EXAMPLES:

```
sage: elias_upper_bound(10,2,3)
232
```

entropy(*x, q*)
Computes the entropy on the q-ary symmetric channel.

gilbert_lower_bound(*n, q, d*)
Returns lower bound for number of elements in the largest code of minimum distance d in $\mathbf{F}_q^n$.

EXAMPLES:

```
sage: gilbert_lower_bound(10,2,3)
128/7
```

griesmer_upper_bound(*n, q, d*)
Returns the Griesmer upper bound for number of elements in the largest code of minimum distance d in $\mathbf{F}_q^n$. Wraps GAP's UpperBoundGriesmer.

EXAMPLES:

```
sage: griesmer_upper_bound(10,2,3)
128
```

gv_bound_asymp(*delta, q*)
Computes the asymptotic GV bound for the information rate, R.

EXAMPLES:

```
sage: f = lambda x: gv_bound_asymp(x,2)
sage: plot(f,0,1)
```

gv_info_rate(*n, delta, q*)
GV lower bound for information rate of a q-ary code of length n minimum distance delta*n

EXAMPLES:

```
sage: RDF(gv_info_rate(100,1/4,3))
0.367049926083
```

hamming_bound_asymp(*delta, q*)
Computes the asymptotic Hamming bound for the information rate.

EXAMPLES:

```
sage: f = lambda x: hamming_bound_asymp(x,2)
sage: plot(f,0,1)
```

hamming_upper_bound(*n, q, d*)
Returns the Hamming upper bound for number of elements in the largest code of minimum distance d in $\mathbf{F}_q^n$. Wraps GAP's UpperBoundHamming.

The Hamming bound (also known as the sphere packing bound) returns an upper bound on the size of a code of length n, minimum distance d, over a field of size q. The Hamming bound is obtained by dividing the contents of the entire space $\mathbf{F}_q^n$ by the contents of a ball with radius floor((d-1)/2). As all these balls are disjoint, they can never contain more than the whole vector space.

$$M \leq \frac{q^n}{V(n,e)},$$

where M is the maximum number of codewords and $V(n,e)$ is equal to the contents of a ball of radius e. This bound is useful for small values of d. Codes for which equality holds are called perfect.

EXAMPLES:

```
sage: hamming_upper_bound(10,2,3)
93
```

mrrw1_bound_asymp(*delta, q*)

Computes the first asymptotic McEliese-Rumsey-Rodemich-Welsh bound for the information rate, provided $0 < \delta < 1 - 1/q$.

EXAMPLES:

```
sage: mrrw1_bound_asymp(1/4,2)
0.354578902665
```

plotkin_bound_asymp(*delta, q*)

Computes the asymptotic Plotkin bound for the information rate, provided $0 < \delta < 1 - 1/q$.

EXAMPLES:

```
sage: plotkin_bound_asymp(1/4,2)
1/2
```

plotkin_upper_bound(*n, q, d*)

Returns Plotkin upper bound for number of elements in the largest code of minimum distance d in $\mathbf{F}_q^n$. Wraps GAP's UpperBoundPlotkin.

EXAMPLES:

```
sage: plotkin_upper_bound(10,2,3)
192
```

singleton_bound_asymp(*delta, q*)

Computes the asymptotic Singleton bound for the information rate.

EXAMPLES:

```
sage: f = lambda x: singleton_bound_asymp(x,2)
sage: plot(f,0,1)
```

singleton_upper_bound(*n, q, d*)

Returns the Singleton upper bound for number of elements in the largest code of minimum distance d in $\mathbf{F}_q^n$. Wraps GAP's UpperBoundSingleton.

This bound is based on the shortening of codes. By shortening an (n, M, d) code d-1 times, an $(n-d+1, M, 1)$ code results, with $M \leq q^n - d + 1$. Thus

$$M \leq q^{n-d+1}.$$

Codes that meet this bound are called maximum distance separable (MDS).

EXAMPLES:

```
sage: singleton_upper_bound(10,2,3)
256
```

volume_hamming(*n, q, r*)

Returns number of elements in a Hamming ball of radius r in $\mathbf{F}_q^n$.

EXAMPLES:

```
sage: volume_hamming(10,2,3)
176
```

CHAPTER

FORTYONE

ARITHMETIC SUBGROUPS OF $\mathrm{SL}_2(\mathbf{Z})$

This chapter describes the basic functionality for finite index subgroups of the modular group $\mathrm{SL}_2(\mathbf{Z})$.

41.1 Arithmetic subgroups (finite index subgroups of $\mathrm{SL}_2(\mathrm{Z})$)

class ArithmeticSubgroup()

Base class for arithmetic subgroups of $\mathrm{SL}_2(\mathbf{Z})$. Not intended to be used directly, but still includes quite a few general-purpose routines which compute data about an arithmetic subgroup assuming that it has a working element testing routine.

are_equivalent(*x*, *y*)

Determine whether x and y are equivalent by an element of self, i.e. whether or not there exists an element g of self such that $g \cdot x = y$.

NOTE: This function should be overridden by all subclasses.

EXAMPLES:

```
sage: sage.modular.arithgroup.congroup_generic.CongruenceSubgroup(5).are_equivalent(0, 0)
...
NotImplementedError
```

are_equivalent_cusps(*x*, *y*, *trans=False*)

Test whether or not cusps x and y are equivalent modulo self. If self has a reduce_cusp() method, use that; otherwise do a slow explicit test.

If trans = False, returns True or False. If trans = True, then return either False or an element of self mapping x onto y.

EXAMPLE:

```
sage: Gamma0(7).are_equivalent_cusps(Cusp(1/3), Cusp(0), trans=True)
[  3  -1]
[-14   5]
sage: Gamma0(7).are_equivalent_cusps(Cusp(1/3), Cusp(1/7))
False
```

as_permutation_group()

Return a representation of this arithmetic subgroup in terms of the permutation action of SL2Z on the cosets of G.

At present this is only implemented for even subgroups.

EXAMPLE:

```
sage: Gamma0(3).as_permutation_group()
Arithmetic subgroup corresponding to permutations L=(2,3,4), R=(1,3,4)
```

coset_reps(*G=None*)

Return coset representatives for self \ G, where G is another arithmetic subgroup that contains self. If G = None, default to G = SL2Z.

For generic arithmetic subgroups G this is carried out by Todd-Coxeter enumeration; here G is treated as a black box, implementing nothing but membership testing.

EXAMPLES:

```
sage: sage.modular.arithgroup.arithgroup_generic.ArithmeticSubgroup().coset_reps()
...
NotImplementedError
sage: sage.modular.arithgroup.arithgroup_generic.ArithmeticSubgroup.coset_reps(Gamma0(3))
[[1 0]
[0 1], [ 0 -1]
[ 1  0], [ 0 -1]
[ 1  1], [ 0 -1]
[ 1  2]]
```

cusp_data(*c*)

Return a triple (g, w, t) where g is an element of self generating the stabiliser of the given cusp, w is the width of the cusp, and t is 1 if the cusp is regular and -1 if not.

EXAMPLES:

```
sage: Gamma1(4).cusp_data(Cusps(1/2))
([ 1 -1] [ 4 -3], 1, -1)
```

cusp_width(*c*)

Return the width of the orbit of cusps represented by c.

EXAMPLES:

```
sage: Gamma0(11).cusp_width(Cusps(oo))
1
sage: Gamma0(11).cusp_width(0)
11
sage: [Gamma0(100).cusp_width(c) for c in Gamma0(100).cusps()]
[100, 1, 4, 1, 1, 1, 4, 25, 1, 1, 4, 1, 25, 4, 1, 4, 1, 1]
```

cusps(*algorithm='default'*)

Return a sorted list of inequivalent cusps for self, i.e. a set of representatives for the orbits of self on $\mathbb{P}^1(\mathbf{Q})$. These should be returned in a reduced form where this makes sense.

INPUTS: **algorithm – which algorithm to use to compute the cusps** of self. 'default' finds representatives for a known complete set of cusps. 'modsym' computes the boundary map on the space of weight two modular symbols associated to self, which finds the cusps for self in the process.

EXAMPLES:

```
sage: Gamma0(36).cusps()
[0, 1/18, 1/12, 1/9, 1/6, 1/4, 1/3, 5/12, 1/2, 2/3, 5/6, Infinity]
sage: Gamma0(36).cusps(algorithm='modsym') == Gamma0(36).cusps()
True
sage: GammaH(36, [19,29]).cusps() == Gamma0(36).cusps()
True
sage: Gamma0(1).cusps()
[Infinity]
```

dimension_cusp_forms(*k=2*)

Return the dimension of the space of weight k cusp forms for this group. This is given by a standard formula in terms of k and various invariants of the group; see Diamond + Shurman, "A First Course in Modular Forms", section 3.5 and 3.6. If k is not given, default to k = 2.

For dimensions of spaces of cusp forms with character for Gamma1, use the standalone function dimension_cusp_forms().

For weight 1 cusp forms this function only works in cases where one can prove solely in terms of Riemann-Roch theory that there aren't any cusp forms (i.e. when the number of regular cusps is strictly greater than the degree of the canonical divisor). Otherwise a NotImplementedError is raised.

EXAMPLE:

```
sage: Gamma1(31).dimension_cusp_forms(2)
26
sage: Gamma1(3).dimension_cusp_forms(1)
0
sage: Gamma1(4).dimension_cusp_forms(1) # irregular cusp
0
sage: Gamma1(31).dimension_cusp_forms(1)
...
NotImplementedError: Computation of dimensions of weight 1 cusp forms spaces not implemented
```

dimension_eis(*k=2*)

Return the dimension of the space of weight k Eisenstein series for this group, which is a subspace of the space of modular forms complementary to the space of cusp forms.

INPUT:

- k - an integer (default 2).

EXAMPLES:

```
sage: GammaH(33,[2]).dimension_eis()
7
sage: GammaH(33,[2]).dimension_eis(3)
0
sage: GammaH(33, [2,5]).dimension_eis(2)
3
sage: GammaH(33, [4]).dimension_eis(1)
4
```

dimension_modular_forms(*k=2*)

Return the dimension of the space of weight k modular forms for this group. This is given by a standard formula in terms of k and various invariants of the group; see Diamond + Shurman, "A First Course in Modular Forms", section 3.5 and 3.6. If k is not given, defaults to k = 2.

For dimensions of spaces of modular forms with character for Gamma1, use the standalone function dimension_modular_forms().

For weight 1 modular forms this function only works in cases where one can prove solely in terms of Riemann-Roch theory that there aren't any cusp forms (i.e. when the number of regular cusps is strictly greater than the degree of the canonical divisor). Otherwise a NotImplementedError is raised.

EXAMPLE:

```
sage: Gamma1(31).dimension_modular_forms(2)
55
sage: Gamma1(3).dimension_modular_forms(1)
1
sage: Gamma1(4).dimension_modular_forms(1) # irregular cusp
1
sage: Gamma1(31).dimension_modular_forms(1)
...
NotImplementedError: Computation of dimensions of weight 1 cusp forms spaces not implemented
```

gen(*i*)

Return the i-th generator of self, i.e. the i-th element of the tuple self.gens().

EXAMPLES:

```
sage: SL2Z.gen(1)
[1 1]
[0 1]
```

generalised_level()

Return the generalised level of self, i.e. the least common multiple of the widths of all cusps. Wohlfart's theorem tells us that this is equal to the (conventional) level of self when self is a congruence subgroup.

EXAMPLE:

```
sage: Gamma0(18).generalised_level()
18
sage: sage.modular.arithgroup.congroup_generic.CongruenceSubgroup(5).index()
...
NotImplementedError
```

generators()

Return generators for this congruence subgroup.

This is carried out using an "inverse Todd-Coxeter" algorithm. A Cython version of this for the special case of Γ_0 and Γ_1 is implemented in the function `congroup_pyx.generators_helper`. See the documentation there for further details. Here we are assuming far less about the group, so the computation is exceptionally slow!

EXAMPLE:

```
sage: Gamma(2).generators()
[[1 2]
[0 1],
[-1  0]
[ 0 -1],
[-1  0]
[ 0 -1],
[ 1  0]
[-2  1],
[-1  2]
[-2  3],
[-1  0]
[ 2 -1],
[1 0]
[2 1]]
```

gens()

Return a tuple of generators for this congruence subgroup.

The generators need not be minimal.

EXAMPLES:

```
sage: SL2Z.gens()
([ 0 -1]
[ 1  0], [1 1]
[0 1])
```

genus()

Return the genus of the modular curve of self.

EXAMPLES:

```
sage: Gamma1(5).genus()
0
sage: Gamma1(31).genus()
26
sage: Gamma1(157).genus() == dimension_cusp_forms(Gamma1(157), 2)
```

```
True
sage: GammaH(7, [2]).genus()
0
sage: [Gamma0(n).genus() for n in [1..23]]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 1, 1, 0, 1, 0, 1, 1, 1, 2, 2]
sage: [n for n in [1..200] if Gamma0(n).genus() == 1]
[11, 14, 15, 17, 19, 20, 21, 24, 27, 32, 36, 49]
```

index()

Return the index of self in the full modular group.

EXAMPLES:

```
sage: Gamma0(17).index()
18
sage: sage.modular.arithgroup.congroup_generic.CongruenceSubgroup(5).index()
...
NotImplementedError
```

is_abelian()

Return True if this arithmetic subgroup is abelian.

Since arithmetic subgroups are always nonabelian, this always returns False.

EXAMPLES:

```
sage: SL2Z.is_abelian()
False
sage: Gamma0(3).is_abelian()
False
sage: Gamma1(12).is_abelian()
False
sage: GammaH(4, [2]).is_abelian()
False
```

is_congruence()

Return True if self is a congruence subgroup.

EXAMPLE:

```
sage: Gamma0(5).is_congruence()
True
sage: sage.modular.arithgroup.arithgroup_generic.ArithmeticSubgroup().is_congruence()
...
NotImplementedError
```

is_even()

Return True precisely if this subgroup contains the matrix -1.

EXAMPLES:

```
sage: SL2Z.is_even()
True
sage: Gamma0(20).is_even()
True
sage: Gamma1(5).is_even()
False
sage: GammaH(11, [3]).is_even()
False
```

is_finite()

Return True if this arithmetic subgroup is finite.

Since arithmetic subgroups are always infinite, this always returns False.

EXAMPLES:

```
sage: SL2Z.is_finite()
False
sage: Gamma0(3).is_finite()
False
sage: Gamma1(12).is_finite()
False
sage: GammaH(4, [2]).is_finite()
False
```

is_normal()

Return True precisely if this subgroup is a normal subgroup of SL2Z.

EXAMPLES:

```
sage: Gamma(3).is_normal()
True
sage: Gamma1(3).is_normal()
False
```

is_odd()

Return True precisely if this subgroup does not contain the matrix -1.

EXAMPLES:

```
sage: SL2Z.is_odd()
False
sage: Gamma0(20).is_odd()
False
sage: Gamma1(5).is_odd()
True
sage: GammaH(11, [3]).is_odd()
True
```

is_regular_cusp(*c*)

Return True if the orbit of the given cusp is a regular cusp for self, otherwise False. This is automatically true if -1 is in self.

EXAMPLES:

```
sage: Gamma1(4).is_regular_cusp(Cusps(1/2))
False
sage: Gamma1(4).is_regular_cusp(Cusps(oo))
True
```

is_subgroup(*right*)

Return True if self is a subgroup of right, and False otherwise. For generic arithmetic subgroups this is done by the absurdly slow algorithm of checking all of the generators of self to see if they are in right.

EXAMPLES:

```
sage: sage.modular.arithgroup.arithgroup_generic.ArithmeticSubgroup().is_subgroup(SL2Z)
...
NotImplementedError
sage: sage.modular.arithgroup.arithgroup_generic.ArithmeticSubgroup.is_subgroup(Gamma1(18),
True
```

ncusps()

Return the number of cusps of this arithmetic subgroup. This is provided as a separate function since for dimension formulae in even weight all we need to know is the number of cusps, and this can be calculated very quickly, while enumerating all cusps is much slower.

EXAMPLES:

```
sage: sage.modular.arithgroup.arithgroup_generic.ArithmeticSubgroup.ncusps(Gamma0(7))
2
```

ngens()

Return the number of generators for this arithmetic subgroup.

This need not be the minimal number of generators of self.

EXAMPLES:

```
sage: Gamma0(22).ngens()
42
sage: Gamma1(14).ngens()
219
sage: GammaH(11, [3]).ngens()
31
sage: SL2Z.ngens()
2
```

nirregcusps()

Return the number of cusps of self that are "irregular", i.e. their stabiliser can only be generated by elements with both eigenvalues -1 rather than +1. If the group contains -1, every cusp is clearly regular.

EXAMPLES:

```
sage: sage.modular.arithgroup.arithgroup_generic.ArithmeticSubgroup.nirregcusps(Gamma1(4))
1
```

nregcusps()

Return the number of cusps of self that are "regular", i.e. their stabiliser has a generator with both eigenvalues +1 rather than -1. If the group contains -1, every cusp is clearly regular.

EXAMPLES:

```
sage: sage.modular.arithgroup.arithgroup_generic.ArithmeticSubgroup.nregcusps(Gamma1(4))
2
```

nu2()

Return the number of orbits of elliptic points of order 2 for this arithmetic subgroup.

EXAMPLES:

```
sage: sage.modular.arithgroup.arithgroup_generic.ArithmeticSubgroup().nu2()
...
NotImplementedError
sage: sage.modular.arithgroup.arithgroup_generic.ArithmeticSubgroup.nu2(Gamma0(1105)) == 8
True
```

nu3()

Return the number of orbits of elliptic points of order 3 for this arithmetic subgroup.

EXAMPLES:

```
sage: sage.modular.arithgroup.arithgroup_generic.ArithmeticSubgroup().nu3()
...
NotImplementedError
sage: sage.modular.arithgroup.arithgroup_generic.ArithmeticSubgroup.nu3(Gamma0(1729)) == 8
True
```

We test that a bug in handling of subgroups not containing -1 is fixed:

```
sage: sage.modular.arithgroup.arithgroup_generic.ArithmeticSubgroup.nu3(GammaH(7, [2]))
2
```

order()

Return the number of elements in this arithmetic subgroup.

Since arithmetic subgroups are always infinite, this always returns infinity.

EXAMPLES:

```
sage: SL2Z.order()
+Infinity
sage: Gamma0(5).order()
+Infinity
sage: Gamma1(2).order()
+Infinity
sage: GammaH(12, [5]).order()
+Infinity
```

projective_index()

Return the index of the image of self in $\mathrm{PSL}_2(\mathbf{Z})$. This is equal to the index of self if self contains -1, and half of this otherwise.

This is equal to the degree of the natural map from the modular curve of self to the j-line.

EXAMPLE:

```
sage: Gamma0(5).projective_index()
6
sage: Gamma1(5).projective_index()
12
```

reduce_cusp(c)

Given a cusp $c \in \mathbb{P}^1(\mathbf{Q})$, return the unique reduced cusp equivalent to c under the action of self, where a reduced cusp is an element $\frac{r}{s}$ with r,s coprime integers, s as small as possible, and r as small as possible for that s.

NOTE: This function should be overridden by all subclasses.

EXAMPLES:

```
sage: sage.modular.arithgroup.arithgroup_generic.ArithmeticSubgroup().reduce_cusp(1/4)
...
NotImplementedError
```

todd_coxeter()

Compute coset representatives for self \ G via Todd-Coxeter enumeration. If G = None, default to G = SL2Z. Also computes generators for G at the same time. Return value is a tuple (list of coset reps, list of generators).

This is *extremely* slow in general.

EXAMPLE:

sage: Gamma0(3).todd_coxeter() ([[1 0] [0 1], [0 -1] [1 0], [0 -1] [1 1], [0 -1] [1 2]], [[1 1] [0 1], [-1 0] [0 -1], [1 0] [-3 1], [-2 -1] [3 1], [-1 -1] [3 2]])

is_ArithmeticSubgroup(x)

Return True if x is of type ArithmeticSubgroup.

EXAMPLE:

```
sage: from sage.modular.arithgroup.all import is_ArithmeticSubgroup
sage: is_ArithmeticSubgroup(GL(2, GF(7)))
False
sage: is_ArithmeticSubgroup(Gamma0(4))
True
```

41.2 Arithmetic subgroups defined by permutations

A theorem of Millington states that an arithmetic subgroup of index N is uniquely determined by two elements generating a transitive subgroup of the symmetric group S_N and satisfying a certain algebraic relation.

These functions are based on Chris Kurth's *KFarey* package.

AUTHORS:

- Chris Kurth (2008): created KFarey package
- David Loeffler (2009): adapted functions from KFarey for inclusion into Sage

class ArithmeticSubgroup_Permutation(*L*, *R*)

An arithmetic subgroup Γ defined by two permutations, giving the action of the parabolic generators

$$L = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}, \quad R = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$$

by right multiplication on the coset representatives $\Gamma\backslash \mathrm{SL}_2(\mathbf{Z})$.

EXAMPLES:

We construct a noncongruence subgroup of index 7 (the smallest possible):

```
sage: a2 = SymmetricGroup(7)([(1,2),(3,4),(5,6)]); a3 = SymmetricGroup(7)([(1,3,5),(2,6,7)])
sage: G = ArithmeticSubgroup_Permutation(a2*a3, ~a2 * ~a3); G
Arithmetic subgroup corresponding to permutations L=(1,6)(2,3,4,5,7), R=(1,7,6,3,4)(2,5)
sage: G.index()
7
sage: G.dimension_cusp_forms(4)
1
sage: G.is_congruence()
False
```

We convert some standard congruence subgroups into permutation form:

```
sage: Gamma0(12).as_permutation_group()
Arithmetic subgroup corresponding to permutations L=(2,3,4,5,6,7,8,9,10,11,12,13)(14,15,16)(17,1
```

The following is the unique index 2 even subgroup of $\mathrm{SL}_2(\mathbf{Z})$:

```
sage: w = SymmetricGroup(2)([2,1])
sage: G = ArithmeticSubgroup_Permutation(w, w)
sage: G.dimension_cusp_forms(6)
1
sage: G.genus()
0
```

We test unpickling:

```
sage: G == loads(dumps(G))
True
sage: G is loads(dumps(G))
False
```

index()

Return the index of self in the full modular group.

EXAMPLE:

```
sage: import sage.modular.arithgroup.arithgroup_perm as ap
sage: ap.HsuExample18().index()
18
```

is_congruence()
Return True if this is a congruence subgroup. Uses Hsu's algorithm, as implemented by Chris Kurth in KFarey.

EXAMPLES:

This example is congruence – it's Gamma0(3) in disguise:

```
sage: import sage.modular.arithgroup.arithgroup_perm as ap
sage: G=ap.ArithmeticSubgroup_Permutation(SymmetricGroup(4)((2,3,4)), SymmetricGroup(4)((1,3
Arithmetic subgroup corresponding to permutations L=(2,3,4), R=(1,3,4)
sage: G.is_congruence()
True
```

This one is noncongruence:

```
sage: import sage.modular.arithgroup.arithgroup_perm as ap
sage: ap.HsuExample10().is_congruence()
False
```

perm_group()
Return the underlying permutation group.

EXAMPLE:

```
sage: import sage.modular.arithgroup.arithgroup_perm as ap
sage: ap.HsuExample10().perm_group()
Permutation Group with generators [(1,4)(2,5,9,10,8)(3,7,6), (1,7,9,10,6)(2,3)(4,5,8)]
```

permutation_action(*x*)
Given an element x of $\mathrm{SL}_2(\mathbf{Z})$, compute the permutation of the cosets of self given by right multiplication by x.

EXAMPLE:

```
sage: import sage.modular.arithgroup.arithgroup_perm as ap
sage: ap.HsuExample10().permutation_action(SL2Z([32, -21, -67, 44]))
(1,10,5,6,3,8,9,2,7,4)
```

HsuExample10()
An example of an index 10 arithmetic subgroup studied by Tim Hsu.

EXAMPLE:

```
sage: import sage.modular.arithgroup.arithgroup_perm as ap
sage: ap.HsuExample10()
Arithmetic subgroup corresponding to permutations L=(1,4)(2,5,9,10,8)(3,7,6), R=(1,7,9,10,6)(2,3
```

HsuExample18()
An example of an index 18 arithmetic subgroup studied by Tim Hsu.

EXAMPLE:

```
sage: import sage.modular.arithgroup.arithgroup_perm as ap
sage: ap.HsuExample18()
Arithmetic subgroup corresponding to permutations L=(1,2)(3,4)(5,6,7)(8,9,10)(11,12,13,14,15,16,
```

LREvalPerm(*w, L, R*)
Given a word w as output by sl2z_word_problem, evaluate the word with the given permutations for L and R. Because we are dealing with a right rather than a left action, arguments are evaluated back to front.

EXAMPLE:

```
sage: import  sage.modular.arithgroup.arithgroup_perm as ap
sage: L = SymmetricGroup(4)('(1,2)(3,4)'); R = SymmetricGroup(4)('(1,2,3,4)')
sage: ap.LREvalPerm([(1,1),(0,1)], L, R) ==  L * R
True
```

convert_to_permgroup(*G*)

Given an arbitrary arithmetic subgroup, convert it to permutation form.

Note that the permutation representation is not always unique, so if G is already of permutation type, then the return value won't necessarily be identical to G, but it will represent the same subgroup.

EXAMPLES:

```
sage: import sage.modular.arithgroup.arithgroup_perm as ap
sage: ap.convert_to_permgroup(Gamma0(5))
Arithmetic subgroup corresponding to permutations L=(2,3,4,5,6), R=(1,3,5,4,6)
sage: ap.convert_to_permgroup(ap.HsuExample10())
Arithmetic subgroup corresponding to permutations L=(1,2)(3,5,6,7,8)(4,9,10), R=(1,9,6,7,10)(2,5
```

eval_word(*B*)

Given a word in the format output by sl2z_word_problem, convert it back into an element of SL2(Z).

EXAMPLES:

```
sage: import sage.modular.arithgroup.arithgroup_perm as ap
sage: ap.eval_word([(0, 1), (1, -1), (0, 0), (1, 3), (0, 2), (1, 9), (0, -1)])
[ 66 -59]
[ 47 -42]
```

sl2z_word_problem(*A, max_iterations=20*)

Given an element of SL2Z, express it as a word in the generators L = [1,1,0,1] and R = [1,0,1,1].

The return format is a list of pairs (a,b), where a = 0 or 1 denoting L or R respectively, and b is an integer exponent.

The parameter iterations (default 20) controls the maximum number of iterations to allow in the program's main loop; an error is raised if the algorithm has not terminated after this many iterations.

EXAMPLE:

```
sage: import sage.modular.arithgroup.arithgroup_perm as ap
sage: L = SL2Z([1,1,0,1]); R = SL2Z([1,0,1,1])
sage: ap.sl2z_word_problem(L)
[(0, 1)]
sage: ap.sl2z_word_problem(R**(-1))
[(1, -1)]
sage: ap.sl2z_word_problem(L*R)
[(0, 1), (1, -1), (0, 0), (1, 2)]
```

41.3 Elements of Arithmetic Subgroups

class ArithmeticSubgroupElement(*parent, x, check=True*)

An element of an arithmetic subgroup of $\mathrm{SL}_2(\mathbf{Z})$.

a()

Return the upper left entry of self.

EXAMPLES:

```
sage: Gamma0(13)([7,1,13,2]).a()
7
```

acton(*z*)

Return the result of the action of self on z as a fractional linear transformation.

EXAMPLES:

```
sage: G = Gamma0(15)
sage: g = G([1, 2, 15, 31])
```

An example of g acting on a symbolic variable:

```
sage: z = var('z')
sage: g.acton(z)
(z + 2)/(15*z + 31)
```

An example involving the Gaussian numbers:

```
sage: K.<i> = NumberField(x^2 + 1)
sage: g.acton(i)
1/1186*i + 77/1186
```

An example with complex numbers:

```
sage: C.<i> = ComplexField()
sage: g.acton(i)
0.0649241146711636 + 0.000843170320404721*I
```

b()

Return the upper right entry of self.

EXAMPLES:

```
sage: Gamma0(13)([7,1,13,2]).b()
1
```

c()

Return the lower left entry of self.

EXAMPLES:

```
sage: Gamma0(13)([7,1,13,2]).c()
13
```

d()

Return the lower right entry of self.

EXAMPLES:

```
sage: Gamma0(13)([7,1,13,2]).d()
2
```

det()

Return the determinant of self, which is always 1.

EXAMPLES:

```
sage: Gamma1(11)([12,11,-11,-10]).det()
1
```

determinant()

Return the determinant of self, which is always 1.

EXAMPLES:

```
sage: Gamma0(691)([1,0,691,1]).determinant()
1
```

matrix()

Return the matrix corresponding to self.

EXAMPLES:

```
sage: x = Gamma1(3)([4,5,3,4]) ; x
[4 5]
[3 4]
sage: x.matrix()
[4 5]
[3 4]
sage: type(x.matrix())
<type 'sage.matrix.matrix_integer_2x2.Matrix_integer_2x2'>
```

41.4 Congruence arithmetic subgroups of $\mathrm{SL}_2(\mathbf{Z})$

Sage can compute extensively with the standard congruence subgroups $\Gamma_0(N)$, $\Gamma_1(N)$, and $\Gamma_H(N)$.

AUTHOR: – William Stein

class CongruenceSubgroup (*level*)

is_congruence()

Return True, since this is a congruence subgroup.

EXAMPLE:

```
sage: Gamma0(7).is_congruence()
True
```

level()

Return the level of this congruence subgroup.

EXAMPLES:

```
sage: SL2Z.level()
1
sage: Gamma0(20).level()
20
sage: Gamma1(11).level()
11
sage: GammaH(14, [2]).level()
14
```

modular_abelian_variety()

Return the modular abelian variety corresponding to the congruence subgroup self.

EXAMPLES:

```
sage: Gamma0(11).modular_abelian_variety()
Abelian variety J0(11) of dimension 1
sage: Gamma1(11).modular_abelian_variety()
Abelian variety J1(11) of dimension 1
sage: GammaH(11,[3]).modular_abelian_variety()
Abelian variety JH(11,[3]) of dimension 1
```

modular_symbols(*sign=0, weight=2, base_ring=Rational Field*)

Return the space of modular symbols of the specified weight and sign on the congruence subgroup self.

EXAMPLES:

```
sage: G = Gamma0(23)
sage: G.modular_symbols()
Modular Symbols space of dimension 5 for Gamma_0(23) of weight 2 with sign 0 over Rational F
sage: G.modular_symbols(weight=4)
Modular Symbols space of dimension 12 for Gamma_0(23) of weight 4 with sign 0 over Rational
sage: G.modular_symbols(base_ring=GF(7))
Modular Symbols space of dimension 5 for Gamma_0(23) of weight 2 with sign 0 over Finite Fie
sage: G.modular_symbols(sign=1)
Modular Symbols space of dimension 3 for Gamma_0(23) of weight 2 with sign 1 over Rational F
```

sturm_bound(*weight=2*)

Returns the Sturm bound for modular forms of the given weight and level this congruence subgroup.

INPUT:

- `weight` - an integer ≥ 2 (default: 2)

EXAMPLES:: sage: Gamma0(11).sturm_bound(2) 2 sage: Gamma0(389).sturm_bound(2) 65 sage: Gamma0(1).sturm_bound(12) 1 sage: Gamma0(100).sturm_bound(2) 30 sage: Gamma0(1).sturm_bound(36) 3 sage: Gamma0(11).sturm_bound() 2 sage: Gamma0(13).sturm_bound() 3 sage: Gamma0(16).sturm_bound() 4 sage: GammaH(16,[13]).sturm_bound() 8 sage: GammaH(16,[15]).sturm_bound() 16 sage: Gamma1(16).sturm_bound() 32 sage: Gamma1(13).sturm_bound() 28 sage: Gamma1(13).sturm_bound(5) 70

FURTHER DETAILS: This function returns a positive integer n such that the Hecke operators $T_1, \ldots, T_n$ acting on *cusp forms* generate the Hecke algebra as a $\mathbf{Z}$-module when the character is trivial or quadratic. Otherwise, $T_1, \ldots, T_n$ generate the Hecke algebra at least as a $\mathbf{Z}[\varepsilon]$-module, where $\mathbf{Z}[\varepsilon]$ is the ring generated by the values of the Dirichlet character ε. Alternatively, this is a bound such that if two cusp forms associated to this space of modular symbols are congruent modulo (λ, q^n), then they are congruent modulo λ.

REFERENCES:

- See the Agashe-Stein appendix to Lario and Schoof, *Some computations with Hecke rings and deformation rings*, Experimental Math., 11 (2002), no. 2, 303-311.
- This result originated in the paper Sturm, *On the congruence of modular forms*, Springer LNM 1240, 275-280, 1987.

REMARK: Kevin Buzzard pointed out to me (William Stein) in Fall 2002 that the above bound is fine for $\Gamma_1(N)$ with character, as one sees by taking a power of f. More precisely, if $f \cong 0 \pmod{p}$ for first s coefficients, then $f^r \cong 0 \pmod{p}$ for first sr coefficents. Since the weight of f^r is $r \cdot k(f)$, it follows that if $s \geq b$, where b is the Sturm bound for $\Gamma_0(N)$ at weight $k(f)$, then f^r has valuation large enough to be forced to be 0 at $r * k(f)$ by Sturm bound (which is valid if we choose r correctly). Thus $f \cong 0 \pmod{p}$. Conclusion: For $\Gamma_1(N)$ with fixed character, the Sturm bound is *exactly* the same as for $\Gamma_0(N)$.

A key point is that we are finding $\mathbf{Z}[\varepsilon]$ generators for the Hecke algebra here, not $\mathbf{Z}$-generators. So if one wants generators for the Hecke algebra over $\mathbf{Z}$, this bound must be suitably modified (and I'm not sure what the modification is).

AUTHORS:

- William Stein

is_CongruenceSubgroup(*x*)

Return True if x is of type CongruenceSubgroup.

EXAMPLES:

```
sage: from sage.modular.arithgroup.congroup_generic import is_CongruenceSubgroup
sage: is_CongruenceSubgroup(SL2Z)
True
sage: is_CongruenceSubgroup(Gamma0(13))
True
sage: is_CongruenceSubgroup(Gamma1(6))
True
sage: is_CongruenceSubgroup(GammaH(11, [3]))
True
sage: is_CongruenceSubgroup(SymmetricGroup(3))
False
```

41.5 Congruence Subgroup $\Gamma_H(N)$

AUTHORS:

- Jordi Quer
- David Loeffler

class GammaH_class (*level, H*)

The congruence subgroup $\Gamma_H(N)$ for some subgroup $H \trianglelefteq (\mathbf{Z}/N\mathbf{Z})^\times$, which is the subgroup of $\mathrm{SL}_2(\mathbf{Z})$ consisting of matrices of the form $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ with $N \mid c$ and $a, b \in H$.

TESTS:

We test calculation of various invariants of the group:

```
sage: GammaH(33,[2]).projective_index()
96
sage: GammaH(33,[2]).genus()
5
sage: GammaH(7,[2]).genus()
0
sage: GammaH(23, [1..22]).genus()
2
sage: Gamma0(23).genus()
2
sage: GammaH(23, [1]).genus()
12
sage: Gamma1(23).genus()
12
```

We calculate the dimensions of some modular forms spaces:

```
sage: GammaH(33,[2]).dimension_cusp_forms(2)
5
sage: GammaH(33,[2]).dimension_cusp_forms(3)
0
sage: GammaH(33,[2,5]).dimension_cusp_forms(2)
3
sage: GammaH(32079, [21676]).dimension_cusp_forms(20)
180266112
```

We can sometimes show that there are no weight 1 cusp forms:

```
sage: GammaH(20, [9]).dimension_cusp_forms(1)
0
```

coset_reps()

Return a set of coset representatives for self \ SL2Z.

EXAMPLES:

```
sage: list(Gamma1(3).coset_reps())
[[1 0]
[0 1], [-1 -2]
[ 3  5], [ 0 -1]
[ 1  0], [-2  1]
[ 5 -3], [1 0]
[1 1], [-3 -2]
[ 8  5], [ 0 -1]
[ 1  2], [-2 -3]
[ 5  7]]
sage: len(list(Gamma1(31).coset_reps())) == 31**2 - 1
True
```

dimension_new_cusp_forms(*k=2, p=0*)

Return the dimension of the space of new (or p-new) weight k cusp forms for this congruence subgroup.

INPUT:

- k - an integer (default: 2), the weight. Not fully implemented for k = 1.
- p - integer (default: 0); if nonzero, compute the p-new subspace.

OUTPUT: Integer

EXAMPLES:

```
sage: GammaH(33,[2]).dimension_new_cusp_forms()
3
sage: Gamma1(4*25).dimension_new_cusp_forms(2, p=5)
225
sage: Gamma1(33).dimension_new_cusp_forms(2)
19
sage: Gamma1(33).dimension_new_cusp_forms(2,p=11)
21
```

divisor_subgroups()

Given this congruence subgroup $\Gamma_H(N)$, return all subgroups $\Gamma_G(M)$ for M a divisor of N and such that G is equal to the image of H modulo M.

EXAMPLES:

```
sage: G = GammaH(33,[2]); G
Congruence Subgroup Gamma_H(33) with H generated by [2]
sage: G._list_of_elements_in_H()
[1, 2, 4, 8, 16, 17, 25, 29, 31, 32]
sage: G.divisor_subgroups()
[Modular Group SL(2,Z),
 Congruence Subgroup Gamma_H(3) with H generated by [2],
 Congruence Subgroup Gamma_H(11) with H generated by [2],
 Congruence Subgroup Gamma_H(33) with H generated by [2]]
```

gamma0_coset_reps()

Return a set of coset representatives for self \ Gamma0(N), where N is the level of self.

EXAMPLE:

```
sage: GammaH(108, [1,-1]).gamma0_coset_reps()
[[1 0] [0 1], [-43 -45] [108 113], [ 31  33] [108 115], [-49 -54]
[108 119], [ 25  28] [108 121], [-19 -22] [108 125], [-17 -20] [108
127], [ 47  57] [108 131], [ 13  16] [108 133], [ 41  52] [108
137], [  7   9] [108 139], [-37 -49] [108 143], [-35 -47] [108
145], [ 29  40] [108 149], [ -5  -7] [108 151], [ 23  33] [108
155], [-11 -16] [108 157], [ 53  79] [108 161]]
```

generators()

Return generators for this congruence subgroup.

The result is cached.

EXAMPLE:

```
sage: for g in GammaH(3, [2]).generators():
...     print g
...     print '---'
[1 1]
[0 1]
 ---
[-1  0]
[ 0 -1]
---
[ 1 -1]
[ 0  1]
---
[1 0]
[3 1]
---
[1 1]
[0 1]
---
[-1  0]
[ 3 -1]
---
[ 1  0]
[-3  1]
---
```

index()

Return the index of self in SL2Z.

EXAMPLE:

```
sage: [G.index() for G in Gamma0(40).gamma_h_subgroups()]
[72, 144, 144, 144, 144, 288, 288, 288, 288, 144, 288, 288, 576, 576, 144, 288, 288, 576, 57
```

is_even()

Return True precisely if this subgroup contains the matrix -1.

EXAMPLES:

```
sage: GammaH(10, [3]).is_even()
True
sage: GammaH(14, [1]).is_even()
False
```

is_subgroup(*other*)

Return True if self is a subgroup of right, and False otherwise.

EXAMPLES:

```
sage: GammaH(24,[7]).is_subgroup(SL2Z)
True
sage: GammaH(24,[7]).is_subgroup(Gamma0(8))
True
sage: GammaH(24, []).is_subgroup(GammaH(24, [7]))
True
sage: GammaH(24, []).is_subgroup(Gamma1(24))
True
sage: GammaH(24, [17]).is_subgroup(GammaH(24, [7]))
False
sage: GammaH(1371, [169]).is_subgroup(GammaH(457, [169]))
True
```

ncusps()

Return the number of orbits of cusps (regular or otherwise) for this subgroup.

EXAMPLE:

```
sage: GammaH(33,[2]).ncusps()
8
sage: GammaH(32079, [21676]).ncusps()
28800
```

AUTHORS:

- Jordi Quer

nirregcusps()

Return the number of irregular cusps for this subgroup.

EXAMPLES:

```
sage: GammaH(3212, [2045, 2773]).nirregcusps()
720
```

nregcusps()

Return the number of orbits of regular cusps for this subgroup. A cusp is regular if we may find a parabolic element generating the stabiliser of that cusp whose eigenvalues are both +1 rather than -1. If G contains -1, all cusps are regular.

EXAMPLES:

```
sage: GammaH(20, [17]).nregcusps()
4
sage: GammaH(20, [17]).nirregcusps()
2
sage: GammaH(3212, [2045, 2773]).nregcusps()
1440
sage: GammaH(3212, [2045, 2773]).nirregcusps()
720
```

AUTHOR:

- Jordi Quer

nu2()

Return the number of orbits of elliptic points of order 2 for this group.

EXAMPLE:

```
sage: [H.nu2() for n in [1..10] for H in Gamma0(n).gamma_h_subgroups()]
[1, 1, 0, 0, 0, 0, 2, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 2, 0, 0]
sage: GammaH(33,[2]).nu2()
0
sage: GammaH(5,[2]).nu2()
2
```

AUTHORS:

•Jordi Quer

nu3()

Return the number of orbits of elliptic points of order 3 for this group.

EXAMPLE:

```
sage: [H.nu3() for n in [1..10] for H in Gamma0(n).gamma_h_subgroups()]
[1, 0, 1, 1, 0, 0, 0, 0, 0, 0, 0, 2, 2, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
sage: GammaH(33,[2]).nu3()
0
sage: GammaH(7,[2]).nu3()
2
```

AUTHORS:

•Jordi Quer

reduce_cusp(c)

Compute a minimal representative for the given cusp c. Returns a cusp c' which is equivalent to the given cusp, and is in lowest terms with minimal positive denominator, and minimal positive numerator for that denominator.

Two cusps u_1/v_1 and u_2/v_2 are equivalent modulo $\Gamma_H(N)$ if and only if

$$v_1 = hv_2 \bmod N \quad \text{and} \quad u_1 = h^{-1}u_2 \bmod \gcd(v_1, N)$$

or

$$v_1 = -hv_2 \bmod N \quad \text{and} \quad u_1 = -h^{-1}u_2 \bmod \gcd(v_1, N)$$

for some $h \in H$.

EXAMPLES:

```
sage: GammaH(6,[5]).reduce_cusp(Cusp(5,3))
1/3
sage: GammaH(12,[5]).reduce_cusp(Cusp(8,9))
1/3
sage: GammaH(12,[5]).reduce_cusp(Cusp(5,12))
Infinity
sage: GammaH(12,[]).reduce_cusp(Cusp(5,12))
5/12
sage: GammaH(21,[5]).reduce_cusp(Cusp(-9/14))
1/7
```

restrict(M)

Return the subgroup of $\Gamma_0(M)$ obtained by taking H to be the image of the H at level N modulo M.

EXAMPLES:

```
sage: G = GammaH(33,[2])
sage: G.restrict(11)
Congruence Subgroup Gamma_H(11) with H generated by [2]
sage: G.restrict(1)
Modular Group SL(2,Z)
sage: G.restrict(15)
...
ValueError: M (=15) must be a divisor of the level (33) of self
```

GammaH_constructor(*level, H*)

Return the congruence subgroup $\Gamma_H(N)$, which is the subgroup of $SL_2(\mathbf{Z})$ consisting of matrices of the form $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ with $N|c$ and $a, b \in H$, for H a specified subgroup of $(\mathbf{Z}/N\mathbf{Z})^\times$.

INPUT:

- level – an integer
- **H – either 0, 1, or a list** – If H is a list, return $\Gamma_H(N)$, where H is the subgroup of $(\mathbf{Z}/N\mathbf{Z})^*$ **generated** by the elements of the list.
  - If H = 0, returns $\Gamma_0(N)$.
  - If H = 1, returns $\Gamma_1(N)$.

EXAMPLES:

```
sage: GammaH(11,0) # indirect doctest
Congruence Subgroup Gamma0(11)
sage: GammaH(11,1)
Congruence Subgroup Gamma1(11)
sage: GammaH(11,[2])
Congruence Subgroup Gamma_H(11) with H generated by [2]
sage: GammaH(11,[2,1])
Congruence Subgroup Gamma_H(11) with H generated by [2]
```

is_GammaH(x)

Return True if x is a congruence subgroup of type GammaH.

EXAMPLES:

```
sage: from sage.modular.arithgroup.all import is_GammaH
sage: is_GammaH(GammaH(13, [2]))
True
sage: is_GammaH(Gamma0(6))
True
sage: is_GammaH(sage.modular.arithgroup.congroup_generic.CongruenceSubgroup(5))
False
```

mumu(N)

Return 0 if any cube divides N. Otherwise return $(-2)^v$ where v is the number of primes that exactly divide N. This is similar to the Moebius function.

INPUT:

- N - an integer at least 1

OUTPUT: Integer

EXAMPLES:

```
sage: from sage.modular.arithgroup.congroup_gammaH import mumu
sage: mumu(27)
0
sage: mumu(6*25)
4
sage: mumu(7*9*25)
-2
sage: mumu(9*25)
1
```

41.6 Congruence Subgroup $\Gamma_1(N)$

class Gamma1_class(*level*)

The congruence subgroup $\Gamma_1(N)$.

TESTS:

```
sage: [Gamma1(n).genus() for n in prime_range(2,100)]
[0, 0, 0, 0, 1, 2, 5, 7, 12, 22, 26, 40, 51, 57, 70, 92, 117, 126, 155, 176, 187, 222, 247, 287,
sage: [Gamma1(n).index() for n in [1..10]]
[1, 3, 8, 12, 24, 24, 48, 48, 72, 72]

sage: [Gamma1(n).dimension_cusp_forms() for n in [1..20]]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 2, 1, 1, 2, 5, 2, 7, 3]
sage: [Gamma1(n).dimension_cusp_forms(1) for n in [1..20]]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
sage: [Gamma1(4).dimension_cusp_forms(k) for k in [1..20]]
[0, 0, 0, 0, 1, 1, 2, 2, 3, 3, 4, 4, 5, 5, 6, 6, 7, 7, 8, 8]
sage: Gamma1(23).dimension_cusp_forms(1)
...
NotImplementedError: Computation of dimensions of weight 1 cusp forms spaces not implemented in
```

dimension_cusp_forms (*k=2, eps=None, algorithm='CohenOesterle'*)

Return the dimension of the space of cusp forms for self, or the dimension of the subspace corresponding to the given character if one is supplied.

INPUT:

- k - an integer (default: 2), the weight.
- eps - either None or a Dirichlet character modulo N, where N is the level of this group. If this is None, then the dimension of the whole space is returned; otherwise, the dimension of the subspace of forms of character eps.
- algorithm – either "CohenOesterle" (the default) or "Quer". This specifies the method to use in the case of nontrivial character: either the Cohen–Oesterle formula as described in Stein's book, or by Moebius inversion using the subgroups GammaH (a method due to Jordi Quer).

EXAMPLES:

We compute the same dimension in two different ways

```
sage: K = CyclotomicField(3)
sage: eps = DirichletGroup(7*43,K).0^2
sage: G = Gamma1(7*43)
```

Via Cohen–Oesterle:

```
sage: Gamma1(7*43).dimension_cusp_forms(2, eps)
28
```

Via Quer's method:

```
sage: Gamma1(7*43).dimension_cusp_forms(2, eps, algorithm="Quer")
28
```

Some more examples:

```
sage: G.<eps> = DirichletGroup(9)
sage: [Gamma1(9).dimension_cusp_forms(k, eps) for k in [1..10]]
[0, 0, 1, 0, 3, 0, 5, 0, 7, 0]
sage: [Gamma1(9).dimension_cusp_forms(k, eps^2) for k in [1..10]]
[0, 0, 0, 2, 0, 4, 0, 6, 0, 8]
```

dimension_eis (*k=2, eps=None, algorithm='CohenOesterle'*)

Return the dimension of the space of Eisenstein series forms for self, or the dimension of the subspace corresponding to the given character if one is supplied.

INPUT:

- k - an integer (default: 2), the weight.

- eps - either None or a Dirichlet character modulo N, where N is the level of this group. If this is None, then the dimension of the whole space is returned; otherwise, the dimension of the subspace of Eisenstein series of character eps.
- algorithm – either "CohenOesterle" (the default) or "Quer". This specifies the method to use in the case of nontrivial character: either the Cohen–Oesterle formula as described in Stein's book, or by Moebius inversion using the subgroups GammaH (a method due to Jordi Quer).

AUTHORS:

- William Stein - Cohen–Oesterle algorithm
- Jordi Quer - algorithm based on GammaH subgroups
- David Loeffler (2009) - code refactoring

EXAMPLES:

The following two computations use different algorithms:

```
sage: [Gamma1(36).dimension_eis(1,eps) for eps in DirichletGroup(36)]
[0, 4, 3, 0, 0, 2, 6, 0, 0, 2, 3, 0]
sage: [Gamma1(36).dimension_eis(1,eps,algorithm="Quer") for eps in DirichletGroup(36)]
[0, 4, 3, 0, 0, 2, 6, 0, 0, 2, 3, 0]
```

So do these:

```
sage: [Gamma1(48).dimension_eis(3,eps) for eps in DirichletGroup(48)]
[0, 12, 0, 4, 0, 8, 0, 4, 12, 0, 4, 0, 8, 0, 4, 0]
sage: [Gamma1(48).dimension_eis(3,eps,algorithm="Quer") for eps in DirichletGroup(48)]
[0, 12, 0, 4, 0, 8, 0, 4, 12, 0, 4, 0, 8, 0, 4, 0]
```

dimension_modular_forms (*k=2, eps=None, algorithm='CohenOesterle'*)

Return the dimension of the space of modular forms for self, or the dimension of the subspace corresponding to the given character if one is supplied.

INPUT:

- k - an integer (default: 2), the weight.
- eps - either None or a Dirichlet character modulo N, where N is the level of this group. If this is None, then the dimension of the whole space is returned; otherwise, the dimension of the subspace of forms of character eps.
- algorithm – either "CohenOesterle" (the default) or "Quer". This specifies the method to use in the case of nontrivial character: either the Cohen–Oesterle formula as described in Stein's book, or by Moebius inversion using the subgroups GammaH (a method due to Jordi Quer).

EXAMPLES:

```
sage: K = CyclotomicField(3)
sage: eps = DirichletGroup(7*43,K).0^2
sage: G = Gamma1(7*43)

sage: G.dimension_modular_forms(2, eps)
32
sage: G.dimension_modular_forms(2, eps, algorithm="Quer")
32
```

dimension_new_cusp_forms (*k=2, eps=None, p=0, algorithm='CohenOesterle'*)

Dimension of the new subspace (or p-new subspace) of cusp forms of weight k and character ε.

INPUT:

- k - an integer (default: 2)
- eps - a Dirichlet character
- p - a prime (default: 0); just the p-new subspace if given

- `algorithm` - either "CohenOesterle" (the default) or "Quer". This specifies the method to use in the case of nontrivial character: either the Cohen–Oesterle formula as described in Stein's book, or by Moebius inversion using the subgroups GammaH (a method due to Jordi Quer).

EXAMPLES:

```
sage: G = DirichletGroup(9)
sage: eps = G.0^3
sage: eps.conductor()
3
sage: [Gamma1(9).dimension_new_cusp_forms(k, eps) for k in [2..10]]
[0, 0, 0, 2, 0, 2, 0, 2, 0]
sage: [Gamma1(9).dimension_cusp_forms(k, eps) for k in [2..10]]
[0, 0, 0, 2, 0, 4, 0, 6, 0]
sage: [Gamma1(9).dimension_new_cusp_forms(k, eps, 3) for k in [2..10]]
[0, 0, 0, 2, 0, 2, 0, 2, 0]
```

Double check using modular symbols (independent calculation):

```
sage: [ModularSymbols(eps,k,sign=1).cuspidal_subspace().new_subspace().dimension()  for k in
[0, 0, 0, 2, 0, 2, 0, 2, 0]
sage: [ModularSymbols(eps,k,sign=1).cuspidal_subspace().new_subspace(3).dimension()  for k i
[0, 0, 0, 2, 0, 2, 0, 2, 0]
```

Another example at level 33:

```
sage: G = DirichletGroup(33)
sage: eps = G.1
sage: eps.conductor()
11
sage: [Gamma1(33).dimension_new_cusp_forms(k, G.1) for k in [2..4]]
[0, 4, 0]
sage: [Gamma1(33).dimension_new_cusp_forms(k, G.1, algorithm="Quer") for k in [2..4]]
[0, 4, 0]
sage: [Gamma1(33).dimension_new_cusp_forms(k, G.1^2) for k in [2..4]]
[2, 0, 6]
sage: [Gamma1(33).dimension_new_cusp_forms(k, G.1^2, p=3) for k in [2..4]]
[2, 0, 6]
```

generators()

Return generators for this congruence subgroup.

The result is cached.

EXAMPLE:

```
sage: for g in Gamma1(3).generators():
...       print g
...       print '---'
[1 1]
[0 1]
---
[-20   9]
[ 51 -23]
---
[ 4  1]
[-9 -2]
---
...
---
[ 4 -1]
[ 9 -2]
---
```

```
[ -5   3]
[-12   7]
---
```

index()

Return the index of self in the full modular group. This is given by the formula

$$N^2 \prod_{\substack{p|N \\ p \text{ prime}}} \left(1 - \frac{1}{p^2}\right).$$

EXAMPLE:

```
sage: Gamma1(180).index()
20736
sage: [Gamma1(n).projective_index() for n in [1..16]]
[1, 3, 4, 6, 12, 12, 24, 24, 36, 36, 60, 48, 84, 72, 96, 96]
```

is_even()

Return True precisely if this subgroup contains the matrix -1.

EXAMPLES:

```
sage: Gamma1(1).is_even()
True
sage: Gamma1(2).is_even()
True
sage: Gamma1(15).is_even()
False
```

is_subgroup(*right*)

Return True if self is a subgroup of right.

EXAMPLES:

```
sage: Gamma1(3).is_subgroup(SL2Z)
True
sage: Gamma1(3).is_subgroup(Gamma1(5))
False
sage: Gamma1(3).is_subgroup(Gamma1(6))
False
sage: Gamma1(6).is_subgroup(Gamma1(3))
True
sage: Gamma1(6).is_subgroup(Gamma0(2))
True
sage: Gamma1(80).is_subgroup(GammaH(40, []))
True
sage: Gamma1(80).is_subgroup(GammaH(40, [21]))
True
```

ncusps()

Return the number of cusps of this subgroup $\Gamma_1(N)$.

EXAMPLES:

```
sage: [Gamma1(n).ncusps() for n in [1..15]]
[1, 2, 2, 3, 4, 4, 6, 6, 8, 8, 10, 10, 12, 12, 16]
sage: [Gamma1(n).ncusps() for n in prime_range(2, 100)]
[2, 2, 4, 6, 10, 12, 16, 18, 22, 28, 30, 36, 40, 42, 46, 52, 58, 60, 66, 70, 72, 78, 82, 88,
```

nu2()

Calculate the number of orbits of elliptic points of order 2 for this subgroup $\Gamma_1(N)$. This is known to be 0 if N > 2.

EXAMPLE:

```
sage: Gamma1(2).nu2()
1
sage: Gamma1(457).nu2()
0
sage: [Gamma1(n).nu2() for n in [1..16]]
[1, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
```

nu3()

Calculate the number of orbits of elliptic points of order 3 for this subgroup $\Gamma_1(N)$. This is known to be 0 if N > 3.

EXAMPLE:

```
sage: Gamma1(2).nu3()
0
sage: Gamma1(3).nu3()
1
sage: Gamma1(457).nu3()
0
sage: [Gamma1(n).nu3() for n in [1..10]]
[1, 0, 1, 0, 0, 0, 0, 0, 0, 0]
```

Gamma1_constructor(N)

Return the congruence subgroup $\Gamma_1(N)$.

EXAMPLES:

```
sage: Gamma1(5) # indirect doctest
Congruence Subgroup Gamma1(5)
sage: G = Gamma1(23)
sage: G is Gamma1(23)
True
sage: G == loads(dumps(G))
True
sage: G is loads(dumps(G))
True
```

is_Gamma1(x)

Return True if x is a congruence subgroup of type Gamma1.

EXAMPLES:

```
sage: from sage.modular.arithgroup.all import is_Gamma1
sage: is_Gamma1(SL2Z)
True
sage: is_Gamma1(Gamma1(13))
True
sage: is_Gamma1(Gamma0(6))
False
sage: is_Gamma1(GammaH(12, []))
False
```

41.7 Congruence Subgroup $\Gamma_0(N)$

class Gamma0_class(*level*)

The congruence subgroup $\Gamma_0(N)$.

TESTS:

```
sage: Gamma0(11).dimension_cusp_forms(2)
1
sage: a = Gamma0(1).dimension_cusp_forms(2); a
0
sage: type(a)
<type 'sage.rings.integer.Integer'>
sage: Gamma0(5).dimension_cusp_forms(0)
0
sage: Gamma0(20).dimension_cusp_forms(1)
0
sage: Gamma0(20).dimension_cusp_forms(4)
6

sage: Gamma0(23).dimension_cusp_forms(2)
2
sage: Gamma0(1).dimension_cusp_forms(24)
2
sage: Gamma0(3).dimension_cusp_forms(3)
0
sage: Gamma0(11).dimension_cusp_forms(-1)
0

sage: Gamma0(22).dimension_new_cusp_forms()
0
sage: Gamma0(100).dimension_new_cusp_forms(2, 5)
5
```

Independently compute the dimension 5 above:

```
sage: m = ModularSymbols(100, 2,sign=1).cuspidal_subspace()
sage: m.new_subspace(5)
Modular Symbols subspace of dimension 5 of Modular Symbols space of dimension 18 for Gamma_0(100
```

coset_reps()

Return representatives for the right cosets of this congruence subgroup in $\mathrm{SL}_2(\mathbf{Z})$ as a generator object.

Use `list(self.coset_reps())` to obtain coset reps as a list.

EXAMPLES:

```
sage: list(Gamma0(5).coset_reps())
[[1 0]
[0 1], [ 0 -1]
[ 1  0], [1 0]
[1 1], [ 0 -1]
[ 1  2], [ 0 -1]
[ 1  3], [ 0 -1]
[ 1  4]]
sage: list(Gamma0(4).coset_reps())
 [[1 0] [0 1],
 [ 0 -1] [ 1  0],
 [1 0] [1 1],
 [ 0 -1] [ 1  2],
 [ 0 -1] [ 1  3],
 [1 0] [2 1]]
sage: list(Gamma0(1).coset_reps())
[[1 0] [0 1]]
```

divisor_subgroups()

Return the subgroups of SL2Z of the form Gamma0(M) that contain this subgroup, i.e. those for M a divisor of N.

EXAMPLE:

```
sage: Gamma0(24).divisor_subgroups()
[Modular Group SL(2,Z),
Congruence Subgroup Gamma0(2),
Congruence Subgroup Gamma0(3),
Congruence Subgroup Gamma0(4),
Congruence Subgroup Gamma0(6),
Congruence Subgroup Gamma0(8),
Congruence Subgroup Gamma0(12),
Congruence Subgroup Gamma0(24)]
```

gamma_h_subgroups()

Return the subgroups of the form $\Gamma_H(N)$ contained in self, where N is the level of self.

EXAMPLES:

```
sage: G = Gamma0(11)
sage: G.gamma_h_subgroups()
[Congruence Subgroup Gamma_H(11) with H generated by [2], Congruence Subgroup Gamma_H(11) wi
sage: G = Gamma0(12)
sage: G.gamma_h_subgroups()
[Congruence Subgroup Gamma_H(12) with H generated by [5, 7], Congruence Subgroup Gamma_H(12)
```

generators()

Return generators for this congruence subgroup.

The result is cached.

EXAMPLE:

```
sage: for g in Gamma0(3).generators():
...       print g
...       print '---'
[1 1]
[0 1]
---
[-1  0]
[ 0 -1]
---
...
---
[ 1  0]
[-3  1]
---
```

index()

Return the index of self in the full modular group. This is given by

$$N \prod_{\substack{p|N \\ p \text{ prime}}} \left(1 + \frac{1}{p}\right).$$

EXAMPLE:: sage: [Gamma0(n).index() for n in [1..19]] [1, 3, 4, 6, 6, 12, 8, 12, 12, 18, 12, 24, 14, 24, 24, 24, 18, 36, 20] sage: Gamma0(32041).index() 32220

is_even()

Return True precisely if this subgroup contains the matrix -1.

Since $\Gamma 0(N)$ always contains the matrix -1, this always returns True.

EXAMPLES:

```
sage: Gamma0(12).is_even()
True
sage: SL2Z.is_even()
True
```

is_subgroup(*right*)

Return True if self is a subgroup of right.

EXAMPLES:

```
sage: G = Gamma0(20)
sage: G.is_subgroup(SL2Z)
True
sage: G.is_subgroup(Gamma0(4))
True
sage: G.is_subgroup(Gamma0(20))
True
sage: G.is_subgroup(Gamma0(7))
False
sage: G.is_subgroup(Gamma1(20))
False
sage: G.is_subgroup(GammaH(40, []))
False
sage: Gamma0(80).is_subgroup(GammaH(40, [31, 21, 17]))
True
sage: Gamma0(2).is_subgroup(Gamma1(2))
True
```

ncusps()

Return the number of cusps of this subgroup $\Gamma_0(N)$.

EXAMPLES:

```
sage: [Gamma0(n).ncusps() for n in [1..19]]
[1, 2, 2, 3, 2, 4, 2, 4, 4, 4, 2, 6, 2, 4, 4, 6, 2, 8, 2]
sage: [Gamma0(n).ncusps() for n in prime_range(2,100)]
[2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2]
```

nu2()

Return the number of elliptic points of order 2 for this congruence subgroup $\Gamma_0(N)$. The number of these is given by a standard formula: 0 if N is divisible by 4 or any prime congruent to -1 mod 4, and otherwise 2^d where d is the number of odd primes dividing N.

EXAMPLE:

```
sage: Gamma0(2).nu2()
1
sage: Gamma0(4).nu2()
0
sage: Gamma0(21).nu2()
0
sage: Gamma0(1105).nu2()
8
sage: [Gamma0(n).nu2() for n in [1..19]]
[1, 1, 0, 0, 2, 0, 0, 0, 0, 2, 0, 0, 2, 0, 0, 0, 2, 0, 0]
```

nu3()

Return the number of elliptic points of order 3 for this congruence subgroup $\Gamma_0(N)$. The number of these is given by a standard formula: 0 if N is divisible by 9 or any prime congruent to -1 mod 3, and otherwise 2^d where d is the number of primes other than 3 dividing N.

EXAMPLE:

```
sage: Gamma0(2).nu3()
0
sage: Gamma0(3).nu3()
1
sage: Gamma0(9).nu3()
0
sage: Gamma0(7).nu3()
2
sage: Gamma0(21).nu3()
2
sage: Gamma0(1729).nu3()
8
```

Gamma0_constructor(*N*)

Return the congruence subgroup Gamma0(N).

EXAMPLES:

```
sage: G = Gamma0(51) ; G # indirect doctest
Congruence Subgroup Gamma0(51)
sage: G == Gamma0(51)
True
sage: G is Gamma0(51)
True
```

is_Gamma0(*x*)

Return True if x is a congruence subgroup of type Gamma0.

EXAMPLES:

```
sage: from sage.modular.arithgroup.all import is_Gamma0
sage: is_Gamma0(SL2Z)
True
sage: is_Gamma0(Gamma0(13))
True
sage: is_Gamma0(Gamma1(6))
False
```

41.8 Congruence Subgroup $\Gamma(N)$

class Gamma_class(*level*)

The principal congruence subgroup $\Gamma(N)$.

Gamma_constructor(*N*)

Return the congruence subgroup $\Gamma(N)$.

EXAMPLES:

```
sage: Gamma(5) # indirect doctest
Congruence Subgroup Gamma(5)
sage: G = Gamma(23)
sage: G is Gamma(23)
True
sage: G == loads(dumps(G))
True
sage: G is loads(dumps(G))
True
```

is_Gamma(*x*)
Return True if x is a congruence subgroup of type Gamma.

EXAMPLES:

```
sage: from sage.modular.arithgroup.all import is_Gamma
sage: is_Gamma(Gamma0(13))
False
sage: is_Gamma(Gamma(4))
True
```

41.9 The modular group $\mathrm{SL}_2(\mathbf{Z})$

class SL2Z_class()
The full modular group $\mathrm{SL}_2(\mathbf{Z})$, regarded as a congruence subgroup of itself.

is_subgroup(*right*)
Return True if self is a subgroup of right.

EXAMPLES:

```
sage: SL2Z.is_subgroup(SL2Z)
True
sage: SL2Z.is_subgroup(Gamma1(1))
True
sage: SL2Z.is_subgroup(Gamma0(6))
False
```

random_element(*bound=100*)
Return a random element of $\mathrm{SL}_2(\mathbf{Z})$ with entries whose absolute value is strictly less than bound (default 100).

(Algorithm: Generate a random pair of integers at most bound. If they are not coprime, throw them away and start again. If they are, find an element of $\mathrm{SL}_2(\mathbf{Z})$ whose bottom row is that, and left-multiply it by $\begin{pmatrix} 1 & w \\ 0 & 1 \end{pmatrix}$ for an integer w randomly chosen from a small enough range that the answer still has entries at most bound.)

It is, unfortunately, not true that all elements of SL2Z with entries < bound appear with equal probability; those with larger bottom rows are favoured, because there are fewer valid possibilities for w.

EXAMPLES:

```
sage: SL2Z.random_element() # random
sage: SL2Z.random_element(5) # still random
```

reduce_cusp(*c*)
Return the unique reduced cusp equivalent to c under the action of self. Always returns Infinity, since there is only one equivalence class of cusps for $SL_2(Z)$.

EXAMPLES:

```
sage: SL2Z.reduce_cusp(Cusps(-1/4))
Infinity
```

is_SL2Z(*x*)
Return True if x is the modular group $\mathrm{SL}_2(\mathbf{Z})$.

EXAMPLES:

```
sage: from sage.modular.arithgroup.all import is_SL2Z
sage: is_SL2Z(SL2Z)
True
sage: is_SL2Z(Gamma0(6))
False
```

CHAPTER

FORTYTWO

GENERAL HECKE ALGEBRAS AND HECKE MODULES

This chapter describes the basic functionality for modules over Hecke algebras, including decompositions, degeneracy maps and so on. For specific examples of Hecke algebras that use this functionality see *Modular Symbols* and *Modular Forms*.

42.1 Hecke modules

class HeckeModule_free_module(*base_ring, level, weight*)

A Hecke module modeled on a free module over a commutative ring.

T(*n*)

Returns the n^{th} Hecke operator T_n. This function is a synonym for `hecke_operator()`.

EXAMPLE:

```
sage: M = ModularSymbols(11,2)
sage: M.T(3)
Hecke operator T_3 on Modular Symbols ...
```

ambient()

Synonym for ambient_hecke_module. Return the ambient module associated to this module.

EXAMPLE:

```
sage: CuspForms(1, 12).ambient()
Modular Forms space of dimension 2 for Modular Group SL(2,Z) of weight 12 over Rational Fiel
```

ambient_hecke_module()

Return the ambient module associated to this module. As this is an abstract base class, return NotImplementedError.

EXAMPLE:

```
sage: sage.modular.hecke.module.HeckeModule_free_module(QQ, 10, 3).ambient_hecke_module()
...
NotImplementedError
```

ambient_module()

Synonym for ambient_hecke_module. Return the ambient module associated to this module.

EXAMPLE:

```
sage: CuspForms(1, 12).ambient_module()
Modular Forms space of dimension 2 for Modular Group SL(2,Z) of weight 12 over Rational Fiel
```

```
sage: sage.modular.hecke.module.HeckeModule_free_module(QQ, 10, 3).ambient_module()
...
NotImplementedError
```

atkin_lehner_operator(*d=None*)

Return the Atkin-Lehner operator W_d on this space, if defined, where d is a divisor of the level N such that N/d and d are coprime.

EXAMPLES:

```
sage: M = ModularSymbols(11)
sage: w = M.atkin_lehner_operator()
sage: w
Hecke module morphism Atkin-Lehner operator W_11 defined by the matrix
[-1  0  0]
[ 0 -1  0]
[ 0  0 -1]
Domain: Modular Symbols space of dimension 3 for Gamma_0(11) of weight ...
Codomain: Modular Symbols space of dimension 3 for Gamma_0(11) of weight ...
sage: M = ModularSymbols(Gamma1(13))
sage: w = M.atkin_lehner_operator()
sage: w.fcp('x')
(x - 1)^7 * (x + 1)^8

sage: M = ModularSymbols(33)
sage: S = M.cuspidal_submodule()
sage: S.atkin_lehner_operator()
Hecke module morphism Atkin-Lehner operator W_33 defined by the matrix
[ 0 -1  0  1 -1  0]
[ 0 -1  0  0  0  0]
[ 0 -1  0  0 -1  1]
[ 1 -1  0  0 -1  0]
[ 0  0  0  0 -1  0]
[ 0 -1  1  0 -1  0]
Domain: Modular Symbols subspace of dimension 6 of Modular Symbols space ...
Codomain: Modular Symbols subspace of dimension 6 of Modular Symbols space ...

sage: S.atkin_lehner_operator(3)
Hecke module morphism Atkin-Lehner operator W_3 defined by the matrix
[ 0  1  0 -1  1  0]
[ 0  1  0  0  0  0]
[ 0  1  0  0  1 -1]
[-1  1  0  0  1  0]
[ 0  0  0  0  1  0]
[ 0  1 -1  0  1  0]
Domain: Modular Symbols subspace of dimension 6 of Modular Symbols space ...
Codomain: Modular Symbols subspace of dimension 6 of Modular Symbols space ...

sage: N = M.new_submodule()
sage: N.atkin_lehner_operator()
Hecke module morphism Atkin-Lehner operator W_33 defined by the matrix
[  1 2/5 4/5]
[  0  -1   0]
[  0   0  -1]
Domain: Modular Symbols subspace of dimension 3 of Modular Symbols space ...
Codomain: Modular Symbols subspace of dimension 3 of Modular Symbols space ...
```

basis()

Returns a basis for self.

EXAMPLES:

```
sage: m = ModularSymbols(43)
sage: m.basis()
((1,0), (1,31), (1,32), (1,38), (1,39), (1,40), (1,41))
```

basis_matrix()

Return the matrix of the basis vectors of self (as vectors in some ambient module)

EXAMPLE:

```
sage: CuspForms(1, 12).basis_matrix()
[1 0]
```

coordinate_vector(*x*)

Write x as a vector with respect to the basis given by self.basis().

EXAMPLES:

```
sage: S = ModularSymbols(11,2).cuspidal_submodule()
sage: S.0
(1,8)
sage: S.basis()
((1,8), (1,9))
sage: S.coordinate_vector(S.0)
(1, 0)
```

decomposition(*bound=None, anemic=True, height_guess=1, proof=None*)

Returns the maximal decomposition of this Hecke module under the action of Hecke operators of index coprime to the level. This is the finest decomposition of self that we can obtain using factors obtained by taking kernels of Hecke operators.

Each factor in the decomposition is a Hecke submodule obtained as the kernel of $f(T_n)^r$ acting on self, where n is coprime to the level and $r = 1$. If anemic is False, instead choose r so that $f(X)^r$ exactly divides the characteristic polynomial.

INPUT:

- `anemic` - bool (default: True), if True, use only Hecke operators of index coprime to the level.
- `bound` - int or None, (default: None). If None, use all Hecke operators up to the Sturm bound, and hence obtain the same result as one would obtain by using every element of the Hecke ring. If a fixed integer, decompose using only Hecke operators T_p, with p prime, up to bound.

OUTPUT:

- `list` - a list of subspaces of self.

EXAMPLES:

```
sage: ModularSymbols(17,2).decomposition()
[
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 for Gamma_0(
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 3 for Gamma_0(
]
sage: ModularSymbols(Gamma1(10),4).decomposition()
[
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 18 for Gamma_1
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 18 for Gamma_1
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 18 for Gamma_1
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 18 for Gamma_1
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 18 for Gamma_1
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 18 for Gamma_1
]
sage: ModularSymbols(GammaH(12, [11])).decomposition()
[
```

```
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 9 for Congruen
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 9 for Congruen
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 9 for Congruen
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 9 for Congruen
Modular Symbols subspace of dimension 5 of Modular Symbols space of dimension 9 for Congruen
]
```

degree()

The degree of this Hecke module (i.e. the rank of the ambient free module)

EXAMPLE:

```
sage: CuspForms(1, 12).degree()
2
```

dual_eigenvector(*names='alpha', lift=True, nz=None*)

Return an eigenvector for the Hecke operators acting on the linear dual of this space. This eigenvector will have entries in an extension of the base ring of degree equal to the dimension of this space.

INPUT:

- `name` - print name of generator for eigenvalue field.
- `lift` - bool (default: True)
- `nz` - if not None, then normalize vector so dot product with this basis vector of ambient space is 1.

OUTPUT: A vector with entries possibly in an extension of the base ring. This vector is an eigenvector for all Hecke operators acting via their transpose.

If lift = False, instead return an eigenvector in the subspace for the Hecke operators on the dual space. I.e., this is an eigenvector for the restrictions of Hecke operators to the dual space.

Note:

1. The answer is cached so subsequent calls always return the same vector. However, the algorithm is randomized, so calls during another session may yield a different eigenvector. This function is used mainly for computing systems of Hecke eigenvalues.
2. One can also view a dual eigenvector as defining (via dot product) a functional phi from the ambient space of modular symbols to a field. This functional phi is an eigenvector for the dual action of Hecke operators on functionals.

EXAMPLE:

```
sage: ModularSymbols(14).cuspidal_subspace().simple_factors()[1].dual_eigenvector()
(0, 1, 0, 0, 0)
```

dual_hecke_matrix(*n*)

The matrix of the n-th Hecke operator acting on the dual embedded representation of self.

EXAMPLE:

```
sage: CuspForms(1, 24).dual_hecke_matrix(5)
[     44656110        -15040]
[-307849789440      28412910]
```

eigenvalue(*n, name='alpha'*)

Assuming that self is a simple space, return the eigenvalue of the n^{th} Hecke operator on self.

INPUT:

- `n` - index of Hecke operator
- `name` - print representation of generator of eigenvalue field

EXAMPLES:

```
sage: A = ModularSymbols(125,sign=1).new_subspace()[0]
sage: A.eigenvalue(7)
-3
sage: A.eigenvalue(3)
-alpha - 2
sage: A.eigenvalue(3,'w')
-w - 2
sage: A.eigenvalue(3,'z').charpoly('x')
x^2 + 3*x + 1
sage: A.hecke_polynomial(3)
x^2 + 3*x + 1

sage: M = ModularSymbols(Gamma1(17)).decomposition()[8].plus_submodule()
sage: M.eigenvalue(2,'a')
a
sage: M.eigenvalue(4,'a')
4/3*a^3 + 17/3*a^2 + 28/3*a + 8/3
```

Note:

1. In fact there are d systems of eigenvalues associated to self, where d is the rank of self. Each of the systems of eigenvalues is conjugate over the base field. This function chooses one of the systems and consistently returns eigenvalues from that system. Thus these are the coefficients a_n for $n \geq 1$ of a modular eigenform attached to self.
2. This function works even for Eisenstein subspaces, though it will not give the constant coefficient of one of the corresponding Eisenstein series (i.e., the generalized Bernoulli number).

factor_number()

If this Hecke module was computed via a decomposition of another Hecke module, this is the corresponding number. Otherwise return -1.

EXAMPLES:

```
sage: ModularSymbols(23)[0].factor_number()
0
sage: ModularSymbols(23).factor_number()
-1
```

gen(n)

Return the nth basis vector of the space.

EXAMPLE:

```
sage: ModularSymbols(23).gen(1)
(1,17)
```

hecke_matrix(n)

The matrix of the n-th Hecke operator acting on given basis.

EXAMPLE:

```
sage: C = CuspForms(1, 16)
sage: C.hecke_matrix(3)
[-3348]
```

hecke_operator(n)

Returns the n-th Hecke operator T_n.

INPUT:

- `ModularSymbols self` - Hecke equivariant space of modular symbols
- `int n` - an integer at least 1.

EXAMPLES:

```
sage: M = ModularSymbols(11,2)
sage: T = M.hecke_operator(3) ; T
Hecke operator T_3 on Modular Symbols space of dimension 3 for Gamma_0(11) of weight 2 with
sage: T.matrix()
[ 4  0 -1]
[ 0 -1  0]
[ 0  0 -1]
sage: T(M.0)
4*(1,0) - (1,9)
sage: S = M.cuspidal_submodule()
sage: T = S.hecke_operator(3) ; T
Hecke operator T_3 on Modular Symbols subspace of dimension 2 of Modular Symbols space of di
sage: T.matrix()
[-1  0]
[ 0 -1]
sage: T(S.0)
-(1,8)
```

hecke_polynomial(*n, var='x'*)

Return the characteristic polynomial of the n-th Hecke operator acting on this space.

INPUT:

- n - integer

OUTPUT: a polynomial

EXAMPLE:

```
sage: ModularSymbols(11,2).hecke_polynomial(3)
x^3 - 2*x^2 - 7*x - 4
```

is_simple()

Return True if this space is simple as a module for the corresponding Hecke algebra. Raises NotImplementedError, as this is an abstract base class.

EXAMPLE:

```
sage: sage.modular.hecke.module.HeckeModule_free_module(QQ, 10, 3).is_simple()
...
NotImplementedError
```

is_splittable()

Returns True if and only if only it is possible to split off a nontrivial generalized eigenspace of self as the kernel of some Hecke operator (not necessarily prime to the level). Note that the direct sum of several copies of the same simple module is not splittable in this sense.

EXAMPLE:

```
sage: M = ModularSymbols(Gamma0(64)).cuspidal_subspace()
sage: M.is_splittable()
True
sage: M.simple_factors()[0].is_splittable()
False
```

is_splittable_anemic()

Returns true if and only if only it is possible to split off a nontrivial generalized eigenspace of self as the kernel of some Hecke operator of index coprime to the level. Note that the direct sum of several copies of the same simple module is not splittable in this sense.

EXAMPLE:

```
sage: M = ModularSymbols(Gamma0(64)).cuspidal_subspace()
sage: M.is_splittable_anemic()
```

```
True
sage: M.simple_factors()[0].is_splittable_anemic()
False
```

is_submodule(*other*)

Return True if self is a submodule of other.

EXAMPLES:

```
sage: M = ModularSymbols(Gamma0(64))
sage: M[0].is_submodule(M)
True
sage: CuspForms(1, 24).is_submodule(ModularForms(1, 24))
True
sage: CuspForms(1, 12).is_submodule(CuspForms(3, 12))
False
```

ngens()

Number of generators of self (equal to the rank).

EXAMPLE:

```
sage: ModularForms(1, 12).ngens()
2
```

projection()

Return the projection map from the ambient space to self.

ALGORITHM: Let B be the matrix whose columns are obtained by concatenating together a basis for the factors of the ambient space. Then the projection matrix onto self is the submatrix of B^{-1} obtained from the rows corresponding to self, i.e., if the basis vectors for self appear as columns n through m of B, then the projection matrix is got from rows n through m of B^{-1}. This is because projection with respect to the B basis is just given by an $m - n + 1$ row slice P of a diagonal matrix D with 1's in the n through m positions, so projection with respect to the standard basis is given by $P \cdot B^{-1}$, which is just rows n through m of B^{-1}.

EXAMPLES:

```
sage: e = EllipticCurve('34a')
sage: m = ModularSymbols(34); s = m.cuspidal_submodule()
sage: d = s.decomposition(7)
sage: d
[
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 9 for Gamma_0(
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 9 for Gamma_0(
]
sage: a = d[0]; a
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 9 for Gamma_0(
sage: pi = a.projection()
sage: pi(m([0,oo]))
-1/6*(2,7) + 1/6*(2,13) - 1/6*(2,31) + 1/6*(2,33)
sage: M = ModularSymbols(53,sign=1)
sage: S = M.cuspidal_subspace()[1] ; S
Modular Symbols subspace of dimension 3 of Modular Symbols space of dimension 5 for Gamma_0(
sage: p = S.projection()
sage: S.basis()
((1,33) - (1,37), (1,35), (1,49))
sage: [ p(x) for x in S.basis() ]
[(1,33) - (1,37), (1,35), (1,49)]
```

system_of_eigenvalues(*n, name='alpha'*)

Assuming that self is a simple space of modular symbols, return the eigenvalues $[a_1, \ldots, a_n max]$ of the Hecke operators on self. See `self.eigenvalue(n)` for more details.

INPUT:

- `n` - number of eigenvalues
- `alpha` - name of generate for eigenvalue field

EXAMPLES: These computations use pseudo-random numbers, so we set the seed for reproducible testing.

```
sage: set_random_seed(0)
```

The computations also use cached results from other computations, so we clear the caches for reproducible testing.

```
sage: ModularSymbols_clear_cache()
```

We compute eigenvalues for newforms of level 62.

```
sage: M = ModularSymbols(62,2,sign=-1)
sage: S = M.cuspidal_submodule().new_submodule()
sage: [A.system_of_eigenvalues(3) for A in S.decomposition()]
[[1, 1, 0], [1, -1, -alpha - 1]]
```

Next we define a function that does the above:

```
sage: def b(N,k=2):
...     t=cputime()
...     S = ModularSymbols(N,k,sign=-1).cuspidal_submodule().new_submodule()
...     for A in S.decomposition():
...         print N, A.system_of_eigenvalues(5)

sage: b(63)
63 [1, 1, 0, -1, 2]
63 [1, alpha, 0, 1, -2*alpha]
```

This example illustrates finding field over which the eigenvalues are defined:

```
sage: M = ModularSymbols(23,2,sign=1).cuspidal_submodule().new_submodule()
sage: v = M.system_of_eigenvalues(10); v
[1, alpha, -2*alpha - 1, -alpha - 1, 2*alpha, alpha - 2, 2*alpha + 2, -2*alpha - 1, 2, -2*al
sage: v[0].parent()
Number Field in alpha with defining polynomial x^2 + x - 1
```

This example illustrates setting the print name of the eigenvalue field.

```
sage: A = ModularSymbols(125,sign=1).new_subspace()[0]
sage: A.system_of_eigenvalues(10)
[1, alpha, -alpha - 2, -alpha - 1, 0, -alpha - 1, -3, -2*alpha - 1, 3*alpha + 2, 0]
sage: A.system_of_eigenvalues(10,'x')
[1, x, -x - 2, -x - 1, 0, -x - 1, -3, -2*x - 1, 3*x + 2, 0]
```

weight()

Returns the weight of this Hecke module.

INPUT:

- `self` - an arbitrary Hecke module

OUTPUT:

- `int` - the weight

EXAMPLES:

```
sage: m = ModularSymbols(20, weight=2)
sage: m.weight()
2
```

zero_submodule()
Return the zero submodule of self.

EXAMPLES:

```
sage: ModularSymbols(11,4).zero_submodule()
Modular Symbols subspace of dimension 0 of Modular Symbols space of dimension 6 for Gamma_0(
sage: CuspForms(11,4).zero_submodule()
Modular Forms subspace of dimension 0 of Modular Forms space of dimension 4 for Congruence S
```

class HeckeModule_generic(*base_ring, level*)
A very general base class for Hecke modules.

We define a Hecke module of weight k to be a module over a commutative ring equipped with an action of operators T_m for all positive integers m coprime to some integer n (the level), which satisfy $T_r T_s = T_{rs}$ for r,s coprime, and for powers of a prime p, $T_{p^r} = T_p T_{p^{r-1}} - \varepsilon(p) p^{k-1} T_{p^{r-2}}$, where $\varepsilon(p)$ is some endomorphism of the module which commutes with the T_m.

We distinguish between *full* Hecke modules, which also have an action of operators T_m for m not assumed to be coprime to the level, and *anemic* Hecke modules, for which this does not hold.

anemic_hecke_algebra()
Return the Hecke algebra associated to this Hecke module.

EXAMPLES:

```
sage: T = ModularSymbols(1,12).hecke_algebra()
sage: A = ModularSymbols(1,12).anemic_hecke_algebra()
sage: T == A
False
sage: A
Anemic Hecke algebra acting on Modular Symbols space of dimension 3 for Gamma_0(1) of weight
sage: A.is_anemic()
True
```

category()
Return the category to which this module belongs, i.e. the category of Hecke modules over the given base ring.

EXAMPLE:

```
sage: ModularForms(3, 3).category()
Category of Hecke modules over Rational Field
```

character()
The character of this space. As this is an abstract base class, return None.

EXAMPLE:

```
sage: sage.modular.hecke.module.HeckeModule_generic(QQ, 10).character() is None
True
```

dimension()
Synonym for rank.

EXAMPLE:

```
sage: M = sage.modular.hecke.module.HeckeModule_generic(QQ, 10).dimension()
...
NotImplementedError: Derived subclasses must implement rank
```

hecke_algebra()
Return the Hecke algebra associated to this Hecke module.

EXAMPLES:

```
sage: T = ModularSymbols(Gamma1(5),3).hecke_algebra()
sage: T
Full Hecke algebra acting on Modular Symbols space of dimension 4 for Gamma_1(5) of weight 3
sage: T.is_anemic()
False

sage: M = ModularSymbols(37,sign=1)
sage: E, A, B = M.decomposition()
sage: A.hecke_algebra() == B.hecke_algebra()
False
```

is_full_hecke_module()

Return True if this space is invariant under all Hecke operators.

Since self is guaranteed to be an anemic Hecke module, the significance of this function is that it also ensures invariance under Hecke operators of index that divide the level.

EXAMPLES:

```
sage: M = ModularSymbols(22); M.is_full_hecke_module()
True
sage: M.submodule(M.free_module().span([M.0.list()]), check=False).is_full_hecke_module()
False
```

is_hecke_invariant(n)

Return True if self is invariant under the Hecke operator T_n.

Since self is guaranteed to be an anemic Hecke module it is only interesting to call this function when n is not coprime to the level.

EXAMPLES:

```
sage: M = ModularSymbols(22).cuspidal_subspace()
sage: M.is_hecke_invariant(2)
True
```

We use check=False to create a nasty "module" that is not invariant under T_2:

```
sage: S = M.submodule(M.free_module().span([M.0.list()]), check=False); S
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 7 for Gamma_0(
sage: S.is_hecke_invariant(2)
False
sage: [n for n in range(1,12) if S.is_hecke_invariant(n)]
[1, 3, 5, 7, 9, 11]
```

is_zero()

Return True if this Hecke module has dimension 0.

EXAMPLES:

```
sage: ModularSymbols(11).is_zero()
False
sage: ModularSymbols(11).old_submodule().is_zero()
True
sage: CuspForms(10).is_zero()
True
sage: CuspForms(1,12).is_zero()
False
```

level()

Returns the level of this modular symbols space.

INPUT:

- `ModularSymbols self` - an arbitrary space of modular symbols

OUTPUT:

- int - the level

EXAMPLES:

```
sage: m = ModularSymbols(20)
sage: m.level()
20
```

rank()

Return the rank of this module over its base ring. Returns NotImplementedError, since this is an abstract base class.

EXAMPLES:

```
sage: sage.modular.hecke.module.HeckeModule_generic(QQ, 10).rank()
...
NotImplementedError: Derived subclasses must implement rank
```

submodule(*X*)

Return the submodule of self corresponding to X. As this is an abstract base class, this raises a NotImplementedError.

EXAMPLES:

```
sage: sage.modular.hecke.module.HeckeModule_generic(QQ, 10).submodule(0)
...
NotImplementedError: Derived subclasses should implement submodule
```

is_HeckeModule(*x*)

Return True if x is a Hecke module.

EXAMPLES:

```
sage: from sage.modular.hecke.module import is_HeckeModule
sage: is_HeckeModule(ModularForms(Gamma0(7), 4))
True
sage: is_HeckeModule(QQ^3)
False
sage: is_HeckeModule(J0(37).homology())
True
```

42.2 Ambient Hecke modules

class AmbientHeckeModule(*base_ring, rank, level, weight*)

An ambient Hecke module, i.e. a Hecke module that is isomorphic as a module over its base ring R to the standard free module R^k for some k. This is the base class for ambient spaces of modular forms and modular symbols, and for Brandt modules.

ambient_hecke_module()

Return the ambient space that contains this ambient space. This is, of course, just this space again.

EXAMPLE:

```
sage: M = ModularForms(11, 4); M.ambient_hecke_module() is M
True
```

complement()

Return the largest Hecke-stable complement of this space.

EXAMPLES:

```
sage: M=ModularSymbols(11,2,1)
sage: M
Modular Symbols space of dimension 2 for Gamma_0(11) of weight 2 with sign 1 over Rational F
sage: M.complement()
Modular Symbols subspace of dimension 0 of Modular Symbols space of dimension 2 for Gamma_0(
sage: C=M.cuspidal_subspace()
sage: C
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 2 for Gamma_0(
sage: C.complement()
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 2 for Gamma_0(
```

decomposition_matrix()

Returns the matrix whose columns form a basis for the canonical sorted decomposition of self coming from the Hecke operators.

If the simple factors are $D_0, \ldots, D_n$, then the first few columns are an echelonized basis for D_0, the next an echelonized basis for D_1, the next for D_2, etc.

EXAMPLE:

```
sage: S = ModularSymbols(37, 2)
sage: S.decomposition_matrix()
[   1    0    0    0 -1/3]
[   0    1   -1    0  1/2]
[   0    0    0    1 -1/2]
[   0    1    1    1    0]
[   0    0    0    0    1]
```

decomposition_matrix_inverse()

Returns the inverse of the matrix returned by decomposition_matrix().

EXAMPLE:

```
sage: S = ModularSymbols(37, 2)
sage: t = S.decomposition_matrix_inverse(); t
[   1    0    0    0  1/3]
[   0  1/2 -1/2  1/2 -1/2]
[   0 -1/2 -1/2  1/2    0]
[   0    0    1    0  1/2]
[   0    0    0    0    1]
sage: t * S.decomposition_matrix() == 1
True
```

degeneracy_map(*level, t=1*)

The t-th degeneracy map from self to the corresponding Hecke module of the given level. The level of self must be a divisor or multiple of level, and t must be a divisor of the quotient.

INPUT:

- `level` - int, the level of the codomain of the map (positive int).
- `t` - int, the parameter of the degeneracy map, i.e., the map is related to $f(q)$ - $f(q^t)$.

OUTPUT: A morphism from self to corresponding the Hecke module of given level.

EXAMPLES:

```
sage: M = ModularSymbols(11,sign=1)
sage: d1 = M.degeneracy_map(33); d1
Hecke module morphism degeneracy map corresponding to f(q) |--> f(q) defined by the matrix
[ 1  0  0  0 -2 -1]
[ 0  0 -2  2  0  0]
Domain: Modular Symbols space of dimension 2 for Gamma_0(11) of weight ...
Codomain: Modular Symbols space of dimension 6 for Gamma_0(33) of weight ...
sage: M.degeneracy_map(33,3).matrix()
```

```
[ 3  2  2  0 -2  1]
[ 0  2  0 -2  0  0]
sage: M = ModularSymbols(33,sign=1)
sage: d2 = M.degeneracy_map(11); d2.matrix()
[  1   0]
[  0 1/2]
[  0  -1]
[  0   1]
[ -1   0]
[ -1   0]
sage: (d2*d1).matrix()
[4 0]
[0 4]

sage: M = ModularSymbols(3,12,sign=1)
sage: M.degeneracy_map(1)
Hecke module morphism degeneracy map corresponding to f(q) |--> f(q) defined by the matrix
[1 0]
[0 0]
[0 1]
[0 1]
[0 1]
Domain: Modular Symbols space of dimension 5 for Gamma_0(3) of weight ...
Codomain: Modular Symbols space of dimension 2 for Gamma_0(1) of weight ...

sage: S = M.cuspidal_submodule()
sage: S.degeneracy_map(1)
Hecke module morphism defined by the matrix
[1 0]
[0 0]
[0 0]
Domain: Modular Symbols subspace of dimension 3 of Modular Symbols space ...
Codomain: Modular Symbols space of dimension 2 for Gamma_0(1) of weight ...

sage: D = ModularSymbols(10,4).cuspidal_submodule().decomposition()
sage: D
[
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 10 for Gamma_0
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 10 for Gamma_0
]
sage: D[1].degeneracy_map(5)
Hecke module morphism defined by the matrix
[   0    0   -1    1]
[   0  1/2  3/2   -2]
[   0   -1    1    0]
[   0 -3/4 -1/4    1]
Domain: Modular Symbols subspace of dimension 4 of Modular Symbols space ...
Codomain: Modular Symbols space of dimension 4 for Gamma_0(5) of weight ...
```

dual_free_module()

The free module dual to self, as a submodule of the dual module of the ambient space. As this space is ambient anyway, this just returns self.free_module().

EXAMPLE:

```
sage: M = ModularForms(2,8); M.dual_free_module()
Vector space of dimension 3 over Rational Field
sage: M.dual_free_module() is M.free_module()
True
```

fcp(*n, var='x'*)

Returns the factorization of the characteristic polynomial of the Hecke operator T_n of index n acting on this space.

INPUT:

- `self` - Hecke module invariant under the Hecke operator of index n.
- `int n` - a positive integer.
- `var` - variable of polynomial (default x)

OUTPUT:

- `list` - list of the pairs (g,e), where g is an irreducible factor of the characteristic polynomial of T_n, and e is its multiplicity.

EXAMPLES:

```
sage: m = ModularSymbols(23, 2, sign=1)
sage: m.fcp(2)
(x - 3) * (x^2 + x - 1)
sage: m.hecke_operator(2).charpoly('x').factor()
(x - 3) * (x^2 + x - 1)
```

free_module()

Return the free module underlying this ambient Hecke module (the forgetful functor from Hecke modules to modules over the base ring)

EXAMPLE:

```
sage: ModularForms(59, 2).free_module()
Vector space of dimension 6 over Rational Field
```

hecke_bound()

Return an integer B such that the Hecke operators T_n, for $n \leq B$, generate the full Hecke algebra as a module over the base ring. Note that we include the n with n not coprime to the level.

At present this returns an unproven guess which appears to be valid for $M_k(\Gamma_0(N))$, where k and N are the weight and level of self. (It is clearly valid for *cuspidal* spaces of any fixed character, as a consequence of the Sturm bound theorem.) It returns a hopelessly wrong answer for spaces of full level Γ_1.

TODO: Get rid of this dreadful bit of code.

EXAMPLE:

```
sage: ModularSymbols(17, 4).hecke_bound()
15
sage: ModularSymbols(Gamma1(17), 4).hecke_bound() # wrong!
15
```

hecke_images(*i, v*)

Return images of the i-th standard basis vector under the Hecke operators T_p for all integers in v.

INPUT:

- `i` - nonnegative integer
- `v` - a list of positive integer

OUTPUT:

- `matrix` - whose rows are the Hecke images

EXAMPLES:

```
sage: M = ModularSymbols(DirichletGroup(13).0, 3)
sage: M.T(2)(M.0).element()
(zeta12 + 4, 0, -1, 1)
sage: M.hecke_images(0, [1,2])
[         1          0          0          0]
[zeta12 + 4          0         -1          1]
```

hecke_module_of_level(*level*)

Return the Hecke module corresponding to self at the given level, which should be either a divisor or a multiple of the level of self. This raises NotImplementedError, and should be overridden in derived classes.

EXAMPLE:

```
sage: sage.modular.hecke.ambient_module.AmbientHeckeModule.hecke_module_of_level(ModularForm
...
NotImplementedError
```

intersection(*other*)

Returns the intersection of self and other, which must both lie in a common ambient space of modular symbols.

EXAMPLES:

```
sage: M = ModularSymbols(43, sign=1)
sage: A = M[0] + M[1]
sage: B = M[1] + M[2]
sage: A.rank(), B.rank()
(2, 3)
sage: C = A.intersection(B); C.rank()  # TODO
1
```

is_ambient()

Returns True if and only if self is an ambient Hecke module.

Warning: self can only be ambient by being of type AmbientHeckeModule.
For example, decomposing a simple ambient space yields a single factor, and that factor is *not* considered an ambient space.

EXAMPLES:

```
sage: m = ModularSymbols(10)
sage: m.is_ambient()
True

sage: a = m[0]  # the unique simple factor
sage: a == m
True
sage: a.is_ambient()
False
```

is_full_hecke_module(*compute=True*)

Returns True if this space is invariant under the action of all Hecke operators, even those that divide the level. This is always true for ambient Hecke modules, so return True.

EXAMPLE:

```
sage: ModularSymbols(11, 4).is_full_hecke_module()
True
```

is_new(*p=None*)

Return True if this module is entirely new.

EXAMPLE:

```
sage: ModularSymbols(11, 4).is_new()
False
sage: ModularSymbols(1, 12).is_new()
True
```

is_old(*p=None*)

Return True if this module is entirely old.

EXAMPLE:

```
sage: ModularSymbols(22).is_old()
True
sage: ModularSymbols(3, 12).is_old()
False
```

is_submodule(*V*)

Returns True if and only if self is a submodule of V. Since this is an ambient space, this returns True if and only if V is equal to self.

EXAMPLE:

```
sage: ModularSymbols(1, 4).is_submodule(ModularSymbols(11,4))
False
sage: ModularSymbols(11, 4).is_submodule(ModularSymbols(11,4))
True
```

linear_combination_of_basis(*v*)

Given a list or vector of length equal to the dimension of self, construct the appropriate linear combination of the basis vectors of self.

EXAMPLE:

```
sage: ModularForms(3, 12).linear_combination_of_basis([1,0,0,0,1])
2*q + 2049*q^2 + 177147*q^3 + 4196177*q^4 + 48830556*q^5 + O(q^6)
```

new_submodule(*p=None*)

Returns the new or p-new submodule of self.

INPUT:

- p - (default: None); if not None, return only the p-new submodule.

OUTPUT: the new or p-new submodule of self

EXAMPLES:

```
sage: m = ModularSymbols(33); m.rank()
9
sage: m.new_submodule().rank()
3
sage: m.new_submodule(3).rank()
4
sage: m.new_submodule(11).rank()
8
```

nonembedded_free_module()

Return the free module corresponding to self as an abstract free module (rather than as a submodule of an ambient free module). As this module is ambient anyway, this just returns `self.free_module()`.

EXAMPLES:

```
sage: M = ModularSymbols(11, 2)
sage: M.nonembedded_free_module() is M.free_module()
True
```

old_submodule(*p=None*)

Returns the old or p-old submodule of self.

INPUT:

- p - (default: None); if not None, return only the p-old submodule.

OUTPUT: the old or p-old submodule of self

EXAMPLES:

```
sage: m = ModularSymbols(33); m.rank()
9
sage: m.old_submodule().rank()
7
sage: m.old_submodule(3).rank()
6
sage: m.new_submodule(11).rank()
8

sage: e = DirichletGroup(16)([-1, 1])
sage: M = ModularSymbols(e, 3, sign=1); M
Modular Symbols space of dimension 4 and level 16, weight 3, character [-1, 1], sign 1, over
sage: M.old_submodule()
Modular Symbols subspace of dimension 3 of Modular Symbols space of dimension 4 and level 16
```

rank()

Return the rank of this ambient Hecke module.

OUTPUT:

Integer

EXAMPLES:

```
sage: M = sage.modular.hecke.ambient_module.AmbientHeckeModule(QQ, 3, 11, 2); M
Generic ambient Hecke module of rank 3, level 11 and weight 2 over Rational Field
sage: M.rank()
3
```

submodule(*M, Mdual=None, check=True*)

Return the Hecke submodule of self generated by M, which may be a submodule of the free module of self, or a list of elements of self.

EXAMPLE:

```
sage: M = ModularForms(37, 2)
sage: A = M.submodule([M.newforms()[0].element(), M.newforms()[1].element()]); A
Modular Forms subspace of dimension 2 of Modular Forms space of dimension 3 for Congruence S
```

submodule_from_nonembedded_module(*V, Vdual=None, check=True*)

Create a submodule of this module, from a submodule of an ambient free module of the same rank as the rank of self.

INPUT:

- `V` - submodule of ambient free module of the same rank as the rank of self.
- `Vdual` - used to pass in dual submodule (may be None)
- `check` - whether to check that submodule is Hecke equivariant

OUTPUT: Hecke submodule of self

EXAMPLE:

```
sage: V = QQ^8
sage: ModularForms(24, 2).submodule_from_nonembedded_module(V.submodule([0]))
Modular Forms subspace of dimension 0 of Modular Forms space of dimension 8 for Congruence S
```

submodule_generated_by_images(*M*)

Return the submodule of this ambient modular symbols space generated by the images under all degeneracy maps of M. The space M must have the same weight, sign, and group or character as this ambient space.

EXAMPLES:

```
sage: ModularSymbols(6, 12).submodule_generated_by_images(ModularSymbols(1,12))
Modular Symbols subspace of dimension 12 of Modular Symbols space of dimension 22 for Gamma_
```

is_AmbientHeckeModule(*x*)

Return True if x is of type AmbientHeckeModule.

EXAMPLES:

```
sage: from sage.modular.hecke.ambient_module import is_AmbientHeckeModule
sage: is_AmbientHeckeModule(ModularSymbols(6))
True
sage: is_AmbientHeckeModule(ModularSymbols(6).cuspidal_subspace())
False
sage: is_AmbientHeckeModule(ModularForms(11))
True
sage: is_AmbientHeckeModule(BrandtModule(2, 3))
True
```

42.3 Submodules of Hecke modules

class HeckeSubmodule(*ambient, submodule, dual_free_module=None, check=True*)

Submodule of a Hecke module.

ambient()

Synonym for ambient_hecke_module.

EXAMPLES:

```
sage: CuspForms(2, 12).ambient()
Modular Forms space of dimension 4 for Congruence Subgroup Gamma0(2) of weight 12 over Ratic
```

ambient_hecke_module()

Return the ambient Hecke module of which this is a submodule.

EXAMPLES:

```
sage: CuspForms(2, 12).ambient_hecke_module()
Modular Forms space of dimension 4 for Congruence Subgroup Gamma0(2) of weight 12 over Ratic
```

complement(*bound=None*)

Return the largest Hecke-stable complement of this space.

EXAMPLES:

```
sage: M = ModularSymbols(15, 6).cuspidal_subspace()
sage: M.complement()
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 20 for Gamma_0
sage: E = EllipticCurve("128a")
sage: ME = E.modular_symbol_space()
sage: ME.complement()
Modular Symbols subspace of dimension 17 of Modular Symbols space of dimension 18 for Gamma_
```

degeneracy_map(*level, t=1*)

The t-th degeneracy map from self to the space of ambient modular symbols of the given level. The level of self must be a divisor or multiple of level, and t must be a divisor of the quotient.

INPUT:

- `level` - int, the level of the codomain of the map (positive int).
- `t` - int, the parameter of the degeneracy map, i.e., the map is related to $f(q)$ - $f(q^t)$.

OUTPUT: A linear function from self to the space of modular symbols of given level with the same weight, character, sign, etc., as this space.

EXAMPLES:

```
sage: D = ModularSymbols(10,4).cuspidal_submodule().decomposition(); D
[
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 10 for Gamma_0
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 10 for Gamma_0
]
sage: d = D[1].degeneracy_map(5); d
Hecke module morphism defined by the matrix
[   0    0   -1    1]
[   0  1/2  3/2   -2]
[   0   -1    1    0]
[   0 -3/4 -1/4    1]
Domain: Modular Symbols subspace of dimension 4 of Modular Symbols space ...
Codomain: Modular Symbols space of dimension 4 for Gamma_0(5) of weight ...

sage: d.rank()
2
sage: d.kernel()
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 10 for Gamma_0
sage: d.image()
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 4 for Gamma_0(
```

dual_free_module(*bound=None, anemic=True, use_star=True*)

Compute embedded dual free module if possible. In general this won't be possible, e.g., if this space is not Hecke equivariant, possibly if it is not cuspidal, or if the characteristic is not 0. In all these cases we raise a RuntimeError exception.

If use_star is True (which is the default), we also use the +/- eigenspaces for the star operator to find the dual free module of self. If the self does not have a star involution, use_star will automatically be set to True.

EXAMPLES:

```
sage: M = ModularSymbols(11, 2)
sage: M.dual_free_module()
Vector space of dimension 3 over Rational Field
sage: Mpc = M.plus_submodule().cuspidal_submodule()
sage: Mcp = M.cuspidal_submodule().plus_submodule()
sage: Mcp.dual_free_module() == Mpc.dual_free_module()
True
sage: Mpc.dual_free_module()
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[  1 5/2   5]

sage: M = ModularSymbols(35,2).cuspidal_submodule()
sage: M.dual_free_module(use_star=False)
Vector space of degree 9 and dimension 6 over Rational Field
Basis matrix:
[   1    0    0    0   -1    0    0    4   -2]
[   0    1    0    0    0    0    0 -1/2  1/2]
[   0    0    1    0    0    0    0 -1/2  1/2]
[   0    0    0    1   -1    0    0    1    0]
[   0    0    0    0    0    1    0   -2    1]
[   0    0    0    0    0    0    1   -2    1]

sage: M = ModularSymbols(40,2)
```

```
sage: Mmc = M.minus_submodule().cuspidal_submodule()
sage: Mcm = M.cuspidal_submodule().minus_submodule()
sage: Mcm.dual_free_module() == Mmc.dual_free_module()
True
sage: Mcm.dual_free_module()
Vector space of degree 13 and dimension 3 over Rational Field
Basis matrix:
[ 0  1  0  0  0  0  1  0 -1 -1  1 -1  0]
[ 0  0  1  0 -1  0 -1  0  1  0  0  0  0]
[ 0  0  0  0  0  1  1  0 -1  0  0  0  0]

sage: M = ModularSymbols(43).cuspidal_submodule()
sage: S = M[0].plus_submodule() + M[1].minus_submodule()
sage: S.dual_free_module(use_star=False)
...
RuntimeError: Computation of embedded dual vector space failed (cut down to rank 6, but shou
sage: S.dual_free_module().dimension() == S.dimension()
True
```

free_module()

Return the free module corresponding to self.

EXAMPLES:

```
sage: M = ModularSymbols(33,2).cuspidal_subspace() ; M
Modular Symbols subspace of dimension 6 of Modular Symbols space of dimension 9 for Gamma_0(
sage: M.free_module()
Vector space of degree 9 and dimension 6 over Rational Field
Basis matrix:
[ 0  1  0  0  0  0  0 -1  1]
[ 0  0  1  0  0  0  0 -1  1]
[ 0  0  0  1  0  0  0 -1  1]
[ 0  0  0  0  1  0  0 -1  1]
[ 0  0  0  0  0  1  0 -1  1]
[ 0  0  0  0  0  0  1 -1  0]
```

intersection(*other*)

Returns the intersection of self and other, which must both lie in a common ambient space of modular symbols.

EXAMPLES:

```
sage: M = ModularSymbols(43, sign=1)
sage: A = M[0] + M[1]
sage: B = M[1] + M[2]
sage: A.dimension(), B.dimension()
(2, 3)
sage: C = A.intersection(B); C.dimension()
1
```

TESTS:

```
sage: M = ModularSymbols(1,80)
sage: M.plus_submodule().cuspidal_submodule().sign() # indirect doctest
1
```

is_ambient()

Return `True` if self is an ambient space of modular symbols.

EXAMPLES:

```
sage: M = ModularSymbols(17,4)
sage: M.cuspidal_subspace().is_ambient()
False
sage: A = M.ambient_hecke_module()
sage: S = A.submodule(A.basis())
sage: sage.modular.hecke.submodule.HeckeSubmodule.is_ambient(S)
True
```

is_new(*p=None*)

Returns True if this Hecke module is p-new. If p is None, returns True if it is new.

EXAMPLES:

```
sage: M = ModularSymbols(1,16)
sage: S = sage.modular.hecke.submodule.HeckeSubmodule(M, M.cuspidal_submodule().free_module(
sage: S.is_new()
True
```

is_old(*p=None*)

Returns True if this Hecke module is p-old. If p is None, returns True if it is old.

EXAMPLES:

```
sage: M = ModularSymbols(50,2)
sage: S = sage.modular.hecke.submodule.HeckeSubmodule(M, M.old_submodule().free_module())
sage: S.is_old()
True
sage: S = sage.modular.hecke.submodule.HeckeSubmodule(M, M.new_submodule().free_module())
sage: S.is_old()
False
```

is_submodule(*V*)

Returns True if and only if self is a submodule of V.

EXAMPLES:

```
sage: M = ModularSymbols(30,4)
sage: S = sage.modular.hecke.submodule.HeckeSubmodule(M, M.cuspidal_submodule().free_module(
sage: S.is_submodule(M)
True
sage: SS = sage.modular.hecke.submodule.HeckeSubmodule(M, M.old_submodule().free_module())
sage: S.is_submodule(SS)
False
```

linear_combination_of_basis(*v*)

Return the linear combination of the basis of self given by the entries of v.

EXAMPLES:

```
sage: M = ModularForms(Gamma0(2),12)
sage: S = sage.modular.hecke.submodule.HeckeSubmodule(M, M.cuspidal_submodule().free_module(
sage: S.basis()
(q + 252*q^3 - 2048*q^4 + 4830*q^5 + O(q^6), q^2 - 24*q^4 + O(q^6))
sage: S.linear_combination_of_basis([3,10])
3*q + 10*q^2 + 756*q^3 - 6384*q^4 + 14490*q^5 + O(q^6)
```

module()

Alias for code{self.free_module()}.

EXAMPLES:

```
sage: M = ModularSymbols(17,4).cuspidal_subspace()
sage: M.free_module() is M.module()
True
```

new_submodule(*p=None*)

Return the new or p-new submodule of this space of modular symbols.

EXAMPLES:

```
sage: M = ModularSymbols(20,4)
sage: M.new_submodule()
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 18 for Gamma_0
sage: S = sage.modular.hecke.submodule.HeckeSubmodule(M, M.cuspidal_submodule().free_module(
sage: S
Rank 12 submodule of a Hecke module of level 20
sage: S.new_submodule()
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 18 for Gamma_0
```

nonembedded_free_module()

Return the free module corresponding to self as an abstract free module, i.e. not as an embedded vector space.

EXAMPLES:

```
sage: M = ModularSymbols(12,6)
sage: S = sage.modular.hecke.submodule.HeckeSubmodule(M, M.cuspidal_submodule().free_module(
sage: S
Rank 14 submodule of a Hecke module of level 12
sage: S.nonembedded_free_module()
Vector space of dimension 14 over Rational Field
```

old_submodule(*p=None*)

Return the old or p-old submodule of this space of modular symbols.

EXAMPLES: We compute the old and new submodules of $\mathbf{S}_2(\Gamma_0(33))$.

```
sage: M = ModularSymbols(33); S = M.cuspidal_submodule(); S
Modular Symbols subspace of dimension 6 of Modular Symbols space of dimension 9 for Gamma_0(
sage: S.old_submodule()
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 9 for Gamma_0(
sage: S.new_submodule()
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 9 for Gamma_0(
```

rank()

Return the rank of self as a free module over the base ring.

EXAMPLE:

```
sage: ModularSymbols(6, 4).cuspidal_subspace().rank()
2
sage: ModularSymbols(6, 4).cuspidal_subspace().dimension()
2
```

submodule(*M, Mdual=None, check=True*)

Construct a submodule of self from the free module M, which must be a subspace of self.

EXAMPLES:

```
sage: M = ModularSymbols(18,4)
sage: S = sage.modular.hecke.submodule.HeckeSubmodule(M, M.cuspidal_submodule().free_module(
sage: S[0]
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 18 for Gamma_0
sage: S.submodule(S[0].free_module())
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 18 for Gamma_0
```

submodule_from_nonembedded_module(*V, Vdual=None, check=True*)

Construct a submodule of self from V. Here V should be a subspace of a vector space whose dimension is the same as that of self.

INPUT:

- V - submodule of ambient free module of the same rank as the rank of self.
- check - whether to check that V is Hecke equivariant.

OUTPUT: Hecke submodule of self

EXAMPLES:

```
sage: M = ModularSymbols(37,2)
sage: S = sage.modular.hecke.submodule.HeckeSubmodule(M, M.cuspidal_submodule().free_module(
sage: V = (QQ**4).subspace([[1,-1,0,1/2],[0,0,1,-1/2]])
sage: S.submodule_from_nonembedded_module(V)
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 5 for Gamma_0(
```

is_HeckeSubmodule(*x*)

Return True if x is of type HeckeSubmodule.

EXAMPLES:

```
sage: sage.modular.hecke.submodule.is_HeckeSubmodule(ModularForms(1, 12))
False
sage: sage.modular.hecke.submodule.is_HeckeSubmodule(CuspForms(1, 12))
True
```

42.4 Elements of Hecke modules

AUTHORS:

- William Stein

class HeckeModuleElement(*parent, x=None*)

Element of a Hecke module.

ambient_module()

Return the ambient Hecke module that contains this element.

EXAMPLES:

```
sage: BrandtModule(37)([0,1,-1]).ambient_module()
Brandt module of dimension 3 of level 37 of weight 2 over Rational Field
```

element()

Return underlying vector space element that defines this Hecke module element.

EXAMPLES:

```
sage: z = BrandtModule(37)([0,1,-1]).element(); z
(0, 1, -1)
sage: type(z)
<type 'sage.modules.vector_rational_dense.Vector_rational_dense'>
```

is_cuspidal()

Return True if this element is cuspidal.

EXAMPLES:

```
sage: M = ModularForms(2, 22); M.0.is_cuspidal()
True
sage: (M.0 + M.4).is_cuspidal()
False
sage: EllipticCurve('37a1').newform().is_cuspidal()
True
```

It works for modular symbols too:

```
sage: M = ModularSymbols(19,2)
sage: M.0.is_cuspidal()
False
sage: M.1.is_cuspidal()
True
```

is_eisenstein()

Return True if this element is Eisenstein. This makes sense for both modular forms and modular symbols.

EXAMPLES:

```
sage: CuspForms(2,8).0.is_eisenstein()
False
sage: M = ModularForms(2,8);(M.0  + M.1).is_eisenstein()
False
sage: M.1.is_eisenstein()
True
sage: ModularSymbols(19,4).0.is_eisenstein()
False
sage: EllipticCurve('37a1').newform().is_eisenstein()
False
```

is_new(*p=None*)

Return True if this element is p-new. If p is None, return True if the element is new.

EXAMPLE:

```
sage: CuspForms(22, 2).0.is_new(2)
False
sage: CuspForms(22, 2).0.is_new(11)
True
sage: CuspForms(22, 2).0.is_new()
False
```

is_old(*p=None*)

Return True if this element is p-old. If p is None, return True if the element is old.

EXAMPLE:

```
sage: CuspForms(22, 2).0.is_old(11)
False
sage: CuspForms(22, 2).0.is_old(2)
True
sage: CuspForms(22, 2).0.is_old()
True
sage: EisensteinForms(144, 2).1.is_old()
False
sage: EisensteinForms(144, 2).1.is_old(2) # not implemented
False
```

is_HeckeModuleElement(*x*)

Return True if x is a Hecke module element, i.e., of type HeckeModuleElement.

EXAMPLES:

```
sage: sage.modular.hecke.all.is_HeckeModuleElement(0)
False
sage: sage.modular.hecke.all.is_HeckeModuleElement(BrandtModule(37)([1,2,3]))
True
```

42.5 Hom spaces between Hecke modules

class HeckeModuleHomspace(*X, Y*)
A space of homomorphisms between two objects in the category of Hecke modules over a given base ring.

is_HeckeModuleHomspace(*x*)
Return True if x is a space of homomorphisms in the category of Hecke modules.

EXAMPLES:

```
sage: M = ModularForms(Gamma0(7), 4)
sage: sage.modular.hecke.homspace.is_HeckeModuleHomspace(Hom(M, M))
True
sage: sage.modular.hecke.homspace.is_HeckeModuleHomspace(Hom(M, QQ))
False
```

42.6 Morphisms of Hecke modules

AUTHORS:

- William Stein

class HeckeModuleMorphism()
Abstract base class for morphisms of Hecke modules.

class HeckeModuleMorphism_matrix(*parent, A, name=''*)
Morphisms of Hecke modules when the morphism is given by a matrix.

Note that care is needed when composing morphisms, because morphisms in Sage act on the left, but their matrices act on the right (!). So if F: A -> B and G : B -> C are morphisms, the composition A -> C is G*F, but its matrix is F.matrix() * G.matrix().

EXAMPLE:

```
sage: A = ModularForms(1, 4)
sage: B = ModularForms(1, 16)
sage: C = ModularForms(1, 28)
sage: F = A.Hom(B)(matrix(QQ,1,2,srange(1, 3)))
sage: G = B.Hom(C)(matrix(QQ,2,3,srange(1, 7)))
sage: G * F
Hecke module morphism defined by the matrix
[ 9 12 15]
Domain: Modular Forms space of dimension 1 for Modular Group SL(2,Z) ...
Codomain: Modular Forms space of dimension 3 for Modular Group SL(2,Z) ...
sage: F * G
...
TypeError: Incompatible composition of morphisms: domain of left morphism must be codomain of ri
```

name(*new=None*)
Return the name of this operator, or set it to a new name.

EXAMPLES:

```
sage: M = ModularSymbols(6)
sage: t = M.Hom(M)(matrix(QQ,3,3,srange(9)), name="spam"); t
Hecke module morphism spam defined by ...
sage: t.name()
```

```
'spam'
sage: t.name("eggs"); t
Hecke module morphism eggs defined by ...
```

is_HeckeModuleMorphism(*x*)

Return True if x is of type HeckeModuleMorphism.

EXAMPLES:

```
sage: sage.modular.hecke.morphism.is_HeckeModuleMorphism(ModularSymbols(6).hecke_operator(7).hec
True
```

is_HeckeModuleMorphism_matrix(*x*)

EXAMPLES:

```
sage: sage.modular.hecke.morphism.is_HeckeModuleMorphism_matrix(ModularSymbols(6).hecke_operator
True
```

42.7 Degeneracy maps

class DegeneracyMap(*matrix, domain, codomain, t*)

A degeneracy map between Hecke modules of different levels.

EXAMPLES: We construct a number of degeneracy maps:

```
sage: M = ModularSymbols(33)
sage: d = M.degeneracy_map(11)
sage: d
Hecke module morphism degeneracy map corresponding to f(q) |--> f(q) defined by the matrix
[ 1  0  0]
[ 0  0  1]
[ 0  0 -1]
[ 0  1 -1]
[ 0  0  1]
[ 0 -1  1]
[-1  0  0]
[-1  0  0]
[-1  0  0]
Domain: Modular Symbols space of dimension 9 for Gamma_0(33) of weight ...
Codomain: Modular Symbols space of dimension 3 for Gamma_0(11) of weight ...
sage: d.t()
1
sage: d = M.degeneracy_map(11,3)
sage: d.t()
3
```

The parameter d must be a divisor of the quotient of the two levels:

```
sage: d = M.degeneracy_map(11,2)
...
ValueError: The level of self (=33) must be a divisor or multiple of level (=11), and t (=2) mus
```

Degeneracy maps can also go from lower level to higher level:

```
sage: M.degeneracy_map(66,2)
Hecke module morphism degeneracy map corresponding to f(q) |--> f(q^2) defined by the matrix
[ 2  0  0  0  0  0  1  0  0  0  1 -1  0  0  0 -1  1  0  0  0  0  0  0 -1]
[ 0  0  1 -1  0 -1  1  0 -1  2  0  0  0 -1  0  0 -1  1  2 -2  0  0  0 -1  1]
[ 0  0  1  0  0  0  0  0  1  0  0  0  1  0  0  0 -1  1  0  0 -1  1  0  0  0]
[ 0  0  0  0  0  0  0  0  0  2 -1  0  0  1  0  0 -1  1  0  0  1  0 -1 -1  1]
[ 0 -1  0  0  1  0  0  0  0  0  0  1  0  0  1  1 -1  0  0 -1  0  0  0  0  0]
[ 0  0  0  0  0  0  0  1 -1  0  0  2 -1  0  0  1  0  0  0 -1  0 -1  1 -1  1]
[ 0  0  0  0  1 -1  0  1 -1  0  0  0  0  0 -1  2  0  0  0  0  1  0  1  0  0]
[ 0  0  1  0  0  0  0  0  0  0  0  0  0  0  0  0  0  1  0  0  0  1  1  0  0]
[ 0  0  0  0  0  0  0  0  0  0 -1  0  0  0  0  0  0  0  0  1  1  1  0  0  0]
Domain: Modular Symbols space of dimension 9 for Gamma_0(33) of weight ...
Codomain: Modular Symbols space of dimension 25 for Gamma_0(66) of weight ...
```

t()

Return the divisor of the quotient of the two levels associated to the degeneracy map.

EXAMPLES:

```
sage: M = ModularSymbols(33)
sage: d = M.degeneracy_map(11,3)
sage: d.t()
3
sage: d = M.degeneracy_map(11,1)
sage: d.t()
1
```

42.8 Hecke algebras

In Sage a "Hecke algebra" always refers to an algebra of endomorphisms of some explicit module, rather than the abstract Hecke algebra of double cosets attached to a subgroup of the modular group.

We distinguish between "anemic Hecke algebras", which are algebras of Hecke operators whose indices do not divide some integer N (the level), and "full Hecke algebras", which include Hecke operators coprime to the level. Morphisms in the category of Hecke modules are not required to commute with the action of the full Hecke algebra, only with the anemic algebra.

AnemicHeckeAlgebra(*M*)

Return the anemic Hecke algebra associated to the Hecke module M. This checks whether or not the object already exists in memory, and if so, returns the existing object rather than a new one.

EXAMPLES:

```
sage: CuspForms(1, 12).anemic_hecke_algebra() # indirect doctest
Anemic Hecke algebra acting on Cuspidal subspace of dimension 1 of Modular Forms space of dimens
```

We test uniqueness:

```
sage: CuspForms(1, 12).anemic_hecke_algebra() is CuspForms(1, 12).anemic_hecke_algebra()
True
```

We can't ensure uniqueness when loading and saving objects from files, but we can ensure equality:

```
sage: CuspForms(1, 12).anemic_hecke_algebra() is loads(dumps(CuspForms(1, 12).anemic_hecke_algeb
False
sage: CuspForms(1, 12).anemic_hecke_algebra() == loads(dumps(CuspForms(1, 12).anemic_hecke_algeb
True
```

HeckeAlgebra(*M*)
Return the full Hecke algebra associated to the Hecke module M. This checks whether or not the object already exists in memory, and if so, returns the existing object rather than a new one.

EXAMPLES:

```
sage: CuspForms(1, 12).hecke_algebra() # indirect doctest
Full Hecke algebra acting on Cuspidal subspace of dimension 1 of Modular Forms space of dimensic
```

We test uniqueness:

```
sage: CuspForms(1, 12).hecke_algebra() is CuspForms(1, 12).hecke_algebra()
True
```

We can't ensure uniqueness when loading and saving objects from files, but we can ensure equality:

```
sage: CuspForms(1, 12).hecke_algebra() is loads(dumps(CuspForms(1, 12).hecke_algebra()))
False
sage: CuspForms(1, 12).hecke_algebra() == loads(dumps(CuspForms(1, 12).hecke_algebra()))
True
```

class **HeckeAlgebra_anemic**(*M*)
An anemic Hecke algebra, generated by Hecke operators with index coprime to the level.

gens()
Return a generator over all Hecke operator T_n for $n = 1, 2, 3, \ldots$, with n coprime to the level. This is an infinite sequence.

EXAMPLES:

```
sage: T = ModularSymbols(12,2).anemic_hecke_algebra()
sage: g = T.gens()
sage: g.next()
Hecke operator T_1 on Modular Symbols space of dimension 5 for Gamma_0(12) of weight 2 with
sage: g.next()
Hecke operator T_5 on Modular Symbols space of dimension 5 for Gamma_0(12) of weight 2 with
```

hecke_operator(*n*)
Return the n-th Hecke operator, for n any positive integer coprime to the level.

EXAMPLES:

```
sage: T = ModularSymbols(Gamma1(5),3).anemic_hecke_algebra()
sage: T.hecke_operator(2)
Hecke operator T_2 on Modular Symbols space of dimension 4 for Gamma_1(5) of weight 3 with s
sage: T.hecke_operator(5)
...
IndexError: Hecke operator T_5 not defined in the anemic Hecke algebra
```

is_anemic()
Return True, since this the anemic Hecke algebra.

EXAMPLES:

```
sage: H = CuspForms(3, 12).anemic_hecke_algebra()
sage: H.is_anemic()
True
```

class **HeckeAlgebra_base**(*M*)
Base class for algebras of Hecke operators on a fixed Hecke module.

basis()
Return a basis for this Hecke algebra as a free module over its base ring. Not implemented at present.

EXAMPLE:

```
sage: ModularSymbols(Gamma1(3), 3).hecke_algebra().basis()
...
NotImplementedError
```

discriminant()

Return the discriminant of this Hecke algebra, i.e. the determinant of the matrix $\mathrm{Tr}(x_i x_j)$ where $x_1, \ldots, x_d$ is a basis for self, and $\mathrm{Tr}(x)$ signifies the trace (in the sense of linear algebra) of left multiplication by x on the algebra (*not* the trace of the operator x acting on the underlying Hecke module!). For further discussion and conjectures see Calegari + Stein, *Conjectures about discriminants of Hecke algebras of prime level*, Springer LNCS 3076.

Not implemented at present.

EXAMPLE:

```
sage: BrandtModule(3, 4).hecke_algebra().discriminant()
...
NotImplementedError
```

gen(n)

Return the n-th Hecke operator.

EXAMPLES:

```
sage: T = ModularSymbols(11).hecke_algebra()
sage: T.gen(2)
Hecke operator T_2 on Modular Symbols space of dimension 3 for Gamma_0(11) of weight 2 with
```

gens()

Return a generator over all Hecke operator T_n for $n = 1, 2, 3, \ldots$. This is infinite.

EXAMPLES:

```
sage: T = ModularSymbols(1,12).hecke_algebra()
sage: g = T.gens()
sage: g.next()
Hecke operator T_1 on Modular Symbols space of dimension 3 for Gamma_0(1) of weight 12 with
sage: g.next()
Hecke operator T_2 on Modular Symbols space of dimension 3 for Gamma_0(1) of weight 12 with
```

hecke_matrix(n)

Return the matrix of the n-th Hecke operator T_n.

EXAMPLES:

```
sage: T = ModularSymbols(1,12).hecke_algebra()
sage: T.hecke_matrix(2)
[ -24    0    0]
[   0  -24    0]
[4860    0 2049]
```

hecke_operator(n)

Return the n-th Hecke operator T_n.

EXAMPLES:

```
sage: T = ModularSymbols(1,12).hecke_algebra()
sage: T.hecke_operator(2)
Hecke operator T_2 on Modular Symbols space of dimension 3 for Gamma_0(1) of weight 12 with
```

is_noetherian()

Return True if this Hecke algebra is Noetherian as a ring. This is true if and only if the base ring is Noetherian.

EXAMPLES:

```
sage: CuspForms(1, 12).anemic_hecke_algebra().is_noetherian()
True
```

level()
Return the level of this Hecke algebra, which is (by definition) the level of the Hecke module on which it acts.
EXAMPLE:

```
sage: ModularSymbols(37).hecke_algebra().level()
37
```

matrix_space()
Return the underlying matrix space of this module.
EXAMPLES:

```
sage: CuspForms(3, 24, base_ring=Qp(5)).anemic_hecke_algebra().matrix_space()
Full MatrixSpace of 7 by 7 dense matrices over 5-adic Field with capped relative precision 2
```

module()
The Hecke module on which this algebra is acting.
EXAMPLES:

```
sage: T = ModularSymbols(1,12).hecke_algebra()
sage: T.module()
Modular Symbols space of dimension 3 for Gamma_0(1) of weight 12 with sign 0 over Rational F
```

ngens()
The size of the set of generators returned by gens(), which is clearly infinity. (This is not necessarily a minimal set of generators.)
EXAMPLES:

```
sage: CuspForms(1, 12).anemic_hecke_algebra().ngens()
+Infinity
```

rank()
The rank of this Hecke algebra as a module over its base ring. Not implemented at present.
EXAMPLE:

```
sage: ModularSymbols(Gamma1(3), 3).hecke_algebra().rank()
...
NotImplementedError
```

class **HeckeAlgebra_full**(*M*)
A full Hecke algebra (including the operators T_n where n is not assumed to be coprime to the level).

anemic_subalgebra()
The subalgebra of self generated by the Hecke operators of index coprime to the level.
EXAMPLE:

```
sage: H = CuspForms(3, 12).hecke_algebra()
sage: H.anemic_subalgebra()
Anemic Hecke algebra acting on Cuspidal subspace of dimension 3 of Modular Forms space of di
```

is_anemic()
Return False, since this the full Hecke algebra.
EXAMPLES:

```
sage: H = CuspForms(3, 12).hecke_algebra()
sage: H.is_anemic()
False
```

is_HeckeAlgebra(*x*)
Return True if x is of type HeckeAlgebra.

EXAMPLES:

```
sage: from sage.modular.hecke.algebra import is_HeckeAlgebra
sage: is_HeckeAlgebra(CuspForms(1, 12).anemic_hecke_algebra())
True
sage: is_HeckeAlgebra(ZZ)
False
```

42.9 Hecke operators

class HeckeAlgebraElement(*parent*)
Base class for elements of Hecke algebras.

apply_sparse(*x*)
Apply this Hecke operator to x, where we avoid computing the matrix of x if possible.

EXAMPLES:

```
sage: M = ModularSymbols(11)
sage: T = M.hecke_operator(23)
sage: T.apply_sparse(M.gen(0))
24*(1,0) - 5*(1,9)
```

charpoly(*var='x'*)
Return the characteristic polynomial of this Hecke operator.

INPUT:

- `var` - string (default: 'x')

OUTPUT: a monic polynomial in the given variable.

EXAMPLES:

```
sage: M = ModularSymbols(Gamma1(6),4)
sage: M.hecke_operator(2).charpoly('x')
x^6 - 14*x^5 + 29*x^4 + 172*x^3 - 124*x^2 - 320*x + 256
```

codomain()
The codomain of this operator. This is the Hecke module associated to the parent Hecke algebra.

EXAMPLE:

```
sage: R = ModularForms(Gamma0(7), 4).hecke_algebra()
sage: sage.modular.hecke.hecke_operator.HeckeAlgebraElement(R).codomain()
Modular Forms space of dimension 3 for Congruence Subgroup Gamma0(7) of weight 4 over Ration
```

decomposition()
Decompose the Hecke module under the action of this Hecke operator.

EXAMPLES:

```
sage: M = ModularSymbols(11)
sage: t2 = M.hecke_operator(2)
sage: t2.decomposition()
[
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 for Gamma_0(
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 3 for Gamma_0(
]
```

```
sage: M = ModularSymbols(33, sign=1).new_submodule()
sage: T = M.hecke_operator(2)
sage: T.decomposition()
[
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 6 for Gamma_0(
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 6 for Gamma_0(
]
```

det()

Return the determinant of this Hecke operator.

EXAMPLES:

```
sage: M = ModularSymbols(23)
sage: T = M.hecke_operator(3)
sage: T.det()
100
```

domain()

The domain of this operator. This is the Hecke module associated to the parent Hecke algebra.

EXAMPLE:

```
sage: R = ModularForms(Gamma0(7), 4).hecke_algebra()
sage: sage.modular.hecke.hecke_operator.HeckeAlgebraElement(R).domain()
 Modular Forms space of dimension 3 for Congruence Subgroup Gamma0(7) of weight 4 over Ratio
```

fcp(*var='x'*)

Return the factorization of the characteristic polynomial of this Hecke operator.

EXAMPLES:

```
sage: M = ModularSymbols(23)
sage: T = M.hecke_operator(3)
sage: T.fcp('x')
(x - 4) * (x^2 - 5)^2
```

hecke_module_morphism()

Return the endomorphism of Hecke modules defined by the matrix attached to this Hecke operator.

EXAMPLES:

```
sage: M = ModularSymbols(Gamma1(13))
sage: t = M.hecke_operator(2)
sage: t
Hecke operator T_2 on Modular Symbols space of dimension 15 for Gamma_1(13) of weight 2 with
sage: t.hecke_module_morphism()
Hecke module morphism T_2 defined by the matrix
[ 2  1  0  0  0  0  0  0  0  0  0  0  0  0 -1]
[ 0  2  0  1  0  0  0 -1  0  0  0  0  0  0  0]
[ 0  0  2  0  0  1 -1  1  0 -1  0  1 -1  0  0]
[ 0  0  0  2  1  0  1  0  0  0  1 -1  0  0  0]
[ 0  0  1  0  2  0  0  0  0  1 -1  0  0  0  1]
[ 1  0  0  0  0  2  0  0  0  0  0  0  1  0  0]
[ 0  0  0  0  0  0  0  1 -1  1 -1  0 -1  1  1]
[ 0  0  0  0  0  0  0 -1  1  1  0  0 -1  1  0]
[ 0  0  0  0  0  0 -1 -1  0  1 -1 -1  1  0 -1]
[ 0  0  0  0  0  0 -2  0  2 -2  0  2 -2  1 -1]
[ 0  0  0  0  0  0  0  0  2 -1  1  0  0  1 -1]
[ 0  0  0  0  0  0 -1  1  2 -1  1  0 -2  2  0]
[ 0  0  0  0  0  0  0  0  1  1  0 -1  0  0  0]
[ 0  0  0  0  0  0 -1  1  1  0  1  1 -1  0  0]
[ 0  0  0  0  0  0  2  0  0  0  2 -1  0  1 -1]
```

```
Domain: Modular Symbols space of dimension 15 for Gamma_1(13) of weight ...
Codomain: Modular Symbols space of dimension 15 for Gamma_1(13) of weight ...
```

image()

Return the image of this Hecke operator.

EXAMPLES:

```
sage: M = ModularSymbols(23)
sage: T = M.hecke_operator(3)
sage: T.fcp('x')
(x - 4) * (x^2 - 5)^2
sage: T.image()
Modular Symbols subspace of dimension 5 of Modular Symbols space of dimension 5 for Gamma_0(
sage: (T-4).image()
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 5 for Gamma_0(
sage: (T**2-5).image()
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 5 for Gamma_0(
```

kernel()

Return the kernel of this Hecke operator.

EXAMPLES:

```
sage: M = ModularSymbols(23)
sage: T = M.hecke_operator(3)
sage: T.fcp('x')
(x - 4) * (x^2 - 5)^2
sage: T.kernel()
Modular Symbols subspace of dimension 0 of Modular Symbols space of dimension 5 for Gamma_0(
sage: (T-4).kernel()
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 5 for Gamma_0(
sage: (T**2-5).kernel()
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 5 for Gamma_0(
```

trace()

Return the trace of this Hecke operator.

```
sage: M = ModularSymbols(1,12)
sage: T = M.hecke_operator(2)
sage: T.trace()
2001
```

class **HeckeAlgebraElement_matrix**(*parent, A*)

An element of the Hecke algebra represented by a matrix.

matrix()

Return the matrix that defines this Hecke algebra element.

EXAMPLES:

```
sage: M = ModularSymbols(1,12)
sage: T = M.hecke_operator(2).matrix_form()
sage: T.matrix()
[ -24    0    0]
[   0  -24    0]
[4860    0 2049]
```

class **HeckeOperator**(*parent, n*)

The Hecke operator T_n for some n (which need not be coprime to the level). The matrix is not computed until it is needed.

index()

Return the index of this Hecke operator, i.e., if this Hecke operator is T_n, return the int n.

EXAMPLES:

```
sage: T = ModularSymbols(11).hecke_operator(17)
sage: T.index()
17
```

matrix()

Return the matrix underlying this Hecke operator.

EXAMPLES:

```
sage: T = ModularSymbols(11).hecke_operator(17)
sage: T.matrix()
[18  0 -4]
[ 0 -2  0]
[ 0  0 -2]
```

matrix_form()

Return the matrix form of this element of a Hecke algebra.

```
sage: T = ModularSymbols(11).hecke_operator(17)
sage: T.matrix_form()
Hecke operator on Modular Symbols space of dimension 3 for Gamma_0(11) of weight 2 with sign
[18  0 -4]
[ 0 -2  0]
[ 0  0 -2]
```

is_HeckeAlgebraElement(*x*)

Return True if x is of type HeckeAlgebraElement.

EXAMPLES:

```
sage: from sage.modular.hecke.hecke_operator import is_HeckeAlgebraElement
sage: M = ModularSymbols(Gamma0(7), 4)
sage: is_HeckeAlgebraElement(M.T(3))
True
sage: is_HeckeAlgebraElement(M.T(3) + M.T(5))
True
```

is_HeckeOperator(*x*)

Return True if x is of type HeckeOperator.

EXAMPLES:

```
sage: from sage.modular.hecke.hecke_operator import is_HeckeOperator
sage: M = ModularSymbols(Gamma0(7), 4)
sage: is_HeckeOperator(M.T(3))
True
sage: is_HeckeOperator(M.T(3) + M.T(5))
False
```

CHAPTER

FORTYTHREE

MODULAR SYMBOLS

43.1 Creation of modular symbols spaces

EXAMPLES: We create a space and output its category.

```
sage: C = HeckeModules(RationalField()); C
Category of Hecke modules over Rational Field
sage: M = ModularSymbols(11)
sage: M.category()
Category of Hecke modules over Rational Field
sage: M in C
True
```

We create a space compute the charpoly, then compute the same but over a bigger field. In each case we also decompose the space using T_2.

```
sage: M = ModularSymbols(23,2,base_ring=QQ)
sage: print M.T(2).charpoly('x').factor()
(x - 3) * (x^2 + x - 1)^2
sage: print M.decomposition(2)
[
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 5 for Gamma_0(23) of we
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 5 for Gamma_0(23) of we
]

sage: M = ModularSymbols(23,2,base_ring=QuadraticField(5, 'sqrt5'))
sage: print M.T(2).charpoly('x').factor()
(x - 3) * (x - 1/2*sqrt5 + 1/2)^2 * (x + 1/2*sqrt5 + 1/2)^2
sage: print M.decomposition(2)
[
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 5 for Gamma_0(23) of we
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 5 for Gamma_0(23) of we
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 5 for Gamma_0(23) of we
]
```

We compute some Hecke operators and do a consistency check:

```
sage: m = ModularSymbols(39, 2)
sage: t2 = m.T(2); t5 = m.T(5)
sage: t2*t5 - t5*t2 == 0
True
```

This tests the bug reported in trac #1220:

```
sage: G = GammaH(36, [13, 19])
sage: G.modular_symbols()
Modular Symbols space of dimension 13 for Congruence Subgroup Gamma_H(36) with H generated by [13, 19
sage: G.modular_symbols().cuspidal_subspace()
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 13 for Congruence Subgr
```

This test catches a tricky corner case for spaces with character:

```
sage: ModularSymbols(DirichletGroup(20).1**3, weight=3, sign=1).cuspidal_subspace()
Modular Symbols subspace of dimension 3 of Modular Symbols space of dimension 6 and level 20, weight
```

ModularSymbols(*group=1, weight=2, sign=0, base_ring=Rational Field, use_cache=True*)

Create an ambient space of modular symbols.

INPUT:

- `group` - A congruence subgroup or a Dirichlet character eps.

weight - int, the weight, which must be = 2.

sign - int, The sign of the involution on modular symbols induced by complex conjugation. The default is 0, which means"no sign", i.e., take the whole space.

base_ring - the base ring. This is ignored if group is a Dirichlet character.

EXAMPLES: First we create some spaces with trivial character:

```
sage: ModularSymbols(Gamma0(11),2).dimension()
3
sage: ModularSymbols(Gamma0(1),12).dimension()
3
```

If we give an integer N for the congruence subgroup, it defaults to $\Gamma_0(N)$:

```
sage: ModularSymbols(1,12,-1).dimension()
1
sage: ModularSymbols(11,4, sign=1)
Modular Symbols space of dimension 4 for Gamma_0(11) of weight 4 with sign 1 over Rational Field
```

We create some spaces for $\Gamma_1(N)$.

```
sage: ModularSymbols(Gamma1(13),2)
Modular Symbols space of dimension 15 for Gamma_1(13) of weight 2 with sign 0 and over Rational
sage: ModularSymbols(Gamma1(13),2, sign=1).dimension()
13
sage: ModularSymbols(Gamma1(13),2, sign=-1).dimension()
2
sage: [ModularSymbols(Gamma1(7),k).dimension() for k in [2,3,4,5]]
[5, 8, 12, 16]
sage: ModularSymbols(Gamma1(5),11).dimension()
20
```

We create a space for $\Gamma_H(N)$:

```
sage: G = GammaH(15,[4,13])
sage: M = ModularSymbols(G,2)
sage: M.decomposition()
[
```

```
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 5 for Congruence S
Modular Symbols subspace of dimension 3 of Modular Symbols space of dimension 5 for Congruence S
]
```

We create a space with character:

```
sage: e = (DirichletGroup(13).0)^2
sage: e.order()
6
sage: M = ModularSymbols(e, 2); M
Modular Symbols space of dimension 4 and level 13, weight 2, character [zeta6], sign 0, over Cyc
sage: f = M.T(2).charpoly('x'); f
x^4 + (-zeta6 - 1)*x^3 - 8*zeta6*x^2 + (10*zeta6 - 5)*x + 21*zeta6 - 21
sage: f.factor()
(x - 2*zeta6 - 1) * (x - zeta6 - 2) * (x + zeta6 + 1)^2
```

More examples of spaces with character:

```
sage: e = DirichletGroup(5, RationalField()).gen(); e
[-1]
sage: m = ModularSymbols(e, 2); m
Modular Symbols space of dimension 2 and level 5, weight 2, character [-1], sign 0, over Rationa

sage: m.T(2).charpoly('x')
x^2 - 1
sage: m = ModularSymbols(e, 6); m.dimension()
6
sage: m.T(2).charpoly('x')
x^6 - 873*x^4 - 82632*x^2 - 1860496
```

We create a space of modular symbols with nontrivial character in characteristic 2.

```
sage: G = DirichletGroup(13,GF(4,'a')); G
Group of Dirichlet characters of modulus 13 over Finite Field in a of size 2^2
sage: e = G.list()[2]; e
[a + 1]
sage: M = ModularSymbols(e,4); M
Modular Symbols space of dimension 8 and level 13, weight 4, character [a + 1], sign 0, over Fin
sage: M.basis()
([X*Y,(1,0)], [X*Y,(1,5)], [X*Y,(1,10)], [X*Y,(1,11)], [X^2,(0,1)], [X^2,(1,10)], [X^2,(1,11)],
sage: M.T(2).matrix()
[    0     0     0     0     0     0     1     1]
[    0     0     0     0     0     0     0     0]
[    0     0     0     0     0 a + 1     1     a]
[    0     0     0     0     0     1 a + 1     a]
[    0     0     0     0 a + 1     0     1     1]
[    0     0     0     0     0     a     1     a]
[    0     0     0     0     0     0 a + 1     a]
[    0     0     0     0     0     0     1     0]
```

TESTS: We test use_cache:

```
sage: ModularSymbols_clear_cache()
sage: M = ModularSymbols(11,use_cache=False)
sage: sage.modular.modsym.modsym._cache
{}
sage: M = ModularSymbols(11,use_cache=True)
sage: sage.modular.modsym.modsym._cache
```

```
{(Congruence Subgroup Gamma0(11), 2, 0, Rational Field): <weakref at ...; to 'ModularSymbolsAmbi
sage: M is ModularSymbols(11,use_cache=True)
True
sage: M is ModularSymbols(11,use_cache=False)
False
```

ModularSymbols_clear_cache()

Clear the global cache of modular symbols spaces.

EXAMPLES:

```
sage: sage.modular.modsym.modsym.ModularSymbols_clear_cache()
sage: sage.modular.modsym.modsym._cache.keys()
[]
sage: M = ModularSymbols(6,2)
sage: sage.modular.modsym.modsym._cache.keys()
[(Congruence Subgroup Gamma0(6), 2, 0, Rational Field)]
sage: sage.modular.modsym.modsym.ModularSymbols_clear_cache()
sage: sage.modular.modsym.modsym._cache.keys()
[]
```

canonical_parameters(*group, weight, sign, base_ring*)

Return the canonically normalized parameters associated to a choice of group, weight, sign, and base_ring. That is, normalize each of these to be of the correct type, perform all appropriate type checking, etc.

EXAMPLES:

```
sage: p1 = sage.modular.modsym.modsym.canonical_parameters(5,int(2),1,QQ) ; p1
(Congruence Subgroup Gamma0(5), 2, 1, Rational Field)
sage: p2 = sage.modular.modsym.modsym.canonical_parameters(Gamma0(5),2,1,QQ) ; p2
(Congruence Subgroup Gamma0(5), 2, 1, Rational Field)
sage: p1 == p2
True
sage: type(p1[1])
<type 'sage.rings.integer.Integer'>
```

43.2 Space of modular symbols (base class)

All the spaces of modular symbols derive from this class. This class is an abstract base class.

class IntegralPeriodMapping(*modsym, A*)

class ModularSymbolsSpace(*group, weight, character, sign, base_ring*)

Base class for spaces of modular symbols.

abelian_variety()

Return the corresponding abelian variety.

INPUT:

- `self` - modular symbols space of weight 2 for a congruence subgroup such as Gamma0, Gamma1 or GammaH.

EXAMPLES:

```
sage: ModularSymbols(Gamma0(11)).cuspidal_submodule().abelian_variety()
Abelian variety J0(11) of dimension 1
sage: ModularSymbols(Gamma1(11)).cuspidal_submodule().abelian_variety()
Abelian variety J1(11) of dimension 1
```

```
sage: ModularSymbols(GammaH(11,[3])).cuspidal_submodule().abelian_variety()
Abelian variety JH(11,[3]) of dimension 1
```

The abelian variety command only works on cuspidal modular symbols spaces:

```
sage: M = ModularSymbols(37)
sage: M[0].abelian_variety()
...
ValueError: self must be cuspidal
sage: M[1].abelian_variety()
Abelian subvariety of dimension 1 of J0(37)
sage: M[2].abelian_variety()
Abelian subvariety of dimension 1 of J0(37)
```

character()

Return the character associated to self.

EXAMPLES:

```
sage: ModularSymbols(12,8).character()
[1, 1]
sage: ModularSymbols(DirichletGroup(25).0, 4).character()
[zeta20]
```

compact_system_of_eigenvalues(*v, names='alpha', nz=None*)

Return a compact system of eigenvalues a_n for $n \in v$. This should only be called on simple factors of modular symbols spaces.

INPUT:

- v - a list of positive integers
- nz - (default: None); if given specifies a column index such that the dual module has that column nonzero.

OUTPUT:

- E - matrix such that E*v is a vector with components the eigenvalues a_n for $n \in v$.
- v - a vector over a number field

EXAMPLES:

```
sage: M = ModularSymbols(43,2,1)[2]; M
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 4 for Gamma_0(
sage: E, v = M.compact_system_of_eigenvalues(prime_range(10))
sage: E
[ 3 -2]
[-3  2]
[-1  2]
[ 1 -2]
sage: v
(1, -1/2*alpha + 3/2)
sage: E*v
(alpha, -alpha, -alpha + 2, alpha - 2)
```

congruence_number(*other, prec=None*)

Given two cuspidal spaces of modular symbols, compute the congruence number, using prec terms of the q-expansions.

The congruence number is defined as follows. If V is the submodule of integral cusp forms corresponding to self (satured in $\mathbf{Z}[[q]]$, by definition) and W is the submodule corresponding to other, each computed to precision prec, the congruence number is the index of $V + W$ in its saturation in $\mathbf{Z}[[q]]$.

If prec is not given it is set equal to the max of the hecke_bound function called on each space.

EXAMPLES:

sage: A, B = ModularSymbols(48, 2).cuspidal_submodule().decomposition() sage: A.congruence_number(B) 2

cuspidal_submodule()

Return the cuspidal submodule of self.

Note: This should be overridden by all derived classes.

EXAMPLES:

```
sage: sage.modular.modsym.space.ModularSymbolsSpace(Gamma0(11),2,DirichletGroup(11).gens()[0
...
NotImplementedError: computation of cuspidal submodule not yet implemented for this class
sage: ModularSymbols(Gamma0(11),2).cuspidal_submodule()
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 3 for Gamma_0(
```

cuspidal_subspace()

Synonym for cuspidal_submodule.

EXAMPLES:

```
sage: m = ModularSymbols(Gamma1(3),12); m.dimension()
8
sage: m.cuspidal_subspace().new_subspace().dimension()
2
```

default_prec()

Get the default precision for computation of q-expansion associated to the ambient space of this space of modular symbols (and all subspaces). Use `set_default_prec` to change the default precision.

EXAMPLES:

```
sage: M = ModularSymbols(15)
sage: M.cuspidal_submodule().q_expansion_basis()
[
q - q^2 - q^3 - q^4 + q^5 + q^6 + O(q^8)
]
sage: M.set_default_prec(20)
```

Notice that setting the default precision of the ambient space affects the subspaces.

```
sage: M.cuspidal_submodule().q_expansion_basis()
[
q - q^2 - q^3 - q^4 + q^5 + q^6 + 3*q^8 + q^9 - q^10 - 4*q^11 + q^12 - 2*q^13 - q^15 - q^16
]
sage: M.cuspidal_submodule().default_prec()
20
```

dimension_of_associated_cuspform_space()

Return the dimension of the corresponding space of cusp forms.

The input space must be cuspidal, otherwise there is no corresponding space of cusp forms.

EXAMPLES:

```
sage: m = ModularSymbols(Gamma0(389),2).cuspidal_subspace(); m.dimension()
64
sage: m.dimension_of_associated_cuspform_space()
32
sage: m = ModularSymbols(Gamma0(389),2,sign=1).cuspidal_subspace(); m.dimension()
32
sage: m.dimension_of_associated_cuspform_space()
32
```

dual_star_involution_matrix()

Return the matrix of the dual star involution, which is induced by complex conjugation on the linear dual of modular symbols.

Note: This should be overridden in all derived classes.

EXAMPLES:

```
sage: sage.modular.modsym.space.ModularSymbolsSpace(Gamma0(11),2,DirichletGroup(11).gens()[0
...
NotImplementedError: computation of dual star involution matrix not yet implemented for this
sage: ModularSymbols(Gamma0(11),2).dual_star_involution_matrix()
[ 1  0  0]
[ 0 -1  0]
[ 0  1  1]
```

eisenstein_subspace()

Synonym for eisenstein_submodule.

EXAMPLES:

```
sage: m = ModularSymbols(Gamma1(3),12); m.dimension()
8
sage: m.eisenstein_subspace().dimension()
2
sage: m.cuspidal_subspace().dimension()
6
```

group()

Returns the group of this modular symbols space.

INPUT:

- `ModularSymbols self` - an arbitrary space of modular symbols

OUTPUT:

- `CongruenceSubgroup` - the congruence subgroup that this is a space of modular symbols for.

ALGORITHM: The group is recorded when this space is created.

EXAMPLES:

```
sage: m = ModularSymbols(20)
sage: m.group()
Congruence Subgroup Gamma0(20)
```

hecke_module_of_level(*level*)

Alias for `self.modular_symbols_of_level(level)`.

EXAMPLE:

```
sage: ModularSymbols(11, 2).hecke_module_of_level(22)
Modular Symbols space of dimension 7 for Gamma_0(22) of weight 2 with sign 0 over Rational F
```

integral_basis()

Return a basis for the **Z**-submodule of this modular symbols space spanned by the generators.

Modular symbols spaces for congruence subgroups have a **Z**-structure. Computing this **Z**-structure is expensive, so by default modular symbols spaces for congruence subgroups in Sage are defined over **Q**. This function returns a tuple of independent elements in this modular symbols space whose **Z**-span is the corresponding space of modular symbols over **Z**.

EXAMPLES:

```
sage: M = ModularSymbols(11)
sage: M.basis()
((1,0), (1,8), (1,9))
sage: M.integral_basis()
((1,0), (1,8), (1,9))
sage: S = M.cuspidal_submodule()
sage: S.basis()
```

```
((1,8), (1,9))
sage: S.integral_basis()
((1,8), (1,9))

sage: M = ModularSymbols(13,4)
sage: M.basis()
([X^2,(0,1)], [X^2,(1,4)], [X^2,(1,5)], [X^2,(1,7)], [X^2,(1,9)], [X^2,(1,10)], [X^2,(1,11)]
sage: M.integral_basis()
([X^2,(0,1)], 1/28*[X^2,(1,4)] + 2/7*[X^2,(1,5)] + 3/28*[X^2,(1,7)] + 11/14*[X^2,(1,9)] + 2/
sage: S = M.cuspidal_submodule()
sage: S.basis()
([X^2,(1,4)] - [X^2,(1,12)], [X^2,(1,5)] - [X^2,(1,12)], [X^2,(1,7)] - [X^2,(1,12)], [X^2,(1
sage: S.integral_basis()
(1/28*[X^2,(1,4)] + 2/7*[X^2,(1,5)] + 3/28*[X^2,(1,7)] + 11/14*[X^2,(1,9)] + 2/7*[X^2,(1,10)
```

This function currently raises a NotImplementedError on modular symbols spaces with character of order bigger than 2:

EXAMPLES:

```
sage: M = ModularSymbols(DirichletGroup(13).0^2, 2); M
Modular Symbols space of dimension 4 and level 13, weight 2, character [zeta6], sign 0, over
sage: M.basis()
((1,0), (1,5), (1,10), (1,11))
sage: M.integral_basis()
...
NotImplementedError
```

integral_hecke_matrix(*n*)

Return the matrix of the $n`thHeckeoperatoractingontheintegralstructureonself(asreturnedby"self.integral_structu$ This is often (but not always) different from the matrix returned by `self.hecke_matrix`, even if the latter has integral entries.

EXAMPLE:

```
sage: M = ModularSymbols(6,4)
sage: M.hecke_matrix(3)
[27  0  0  0  6 -6]
[ 0  1 -4  4  8 10]
[18  0  1  0  6 -6]
[18  0  4 -3  6 -6]
[ 0  0  0  0  9 18]
[ 0  0  0  0 12 15]
sage: M.integral_hecke_matrix(3)
[ 27   0   0   0   6  -6]
[  0   1  -8   8  12  14]
[ 18   0   5  -4  14   8]
[ 18   0   8  -7   2 -10]
[  0   0   0   0   9  18]
[  0   0   0   0  12  15]
```

integral_period_mapping()

Return the integral period mapping associated to self.

This is a homomorphism to a vector space whose kernel is the same as the kernel of the period mapping associated to self, normalized so the image of integral modular symbols is exactly $\mathbf{Z}^n$.

EXAMPLES:

```
sage: m = ModularSymbols(23).cuspidal_submodule()
sage: i = m.integral_period_mapping()
sage: i
```

```
Integral period mapping associated to Modular Symbols subspace of dimension 4 of Modular Sym
sage: i.matrix()
[-1/11  1/11     0  3/11]
[    1     0     0     0]
[    0     1     0     0]
[    0     0     1     0]
[    0     0     0     1]
sage: [i(b) for b in m.integral_structure().basis()]
[(1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1)]
sage: [i(b) for b in m.ambient_module().basis()]
[(-1/11, 1/11, 0, 3/11),
 (1, 0, 0, 0),
 (0, 1, 0, 0),
 (0, 0, 1, 0),
 (0, 0, 0, 1)]
```

We compute the image of the winding element:

```
sage: m = ModularSymbols(37,sign=1)
sage: a = m[1]
sage: f = a.integral_period_mapping()
sage: e = m([0,oo])
sage: f(e)
(-2/3)
```

The input space must be cuspidal:

```
sage: m = ModularSymbols(37,2,sign=1)
sage: m.integral_period_mapping()
...
ValueError: integral mapping only defined for cuspidal spaces
```

integral_structure()

Return the $\mathbf{Z}$-structure of this modular symbols spaces generated by all integral modular symbols.

EXAMPLES:

```
sage: M = ModularSymbols(11,4)
sage: M.integral_structure()
Free module of degree 6 and rank 6 over Integer Ring
Echelon basis matrix:
[    1     0     0     0     0     0]
[    0  1/14   1/7  5/14   1/2 13/14]
[    0     0   1/2     0     0   1/2]
[    0     0     0     1     0     0]
[    0     0     0     0     1     0]
[    0     0     0     0     0     1]
sage: M.cuspidal_submodule().integral_structure()
Free module of degree 6 and rank 4 over Integer Ring
Echelon basis matrix:
[     0   1/14    1/7   5/14    1/2 -15/14]
[     0      0    1/2      0      0   -1/2]
[     0      0      0      1      0     -1]
[     0      0      0      0      1     -1]
```

intersection_number(M)

Given modular symbols spaces self and M in some common ambient space, returns the intersection number of these two spaces. This is the index in their saturation of the sum of their underlying integral structures.

If self and M are of weight two and defined over QQ, and correspond to newforms f and g, then this number equals the order of the intersection of the modular abelian varieties attached to f and g.

EXAMPLES:

```
sage: m = ModularSymbols(389,2)
sage: d = m.decomposition(2)
sage: eis = d[0]
sage: ell = d[1]
sage: af = d[-1]
sage: af.intersection_number(eis)
97
sage: af.intersection_number(ell)
400
```

is_ambient()

Return True if self is an ambient space of modular symbols.

EXAMPLES:

```
sage: ModularSymbols(21,4).is_ambient()
True
sage: ModularSymbols(21,4).cuspidal_submodule().is_ambient()
False
```

is_cuspidal()

Return True if self is a cuspidal space of modular symbols.

Note: This should be overridden in all derived classes.

EXAMPLES:

```
sage: sage.modular.modsym.space.ModularSymbolsSpace(Gamma0(11),2,DirichletGroup(11).gens()[0
...
NotImplementedError: computation of cuspidal subspace not yet implemented for this class
sage: ModularSymbols(Gamma0(11),2).is_cuspidal()
False
```

is_simple()

Return whether not this modular symbols space is simple as a module over the anemic Hecke algebra adjoin *.

EXAMPLES:

```
sage: m = ModularSymbols(Gamma0(33),2,sign=1)
sage: m.is_simple()
False
sage: o = m.old_subspace()
sage: o.decomposition()
[
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 6 for Gamma_0(
Modular Symbols subspace of dimension 3 of Modular Symbols space of dimension 6 for Gamma_0(
]
sage: C=ModularSymbols(1,14,0,GF(5)).cuspidal_submodule()
sage: C
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 2 for Gamma_0(
sage: C.is_simple()
True
```

minus_submodule(*compute_dual=True*)

Return the subspace of self on which the star involution acts as -1.

INPUT:

- `compute_dual` - bool (default: True) also compute dual subspace. This are useful for many algorithms.

OUTPUT: subspace of modular symbols

EXAMPLES:

```
sage: ModularSymbols(14,4)
Modular Symbols space of dimension 12 for Gamma_0(14) of weight 4 with sign 0 over Rational
sage: ModularSymbols(14,4).minus_submodule()
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 12 for Gamma_0
```

modular_symbols_of_sign(*sign, bound=None*)

Returns a space of modular symbols with the same defining properties (weight, level, etc.) and Hecke eigenvalues as this space except with given sign.

INPUT:

- `self` - a cuspidal space of modular symbols
- `sign` - an integer, one of -1, 0, or 1
- `bound` - integer (default: None); if specified only use Hecke operators up to the given bound.

EXAMPLES:

```
sage: S = ModularSymbols(Gamma0(11),2,sign=0).cuspidal_subspace()
sage: S
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 3 for Gamma_0(
sage: S.modular_symbols_of_sign(-1)
Modular Symbols space of dimension 1 for Gamma_0(11) of weight 2 with sign -1 over Rational

sage: S = ModularSymbols(43,2,sign=1)[2]; S
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 4 for Gamma_0(
sage: S.modular_symbols_of_sign(-1)
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 3 for Gamma_0(

sage: S.modular_symbols_of_sign(0)
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 7 for Gamma_0(

sage: S = ModularSymbols(389,sign=1)[3]; S
Modular Symbols subspace of dimension 3 of Modular Symbols space of dimension 33 for Gamma_0
sage: S.modular_symbols_of_sign(-1)
Modular Symbols subspace of dimension 3 of Modular Symbols space of dimension 32 for Gamma_0
sage: S.modular_symbols_of_sign(0)
Modular Symbols subspace of dimension 6 of Modular Symbols space of dimension 65 for Gamma_0

sage: S = ModularSymbols(23,sign=1,weight=4)[2]; S
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 7 for Gamma_0(
sage: S.modular_symbols_of_sign(1) is S
True
sage: S.modular_symbols_of_sign(0)
Modular Symbols subspace of dimension 8 of Modular Symbols space of dimension 12 for Gamma_0
sage: S.modular_symbols_of_sign(-1)
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 5 for Gamma_0(
```

multiplicity(*S, check_simple=True*)

Return the multiplicity of the simple modular symbols space S in self. S must be a simple anemic Hecke module.

ASSUMPTION: self is an anemic Hecke module with the same weight and group as S, and S is simple.

EXAMPLES:

```
sage: M = ModularSymbols(11,2,sign=1)
sage: N1, N2 = M.decomposition()
sage: N1.multiplicity(N2)
0
sage: M.multiplicity(N1)
1
```

```
sage: M.multiplicity(ModularSymbols(14,2))
0
```

new_subspace(*p=None*)

Synonym for new_submodule.

EXAMPLES:

```
sage: m = ModularSymbols(Gamma0(5),12); m.dimension()
12
sage: m.new_subspace().dimension()
6
sage: m = ModularSymbols(Gamma1(3),12); m.dimension()
8
sage: m.new_subspace().dimension()
2
```

ngens()

The number of generators of self.

INPUT:

- `ModularSymbols self` - arbitrary space of modular symbols.

OUTPUT:

- `int` - the number of generators, which is the same as the dimension of self.

ALGORITHM: Call the dimension function.

EXAMPLES:

```
sage: m = ModularSymbols(33)
sage: m.ngens()
9
sage: m.rank()
9
sage: ModularSymbols(100, weight=2, sign=1).ngens()
18
```

old_subspace(*p=None*)

Synonym for old_submodule.

EXAMPLES:

```
sage: m = ModularSymbols(Gamma1(3),12); m.dimension()
8
sage: m.old_subspace().dimension()
6
```

plus_submodule(*compute_dual=True*)

Return the subspace of self on which the star involution acts as +1.

INPUT:

- `compute_dual` - bool (default: True) also compute dual subspace. This are useful for many algorithms.

OUTPUT: subspace of modular symbols

EXAMPLES:

```
sage: ModularSymbols(17,2)
Modular Symbols space of dimension 3 for Gamma_0(17) of weight 2 with sign 0 over Rational F
sage: ModularSymbols(17,2).plus_submodule()
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 3 for Gamma_0(
```

q_eigenform(*prec, names=None*)

Returns the q-expansion to precision prec of a new eigenform associated to self, where self must be new, cuspidal, and simple.

EXAMPLES:

```
sage: ModularSymbols(2, 8)[1].q_eigenform(5, 'a')
q - 8*q^2 + 12*q^3 + 64*q^4 + O(q^5)
sage: ModularSymbols(2, 8)[0].q_eigenform(5,'a')
...
ArithmeticError: self must be cuspidal.
```

q_expansion_basis(*prec=None, algorithm='default'*)

Returns a basis of q-expansions (as power series) to precision prec of the space of modular forms associated to self. The q-expansions are defined over the same base ring as self, and a put in echelon form.

INPUT:

- `self` - a space of CUSPIDAL modular symbols
- `prec` - an integer
- `algorithm` - string:
- `'default' (default)` - decide which algorithm to use based on heuristics
- `'hecke'` - compute basis by computing homomorphisms T - K, where T is the Hecke algebra
- `'eigen'` - compute basis using eigenvectors for the Hecke action and Atkin-Lehner-Li theory to patch them together
- `'all'` - compute using hecke_dual and eigen algorithms and verify that the results are the same.

The computed basis is *not* cached, though of course Hecke operators used in computing the basis are cached.

EXAMPLES:

```
sage: M = ModularSymbols(1, 12).cuspidal_submodule()
sage: M.q_expansion_basis(8)
[
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 - 6048*q^6 - 16744*q^7 + O(q^8)
]

sage: M.q_expansion_basis(8, algorithm='eigen')
[
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 - 6048*q^6 - 16744*q^7 + O(q^8)
]

sage: M = ModularSymbols(1, 24).cuspidal_submodule()
sage: M.q_expansion_basis(8, algorithm='eigen')
[
q + 195660*q^3 + 12080128*q^4 + 44656110*q^5 - 982499328*q^6 - 147247240*q^7 + O(q^8),
q^2 - 48*q^3 + 1080*q^4 - 15040*q^5 + 143820*q^6 - 985824*q^7 + O(q^8)
]

sage: M = ModularSymbols(11, 2, sign=-1).cuspidal_submodule()
sage: M.q_expansion_basis(8, algorithm='eigen')
[
q - 2*q^2 - q^3 + 2*q^4 + q^5 + 2*q^6 - 2*q^7 + O(q^8)
]

sage: M = ModularSymbols(Gamma1(13), 2, sign=1).cuspidal_submodule()
sage: M.q_expansion_basis(8, algorithm='eigen')
[
q - 4*q^3 - q^4 + 3*q^5 + 6*q^6 + O(q^8),
```

```
q^2 - 2*q^3 - q^4 + 2*q^5 + 2*q^6 + O(q^8)
]

sage: M = ModularSymbols(Gamma1(5), 3, sign=-1).cuspidal_submodule()
sage: M.q_expansion_basis(8, algorithm='eigen')    # dimension is 0
[]

sage: M = ModularSymbols(Gamma1(7), 3, sign=-1).cuspidal_submodule()
sage: M.q_expansion_basis(8)
[
q - 3*q^2 + 5*q^4 - 7*q^7 + O(q^8)
]

sage: M = ModularSymbols(43, 2, sign=0).cuspidal_submodule()
sage: M[0]
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 7 for Gamma_0(
sage: M[0].q_expansion_basis()
[
q - 2*q^2 - 2*q^3 + 2*q^4 - 4*q^5 + 4*q^6 + O(q^8)
]
sage: M[1]
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 7 for Gamma_0(
sage: M[1].q_expansion_basis()
[
q + 2*q^5 - 2*q^6 - 2*q^7 + O(q^8),
q^2 - q^3 - q^5 + q^7 + O(q^8)
]
```

q_expansion_cuspforms (*prec=None*)

Returns a function f(i,j) such that each value f(i,j) is the q-expansion, to the given precision, of an element of the corresponding space S of cusp forms. Together these functions span S. Here i, j are integers with $0 \leq i, j < d$, where d is the dimension of self.

For a reduced echelon basis, use the function `q_expansion_basis` instead.

More precisely, this function returns the q-expansions obtained by taking the ij entry of the matrices of the Hecke operators T_n acting on the subspace of the linear dual of modular symbols corresponding to self.

EXAMPLES:

```
sage: S = ModularSymbols(11,2, sign=1).cuspidal_submodule()
sage: f = S.q_expansion_cuspforms(8)
sage: f(0,0)
q - 2*q^2 - q^3 + 2*q^4 + q^5 + 2*q^6 - 2*q^7 + O(q^8)

sage: S = ModularSymbols(37,2).cuspidal_submodule()
sage: f = S.q_expansion_cuspforms(8)
sage: f(0,0)
q + q^3 - 2*q^4 - q^7 + O(q^8)
sage: f(3,3)
q - 2*q^2 - 3*q^3 + 2*q^4 - 2*q^5 + 6*q^6 - q^7 + O(q^8)
sage: f(1,2)
q^2 + 2*q^3 - 2*q^4 + q^5 - 3*q^6 + O(q^8)

sage: S = ModularSymbols(Gamma1(13),2,sign=-1).cuspidal_submodule()
sage: f = S.q_expansion_cuspforms(8)
sage: f(0,0)
q - 2*q^2 + q^4 - q^5 + 2*q^6 + O(q^8)
sage: f(0,1)
q^2 - 2*q^3 - q^4 + 2*q^5 + 2*q^6 + O(q^8)
```

```
sage: S = ModularSymbols(1,12,sign=-1).cuspidal_submodule()
sage: f = S.q_expansion_cuspforms(8)
sage: f(0,0)
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 - 6048*q^6 - 16744*q^7 + O(q^8)
```

q_expansion_module (*prec=None, R=None*)

Return a basis over R for the space spanned by the coefficient vectors of the q-expansions corresponding to self. If R is not the base ring of self, returns the restriction of scalars down to R (for this, self must have base ring $\mathbf{Q}$ or a number field).

INPUT:

- `self` - must be cuspidal
- `prec` - an integer (default: self.default_prec())
- `R` - either ZZ, QQ, or the base_ring of self (which is the default)

OUTPUT: A free module over R.

TODO - extend to more general R (though that is fairly easy for the user to get by just doing base_extend or change_ring on the output of this function).

Note that the prec needed to distinguish elements of the restricted-down-to-R basis may be bigger than `self.hecke_bound()`, since one must use the Sturm bound for modular forms on $\Gamma_H(N)$.

EXAMPLES WITH SIGN 1 and R=QQ:

Basic example with sign 1:

```
sage: M = ModularSymbols(11, sign=1).cuspidal_submodule()
sage: M.q_expansion_module(5, QQ)
Vector space of degree 5 and dimension 1 over Rational Field
Basis matrix:
[ 0  1 -2 -1  2]
```

Same example with sign -1:

```
sage: M = ModularSymbols(11, sign=-1).cuspidal_submodule()
sage: M.q_expansion_module(5, QQ)
Vector space of degree 5 and dimension 1 over Rational Field
Basis matrix:
[ 0  1 -2 -1  2]
```

An example involving old forms:

```
sage: M = ModularSymbols(22, sign=1).cuspidal_submodule()
sage: M.q_expansion_module(5, QQ)
Vector space of degree 5 and dimension 2 over Rational Field
Basis matrix:
[ 0  1  0 -1 -2]
[ 0  0  1  0 -2]
```

An example that (somewhat spuriously) is over a number field:

```
sage: x = polygen(QQ)
sage: k = NumberField(x^2+1, 'a')
sage: M = ModularSymbols(11, base_ring=k, sign=1).cuspidal_submodule()
sage: M.q_expansion_module(5, QQ)
Vector space of degree 5 and dimension 1 over Rational Field
Basis matrix:
[ 0  1 -2 -1  2]
```

An example that involves an eigenform with coefficients in a number field:

```
sage: M = ModularSymbols(23, sign=1).cuspidal_submodule()
sage: M.q_eigenform(4, 'gamma')
```

```
q + gamma*q^2 + (-2*gamma - 1)*q^3 + O(q^4)
sage: M.q_expansion_module(11, QQ)
Vector space of degree 11 and dimension 2 over Rational Field
Basis matrix:
[ 0  1  0 -1 -1  0 -2  2 -1  2  2]
[ 0  0  1 -2 -1  2  1  2 -2  0 -2]
```

An example that is genuinely over a base field besides QQ.

```
sage: eps = DirichletGroup(11).0
sage: M = ModularSymbols(eps,3,sign=1).cuspidal_submodule(); M
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 2 and level 11
sage: M.q_eigenform(4, 'beta')
q + (-zeta10^3 + 2*zeta10^2 - 2*zeta10)*q^2 + (2*zeta10^3 - 3*zeta10^2 + 3*zeta10 - 2)*q^3 +
sage: M.q_expansion_module(7, QQ)
Vector space of degree 7 and dimension 4 over Rational Field
Basis matrix:
[  0   1   0   0   0 -40  64]
[  0   0   1   0   0 -24  41]
[  0   0   0   1   0 -12  21]
[  0   0   0   0   1  -4   4]
```

An example involving an eigenform rational over the base, but the base is not QQ.

```
sage: k.<a> = NumberField(x^2-5)
sage: M = ModularSymbols(23, base_ring=k, sign=1).cuspidal_submodule()
sage: D = M.decomposition(); D
[
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 for Gamma_0(
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 for Gamma_0(
]
sage: M.q_expansion_module(8, QQ)
Vector space of degree 8 and dimension 2 over Rational Field
Basis matrix:
[ 0  1  0 -1 -1  0 -2  2]
[ 0  0  1 -2 -1  2  1  2]
```

An example involving an eigenform not rational over the base and for which the base is not QQ.

```
sage: eps = DirichletGroup(25).0^2
sage: M = ModularSymbols(eps,2,sign=1).cuspidal_submodule(); M
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 4 and level 25
sage: D = M.decomposition(); D
[
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 4 and level 25
]
sage: D[0].q_eigenform(4, 'mu')
q + mu*q^2 + ((zeta10^3 + zeta10 - 1)*mu + zeta10^2 - 1)*q^3 + O(q^4)
sage: D[0].q_expansion_module(11, QQ)
Vector space of degree 11 and dimension 8 over Rational Field
Basis matrix:
[  0   1   0   0   0   0   0   0 -20  -3   0]
[  0   0   1   0   0   0   0   0 -16  -1   0]
[  0   0   0   1   0   0   0   0 -11  -2   0]
[  0   0   0   0   1   0   0   0  -8  -1   0]
[  0   0   0   0   0   1   0   0  -5  -1   0]
[  0   0   0   0   0   0   1   0  -3  -1   0]
[  0   0   0   0   0   0   0   1  -2   0   0]
[  0   0   0   0   0   0   0   0   0   0   1]
sage: D[0].q_expansion_module(11)
```

```
Vector space of degree 11 and dimension 2 over Cyclotomic Field of order 10 and degree 4
Basis matrix:
[                                  0                                   1
[                                  0                                   0
```

EXAMPLES WITH SIGN 0 and R=QQ:

TODO - this doesn't work yet as it's not implemented!!

```
sage: M = ModularSymbols(11,2).cuspidal_submodule() #not tested
sage: M.q_expansion_module() #not tested
... boom ...
```

EXAMPLES WITH SIGN 1 and R=ZZ (computes saturation):

```
sage: M = ModularSymbols(43,2, sign=1).cuspidal_submodule()
sage: M.q_expansion_module(8, QQ)
Vector space of degree 8 and dimension 3 over Rational Field
Basis matrix:
[   0    1    0    0    0    2   -2   -2]
[   0    0    1    0 -1/2    1 -3/2    0]
[   0    0    0    1 -1/2    2 -3/2   -1]
sage: M.q_expansion_module(8, ZZ)
Free module of degree 8 and rank 3 over Integer Ring
Echelon basis matrix:
[ 0  1  0  0  0  2 -2 -2]
[ 0  0  1  1 -1  3 -3 -1]
[ 0  0  0  2 -1  4 -3 -2]
```

rational_period_mapping()

Return the rational period mapping associated to self.

This is a homomorphism to a vector space whose kernel is the same as the kernel of the period mapping associated to self. For this to exist, self must be Hecke equivariant.

Use `integral_period_mapping` to obtain a homomorphism to a $\mathbf{Z}$-module, normalized so the image of integral modular symbols is exactly $\mathbf{Z}^n$.

EXAMPLES:

```
sage: M = ModularSymbols(37)
sage: A = M[1]; A
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 5 for Gamma_0(
sage: r = A.rational_period_mapping(); r
Rational period mapping associated to Modular Symbols subspace of dimension 2 of Modular Sym
sage: r(M.0)
(0, 0)
sage: r(M.1)
(1, 0)
sage: r.matrix()
[ 0  0]
[ 1  0]
[ 0  1]
[-1 -1]
[ 0  0]
sage: r.domain()
Modular Symbols space of dimension 5 for Gamma_0(37) of weight 2 with sign 0 over Rational F
sage: r.codomain()
Vector space of degree 2 and dimension 2 over Rational Field
Basis matrix:
[1 0]
[0 1]
```

set_default_prec(*prec*)

Set the default precision for computation of q-expansion associated to the ambient space of this space of modular symbols (and all subspaces).

EXAMPLES:

```
sage: M = ModularSymbols(Gamma1(13),2)
sage: M.set_default_prec(5)
sage: M.cuspidal_submodule().q_expansion_basis()
[
q - 4*q^3 - q^4 + O(q^5),
q^2 - 2*q^3 - q^4 + O(q^5)
]
```

set_precision(*prec*)

Same as self.set_default_prec(prec).

EXAMPLES:

```
sage: M = ModularSymbols(17,2)
sage: M.cuspidal_submodule().q_expansion_basis()
[
q - q^2 - q^4 - 2*q^5 + 4*q^7 + O(q^8)
]
sage: M.set_precision(10)
sage: M.cuspidal_submodule().q_expansion_basis()
[
q - q^2 - q^4 - 2*q^5 + 4*q^7 + 3*q^8 - 3*q^9 + O(q^10)
]
```

sign()

Returns the sign of self.

For efficiency reasons, it is often useful to compute in the (largest) quotient of modular symbols where the * involution acts as +1, or where it acts as -1.

INPUT:

- `ModularSymbols self` - arbitrary space of modular symbols.

OUTPUT:

- `int` - the sign of self, either -1, 0, or 1.
- `-1` - if this is factor of quotient where * acts as -1,
- `+1` - if this is factor of quotient where * acts as +1,
- `0` - if this is full space of modular symbols (no quotient).

EXAMPLES:

```
sage: m = ModularSymbols(33)
sage: m.rank()
9
sage: m.sign()
0
sage: m = ModularSymbols(33, sign=0)
sage: m.sign()
0
sage: m.rank()
9
sage: m = ModularSymbols(33, sign=-1)
sage: m.sign()
-1
sage: m.rank()
3
```

sign_submodule(*sign, compute_dual=True*)

Return the subspace of self that is fixed under the star involution.

INPUT:

- `sign` - int (either -1, 0 or +1)
- `compute_dual` - bool (default: True) also compute dual subspace. This are useful for many algorithms.

OUTPUT: subspace of modular symbols

EXAMPLES:

```
sage: M = ModularSymbols(29,2)
sage: M.sign_submodule(1)
Modular Symbols subspace of dimension 3 of Modular Symbols space of dimension 5 for Gamma_0(
sage: M.sign_submodule(-1)
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 5 for Gamma_0(
sage: M.sign_submodule(-1).sign()
-1
```

simple_factors()

Returns a list modular symbols spaces S where S is simple spaces of modular symbols (for the anemic Hecke algebra) and self is isomorphic to the direct sum of the S with some multiplicities, as a module over the *anemic* Hecke algebra. For the multiplicities use factorization() instead.

ASSUMPTION: self is a module over the anemic Hecke algebra.

EXAMPLES:

```
sage: ModularSymbols(1,100,sign=-1).simple_factors()
[Modular Symbols subspace of dimension 8 of Modular Symbols space of dimension 8 for Gamma_0
sage: ModularSymbols(1,16,0,GF(5)).simple_factors()
[Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 for Gamma_0
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 for Gamma_0(
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 for Gamma_0(
```

star_decomposition()

Decompose self into subspaces which are eigenspaces for the star involution.

EXAMPLE:

```
sage: ModularSymbols(Gamma1(19), 2).cuspidal_submodule().star_decomposition()
[
Modular Symbols subspace of dimension 7 of Modular Symbols space of dimension 31 for Gamma_1
Modular Symbols subspace of dimension 7 of Modular Symbols space of dimension 31 for Gamma_1
]
```

star_eigenvalues()

Returns the eigenvalues of the star involution acting on self.

EXAMPLES:

```
sage: M = ModularSymbols(11)
sage: D = M.decomposition()
sage: M.star_eigenvalues()
[1, -1]
sage: D[0].star_eigenvalues()
[1]
sage: D[1].star_eigenvalues()
[1, -1]
sage: D[1].plus_submodule().star_eigenvalues()
[1]
sage: D[1].minus_submodule().star_eigenvalues()
[-1]
```

star_involution()
Return the star involution on self, which is induced by complex conjugation on modular symbols. Not implemented in this abstract base class.

EXAMPLES:

```
sage: M = ModularSymbols(11, 2); sage.modular.modsym.space.ModularSymbolsSpace.star_involuti
...
NotImplementedError
```

sturm_bound()
Returns the Sturm bound for this space of modular symbols.

Type `sturm_bound?` for more details.

EXAMPLES:

```
sage: ModularSymbols(11,2).sturm_bound()
2
sage: ModularSymbols(389,2).sturm_bound()
65

```

class **PeriodMapping**(*modsym, A*)
Base class for representing a period mapping attached to a space of modular symbols. To be used via the derived classes RationalPeriodMapping and IntegralPeriodMapping.

codomain()
Return the codomain of this mapping.

EXAMPLE:

Note that this presently returns the wrong answer, as a consequence of various bugs in the free module routines:

```
sage: ModularSymbols(11, 2).cuspidal_submodule().integral_period_mapping().codomain()
Vector space of degree 2 and dimension 2 over Rational Field
Basis matrix:
[1 0]
[0 1]
```

domain()
Return the domain of this mapping (which is the ambient space of the corresponding modular symbols space).

EXAMPLE:

```
sage: ModularSymbols(17, 2).cuspidal_submodule().integral_period_mapping().domain()
Modular Symbols space of dimension 3 for Gamma_0(17) of weight 2 with sign 0 over Rational F
```

matrix()
Return the matrix of this period mapping.

EXAMPLE:

```
sage: ModularSymbols(11, 2).cuspidal_submodule().integral_period_mapping().matrix()
[  0 1/5]
[  1   0]
[  0   1]
```

modular_symbols_space()
Return the space of modular symbols to which this period mapping corresponds.
EXAMPLES:

```
sage: ModularSymbols(17, 2).rational_period_mapping().modular_symbols_space()
Modular Symbols space of dimension 3 for Gamma_0(17) of weight 2 with sign 0 over Rational F
```

class RationalPeriodMapping(*modsym, A*)

is_ModularSymbolsSpace(*x*)
Return True if x is a space of modular symbols.
EXAMPLES:

```
sage: M = ModularForms(3, 2)
sage: sage.modular.modsym.space.is_ModularSymbolsSpace(M)
False
sage: sage.modular.modsym.space.is_ModularSymbolsSpace(M.modular_symbols(sign=1))
True
```

43.3 Ambient spaces of modular symbols.

This module defines the following classes. There is an abstract base class `ModularSymbolsAmbient`, derived from `space.ModularSymbolsSpace` and `hecke.AmbientHeckeModule`. As this is an abstract base class, only derived classes should be instantiated. There are five derived classes:

- `ModularSymbolsAmbient_wtk_g0`, for modular symbols of general weight k for $\Gamma_0(N)$;
- `ModularSymbolsAmbient_wt2_g0` (derived from `ModularSymbolsAmbient_wtk_g0`), for modular symbols of weight 2 for $\Gamma_0(N)$;
- `ModularSymbolsAmbient_wtk_g1`, for modular symbols of general weight k for $\Gamma_1(N)$;
- `ModularSymbolsAmbient_wtk_gamma_h`, for modular symbols of general weight k for Γ_H, where H is a subgroup of $\mathbf{Z}/N\mathbf{Z}$;
- `ModularSymbolsAmbient_wtk_eps`, for modular symbols of general weight k and character ϵ.

EXAMPLES:

We compute a space of modular symbols modulo 2. The dimension is different from that of the corresponding space in characteristic 0:

```
sage: M = ModularSymbols(11,4,base_ring=GF(2)); M
Modular Symbols space of dimension 7 for Gamma_0(11) of weight 4
with sign 0 over Finite Field of size 2
sage: M.basis()
([X*Y,(1,0)], [X*Y,(1,8)], [X*Y,(1,9)], [X^2,(0,1)], [X^2,(1,8)], [X^2,(1,9)], [X^2,(1,10)])
sage: M0 =  ModularSymbols(11,4,base_ring=QQ); M0
Modular Symbols space of dimension 6 for Gamma_0(11) of weight 4
with sign 0 over Rational Field
sage: M0.basis()
([X^2,(0,1)], [X^2,(1,6)], [X^2,(1,7)], [X^2,(1,8)], [X^2,(1,9)], [X^2,(1,10)])
```

The characteristic polynomial of the Hecke operator T_2 has an extra factor x.

```
sage: M.T(2).matrix().fcp('x')
(x + 1)^2 * x^5
sage: M0.T(2).matrix().fcp('x')
(x - 9)^2 * (x^2 - 2*x - 2)^2
```

class ModularSymbolsAmbient(*group, weight, sign, base_ring, character=None*)

An ambient space of modular symbols for a congruence subgroup of $SL_2(\mathbf{Z})$.

This class is an abstract base class, so only derived classes should be instantiated.

INPUT:

- `weight` - an integer
- `group` - a congruence subgroup.
- `sign` - an integer, either -1, 0, or 1
- `base_ring` - a commutative ring

boundary_map()

Return the boundary map to the corresponding space of boundary modular symbols.

EXAMPLES:

```
sage: ModularSymbols(20,2).boundary_map()
Hecke module morphism boundary map defined by the matrix
[ 1 -1  0  0  0  0]
[ 0  1 -1  0  0  0]
[ 0  1  0 -1  0  0]
[ 0  0  0 -1  1  0]
[ 0  1  0 -1  0  0]
[ 0  0  1 -1  0  0]
[ 0  1  0  0  0 -1]
Domain: Modular Symbols space of dimension 7 for Gamma_0(20) of weight ...
Codomain: Space of Boundary Modular Symbols for Congruence Subgroup Gamma0(20) ...
sage: type(ModularSymbols(20,2).boundary_map())
<class 'sage.modular.hecke.morphism.HeckeModuleMorphism_matrix'>
```

boundary_space()

Return the subspace of boundary modular symbols of this modular symbols ambient space.

EXAMPLES:

```
sage: ModularSymbols(20,2).boundary_space()
Space of Boundary Modular Symbols for Congruence Subgroup Gamma0(20) of weight 2 and over Ra
sage: ModularSymbols(20,2).dimension()
7
sage: ModularSymbols(20,2).boundary_space().dimension()
6
```

compact_newform_eigenvalues(*v, names='alpha'*)

Return compact systems of eigenvalues for each Galois conjugacy class of cuspidal newforms in this ambient space.

INPUT:

- `v` - list of positive integers

OUTPUT:

- `list` - of pairs (E, x), where E*x is a vector with entries the eigenvalues a_n for $n \in v$.

EXAMPLES:

```
sage: M = ModularSymbols(43,2,1)
sage: X = M.compact_newform_eigenvalues(prime_range(10))
sage: X[0][0] * X[0][1]
(-2, -2, -4, 0)
sage: X[1][0] * X[1][1]
(alpha1, -alpha1, -alpha1 + 2, alpha1 - 2)

sage: M = ModularSymbols(DirichletGroup(24,QQ).1,2,sign=1)
sage: M.compact_newform_eigenvalues(prime_range(10),'a')
[([-1/2 -1/2]
[ 1/2 -1/2]
[  -1    1]
[  -2    0], (1, -2*a0 - 1))]
sage: a = M.compact_newform_eigenvalues([1..10],'a')[0]
sage: a[0]*a[1]
(1, a0, a0 + 1, -2*a0 - 2, -2*a0 - 2, -a0 - 2, -2, 2*a0 + 4, -1, 2*a0 + 4)
sage: M = ModularSymbols(DirichletGroup(13).0^2,2,sign=1)
sage: M.compact_newform_eigenvalues(prime_range(10),'a')
[([  -zeta6 - 1]
[ 2*zeta6 - 2]
[-2*zeta6 + 1]
[           0], (1))]
sage: a = M.compact_newform_eigenvalues([1..10],'a')[0]
sage: a[0]*a[1]
(1, -zeta6 - 1, 2*zeta6 - 2, zeta6, -2*zeta6 + 1, -2*zeta6 + 4, 0, 2*zeta6 - 1, -zeta6, 3*ze
```

compute_presentation()

Compute and cache the presentation of this space.

EXAMPLES:

```
sage: ModularSymbols(11,2).compute_presentation() # no output
```

cuspidal_submodule()

The cuspidal submodule of this modular symbols ambient space.

EXAMPLES:

```
sage: M = ModularSymbols(12,2,0,GF(5)) ; M
Modular Symbols space of dimension 5 for Gamma_0(12) of weight 2 with sign 0 over Finite Fie
sage: M.cuspidal_submodule()
Modular Symbols subspace of dimension 0 of Modular Symbols space of dimension 5 for Gamma_0(
sage: ModularSymbols(1,24,-1).cuspidal_submodule()
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 2 for Gamma_0(
```

The cuspidal submodule of the cuspidal submodule is itself:

```
sage: M = ModularSymbols(389)
sage: S = M.cuspidal_submodule()
sage: S.cuspidal_submodule() is S
True
```

cusps()

Return the set of cusps for this modular symbols space.

EXAMPLES:

```
sage: ModularSymbols(20,2).cusps()
[Infinity, 0, -1/4, 1/5, -1/2, 1/10]
```

dual_star_involution_matrix()

Return the matrix of the dual star involution, which is induced by complex conjugation on the linear dual of modular symbols.

EXAMPLES:

```
sage: ModularSymbols(20,2).dual_star_involution_matrix()
[1 0 0 0 0 0 0]
[0 1 0 0 0 0 0]
[0 0 0 0 1 0 0]
[0 0 0 1 0 0 0]
[0 0 1 0 0 0 0]
[0 0 0 0 0 1 0]
[0 0 0 0 0 0 1]
```

eisenstein_submodule()

Return the Eisenstein submodule of this space of modular symbols.

EXAMPLES:

```
sage: ModularSymbols(20,2).eisenstein_submodule()
Modular Symbols subspace of dimension 5 of Modular Symbols space of dimension 7 for Gamma_0(
```

element(x)

Creates and returns an element of self from a modular symbol, if possible.

INPUT:

- x - an object of one of the following types: ModularSymbol, ManinSymbol.

OUTPUT:

ModularSymbol - a modular symbol with parent self.

EXAMPLES:

```
sage: M = ModularSymbols(11,4,1)
sage: M.T(3)
Hecke operator T_3 on Modular Symbols space of dimension 4 for Gamma_0(11) of weight 4 with
sage: M.T(3)(M.0)
28*[X^2,(0,1)] + 2*[X^2,(1,7)] - [X^2,(1,9)] - [X^2,(1,10)]
sage: M.T(3)(M.0).element()
(28, 2, -1, -1)
```

factor()

Returns a list of pairs (S, e) where S is spaces of modular symbols and self is isomorphic to the direct sum of the S^e as a module over the *anemic* Hecke algebra adjoin the star involution. The cuspidal S are all simple, but the Eisenstein factors need not be simple.

EXAMPLES:

```
sage: ModularSymbols(Gamma0(22), 2).factorization()
(Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 for Gamma_0
(Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 for Gamma_0
(Modular Symbols subspace of dimension 3 of Modular Symbols space of dimension 7 for Gamma_0

sage: ModularSymbols(1,6,0,GF(2)).factorization()
(Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 2 for Gamma_0
(Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 2 for Gamma_0

sage: ModularSymbols(18,2).factorization()
(Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 7 for Gamma_0
(Modular Symbols subspace of dimension 5 of Modular Symbols space of dimension 7 for Gamma_0

sage: M = ModularSymbols(DirichletGroup(38,CyclotomicField(3)).0^2,  2, +1); M
Modular Symbols space of dimension 7 and level 38, weight 2, character [zeta3], sign 1, over
sage: M.factorization()                    # long time (about 8 seconds)
(Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 7 and level 3
(Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 7 and level 3
```

```
(Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 7 and level 3
(Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 7 and level 3
```

factorization()

Returns a list of pairs (S, e) where S is spaces of modular symbols and self is isomorphic to the direct sum of the S^e as a module over the *anemic* Hecke algebra adjoin the star involution. The cuspidal S are all simple, but the Eisenstein factors need not be simple.

EXAMPLES:

```
sage: ModularSymbols(Gamma0(22), 2).factorization()
(Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 for Gamma_0
(Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 for Gamma_0
(Modular Symbols subspace of dimension 3 of Modular Symbols space of dimension 7 for Gamma_0

sage: ModularSymbols(1,6,0,GF(2)).factorization()
(Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 2 for Gamma_0
(Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 2 for Gamma_0

sage: ModularSymbols(18,2).factorization()
(Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 7 for Gamma_0
(Modular Symbols subspace of dimension 5 of Modular Symbols space of dimension 7 for Gamma_0

sage: M = ModularSymbols(DirichletGroup(38,CyclotomicField(3)).0^2,  2, +1); M
Modular Symbols space of dimension 7 and level 38, weight 2, character [zeta3], sign 1, over
sage: M.factorization()                    # long time (about 8 seconds)
(Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 7 and level 3
(Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 7 and level 3
(Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 7 and level 3
(Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 7 and level 3
```

integral_structure(*algorithm='default'*)

Return the $\mathbf{Z}$-structure of this modular symbols space, generated by all integral modular symbols.

INPUT:

- `algorithm` - string (default: 'default' - choose heuristically)
  - `'pari'` - use pari for the HNF computation
  - `'padic'` - use p-adic algorithm (only good for dense case)

ALGORITHM: It suffices to consider lattice generated by the free generating symbols $X^iY^{k-2-i}.(u, v)$ after quotienting out by the S (and I) relations, since the quotient by these relations is the same over any ring.

EXAMPLES: In weight 2 the rational basis is often integral.

```
sage: M = ModularSymbols(11,2)
sage: M.integral_structure()
Free module of degree 3 and rank 3 over Integer Ring
Echelon basis matrix:
[1 0 0]
[0 1 0]
[0 0 1]
```

This is rarely the case in higher weight:

```
sage: M = ModularSymbols(6,4)
sage: M.integral_structure()
Free module of degree 6 and rank 6 over Integer Ring
Echelon basis matrix:
[  1   0   0   0   0   0]
[  0   1   0   0   0   0]
```

```
[  0   0 1/2 1/2 1/2 1/2]
[  0   0   0   1   0   0]
[  0   0   0   0   1   0]
[  0   0   0   0   0   1]
```

Here is an example involving $\Gamma_1(N)$.

```
sage: M = ModularSymbols(Gamma1(5),6)
sage: M.integral_structure()
Free module of degree 10 and rank 10 over Integer Ring
Echelon basis matrix:
[     1      0      0      0      0      0      0      0      0      0]
[     0      1      0      0      0      0      0      0      0      0]
[     0      0  1/102      0  5/204  1/136  23/24   3/17 43/136 69/136]
[     0      0      0   1/48      0   1/48  23/24    1/6    1/8  17/24]
[     0      0      0      0   1/24      0  23/24    1/3    1/6    1/2]
[     0      0      0      0      0   1/24  23/24    1/3  11/24   5/24]
[     0      0      0      0      0      0      1      0      0      0]
[     0      0      0      0      0      0      0    1/2      0    1/2]
[     0      0      0      0      0      0      0      0    1/2    1/2]
[     0      0      0      0      0      0      0      0      0      1]
```

is_cuspidal()

Returns True if this space is cuspidal, else False.

EXAMPLES:

```
sage: M = ModularSymbols(20,2)
sage: M.is_cuspidal()
False
sage: S = M.cuspidal_subspace()
sage: S.is_cuspidal()
True
sage: S = M.eisenstein_subspace()
sage: S.is_cuspidal()
False
```

is_eisenstein()

Returns True if this space is Eisenstein, else False.

EXAMPLES:

```
sage: M = ModularSymbols(20,2)
sage: M.is_eisenstein()
False
sage: S = M.eisenstein_submodule()
sage: S.is_eisenstein()
True
sage: S = M.cuspidal_subspace()
sage: S.is_eisenstein()
False
```

manin_basis()

Return a list of indices into the list of Manin generators (see `self.manin_generators()`) such that those symbols form a basis for the quotient of the $\mathbf{Q}$-vector space spanned by Manin symbols modulo the relations.

EXAMPLES:

```
sage: M = ModularSymbols(2,2)
sage: M.manin_basis()
[1]
```

```
sage: [M.manin_generators()[i] for i in M.manin_basis()]
[(1,0)]
sage: M = ModularSymbols(6,2)
sage: M.manin_basis()
[1, 10, 11]
sage: [M.manin_generators()[i] for i in M.manin_basis()]
[(1,0), (3,1), (3,2)]
```

manin_generators()

Return list of all Manin symbols for this space. These are the generators in the presentation of this space by Manin symbols.

EXAMPLES:

```
sage: M = ModularSymbols(2,2)
sage: M.manin_generators()
[(0,1), (1,0), (1,1)]

sage: M = ModularSymbols(1,6)
sage: M.manin_generators()
[[Y^4,(0,0)], [X*Y^3,(0,0)], [X^2*Y^2,(0,0)], [X^3*Y,(0,0)], [X^4,(0,0)]]
```

manin_gens_to_basis()

Return the matrix expressing the manin symbol generators in terms of the basis.

EXAMPLES:

```
sage: ModularSymbols(11,2).manin_gens_to_basis()
[-1  0  0]
[ 1  0  0]
[ 0  0  0]
[ 0  0  1]
[ 0 -1  1]
[ 0 -1  0]
[ 0  0 -1]
[ 0  0 -1]
[ 0  1 -1]
[ 0  1  0]
[ 0  0  1]
[ 0  0  0]
```

manin_symbol(*x*, *check=True*)

Construct a Manin Symbol from the given data.

INPUT:

- x (list) – either $[u, v]$ or $[i, u, v]$, where $0 \leq i \leq k-2$ where k is the weight, and u,'v' are integers defining a valid element of $\mathbb{P}^1(N)$, where N is the level.

OUTPUT:

(ManinSymbol) the monomial Manin Symbol associated to $[i; (u, v)]$, with $i = 0$ if not supplied, corresponding to the symbol $[X^i * Y^{k-2-i}, (u, v)]$.

EXAMPLES:

```
sage: M = ModularSymbols(11,4,1)
sage: M.manin_symbol([2,5,6])
[X^2,(1,10)]
```

manin_symbols()

Return the list of Manin symbols for this modular symbols ambient space.

EXAMPLES:

```
sage: ModularSymbols(11,2).manin_symbols()
Manin Symbol List of weight 2 for Gamma0(11)
```

manin_symbols_basis()

A list of Manin symbols that form a basis for the ambient space self. INPUT:

- `ModularSymbols self` - an ambient space of modular symbols

OUTPUT:

- `list` - a list of 2-tuples (if the weight is 2) or 3-tuples, which represent the Manin symbols basis for self.

EXAMPLES:

```
sage: m = ModularSymbols(23)
sage: m.manin_symbols_basis()
[(1,0), (1,17), (1,19), (1,20), (1,21)]
sage: m = ModularSymbols(6, weight=4, sign=-1)
sage: m.manin_symbols_basis()
[[X^2,(2,1)]]
```

modular_symbol(*x, check=True*)

Create a modular symbol in this space.

INPUT:

- x (list) – a list of either 2 or 3 entries:
  - –2 entries: $[\alpha, \beta]$ where α and β are cusps;
  - –3 entries: $[i, \alpha, \beta]$ where $0 \leq i \leq k-2$ and α and β are cusps;
- `check` (bool, default True) – flag that determines whether the input x needs processing: use check=False for efficiency if the input x is a list of length 3 whose first entry is an Integer, and whose second and third entries are Cusps (se examples).

OUTPUT:

(Modular Symbol) The modular symbol $Y^{k-2}\{\alpha, \beta\}$. or $X^i Y^{k-2-i}\{\alpha, \beta\}$.

EXAMPLES:

```
sage: set_modsym_print_mode('modular')
sage: M = ModularSymbols(11)
sage: M.modular_symbol([2/11, oo])
-{-1/9, 0}
sage: M.1
{-1/8, 0}
sage: M.modular_symbol([-1/8, 0])
{-1/8, 0}
sage: M.modular_symbol([0, -1/8, 0])
{-1/8, 0}
sage: M.modular_symbol([10, -1/8, 0])
...
ValueError: The first entry of the tuple (=[10, -1/8, 0]) must be an integer between 0 and k

sage: N = ModularSymbols(6,4)
sage: set_modsym_print_mode('manin')
sage: N([1,Cusp(-1/4),Cusp(0)])
17/2*[X^2,(2,3)] - 9/2*[X^2,(2,5)] + 15/2*[X^2,(3,1)] - 15/2*[X^2,(3,2)]
sage: N([1,Cusp(-1/2),Cusp(0)])
1/2*[X^2,(2,3)] + 3/2*[X^2,(2,5)] + 3/2*[X^2,(3,1)] - 3/2*[X^2,(3,2)]
```

Use check=False for efficiency if the input x is a list of length 3 whose first entry is an Integer, and whose second and third entries are cusps:

```
sage: M.modular_symbol([0, Cusp(2/11), Cusp(oo)], check=False)
-(1,9)

sage: set_modsym_print_mode()    # return to default.
```

modular_symbol_sum(*x, check=True*)

Construct a modular symbol sum.

INPUT:

- x (list) – $[f, \alpha, \beta]$ where $f = \sum_{i=0}^{k-2} a_i X^i Y^{k-2-i}$ is a homogeneous polynomial over $\mathbf{Z}$ of degree k and α and β are cusps.
- check (bool, default True) – if True check the validity of the input tuple x

OUTPUT:

The sum $\sum_{i=0}^{k-2} a_i[i, \alpha, \beta]$ as an element of this modular symbol space.

EXAMPLES:

sage: M = ModularSymbols(11,4) sage: R.<X,Y>=QQ[] sage: M.modular_symbol_sum([X*Y,Cusp(0),Cusp(Infinity)]) -3/14*[X^2,(1,6)] + 1/14*[X^2,(1,7)] - 1/14*[X^2,(1,8)] + 1/2*[X^2,(1,9)] - 2/7*[X^2,(1,10)]

modular_symbols_of_sign(*sign*)

Returns a space of modular symbols with the same defining properties (weight, level, etc.) as this space except with given sign.

INPUT:

- sign (int) – A sign ($+1$, -1 or 0).

OUTPUT:

(ModularSymbolsAmbient) A space of modular symbols with the same defining properties (weight, level, etc.) as this space except with given sign.

EXAMPLES:

```
sage: M = ModularSymbols(Gamma0(11),2,sign=0)
sage: M
Modular Symbols space of dimension 3 for Gamma_0(11) of weight 2 with sign 0 over Rational F
sage: M.modular_symbols_of_sign(-1)
Modular Symbols space of dimension 1 for Gamma_0(11) of weight 2 with sign -1 over Rational
sage: M = ModularSymbols(Gamma1(11),2,sign=0)
sage: M.modular_symbols_of_sign(-1)
Modular Symbols space of dimension 1 for Gamma_1(11) of weight 2 with sign -1 and over Ratio
```

modular_symbols_of_weight(*k*)

Returns a space of modular symbols with the same defining properties (weight, sign, etc.) as this space except with weight k.

INPUT:

- k (int) – A positive integer.

OUTPUT:

(ModularSymbolsAmbient) A space of modular symbols with the same defining properties (level, sign) as this space except with given weight.

EXAMPLES:

```
sage: M = ModularSymbols(Gamma1(6),2,sign=0)
sage: M.modular_symbols_of_weight(3)
Modular Symbols space of dimension 4 for Gamma_1(6) of weight 3 with sign 0 and over Rationa
```

new_submodule(*p=None*)

Returns the new or p-new submodule of this moduluar symbols ambient space.

INPUT:

- p - (default: None); if not None, return only the p-new submodule.

OUTPUT:

The new or p-new submodule of this modular symbols ambient space.

EXAMPLES:

```
sage: ModularSymbols(100).new_submodule()
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 31 for Gamma_0
sage: ModularSymbols(389).new_submodule()
Modular Symbols space of dimension 65 for Gamma_0(389) of weight 2 with sign 0 over Rational
```

p1list()

Return a P1list of the level of this modular symbol space.

EXAMPLES:

```
sage: ModularSymbols(11,2).p1list()
The projective line over the integers modulo 11
```

rank()

Returns the rank of this modular symbols ambient space.

OUTPUT:

(int) The rank of this space of modular symbols.

EXAMPLES:

```
sage: M = ModularSymbols(389)
sage: M.rank()
65

sage: ModularSymbols(11,sign=0).rank()
3
sage: ModularSymbols(100,sign=0).rank()
31
sage: ModularSymbols(22,sign=1).rank()
5
sage: ModularSymbols(1,12).rank()
3
sage: ModularSymbols(3,4).rank()
2
sage: ModularSymbols(8,6,sign=-1).rank()
3
```

star_involution()

Return the star involution on this modular symbols space.

OUTPUT:

(matrix) The matrix of the star involution on this space, which is induced by complex conjugation on modular symbols, with respect to the standard basis.

EXAMPLES:

```
sage: ModularSymbols(20,2).star_involution()
Hecke module morphism Star involution on Modular Symbols space of dimension 7 for Gamma_0(20
[1 0 0 0 0 0 0]
[0 1 0 0 0 0 0]
[0 0 0 0 1 0 0]
[0 0 0 1 0 0 0]
[0 0 1 0 0 0 0]
[0 0 0 0 0 1 0]
[0 0 0 0 0 0 1]
Domain: Modular Symbols space of dimension 7 for Gamma_0(20) of weight ...
Codomain: Modular Symbols space of dimension 7 for Gamma_0(20) of weight ...
```

submodule(*M, dual_free_module=None, check=True*)

Return the submodule with given generators or free module M.

INPUT:

- M - either a submodule of this ambient free module, or generators for a submodule;
- **dual_free_module (bool, default None) – this may be** useful to speed up certain calculations; it is the corresponding submodule of the ambient dual module;
- **check (bool, default True) – if True, check that M is** a submodule, i.e. is invariant under all Hecke operators.

OUTPUT:

A subspace of this modular symbol space.

EXAMPLES:

```
sage: M = ModularSymbols(11)
sage: M.submodule([M.0])
...
ValueError: The submodule must be invariant under all Hecke operators.
sage: M.eisenstein_submodule().basis()
((1,0) - 1/5*(1,9),)
sage: M.basis()
((1,0), (1,8), (1,9))
sage: M.submodule([M.0 - 1/5*M.2])
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 for Gamma_0(
```

Note: It would make more sense to only check that M is invariant under the Hecke operators with index coprime to the level. Unfortunately, I do not know a reasonable algorithm for determining whether a module is invariant under just the anemic Hecke algebra, since I do not know an analogue of the Sturm bound for the anemic Hecke algebra. - William Stein, 2007-07-27

twisted_winding_element(*i, eps*)

Return the twisted winding element of given degree and character.

INPUT:

- i (int) – an integer, $0 \leq i \leq k-2$ where k is the weight.
- eps (character) – a Dirichlet character

OUTPUT:

(modular symbol) The so-called 'twisted winding element':

$$\sum_{a \in (\mathbf{Z}/m\mathbf{Z})^\times} \varepsilon(a) * [i, 0, a/m].$$

Note: This will only work if the base ring of the modular symbol space contains the character values.

EXAMPLES:

```
sage: eps = DirichletGroup(5)[2]
sage: K = eps.base_ring()
sage: M = ModularSymbols(37,2,0,K)
sage: M.twisted_winding_element(0,eps)
2*(1,23) + (-2)*(1,32) + 2*(1,34)
```

class ModularSymbolsAmbient_wt2_g0(*N, sign, F*)

Modular symbols for $\Gamma_0(N)$ of integer weight 2 over the field F.

INPUT:

- N - int, the level
- sign - int, either -1, 0, or 1

OUTPUT:

The space of modular symbols of weight 2, trivial character, level N and given sign.

EXAMPLES:

```
sage: ModularSymbols(Gamma0(12),2)
Modular Symbols space of dimension 5 for Gamma_0(12) of weight 2 with sign 0 over Rational Field
```

boundary_space()

Return the space of boundary mdular symbols for this space.

EXAMPLES:

```
sage: M = ModularSymbols(100,2)
sage: M.boundary_space()
Space of Boundary Modular Symbols for Congruence Subgroup Gamma0(100) of weight 2 and over R
```

class ModularSymbolsAmbient_wtk_eps(*eps, weight, sign=0*)

boundary_space()

Return the space of boundary modular symbols for this space.

EXAMPLES:

```
sage: eps = DirichletGroup(5).gen(0)
sage: M = ModularSymbols(eps, 2)
sage: M.boundary_space()
Boundary Modular Symbols space of level 5, weight 2, character [zeta4] and dimension 0 over
```

manin_symbols()

Return the Manin symbol list of this modular symbol space.

EXAMPLES:

```
sage: eps = DirichletGroup(5).gen(0)
sage: M = ModularSymbols(eps, 2)
sage: M.manin_symbols()
Manin Symbol List of weight 2 for Gamma1(5) with character [zeta4]
sage: len(M.manin_symbols())
6
```

modular_symbols_of_level(*N*)

Returns a space of modular symbols with the same parameters as this space except with level N.

INPUT:

- N (int) – a positive integer.

OUTPUT:

(Modular Symbol space) A space of modular symbols with the same defining properties (weight, sign, etc.) as this space except with level N.

EXAMPLES:

```
sage: eps = DirichletGroup(5).gen(0)
sage: M = ModularSymbols(eps, 2); M
Modular Symbols space of dimension 0 and level 5, weight 2, character [zeta4], sign 0, over
sage: M.modular_symbols_of_level(15)
Modular Symbols space of dimension 0 and level 15, weight 2, character [1, zeta4], sign 0, o
```

modular_symbols_of_sign(*sign*)

Returns a space of modular symbols with the same defining properties (weight, level, etc.) as this space except with given sign.

INPUT:

- sign (int) – A sign ($+1$, -1 or 0).

OUTPUT:

(ModularSymbolsAmbient) A space of modular symbols with the same defining properties (weight, level, etc.) as this space except with given sign.

EXAMPLES:

```
sage: eps = DirichletGroup(5).gen(0)
sage: M = ModularSymbols(eps, 2); M
Modular Symbols space of dimension 0 and level 5, weight 2, character [zeta4], sign 0, over
sage: M.modular_symbols_of_sign(0) == M
True
sage: M.modular_symbols_of_sign(+1)
Modular Symbols space of dimension 0 and level 5, weight 2, character [zeta4], sign 1, over
sage: M.modular_symbols_of_sign(-1)
Modular Symbols space of dimension 0 and level 5, weight 2, character [zeta4], sign -1, over
```

modular_symbols_of_weight(*k*)

Returns a space of modular symbols with the same defining properties (weight, sign, etc.) as this space except with weight k.

INPUT:

- k (int) – A positive integer.

OUTPUT:

(ModularSymbolsAmbient) A space of modular symbols with the same defining properties (level, sign) as this space except with given weight.

EXAMPLES:

```
sage: eps = DirichletGroup(5).gen(0)
sage: M = ModularSymbols(eps, 2); M
Modular Symbols space of dimension 0 and level 5, weight 2, character [zeta4], sign 0, over
sage: M.modular_symbols_of_weight(3)
Modular Symbols space of dimension 2 and level 5, weight 3, character [zeta4], sign 0, over
sage: M.modular_symbols_of_weight(2) == M
True
```

class **ModularSymbolsAmbient_wtk_g0**(*N, k, sign, F*)

Modular symbols for $\Gamma_0(N)$ of integer weight $k > 2$ over the field F.

For weight 2, it is faster to use ModularSymbols_wt2_g0.

INPUT:

- N - int, the level
- k - integer weight = 2.
- sign - int, either -1, 0, or 1
- F - field

EXAMPLES:

```
sage: ModularSymbols(1,12)
Modular Symbols space of dimension 3 for Gamma_0(1) of weight 12 with sign 0 over Rational Field
sage: ModularSymbols(1,12, sign=1).dimension()
2
sage: ModularSymbols(15,4, sign=-1).dimension()
4
sage: ModularSymbols(6,6).dimension()
10
sage: ModularSymbols(36,4).dimension()
36
```

boundary_space()
Return the space of boundary modular symbols for this space.
EXAMPLES:

```
sage: M = ModularSymbols(100,2)
sage: M.boundary_space()
Space of Boundary Modular Symbols for Congruence Subgroup Gamma0(100) of weight 2 and over R
```

manin_symbols()
Return the Manin symbol list of this modular symbol space.
EXAMPLES:

```
sage: M = ModularSymbols(100,4)
sage: M.manin_symbols()
Manin Symbol List of weight 4 for Gamma0(100)
sage: len(M.manin_symbols())
540
```

modular_symbols_of_level(*N*)
Returns a space of modular symbols with the same parameters as this space except with level N.
INPUT:

- N (int) – a positive integer.

OUTPUT:
(Modular Symbol space) A space of modular symbols with the same defining properties (weight, sign, etc.) as this space except with level N.
For example, if self is the space of modular symbols of weight 2 for $\Gamma_0(22)$, and level is 11, then this function returns the modular symbol space of weight 2 for $\Gamma_0(11)$.
EXAMPLES:

```
sage: M = ModularSymbols(11)
sage: M.modular_symbols_of_level(22)
Modular Symbols space of dimension 7 for Gamma_0(22) of weight 2 with sign 0 over Rational F
sage: M = ModularSymbols(Gamma1(6))
sage: M.modular_symbols_of_level(12)
Modular Symbols space of dimension 9 for Gamma_1(12) of weight 2 with sign 0 and over Ration
```

class **ModularSymbolsAmbient_wtk_g1**(*level, weight, sign, F*)
INPUT:

- level - int, the level
- weight - int, the weight = 2
- sign - int, either -1, 0, or 1
- F - field

EXAMPLES:

```
sage: ModularSymbols(Gamma1(17),2)
Modular Symbols space of dimension 25 for Gamma_1(17) of weight 2 with sign 0 and over Rational
sage: [ModularSymbols(Gamma1(7),k).dimension() for k in [2,3,4,5]]
[5, 8, 12, 16]

sage: ModularSymbols(Gamma1(7),3)
Modular Symbols space of dimension 8 for Gamma_1(7) of weight 3 with sign 0 and over Rational Fi
```

boundary_space()
Return the space of boundary mdular symbols for this space.
EXAMPLES:

```
sage: M = ModularSymbols(100,2)
sage: M.boundary_space()
Space of Boundary Modular Symbols for Congruence Subgroup Gamma0(100) of weight 2 and over R
```

manin_symbols()
Return the Manin symbol list of this modular symbol space.
EXAMPLES:

```
sage: M = ModularSymbols(Gamma1(30),4)
sage: M.manin_symbols()
Manin Symbol List of weight 4 for Gamma1(30)
sage: len(M.manin_symbols())
1728
```

modular_symbols_of_level(N)
Returns a space of modular symbols with the same parameters as this space except with level N.
INPUT:

- N (int) – a positive integer.

OUTPUT:
(Modular Symbol space) A space of modular symbols with the same defining properties (weight, sign, etc.) as this space except with level N.
For example, if self is the space of modular symbols of weight 2 for $\Gamma_0(22)$, and level is 11, then this function returns the modular symbol space of weight 2 for $\Gamma_0(11)$.
EXAMPLES:

```
sage: M = ModularSymbols(Gamma1(30),4); M
Modular Symbols space of dimension 144 for Gamma_1(30) of weight 4 with sign 0 and over Rati
sage: M.modular_symbols_of_level(22)
Modular Symbols space of dimension 90 for Gamma_1(22) of weight 4 with sign 0 and over Ratio
```

class **ModularSymbolsAmbient_wtk_gamma_h**(*group, weight, sign, F*)

boundary_space()
Return the space of boundary modular symbols for this space.
EXAMPLES:

```
sage: M = ModularSymbols(GammaH(15,[4]),2)
sage: M.boundary_space()
Boundary Modular Symbols space for Congruence Subgroup Gamma_H(15) with H generated by [4] o
```

manin_symbols()
Return the Manin symbol list of this modular symbol space.
EXAMPLES:

```
sage: M = ModularSymbols(GammaH(15,[4]),2)
sage: M.manin_symbols()
Manin Symbol List of weight 2 for Congruence Subgroup Gamma_H(15) with H generated by [4]
sage: len(M.manin_symbols())
96
```

modular_symbols_of_level(N)
Returns a space of modular symbols with the same parameters as this space except with level N.
Note: Not implemented for this class.
TESTS:

```
sage: M = ModularSymbols(GammaH(15,[4]),2)
sage: M.modular_symbols_of_level(30)
...
NotImplementedError
```

43.4 Subspace of ambient spaces of modular symbols

class ModularSymbolsSubspace(*ambient_hecke_module, submodule, dual_free_module=None, check=False*)

Subspace of ambient space of modular symbols

boundary_map()

The boundary map to the corresponding space of boundary modular symbols. (This is the restriction of the map on the ambient space.)

EXAMPLES:

```
sage: M = ModularSymbols(1, 24, sign=1) ; M
Modular Symbols space of dimension 3 for Gamma_0(1) of weight 24 with sign 1 over Rational F
sage: M.basis()
([X^18*Y^4,(0,0)], [X^20*Y^2,(0,0)], [X^22,(0,0)])
sage: M.cuspidal_submodule().basis()
([X^18*Y^4,(0,0)], [X^20*Y^2,(0,0)])
sage: M.eisenstein_submodule().basis()
([X^18*Y^4,(0,0)] + 166747/324330*[X^20*Y^2,(0,0)] + 236364091/6742820700*[X^22,(0,0)],)
sage: M.boundary_map()
Hecke module morphism boundary map defined by the matrix
[ 0]
[ 0]
[-1]
Domain: Modular Symbols space of dimension 3 for Gamma_0(1) of weight ...
Codomain: Space of Boundary Modular Symbols for Modular Group SL(2,Z) ...
sage: M.cuspidal_subspace().boundary_map()
Hecke module morphism defined by the matrix
[0]
[0]
Domain: Modular Symbols subspace of dimension 2 of Modular Symbols space ...
Codomain: Space of Boundary Modular Symbols for Modular Group SL(2,Z) ...
sage: M.eisenstein_submodule().boundary_map()
Hecke module morphism defined by the matrix
[-236364091/6742820700]
Domain: Modular Symbols subspace of dimension 1 of Modular Symbols space ...
Codomain: Space of Boundary Modular Symbols for Modular Group SL(2,Z) ...
```

cuspidal_submodule()

Return the cuspidal subspace of this subspace of modular symbols.

EXAMPLES:

```
sage: S = ModularSymbols(42,4).cuspidal_submodule() ; S
Modular Symbols subspace of dimension 40 of Modular Symbols space of dimension 48 for Gamma_
sage: S.is_cuspidal()
True
sage: S.cuspidal_submodule()
Modular Symbols subspace of dimension 40 of Modular Symbols space of dimension 48 for Gamma_
```

The cuspidal submodule of the cuspidal submodule is just itself:

```
sage: S.cuspidal_submodule() is S
True
```

```
sage: S.cuspidal_submodule() == S
True
```

An example where we abuse the _set_is_cuspidal function:

```
sage: M = ModularSymbols(389)
sage: S = M.eisenstein_submodule()
sage: S._set_is_cuspidal(True)
sage: S.cuspidal_submodule()
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 65 for Gamma_0
```

dual_star_involution_matrix()

Return the matrix of the dual star involution, which is induced by complex conjugation on the linear dual of modular symbols.

EXAMPLES:

```
sage: S = ModularSymbols(6,4) ; S.dual_star_involution_matrix()
[ 1  0  0  0  0  0]
[ 0  1  0  0  0  0]
[ 0 -2  1  2  0  0]
[ 0  2  0 -1  0  0]
[ 0 -2  0  2  1  0]
[ 0  2  0 -2  0  1]
sage: S.star_involution().matrix().transpose() == S.dual_star_involution_matrix()
True
```

eisenstein_subspace()

Return the Eisenstein subspace of this space of modular symbols.

EXAMPLES:

```
sage: ModularSymbols(24,4).eisenstein_subspace()
Modular Symbols subspace of dimension 8 of Modular Symbols space of dimension 24 for Gamma_0
sage: ModularSymbols(20,2).cuspidal_subspace().eisenstein_subspace()
Modular Symbols subspace of dimension 0 of Modular Symbols space of dimension 7 for Gamma_0(
```

factorization()

Returns a list of pairs (S, e) where S is simple spaces of modular symbols and self is isomorphic to the direct sum of the S^e as a module over the *anemic* Hecke algebra adjoin the star involution.

The cuspidal S are all simple, but the Eisenstein factors need not be simple.

The factors are sorted by dimension - don't depend on much more for now.

ASSUMPTION: self is a module over the anemic Hecke algebra.

EXAMPLES: Note that if the sign is 1 then the cuspidal factors occur twice, one with each star eigenvalue.

```
sage: M = ModularSymbols(11)
sage: D = M.factorization(); D
(Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 for Gamma_0
(Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 for Gamma_0
(Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 for Gamma_0
sage: [A.T(2).matrix() for A, _ in D]
[[-2], [3], [-2]]
sage: [A.star_eigenvalues() for A, _ in D]
[[-1], [1], [1]]
```

In this example there is one old factor squared.

```
sage: M = ModularSymbols(22,sign=1)
sage: S = M.cuspidal_submodule()
sage: S.factorization()
(Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 2 for Gamma_0
```

```
sage: M = ModularSymbols(Gamma0(22), 2, sign=1)
sage: M1 = M.decomposition()[1]
sage: M1.factorization()
Modular Symbols subspace of dimension 3 of Modular Symbols space of dimension 5 for Gamma_0(
```

hecke_bound()

Compute the Hecke bound for self; that is, a number n such that the T_m for m = n generate the Hecke algebra.

EXAMPLES:

```
sage: M = ModularSymbols(24,8)
sage: M.hecke_bound()
53
sage: M.cuspidal_submodule().hecke_bound()
32
sage: M.eisenstein_submodule().hecke_bound()
53
```

is_cuspidal()

Return True if self is cuspidal.

EXAMPLES:

```
sage: ModularSymbols(42,4).cuspidal_submodule().is_cuspidal()
True
sage: ModularSymbols(12,6).eisenstein_submodule().is_cuspidal()
False
```

is_eisenstein()

Return True if self is an Eisenstein subspace.

EXAMPLES:

```
sage: ModularSymbols(22,6).cuspidal_submodule().is_eisenstein()
False
sage: ModularSymbols(22,6).eisenstein_submodule().is_eisenstein()
True
```

star_involution()

Return the star involution on self, which is induced by complex conjugation on modular symbols.

EXAMPLES:

```
sage: M = ModularSymbols(1,24)
sage: M.star_involution()
Hecke module morphism Star involution on Modular Symbols space of dimension 5 for Gamma_0(1)
[ 1  0  0  0  0]
[ 0 -1  0  0  0]
[ 0  0  1  0  0]
[ 0  0  0 -1  0]
[ 0  0  0  0  1]
Domain: Modular Symbols space of dimension 5 for Gamma_0(1) of weight ...
Codomain: Modular Symbols space of dimension 5 for Gamma_0(1) of weight ...
sage: M.cuspidal_subspace().star_involution()
Hecke module morphism defined by the matrix
[ 1  0  0  0]
[ 0 -1  0  0]
[ 0  0  1  0]
[ 0  0  0 -1]
Domain: Modular Symbols subspace of dimension 4 of Modular Symbols space ...
Codomain: Modular Symbols subspace of dimension 4 of Modular Symbols space ...
sage: M.plus_submodule().star_involution()
```

```
Hecke module morphism defined by the matrix
[1 0 0]
[0 1 0]
[0 0 1]
Domain: Modular Symbols subspace of dimension 3 of Modular Symbols space ...
Codomain: Modular Symbols subspace of dimension 3 of Modular Symbols space ...
sage: M.minus_submodule().star_involution()
Hecke module morphism defined by the matrix
[-1  0]
[ 0 -1]
Domain: Modular Symbols subspace of dimension 2 of Modular Symbols space ...
Codomain: Modular Symbols subspace of dimension 2 of Modular Symbols space ...
```

43.5 A single element of an ambient space of modular symbols.

class ModularSymbolsElement (*parent, x, check=True*)

An element of a space of modular symbols.

TESTS:

```
sage: x = ModularSymbols(3, 12).cuspidal_submodule().gen(0)
sage: x == loads(dumps(x))
True
```

list()

Return a list of the coordinates of self in terms of a basis for the ambient space.

EXAMPLE:

```
sage: ModularSymbols(37, 2).0.list()
[1, 0, 0, 0, 0]
```

manin_symbol_rep()

Returns a representation of self as a formal sum of Manin symbols.

(The result is cached for future use.)

EXAMPLE:

```
sage: ModularSymbols(37, 4).0.manin_symbol_rep()
[X^2,(0,1)]
```

modular_symbol_rep()

Returns a representation of self as a formal sum of modular symbols.

(The result is cached for future use.)

EXAMPLE:

```
sage: ModularSymbols(37, 4).0.modular_symbol_rep()
X^2*{0, Infinity}
```

is_ModularSymbolsElement(*x*)

Return True if x is an element of a modular symbols space.

EXAMPLES:

```
sage: sage.modular.modsym.element.is_ModularSymbolsElement(ModularSymbols(11, 2).0)
True
sage: sage.modular.modsym.element.is_ModularSymbolsElement(13)
False
```

set_modsym_print_mode(*mode='manin'*)

Set the mode for printing of elements of modular symbols spaces.

INPUT:

- `mode` - a string. The possibilities are as follows:
- `'manin'` - (the default) formal sums of Manin symbols [P(X,Y),(u,v)]
- `'modular'` - formal sums of Modular symbols P(X,Y)*alpha,beta, where alpha and beta are cusps
- `'vector'` - as vectors on the basis for the ambient space

OUTPUT: none

EXAMPLE:

```
sage: M = ModularSymbols(13, 8)
sage: x = M.0 + M.1 + M.14
sage: set_modsym_print_mode('manin'); x
[X^5*Y,(1,11)] + [X^5*Y,(1,12)] + [X^6,(1,11)]
sage: set_modsym_print_mode('modular'); x
1610510*X^6*{-1/11, 0} - 248832*X^6*{-1/12, 0} + 893101*X^5*Y*{-1/11, 0} - 103680*X^5*Y*{-1/12,
sage: set_modsym_print_mode('vector'); x
(1, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0)
sage: set_modsym_print_mode()
```

43.6 Modular symbols {alpha, beta}

The ModularSymbol class represents a single modular symbol $X^i Y^{k-2-i}\{\alpha, \beta\}$.

AUTHOR:

- William Stein (2005, 2009)

TESTS:

```
sage: s = ModularSymbols(11).2.modular_symbol_rep()[0][1]; s
{-1/9, 0}
sage: loads(dumps(s)) == s
True
```

class ModularSymbol(*space, i, alpha, beta*)

The modular symbol $X^i \cdot Y^{k-2-i} \cdot \{\alpha, \beta\}$.

alpha()

For a symbol of the form $X^i Y^{k-2-i}\{\alpha, \beta\}$, return α.

EXAMPLES:

```
sage: s = ModularSymbols(11,4).1.modular_symbol_rep()[0][1]; s
X^2*{-1/6, 0}
sage: s.alpha()
-1/6
sage: type(s.alpha())
<class 'sage.modular.cusps.Cusp'>
```

apply(*g*)

Act on this symbol by the element $g \in \mathrm{GL}_2(\mathbf{Q})$.

INPUT:

- g – a list [a,b,c,d], corresponding to the 2x2 matrix $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{GL}_2(\mathbf{Q})$.

OUTPUT:

- FormalSum – a formal sum $\sum_i c_i x_i$, where c_i are scalars and x_i are ModularSymbol objects, such that the sum $\sum_i c_i x_i$ is the image of this symbol under the action of g. No reduction is performed modulo the relations that hold in self.space().

The action of g on symbols is by

$$P(X,Y)\{\alpha,\beta\} \mapsto P(dX - bY, -cx + aY)\{g(\alpha), g(\beta)\}.$$

Note that for us we have $P = X^i Y^{k-2-i}$, which simplifies computation of the polynomial part slightly.

EXAMPLES:

```
sage: s = ModularSymbols(11,2).1.modular_symbol_rep()[0][1]; s
{-1/8, 0}
sage: a=1;b=2;c=3;d=4; s.apply([a,b,c,d])
{15/29, 1/2}
sage: x = -1/8;  (a*x+b)/(c*x+d)
15/29
sage: x = 0;  (a*x+b)/(c*x+d)
1/2
sage: s = ModularSymbols(11,4).1.modular_symbol_rep()[0][1]; s
X^2*{-1/6, 0}
sage: s.apply([a,b,c,d])
16*X^2*{11/21, 1/2} - 16*X*Y*{11/21, 1/2} + 4*Y^2*{11/21, 1/2}
sage: P = s.polynomial_part()
sage: X,Y = P.parent().gens()
sage: P(d*X-b*Y, -c*X+a*Y)
16*X^2 - 16*X*Y + 4*Y^2
sage: x=-1/6; (a*x+b)/(c*x+d)
11/21
sage: x=0; (a*x+b)/(c*x+d)
1/2
sage: type(s.apply([a,b,c,d]))
<class 'sage.structure.formal_sum.FormalSum'>
```

beta()

For a symbol of the form $X^i Y^{k-2-i}\{\alpha,\beta\}$, return β.

EXAMPLES:

```
sage: s = ModularSymbols(11,4).1.modular_symbol_rep()[0][1]; s
X^2*{-1/6, 0}
sage: s.beta()
0
sage: type(s.beta())
<class 'sage.modular.cusps.Cusp'>
```

i()

For a symbol of the form $X^i Y^{k-2-i}\{\alpha,\beta\}$, return i.

EXAMPLES:

```
sage: s = ModularSymbols(11).2.modular_symbol_rep()[0][1]
sage: s.i()
0
sage: s = ModularSymbols(1,28).0.modular_symbol_rep()[0][1]; s
X^22*Y^4*{0, Infinity}
sage: s.i()
22
```

manin_symbol_rep()
Returns a representation of self as a formal sum of Manin symbols. (The result is not cached.)
EXAMPLES:

```
sage: M = ModularSymbols(11,4)
sage: s = M.1.modular_symbol_rep()[0][1]; s
X^2*{-1/6, 0}
sage: s.manin_symbol_rep()
-[Y^2,(1,1)] - 2*[X*Y,(-1,0)] - [X^2,(-6,1)] - [X^2,(-1,0)]
sage: M(s.manin_symbol_rep()) == M([2,-1/6,0])
True
```

polynomial_part()
Return the polynomial part of this symbol, i.e. for a symbol of the form $X^iY^{k-2-i}\{\alpha,\beta\}$, return X^iY^{k-2-i}.
EXAMPLES:

```
sage: s = ModularSymbols(11).2.modular_symbol_rep()[0][1]
sage: s.polynomial_part()
1
sage: s = ModularSymbols(1,28).0.modular_symbol_rep()[0][1]; s
X^22*Y^4*{0, Infinity}
sage: s.polynomial_part()
X^22*Y^4
```

space()
The list of Manin symbols to which this symbol belongs.
EXAMPLES:

```
sage: s = ModularSymbols(11).2.modular_symbol_rep()[0][1]
sage: s.space()
Manin Symbol List of weight 2 for Gamma0(11)
```

weight()
Return the weight of the modular symbols space to which this symbol belongs; i.e. for a symbol of the form $X^iY^{k-2-i}\{\alpha,\beta\}$, return k.
EXAMPLES:

```
sage: s = ModularSymbols(1,28).0.modular_symbol_rep()[0][1]
sage: s.weight()
28
```

43.7 Manin symbols

This module defines the class ManinSymbol. A Manin Symbol of weight k, level N has the form $[P(X,Y),(u:v)]$ where $P(X,Y) \in \mathbb{Z}[X,Y]$ is homogeneous of weight $k-2$ and $(u:v) \in \mathbb{P}^1(\mathbb{Z}/N\mathbb{Z})$. The ManinSymbol class holds a "monomial Manin Symbol" of the simpler form $[X^iY^{k-2-i},(u:v)]$, which is stored as a triple (i,u,v); the weight and level are obtained from the parent structure, which is a ManinSymbolList.

Integer matrices $[a,b;c,d]$ act on Manin Symbols on the right, sending $[P(X,Y),(u,v)]$ to $[P(aX+bY,cX+dY),(u,v)g]$. Diagonal matrices (with $b=c=0$, such as $I=[-1,0;0,1]$ and $J=[-1,0;0,-1]$) and anti-diagonal matrices (with $a=d=0$, such as $S=[0,-1;1,0]$) map monomiai Manin Symbols to monomial Manin Symbols, up to a scalar factor. For general matrices (such as $T=[0,1,-1,-1]$ and $T^2=[-1,-1;0,1]$) the image of a monomial Manin Symbol is expressed as a formal sum of monomial Manin Symbols, with integer coefficients.

There are various different classes holding lists of Manin symbols of different types. The hierarchy is as follows:

```
class ManinSymbolList(SageObject)

class ManinSymbolList_group(ManinSymbolList)
    class ManinSymbolList_gamma0(ManinSymbolList_group)
    class ManinSymbolList_gamma1(ManinSymbolList_group)
    class ManinSymbolList_gamma_h(ManinSymbolList_group)

class ManinSymbolList_character(ManinSymbolList)
```

class ManinSymbol (*parent, t*)

A Manin symbol $[X^i \cdot Y^{k-2-i}, (u, v)]$.

INPUT:

- `parent` - ManinSymbolList.
- `t` - a 3-tuple (i, u, v) of integers.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbol, ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,2)
sage: s = ManinSymbol(m,(2,2,3)); s
(2,3)
sage: s == loads(dumps(s))
True

::

sage: m = ManinSymbolList_gamma0(5,8)
sage: s = ManinSymbol(m,(2,2,3)); s
[X^2*Y^4,(2,3)]
```

apply (*a, b, c, d*)

Return the image of self under the matrix $[a, b; c, d]$.

Not implemented for raw ManinSymbol objects, only for members of ManinSymbolLists.

EXAMPLE:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbol, ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,2)
sage: m.apply(10,[1,0,0,1]) # not implemented for base class
```

copy ()

Return a copy of this ManinSymbol.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbol, ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: s = ManinSymbol(m,(2,2,3))
sage: s2=s.copy()
sage: s2
[X^2*Y^4,(2,3)]
```

endpoints (*N=None*)

Returns cusps $alpha$, $beta$ such that this Manin symbol, viewed as a symbol for level N, is $X^i * Y^{k-2-i}\{alpha, beta\}$.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbol, ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: s = ManinSymbol(m,(2,2,3)); s
[X^2*Y^4,(2,3)]
sage: s.endpoints()
(1/3, 1/2)
```

i

Return the i field of this ManinSymbol (i, u, v).

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbol, ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: s = ManinSymbol(m,(2,2,3))
sage: s._ManinSymbol__get_i()
2
sage: s.i
2
```

level()

Return the level of this ManinSymbol.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbol, ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: s = ManinSymbol(m,(2,2,3))
sage: s.level()
5
```

lift_to_sl2z(*N=None*)

Returns a lift of this Manin Symbol to $SL_2(\mathbb{Z})$.

If this Manin symbol is (c, d) and N is its level, this function returns a list $[a, b, c', d']$ that defines a 2x2 matrix with determinant 1 and integer entries, such that $c = c'$ (mod N) and $d = d'$ (mod N).

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbol, ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: s = ManinSymbol(m,(2,2,3))
sage: s
[X^2*Y^4,(2,3)]
sage: s.lift_to_sl2z()
[1, 1, 2, 3]
```

modular_symbol_rep()

Returns a representation of self as a formal sum of modular symbols.

The result is not cached.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbol, ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: s = ManinSymbol(m,(2,2,3))
sage: s.modular_symbol_rep()
 144*X^6*{1/3, 1/2} - 384*X^5*Y*{1/3, 1/2} + 424*X^4*Y^2*{1/3, 1/2} - 248*X^3*Y^3*{1/3, 1/2}
```

parent()

Return the parent of this ManinSymbol.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbol, ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: s = ManinSymbol(m,(2,2,3))
sage: s.parent()
Manin Symbol List of weight 8 for Gamma0(5)
```

tuple()

Return the 3-tuple (i, u, v) of this ManinSymbol.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbol, ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: s = ManinSymbol(m,(2,2,3))
sage: s.tuple()
(2, 2, 3)
```

u

Return the u field of this ManinSymbol (i, u, v).

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbol, ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: s = ManinSymbol(m,(2,2,3))
sage: s.u # indirect doctest
2
```

v

Return the v field of this ManinSymbol (i, u, v).

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbol, ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: s = ManinSymbol(m,(2,2,3))
sage: s.v # indirect doctest
3
```

weight()

Return the weight of this ManinSymbol.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbol, ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: s = ManinSymbol(m,(2,2,3))
sage: s.weight()
8
```

class **ManinSymbolList**(*weight, list*)

Base class for lists of all Manin symbols for a given weight, group or character.

apply(*j, X*)

Apply the matrix $X = [a, b; c, d]$ to the j-th Manin symbol.

Implemented in derived classes.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList
sage: m = ManinSymbolList(6,P1List(11))
sage: m.apply(10, [1,2,0,1])
...
NotImplementedError: Only implemented in derived classes
```

apply_I (j)

Apply the matrix $I = [-1, 0; 0, 1]$ to the j-th Manin symbol.

Implemented in derived classes.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList
sage: m = ManinSymbolList(6,P1List(11))
sage: m.apply_I(10)
...
NotImplementedError: Only implemented in derived classes
```

apply_S (j)

Apply the matrix $S = [0, -1; 1, 0]$ to the j-th Manin symbol.

Implemented in derived classes.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList
sage: m = ManinSymbolList(6,P1List(11))
sage: m.apply_S(10)
...
NotImplementedError: Only implemented in derived classes
```

apply_T (j)

Apply the matrix $T = [0, 1; -1, -1]$ to the j-th Manin symbol.

Implemented in derived classes.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList
sage: m = ManinSymbolList(6,P1List(11))
sage: m.apply_T(10)
...
NotImplementedError: Only implemented in derived classes
```

apply_TT (j)

Apply the matrix $TT = T^2 = [-1, -1; 0, 1]$ to the j-th Manin symbol.

Implemented in derived classes.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList
sage: m = ManinSymbolList(6,P1List(11))
sage: m.apply_TT(10)
...
NotImplementedError: Only implemented in derived classes
```

index (x)

Return the index of x in the list of Manin symbols, where x is a 3-tuple of ints. If x is not in the list, then return -1.

INPUT:

- x - 3-tuple of integers, (i, u, v) defining a valid Manin symbol, which need not be normalized.

OUTPUT:

(int) the index of the normalized Manin symbol equivalent to (i, u, v).

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList
sage: m = ManinSymbolList(6,P1List(11))
sage: m.index(m[2])
```

```
2
sage: all([i == m.index(m[i]) for i in xrange(len(m))])
True
```

manin_symbol(*i*)

Returns the i'th ManinSymbol in this ManinSymbolList.

INPUT:

- `i` - integer, a valid index of a symbol in this list.

OUTPUT:

`ManinSymbol` - the i'th Manin symbol in the list.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList
sage: m = ManinSymbolList(6,P1List(11))
sage: m.manin_symbol(3) # not implemented for base class

sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(6, 4)
sage: s = m.manin_symbol(3); s
[Y^2,(1,2)]
sage: type(s)
<class 'sage.modular.modsym.manin_symbols.ManinSymbol'>
```

manin_symbol_list()

Returns all the ManinSymbols in this ManinSymbolList as a list

Cached for subsequent calls.

OUTPUT:

a list of `ManinSymbol` objects, which is a copy of the complete list of Manin symbols.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList
sage: m = ManinSymbolList(6,P1List(11))
sage: m.manin_symbol_list() # not implemented for the base class

sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(6, 4)
sage: m.manin_symbol_list()
[[Y^2,(0,1)],
[Y^2,(1,0)],
[Y^2,(1,1)],
...
[X^2,(3,1)],
[X^2,(3,2)]]
```

normalize(*x*)

Returns a normalized ManinSymbol from x.

To be implemented in derived classes.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList
sage: m = ManinSymbolList(6,P1List(11))
sage: m.normalize((0,6,7)) # not implemented in base class
```

weight()

Returns the weight of the ManinSymbols in this ManinSymbolList.

OUTPUT:

integer - the weight of the Manin symbols in the list.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(6, 4)
sage: m.weight()
4
```

class ManinSymbolList_character(*character, weight*)

List of Manin Symbols with character.

INPUT:

- character - (DirichletCharacter) the Dirichlet character.
- weight - (integer) the weight.

EXAMPLE:

```
sage: eps = DirichletGroup(4).gen(0)
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_character
sage: m = ManinSymbolList_character(eps,2); m
Manin Symbol List of weight 2 for Gamma1(4) with character [-1]
sage: m.manin_symbol_list()
[(0,1), (1,0), (1,1), (1,2), (1,3), (2,1)]
sage: m == loads(dumps(m))
True
```

apply(*j, m*)

Apply the integer matrix $m = [a, b; c, d]$ to the j-th Manin symbol.

INPUT:

- j (integer): the index of the symbol to act on.
- m (list of ints): $[a, b, c, d]$ where $m = [a, b; c, d]$ is the matrix to be applied.

OUTPUT:

A list of pairs (j, c_i), where each c_i is an integer, j is an integer (the j-th Manin symbol), and the sum $c_i * x_i$ is the image of self under the right action of the matrix $[a, b; c, d]$. Here the right action of $g = [a, b; c, d]$ on a Manin symbol $[P(X, Y), (u, v)]$ is by definition $[P(aX + bY, cX + dY), (u, v) * g]$.

EXAMPLES:

```
sage: eps = DirichletGroup(4).gen(0)
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_character
sage: m = ManinSymbolList_character(eps,4)
sage: m[6]
(1, 0, 1)
sage: m.apply(4, [1,0,0,1])
[(4, 1)]
sage: m.apply(1, [-1,0,0,1])
[(1, -1)]
```

apply_I(*j*)

Apply the matrix $I = [-1, 0, 0, 1]$ to the j-th Manin symbol.

INPUT:

- j - (integer) a symbol index

OUTPUT:

(k, s) where k is the index of the symbol obtained by acting on the j'th symbol with I, and s is the parity of of the j'th symbol.

EXAMPLE:

```
sage: eps = DirichletGroup(4).gen(0)
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_character
sage: m = ManinSymbolList_character(eps,2); m
Manin Symbol List of weight 2 for Gamma1(4) with character [-1]
sage: m.apply_I(4)
(2, -1)
sage: [m.apply_I(i) for i in xrange(len(m))]
[(0, 1), (1, -1), (4, -1), (3, -1), (2, -1), (5, 1)]
```

apply_S (*j*)

Apply the matrix $S = [0, 1; -1, 0]$ to the j-th Manin symbol.

INPUT:

- j - (integer) a symbol index.

OUTPUT:

(k, s) where k is the index of the symbol obtained by acting on the j'th symbol with S, and s is the parity of of the j'th symbol.

EXAMPLE:

```
sage: eps = DirichletGroup(4).gen(0)
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_character
sage: m = ManinSymbolList_character(eps,2); m
Manin Symbol List of weight 2 for Gamma1(4) with character [-1]
sage: m.apply_S(4)
(2, -1)
sage: [m.apply_S(i) for i in xrange(len(m))]
[(1, 1), (0, -1), (4, 1), (5, -1), (2, -1), (3, 1)]
```

apply_T (*j*)

Apply the matrix $T = [0, 1, -1, -1]$ to the j-th Manin symbol.

INPUT:

- j - (integer) a symbol index.

OUTPUT:

A list of pairs (j, c_i), where each c_i is an integer, j is an integer (the j-th Manin symbol), and the sum $c_i * x_i$ is the image of self under the right action of the matrix T.

EXAMPLE:

```
sage: eps = DirichletGroup(4).gen(0)
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_character
sage: m = ManinSymbolList_character(eps,2); m
Manin Symbol List of weight 2 for Gamma1(4) with character [-1]
sage: m.apply_T(4)
[(1, -1)]
sage: [m.apply_T(i) for i in xrange(len(m))]
[[(4, 1)], [(0, -1)], [(3, 1)], [(5, 1)], [(1, -1)], [(2, 1)]]
```

apply_TT (*j*)

Apply the matrix $TT = [-1, -1, 0, 1]$ to the j-th Manin symbol.

INPUT:

- j - (integer) a symbol index

OUTPUT:

A list of pairs (j, c_i), where each c_i is an integer, j is an integer (the j-th Manin symbol), and the sum $c_i * x_i$ is the image of self under the right action of the matrix T^2.

EXAMPLE:

```
sage: eps = DirichletGroup(4).gen(0)
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_character
sage: m = ManinSymbolList_character(eps,2); m
Manin Symbol List of weight 2 for Gamma1(4) with character [-1]
sage: m.apply_TT(4)
[(0, 1)]
sage: [m.apply_TT(i) for i in xrange(len(m))]
[[(1, -1)], [(4, -1)], [(5, 1)], [(2, 1)], [(0, 1)], [(3, 1)]]
```

character()

Return the character of this ManinSymbolList_character object.

OUTPUT:

The Dirichlet character of this Manin symbol list.

EXAMPLE:

```
sage: eps = DirichletGroup(4).gen(0)
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_character
sage: m = ManinSymbolList_character(eps,2); m
Manin Symbol List of weight 2 for Gamma1(4) with character [-1]
sage: m.character()
[-1]
```

index(x)

Returns the index in the list of standard Manin symbols of a symbol that is equivalent, modulo a scalar s, to x. Returns the index and the scalar.

If x is not in the list, return (-1, 0).

INPUT:

- x - 3-tuple of integers (i, u, v), defining an element of this list of Manin symbols, which need not be normalized.

OUTPUT:

(i, s) where i (int) is the index of the Manin symbol equivalent to (i, u, v) (or -1) and s is the scalar (an element of the base field) or the int 0.

EXAMPLE:

```
sage: eps = DirichletGroup(4).gen(0)
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_character
sage: m = ManinSymbolList_character(eps,4); m
Manin Symbol List of weight 4 for Gamma1(4) with character [-1]
sage: [m.index(s.tuple()) for s in m.manin_symbol_list()]
[(0, 1),
(1, 1),
(2, 1),
(3, 1),
...
(16, 1),
(17, 1)]
```

level()

Return the level of this ManinSymbolList.

OUTPUT:

integer - the level of the symbols in this list.

EXAMPLES:

```
sage: eps = DirichletGroup(4).gen(0)
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_character
```

```
sage: ManinSymbolList_character(eps,4).level()
4
```

normalize(*x*)

Returns the normalization of the Manin Symbol `x` with respect to this list, togther with the normalizing scalar.

INPUT:

- `x` - 3-tuple of integers `(i,u,v)`, defining an element of this list of Manin symbols, which need not be normalized.

OUTPUT:

`((i,u,v),s)`, where `(i,u,v)` is the normalized Manin symbol equivalent to `x`, and `s` is the normalizing scalar.

EXAMPLE:

```
sage: eps = DirichletGroup(4).gen(0)
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_character
sage: m = ManinSymbolList_character(eps,4); m
Manin Symbol List of weight 4 for Gamma1(4) with character [-1]
sage: [m.normalize(s.tuple()) for s in m.manin_symbol_list()]
[((0, 0, 1), 1),
((0, 1, 0), 1),
((0, 1, 1), 1),
...
((2, 1, 3), 1),
((2, 2, 1), 1)]
```

class ManinSymbolList_gamma0(*level, weight*)

Class for Manin Symbols for $\Gamma_0(N)$.

INPUT:

- `level` - (integer): the level.
- `weight` - (integer): the weight.

EXAMPLE:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,2); m
Manin Symbol List of weight 2 for Gamma0(5)
sage: m.manin_symbol_list()
[(0,1), (1,0), (1,1), (1,2), (1,3), (1,4)]
sage: m = ManinSymbolList_gamma0(6,4); m
Manin Symbol List of weight 4 for Gamma0(6)
sage: len(m)
36
```

class ManinSymbolList_gamma1(*level, weight*)

Class for Manin Symbols for $\Gamma_1(N)$.

INPUT:

- `level` - (integer): the level.
- `weight` - (integer): the weight.

EXAMPLE:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma1
sage: m = ManinSymbolList_gamma1(5,2); m
Manin Symbol List of weight 2 for Gamma1(5)
sage: m.manin_symbol_list()
[(0,1),
(0,2),
(0,3),
...
(4,3),
(4,4)]
sage: m = ManinSymbolList_gamma1(6,4); m
Manin Symbol List of weight 4 for Gamma1(6)
sage: len(m)
72
sage: m == loads(dumps(m))
True
```

class ManinSymbolList_gamma_h(*group, weight*)

Class for Manin Symbols for $\Gamma_H(N)$.

INPUT:

- `group` - (integer): the congruence subgroup.
- `weight` - (integer): the weight.

EXAMPLE:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma_h
sage: G = GammaH(117, [4])
sage: m = ManinSymbolList_gamma_h(G,2); m
Manin Symbol List of weight 2 for Congruence Subgroup Gamma_H(117) with H generated by [4]
sage: m.manin_symbol_list()[100:110]
[(1,88),
(1,89),
(1,90),
(1,91),
(1,92),

(1,96),
(1,97)]
sage: len(m.manin_symbol_list())
2016
sage: m == loads(dumps(m))
True
```

group()

Return the group associated to self.

EXAMPLES:

```
sage: ModularSymbols(GammaH(12, [5]), 2).manin_symbols().group()
Congruence Subgroup Gamma_H(12) with H generated by [5]
```

class ManinSymbolList_group(*level, weight, syms*)

Base class for Manin symbol lists for a given group.

INPUT:

- `level` - integer level

- `weight` - integer weight
- `syms` - something with a normalize and list method, e.g., P1List.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_group
sage: ManinSymbolList_group(11, 2, P1List(11))
<class 'sage.modular.modsym.manin_symbols.ManinSymbolList_group'>
```

apply (*j*, *m*)

Apply the matrix $m = [a, b; c, d]$ to the j-th Manin symbol.

INPUT:

- `j` - (int) a symbol index
- `m = [a, b, c, d]` a list of 4 integers, which defines a 2x2 matrix.

OUTPUT:

a list of pairs (j_i, α_i), where each α_i is a nonzero integer, j_i is an integer (index of the j_i-th Manin symbol), and $\sum_i \alpha_i x_{j_i}$ is the image of the j-th Manin symbol under the right action of the matrix [a,b;c,d]. Here the right action of g=[a,b;c,d] on a Manin symbol $[P(X, Y), (u, v)]$ is $[P(aX + bY, cX + dY), (u, v)g]$.

EXAMPLE:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: m.apply(40,[2,3,1,1])
[(0, 729), (6, 2916), (12, 4860), (18, 4320), (24, 2160), (30, 576), (36, 64)]
```

apply_I (*j*)

Apply the matrix $I = [-1, 0, 0, 1]$ to the j-th Manin symbol.

INPUT:

- `j` - (int) a symbol index

OUTPUT:

`(k, s)` where k is the index of the symbol obtained by acting on the j'th symbol with I, and s is the parity of of the j'th symbol (a Python `int`, either 1 or -1)

EXAMPLE:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: m.apply_I(4)
(3, 1)
sage: [m.apply_I(i) for i in xrange(10)]
[(0, 1),
(1, 1),
(5, 1),
(4, 1),
(3, 1),
(2, 1),
(6, -1),
(7, -1),
(11, -1),
(10, -1)]
```

apply_S (*j*)

Apply the matrix $S = [0, -1, 1, 0]$ to the j-th Manin symbol.

INPUT:

- `j` - (int) a symbol index

OUTPUT:

`(k, s)` where k is the index of the symbol obtained by acting on the j'th symbol with S, and s is the parity of of the j'th symbol (a Python `int`, either 1 or -1).

EXAMPLE:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: m.apply_S(4)
(40, 1)
sage: [m.apply_S(i) for i in xrange(len(m))]
[(37, 1),
(36, 1),
(41, 1),
(39, 1),
(40, 1),
(38, 1),
(31, -1),
(30, -1),
(35, -1),
(33, -1),
(34, -1),
(32, -1),
...
(4, 1),
(2, 1)]
```

apply_T (*j*)

Apply the matrix $T = [0, 1, -1, -1]$ to the j-th Manin symbol.

INPUT:

- `j` - (int) a symbol index

OUTPUT: see documentation for apply()

EXAMPLE:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: m.apply_T(4)
[(3, 1), (9, -6), (15, 15), (21, -20), (27, 15), (33, -6), (39, 1)]
sage: [m.apply_T(i) for i in xrange(10)]
[[(5, 1), (11, -6), (17, 15), (23, -20), (29, 15), (35, -6), (41, 1)],
[(0, 1), (6, -6), (12, 15), (18, -20), (24, 15), (30, -6), (36, 1)],
[(4, 1), (10, -6), (16, 15), (22, -20), (28, 15), (34, -6), (40, 1)],
[(2, 1), (8, -6), (14, 15), (20, -20), (26, 15), (32, -6), (38, 1)],
[(3, 1), (9, -6), (15, 15), (21, -20), (27, 15), (33, -6), (39, 1)],
[(1, 1), (7, -6), (13, 15), (19, -20), (25, 15), (31, -6), (37, 1)],
[(5, 1), (11, -5), (17, 10), (23, -10), (29, 5), (35, -1)],
[(0, 1), (6, -5), (12, 10), (18, -10), (24, 5), (30, -1)],
[(4, 1), (10, -5), (16, 10), (22, -10), (28, 5), (34, -1)],
[(2, 1), (8, -5), (14, 10), (20, -10), (26, 5), (32, -1)]]
```

apply_TT (*j*)

Apply the matrix $TT = [-1, -1, 0, 1]$ to the j-th Manin symbol.

INPUT:

- `j` - (int) a symbol index

OUTPUT: see documentation for apply()

EXAMPLE:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: m.apply_TT(4)
[(38, 1)]
sage: [m.apply_TT(i) for i in xrange(10)]
[[(37, 1)],
[(41, 1)],
[(39, 1)],
[(40, 1)],
[(38, 1)],
[(36, 1)],
[(31, -1), (37, 1)],
[(35, -1), (41, 1)],
[(33, -1), (39, 1)],
[(34, -1), (40, 1)]]
```

level()

Return the level of this ManinSymbolList.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma0
sage: ManinSymbolList_gamma0(5,2).level()
5

sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma1
sage: ManinSymbolList_gamma1(51,2).level()
51

sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma_h
sage: ManinSymbolList_gamma_h(GammaH(117, [4]),2).level()
117
```

normalize(*x*)

Returns the normalization of the ModSym `x` with respect to this list.

INPUT:

- `x` - (3-tuple of ints) a tuple defining a ManinSymbol.

OUTPUT:

`(i,u,v)` - (3-tuple of ints) another tuple defining the associated normalized ManinSymbol.

EXAMPLE:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma0
sage: m = ManinSymbolList_gamma0(5,8)
sage: [m.normalize(s.tuple()) for s in m.manin_symbol_list()][:10]
[(0, 0, 1),
(0, 1, 0),
(0, 1, 1),
(0, 1, 2),
(0, 1, 3),
(0, 1, 4),
(1, 0, 1),
(1, 1, 0),
(1, 1, 1),
(1, 1, 2)]
```

is_ManinSymbol(*x*)

Returns True if `x` is a ManinSymbol.

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbol, ManinSymbolList_gamma0, is_Mani
sage: m = ManinSymbolList_gamma0(6, 4)
sage: is_ManinSymbol(m[3])
False
sage: s = ManinSymbol(m,m[3])
sage: s
[Y^2,(1,2)]
sage: is_ManinSymbol(s)
True
```

43.8 Space of boundary modular symbols.

Used mainly for computing the cuspidal subspace of modular symbols. The space of boundary symbols of sign 0 is isomorphic as a Hecke module to the dual of the space of Eisenstein series, but this does not give a useful method of computing Eisenstein series, since there is no easy way to extract the constant terms.

We represent boundary modular symbols as a sum of Manin symbols of the form $[P, u/v]$, where u/v is a cusp for our group G. The group of boundary modular symbols naturally embeds into a vector space $B_k(G)$ (see Stein, section 8.4, or Merel, section 1.4, where this space is called $\mathbf{C}[\Gamma\backslash\mathbf{Q}]_k$, for a definition), which is a finite dimensional $\mathbf{Q}$ vector space of dimension equal to the number of cusps for G. The embedding takes $[P, u/v]$ to $P(u, v) \cdot [(u, v)]$. We represent the basis vectors by pairs $[(u, v)]$ with u, v coprime. On $B_k(G)$, we have the relations

$$[\gamma \cdot (u, v)] = [(u, v)]$$

for all $\gamma \in G$ and

$$[(\lambda u, \lambda v)] = \mathrm{sign}(\lambda)^k [(u, v)]$$

for all $\lambda \in \mathbf{Q}^\times$.

It's possible for these relations to kill a class, i.e., for a pair $[(u, v)]$ to be 0. For example, when $N = 4$ and $k = 3$ then $(-1, -2)$ is equivalent mod $\Gamma_1(4)$ to $(1, 2)$ since $2 = -2 \bmod 4$ and $1 = -1 \bmod 2$. But since k is odd, $[(-1, -2)]$ is also equivalent to $-[(1, 2)]$. Thus this symbol is equivalent to its negative, hence 0 (notice that this wouldn't be the case in characteristic 2). This happens for any irregular cusp when the weight is odd; there are no irregular cusps on $\Gamma_1(N)$ except when $N = 4$, but there can be more on Γ_H groups. See also prop 2.30 of Stein's Ph.D. thesis.

In addition, in the case that our space is of sign $\sigma = 1$ or -1, we also have the relation $[(-u, v)] = \sigma \cdot [(u, v)]$. This relation can also combine with the above to kill a cusp class - for instance, take (u,v) = (1,3) for $\Gamma_1(5)$. Then since the cusp $\frac{1}{3}$ is $\Gamma_1(5)$-equivalent to the cusp $-\frac{1}{3}$, we have that $[(1, 3)] = [(-1, 3)]$. Now, on the minus subspace, we also have that $[(-1, 3)] = -[(1, 3)]$, which means this class must vanish. Notice that this cannot be used to show that $[(1, 0)]$ or $[(0, 1)]$ is 0.

Note: Special care must be taken when working with the images of the cusps 0 and ∞ in $B_k(G)$. For all cusps *except* 0 and ∞, multiplying the cusp by -1 corresponds to taking $[(u, v)]$ to $[(-u, v)]$ in $B_k(G)$. This means that $[(u, v)]$ is equivalent to $[(-u, v)]$ whenever $\frac{u}{v}$ is equivalent to $-\frac{u}{v}$, except in the case of 0 and ∞. We have the following conditions for $[(1, 0)]$ and $[(0, 1)]$:

- $[(0, 1)] = \sigma \cdot [(0, 1)]$, so $[(0, 1)]$ is 0 exactly when $\sigma = -1$.
- $[(1, 0)] = \sigma \cdot [(-1, 0)]$ and $[(1, 0)] = (-1)^k [(-1, 0)]$, so $[(1, 0)] = 0$ whenever $\sigma \neq (-1)^k$.

Note: For all the spaces of boundary symbols below, no work is done to determine the cusps for G at creation time. Instead, cusps are added as they are discovered in the course of computation. As a result, the rank of a space can change as a computation proceeds.

class BoundarySpace(*group=Modular Group SL(2, Z), weight=2, sign=0, base_ring=Rational Field, character=None*)

character()

Return the Dirichlet character assocaited to this space of boundary modular symbols.

EXAMPLES:

```
sage: ModularSymbols(DirichletGroup(7).0, 6).boundary_space().character()
[zeta6]
```

free_module()

Return the underlying free module for self.

EXAMPLES:

```
sage: B = ModularSymbols(Gamma1(7), 5, sign=-1).boundary_space()
sage: B.free_module()
Sparse vector space of dimension 0 over Rational Field
sage: x = B(Cusp(0)) ; y = B(Cusp(1/7)) ; B.free_module()
Sparse vector space of dimension 2 over Rational Field
```

gen(*i=0*)

Return the i-th generator of this space.

EXAMPLES:

```
sage: B = ModularSymbols(Gamma0(24), 4).boundary_space()
sage: B.gen(0)
...
ValueError: only 0 generators known for Space of Boundary Modular Symbols for Congruence Sub
sage: B(Cusp(1/3))
[1/3]
sage: B.gen(0)
[1/3]
```

group()

Return the congruence subgroup associated to this space of boundary modular symbols.

EXAMPLES:

```
sage: ModularSymbols(GammaH(14,[3]), 2).boundary_space().group()
Congruence Subgroup Gamma_H(14) with H generated by [3]
```

is_ambient()

Return True if self is a space of boundary symbols associated to an ambient space of modular symbols.

EXAMPLES:

```
sage: M = ModularSymbols(Gamma1(6), 4)
sage: M.is_ambient()
True
sage: M.boundary_space().is_ambient()
True
```

rank()

The rank of the space generated by boundary symbols that have been found so far in the course of computing the boundary map.

> **Warning:** This number may change as more elements are coerced into this space!! (This is an implementation detail that will likely change.)

EXAMPLES:

```
sage: M = ModularSymbols(Gamma0(72), 2) ; B = M.boundary_space()
sage: B.rank()
0
sage: _ = [ B(x) for x in M.basis() ]
sage: B.rank()
16
```

sign()

Return the sign of the complex conjugation involution on this space of boundary modular symbols.

EXAMPLES:

```
sage: ModularSymbols(13,2,sign=-1).boundary_space().sign()
-1
```

weight()

Return the weight of this space of boundary modular symbols.

EXAMPLES:

```
sage: ModularSymbols(Gamma1(9), 5).boundary_space().weight()
5
```

class **BoundarySpaceElement**(*parent, x*)

coordinate_vector()

Return self as a vector on the QQ-vector space with basis self.parent()._known_cusps().

EXAMPLES:

```
sage: B = ModularSymbols(18,4,sign=1).boundary_space()
sage: x = B(Cusp(1/2)) ; x
[1/2]
sage: x.coordinate_vector()
(1)
sage: ((18/5)*x).coordinate_vector()
(18/5)
sage: B(Cusp(0))
[0]
sage: x.coordinate_vector()
(1)
sage: x = B(Cusp(1/2)) ; x
[1/2]
sage: x.coordinate_vector()
(1, 0)
```

class **BoundarySpace_wtk_eps**(*eps, weight, sign=0*)

class **BoundarySpace_wtk_g0**(*level, weight, sign, F*)

class **BoundarySpace_wtk_g1**(*level, weight, sign, F*)

class **BoundarySpace_wtk_gamma_h**(*group, weight, sign, F*)

43.9 Heilbronn matrix computation

class **Heilbronn**()

apply()

Return a list of pairs ((c,d),m), which is obtained as follows: 1) Compute the images (a,b) of the vector (u,v) (mod N) acted on by each of the HeilbronnCremona matrices in self. 2) Reduce each (a,b) to canonical form (c,d) using p1normalize 3) Sort. 4) Create the list ((c,d),m), where m is the number of times that (c,d) appears in the list created in steps 1-3 above. Note that the pairs ((c,d),m) are sorted lexicographically by (c,d).

INPUT:

- `u, v, N` - integers

OUTPUT: list

EXAMPLES:

```
sage: H = sage.modular.modsym.heilbronn.HeilbronnCremona(2); H
The Cremona-Heilbronn matrices of determinant 2
sage: H.apply(1,2,7)
[((1, 5), 1), ((1, 6), 1), ((1, 1), 1), ((1, 4), 1)]
```

to_list()

Return the list of Heilbronn matrices corresponding to self. Each matrix is given as a list of four ints.

EXAMPLES:

```
sage: H = HeilbronnCremona(2); H
The Cremona-Heilbronn matrices of determinant 2
sage: H.to_list()
[[1, 0, 0, 2], [2, 0, 0, 1], [2, 1, 0, 1], [1, 0, 1, 2]]
```

class **HeilbronnCremona**()

p

class **HeilbronnMerel**()

n

hecke_images_gamma0_weight2()

INPUT:

- `u, v, N` - integers so that gcd(u,v,N) = 1
- `indices` - a list of positive integers
- `R` - matrix over QQ that writes each elements of P1 = P1List(N) in terms of a subset of P1.

OUTPUT: a dense matrix with rational entries whose columns are the images T_n(x) for n in indices and x the Manin symbol (u,v), expressed in terms of the basis.

EXAMPLES:

```
sage: M = ModularSymbols(23,2,1)
sage: A = sage.modular.modsym.heilbronn.hecke_images_gamma0_weight2(1,0,23,[1..6],M.manin_gens_t
sage: A
[ 1  0  0]
[ 3  0 -1]
[ 4 -2 -1]
[ 7 -2 -2]
[ 6  0 -2]
[12 -2 -4]
sage: z = M((1,0))
sage: [M.T(n)(z).element() for n in [1..6]]
[(1, 0, 0), (3, 0, -1), (4, -2, -1), (7, -2, -2), (6, 0, -2), (12, -2, -4)]
```

hecke_images_gamma0_weight_k()

INPUT:

- u, v, N - integers so that gcd(u,v,N) = 1
- i - integer with 0 = i = k-2
- k - weight
- indices - a list of positive integers
- R - matrix over QQ that writes each elements of P1 = P1List(N) in terms of a subset of P1.

OUTPUT: a dense matrix with rational entries whose columns are the images T_n(x) for n in indices and x the Manin symbol $[X^i * Y^(k-2-i), (u,v)]$, expressed in terms of the basis.

EXAMPLES:

```
sage: M = ModularSymbols(15,6,sign=-1)
sage: R = M.manin_gens_to_basis()
sage: sage.modular.modsym.heilbronn.hecke_images_gamma0_weight_k(4,1,3,15,6,[1,11,12], R)
[       0        0      1/8     -1/8        0        0        0        0]
[-4435/22 -1483/22     -112 -4459/22  2151/22 -5140/11  4955/22  2340/11]
[ 1253/22  1981/22       -2  3177/22 -1867/22  6560/11 -7549/22  -612/11]
sage: x = M((3,4,1)) ; x.element()
(0, 0, 1/8, -1/8, 0, 0, 0, 0)
sage: M.T(11)(x).element()
(-4435/22, -1483/22, -112, -4459/22, 2151/22, -5140/11, 4955/22, 2340/11)
sage: M.T(12)(x).element()
(1253/22, 1981/22, -2, 3177/22, -1867/22, 6560/11, -7549/22, -612/11)
```

hecke_images_nonquad_character_weight2()

Return images of the Hecke operators T_n for n in the list indices, where chi must be a quadratic Dirichlet character with values in QQ.

R is assumed to be the relation matrix of a weight modular symbols space over QQ with character chi.

INPUT:

- u, v, N - integers so that gcd(u,v,N) = 1
- indices - a list of positive integers
- chi - a Dirichlet character that takes values in a nontrivial extension of QQ.
- R - matrix over QQ that writes each elements of P1 = P1List(N) in terms of a subset of P1.

OUTPUT: a dense matrix with entries in the field QQ(chi) (the values of chi) whose columns are the images T_n(x) for n in indices and x the Manin symbol (u,v), expressed in terms of the basis.

EXAMPLES:

```
sage: chi = DirichletGroup(13).0^2
sage: M = ModularSymbols(chi)
sage: eps = M.character()
sage: R = M.manin_gens_to_basis()
sage: sage.modular.modsym.heilbronn.hecke_images_nonquad_character_weight2(1,0,13,[1,2,6],eps,R)
[           1            0            0            0]
[   zeta6 + 2            0            0           -1]
[           7 -2*zeta6 + 1   -zeta6 - 1     -2*zeta6]
sage: x = M((1,0)); x.element()
(1, 0, 0, 0)
sage: M.T(2)(x).element()
(zeta6 + 2, 0, 0, -1)
sage: M.T(6)(x).element()
(7, -2*zeta6 + 1, -zeta6 - 1, -2*zeta6)
```

hecke_images_quad_character_weight2()

INPUT:

- u, v, N - integers so that gcd(u,v,N) = 1
- indices - a list of positive integers
- chi - a Dirichlet character that takes values in QQ
- R - matrix over QQ(chi) that writes each elements of P1 = P1List(N) in terms of a subset of P1.

OUTPUT: a dense matrix with entries in the rational field QQ (the values of chi) whose columns are the images T_n(x) for n in indices and x the Manin symbol (u,v), expressed in terms of the basis.

EXAMPLES:

```
sage: chi = DirichletGroup(29,QQ).0
sage: M = ModularSymbols(chi)
sage: R = M.manin_gens_to_basis()
sage: sage.modular.modsym.heilbronn.hecke_images_quad_character_weight2(2,1,29,[1,3,4],chi,R)
[ 0  0  0  0  0 -1]
[ 0  1  0  1  1  1]
[ 0 -2  0  2 -2 -1]
sage: x = M((2,1)) ; x.element()
(0, 0, 0, 0, 0, -1)
sage: M.T(3)(x).element()
(0, 1, 0, 1, 1, 1)
sage: M.T(4)(x).element()
(0, -2, 0, 2, -2, -1)
```

43.10 List of Elements of $\mathbb{P}^1(\mathbf{Z}/N\mathbf{Z})$

class P1List()

The class for $\mathbb{P}^1(\mathbf{Z}/N\mathbf{Z})$, the projective line modulo N.

EXAMPLES:

```
sage: P = P1List(12); P
The projective line over the integers modulo 12
sage: list(P)
[(0, 1), (1, 0), (1, 1), (1, 2), (1, 3), (1, 4), (1, 5), (1, 6), (1, 7), (1, 8), (1, 9), (1, 10)]
```

Saving and loading works.

```
sage: loads(dumps(P)) == P
True
```

N()

Returns the level or modulus of this P1List.

EXAMPLES:

```
sage: L = P1List(120)
sage: L.N()
120
```

apply_I()

Return the index of the result of applying the matrix $I = [-1, 0; 0, 1]$ to the i'th element of this P1List.

INPUT:

- i - integer (the index of the element to act on).

EXAMPLES:

```
sage: L = P1List(120)
sage: L[10]
(1, 9)
sage: L.apply_I(10)
112
sage: L[112]
(1, 111)
sage: L.normalize(-1,9)
(1, 111)

This operation is an involution:

sage: all([L.apply_I(L.apply_I(i))==i for i in xrange(len(L))])
True
```

apply_S()

Return the index of the result of applying the matrix $S = [0, -1; 1, 0]$ to the i'th element of this P1List.

INPUT:

- i - integer (the index of the element to act on).

EXAMPLES:

```
sage: L = P1List(120)
sage: L[10]
(1, 9)
sage: L.apply_S(10)
159
sage: L[159]
(3, 13)
sage: L.normalize(-9,1)
(3, 13)

This operation is an involution:

sage: all([L.apply_S(L.apply_S(i))==i for i in xrange(len(L))])
True
```

apply_T()

Return the index of the result of applying the matrix $T = [0, 1; -1, -1]$ to the i'th element of this P1List.

INPUT:

- i - integer (the index of the element to act on).

EXAMPLES:

```
sage: L = P1List(120)
sage: L[10]
(1, 9)
sage: L.apply_T(10)
157
sage: L[157]
(3, 10)
sage: L.normalize(9,-10)
(3, 10)

This operation has order three:

sage: all([L.apply_T(L.apply_T(L.apply_T(i)))==i for i in xrange(len(L))])
True
```

index()

Returns the index of the class of (u, v) in the fixed list of representatives of $\mathbb{P}^1(\mathbf{Z}/N\mathbf{Z})$.

INPUT:

•u, v - integers, with $\gcd(u, v, N) = 1$.

OUTPUT:

•i - the index of u, v, in the P1list.

EXAMPLES:

```
sage: L = P1List(120)
sage: L[100]
(1, 99)
sage: L.index(1,99)
100
sage: all([L.index(L[i][0],L[i][1])==i for i in range(len(L))])
True
```

index_of_normalized_pair()

Returns the index of the class of (u, v) in the fixed list of representatives of $\mathbb{P}^1(\mathbf{Z}/N\mathbf{Z})$.

INPUT:

•u, v - integers, with $\gcd(u, v, N) = 1$, normalized so they lie in the list.

OUTPUT:

•i - the index of $(u : v)$, in the P1list.

EXAMPLES:

```
sage: L = P1List(120)
sage: L[100]
(1, 99)
sage: L.index_of_normalized_pair(1,99)
100
sage: all([L.index_of_normalized_pair(L[i][0],L[i][1])==i for i in range(len(L))])
True
```

lift_to_sl2z()

Lift the i'th element of this P1list to an element of $SL(2, \mathbf{Z})$.

If the i'th element is (c, d), this function computes and returns a list $[a, b, c', d']$ that defines a 2x2 matrix with determinant 1 and integer entries, such that $c = c'$ (mod N) and $d = d'$ (mod N).

INPUT:

•i - integer (the index of the element to lift).

EXAMPLES:

```
sage: p = P1List(11)
sage: p.list()[3]
(1, 2)

sage: p.lift_to_sl2z(3)
[0, -1, 1, 2]
```

AUTHORS:

•Justin Walker

list()

Returns the underlyng list of this P1List object.

EXAMPLES:

```
sage: L = P1List(8)
sage: type(L)
<type 'sage.modular.modsym.p1list.P1List'>
sage: type(L.list())
<type 'list'>
```

normalize()

Returns a normalised element of $\mathbb{P}^1(\mathbf{Z}/N\mathbf{Z})$.

INPUT:

- u, v - integers, with $\gcd(u, v, N) = 1$.

OUTPUT:

- a 2-tuple (uu, vv) where $(uu : vv)$ is a *normalized* representative of $(u : v)$.

NOTE: See also normalize_with_scalar() which also returns the normalizing scalar.

EXAMPLES:

```
sage: L = P1List(120)
sage: (u,v) = (555555555,7777)
sage: uu,vv = L.normalize(555555555,7777)
sage: (uu,vv)
(15, 13)
sage: (uu*v-vv*u) % L.N() == 0
True
```

normalize_with_scalar()

Returns a normalised element of $\mathbb{P}^1(\mathbf{Z}/N\mathbf{Z})$, together with the normalizing scalar.

INPUT:

- u, v - integers, with $\gcd(u, v, N) = 1$.

OUTPUT:

- a 3-tuple (uu, vv, ss) where $(uu : vv)$ is a *normalized* representative of $(u : v)$, and ss is a scalar such that $(ss * uu, ss * vv) = (u, v) \pmod N$.

EXAMPLES:

```
sage: L = P1List(120)
sage: (u,v) = (555555555,7777)
sage: uu,vv,ss = L.normalize_with_scalar(555555555,7777)
sage: (uu,vv)
(15, 13)
sage: ((ss*uu-u)%L.N(), (ss*vv-v)%L.N())
(0, 0)
sage: (uu*v-vv*u) % L.N() == 0
True
```

class **export**()

lift_to_sl2z()

Return a list of Python ints $[a, b, c', d']$ that are the entries of a 2x2 matrix with determinant 1 and lower two entries congruent to c, d modulo N.

INPUT:

- c, d, N - integers such that $\gcd(c, d, N) = 1$.

EXAMPLES:

```
sage: lift_to_sl2z(2,3,6)
[1, 1, 2, 3]
sage: lift_to_sl2z(15,6,24)
[-2, -17, 15, 126]
sage: lift_to_sl2z(15,6,2400000)
[-2L, -320001L, 15L, 2400006L]
```

lift_to_sl2z_int()

Lift a pair (c, d) to an element of $SL(2, \mathbf{Z})$.

(c, d) is assumed to be an element of $\mathbb{P}^1(\mathbf{Z}/N\mathbf{Z})$. This function computes and returns a list $[a, b, c', d']$ that defines a 2x2 matrix, with determinant 1 and integer entries, such that $c = c' \pmod N$ and $d = d' \pmod N$.

INPUT:

- c, d, N - integers such that $\gcd(c, d, N) = 1$.

EXAMPLES:

```
sage: from sage.modular.modsym.p1list import lift_to_sl2z_int
sage: lift_to_sl2z_int(2,6,11)
[1, 8, 2, 17]
sage: m=Matrix(Integers(),2,2,lift_to_sl2z_int(2,6,11))
sage: m
[ 1  8]
[ 2 17]
```

AUTHOR:

- Justin Walker

lift_to_sl2z_llong()

Lift a pair (c, d) (modulo N) to an element of $SL(2, \mathbf{Z})$.

(c, d) is assumed to be an element of $\mathbb{P}^1(\mathbf{Z}/N\mathbf{Z})$. This function computes and returns a list $[a, b, c', d']$ that defines a 2x2 matrix, with determinant 1 and integer entries, such that $c = c' \pmod N$ and $d = d' \pmod N$.

INPUT:

- c, d, N - integers such that $\gcd(c, d, N) = 1$.

EXAMPLES:

```
sage: from sage.modular.modsym.p1list import lift_to_sl2z_llong
sage: lift_to_sl2z_llong(2,6,11)
[1L, 8L, 2L, 17L]
sage: m=Matrix(Integers(),2,2,lift_to_sl2z_llong(2,6,11))
sage: m
[ 1  8]
[ 2 17]
```

AUTHOR:

- Justin Walker

p1_normalize()

Computes the canonical representative of $\mathbb{P}^1(\mathbf{Z}/N\mathbf{Z})$ equivalent to (u, v) along with a transforming scalar.

INPUT:

- N - an integer
- u - an integer

- v - an integer

OUTPUT: If gcd(u,v,N) = 1, then returns

- uu - an integer
- vv - an integer
- ss - an integer such that $(ss * uu, ss * vv)$ is equivalent to (u, v) mod N; if $\gcd(u, v, N) \neq 1$, returns 0, 0, 0.

EXAMPLES:

```
sage: from sage.modular.modsym.p1list import p1_normalize
sage: p1_normalize(90,7,77)
(1, 11, 7)
sage: p1_normalize(90,7,78)
(1, 24, 7)
sage: (7*24-78*1) % 90
0
sage: (7*24) % 90
78
```

```
sage: from sage.modular.modsym.p1list import p1_normalize
sage: p1_normalize(50001,12345,54322)
(3, 4667, 4115)
sage: (12345*4667-54321*3) % 50001
3
sage: 4115*3 % 50001
12345
sage: 4115*4667 % 50001 == 54322 % 50001
True
```

p1_normalize_int()

Computes the canonical representative of $\mathbb{P}^1(\mathbf{Z}/N\mathbf{Z})$ equivalent to (u, v) along with a transforming scalar.

INPUT:

- N - an integer
- u - an integer
- v - an integer

OUTPUT: If gcd(u,v,N) = 1, then returns

- uu - an integer
- vv - an integer
- ss - an integer such that $(ss * uu, ss * vv)$ is congruent to (u, v) (mod N); if $\gcd(u, v, N) \neq 1$, returns 0, 0, 0.

EXAMPLES:

```
sage: from sage.modular.modsym.p1list import p1_normalize_int
sage: p1_normalize_int(90,7,77)
(1, 11, 7)
sage: p1_normalize_int(90,7,78)
(1, 24, 7)
sage: (7*24-78*1) % 90
0
sage: (7*24) % 90
78
```

p1_normalize_llong()

Computes the canonical representative of $\mathbb{P}^1(\mathbf{Z}/N\mathbf{Z})$ equivalent to (u, v) along with a transforming scalar.

INPUT:

- N - an integer
- u - an integer
- v - an integer

OUTPUT: If gcd(u,v,N) = 1, then returns

- uu - an integer
- vv - an integer
- ss - an integer such that $(ss * uu, ss * vv)$ is equivalent to (u, v) mod N;

  if $\gcd(u, v, N) \neq 1$, returns 0, 0, 0.

EXAMPLES:

```
sage: from sage.modular.modsym.p1list import p1_normalize_llong
sage: p1_normalize_llong(90000,7,77)
(1, 11, 7)
sage: p1_normalize_llong(90000,7,78)
(1, 77154, 7)
sage: (7*77154-78*1) % 90000
0
sage: (7*77154) % 90000
78
```

p1list()

Returns the elements of the projective line modulo N, $\mathbb{P}^1(\mathbf{Z}/N\mathbf{Z})$, as a plain list of 2-tuples.

INPUT:

- N (integer) - a positive integer (less than 2^31).

OUTPUT:

A list of the elements of the projective line $\mathbb{P}^1(\mathbf{Z}/N\mathbf{Z})$, as plain 2-tuples.

EXAMPLES:

```
sage: from sage.modular.modsym.p1list import p1list
sage: list(p1list(7))
[(0, 1), (1, 0), (1, 1), (1, 2), (1, 3), (1, 4), (1, 5), (1, 6)]
sage: N=23456
sage: len(p1list(N)) == N*prod([1+1/p for p,e in N.factor()])
True
```

p1list_int()

Returns a list of the normalized elements of $\mathbb{P}^1(\mathbf{Z}/N\mathbf{Z})$.

INPUT:

- N - integer (the level or modulus).

EXAMPLES:

```
sage: from sage.modular.modsym.p1list import p1list_int
sage: p1list_int(6)
[(0, 1),
(1, 0),
(1, 1),
(1, 2),
(1, 3),
(1, 4),
(1, 5),
(2, 1),
(2, 3),
(2, 5),
(3, 1),
(3, 2)]

sage: p1list_int(120)
[(0, 1),
(1, 0),
(1, 1),
(1, 2),
(1, 3),
...
(30, 7),
(40, 1),
(40, 3),
(40, 11),
(60, 1)]
```

p1list_llong()

Returns a list of the normalized elements of $\mathbb{P}^1(\mathbf{Z}/N\mathbf{Z})$, as a plain list of 2-tuples.

INPUT:

- N - integer (the level or modulus).

EXAMPLES:

```
sage: from sage.modular.modsym.p1list import p1list_llong
sage: N = 50000
sage: L = p1list_llong(50000)
sage: len(L) == N*prod([1+1/p for p,e in N.factor()])
True
sage: L[0]
(0, 1)
sage: L[len(L)-1]
(25000, 1)
```

43.11 List of coset represenatives for $\Gamma_1(N)$ in $\mathrm{SL}_2(\mathbf{Z})$.

class G1list(N)

A class representing a list of coset representatives for $\Gamma_1(N)$ in $\mathrm{SL}_2(\mathbf{Z})$. What we actually calculate is a list of elements of $(\mathbf{Z}/N\mathbf{Z})^2$ of exact order N.

TESTS:

```
sage: L = sage.modular.modsym.g1list.G1list(18)
sage: loads(dumps(L)) == L
True
```

list()

Return a list of vectors representing the cosets. Do not change the returned list!

EXAMPLE:

```
sage: L = sage.modular.modsym.g1list.G1list(4); L.list()
[(0, 1), (0, 3), (1, 0), (1, 1), (1, 2), (1, 3), (2, 1), (2, 3), (3, 0), (3, 1), (3, 2), (3,
```

normalize(*u*, *v*)

Given a pair (u, v) of integers, return the unique pair (u', v') such that the pair (u', v') appears in `self.list()` and (u, v) is equivalent to (u', v'). This is rather trivial, but is here for consistency with the `P1List` class which is the equivalent for Γ_0 (where the problem is rather harder).

This will only make sense if $\gcd(u, v, N) = 1$; otherwise the output will not be an element of self.

EXAMPLE:

```
sage: L = sage.modular.modsym.g1list.G1list(4); L.normalize(6, 1)
(2, 1)
sage: L = sage.modular.modsym.g1list.G1list(4); L.normalize(6, 2) # nonsense!
(2, 2)
```

43.12 List of coset represenatives for $\Gamma_H(N)$ in $\mathrm{SL}_2(\mathbf{Z})$.

class GHlist(*group*)

A class representing a list of coset representatives for $\Gamma_H(N)$ in $\mathrm{SL}_2(\mathbf{Z})$.

TESTS:

```
sage: L = sage.modular.modsym.ghlist.GHlist(GammaH(18,[13]))
sage: loads(dumps(L)) == L
True
```

list()

Return a list of vectors representing the cosets. Do not change the returned list!

EXAMPLE:

```
sage: L = sage.modular.modsym.ghlist.GHlist(GammaH(4,[])); L.list()
[(0, 1), (0, 3), (1, 0), (1, 1), (1, 2), (1, 3), (2, 1), (2, 3), (3, 0), (3, 1), (3, 2), (3,
```

normalize(*u*, *v*)

Given a pair (u, v) of integers, return the unique pair (u', v') such that the pair (u', v') appears in `self.list()` and (u, v) is equivalent to (u', v').

This will only make sense if $\gcd(u, v, N) = 1$; otherwise the output will not be an element of self.

EXAMPLES:

```
sage: sage.modular.modsym.ghlist.GHlist(GammaH(24, [17, 19])).normalize(17, 6)
(1, 6)
sage: sage.modular.modsym.ghlist.GHlist(GammaH(24, [7, 13])).normalize(17, 6)
(5, 6)
sage: sage.modular.modsym.ghlist.GHlist(GammaH(24, [5, 23])).normalize(17, 6)
(7, 18)
```

43.13 Relation matrices for ambient modular symbols spaces

This file contains functions that are used by the various ambient modular symbols classes to compute presentations of spaces in terms of generators and relations, using the standard methods based on Manin symbols.

T_relation_matrix_wtk_g0 (*syms, mod, field, sparse*)

Compute a matrix whose echelon form gives the quotient by 3-term T relations. Despite the name, this is used for all modular symbols spaces (including those with character and those for Γ_1 and Γ_H groups), not just Γ_0.

INPUT:

- `syms` - ManinSymbols
- `mod` - list that gives quotient modulo some two-term relations, i.e., the S relations, and if sign is nonzero, the I relations.
- `field` - base_ring
- `sparse` - (True or False) whether to use sparse rather than dense linear algebra

OUTPUT: A sparse matrix whose rows correspond to the reduction of the T relations modulo the S and I relations.

EXAMPLE:

```
sage: from sage.modular.modsym.relation_matrix import *
sage: L = sage.modular.modsym.manin_symbols.ManinSymbolList_gamma_h(GammaH(36, [17,19]), 2)
sage: modS = sparse_2term_quotient(modS_relations(L), 216, QQ)
sage: T_relation_matrix_wtk_g0(L, modS, QQ, False)
72 x 216 dense matrix over Rational Field
sage: T_relation_matrix_wtk_g0(L, modS, GF(17), True)
72 x 216 sparse matrix over Finite Field of size 17
```

compute_presentation (*syms, sign, field, sparse=None*)

Compute the presentation for self, as a quotient of Manin symbols modulo relations.

INPUT:

- `syms` - manin_symbols.ManinSymbols
- `sign` - integer (-1, 0, 1)
- `field` - a field

OUTPUT:

- sparse matrix whose rows give each generator in terms of a basis for the quotient
- list of integers that give the basis for the quotient
- mod: list where mod[i]=(j,s) means that x_i = s*x_j modulo the 2-term S (and possibly I) relations.

ALGORITHM:

1. Let $S = [0, -1; 1, 0], T = [0, -1; 1, -1]$, and $I = [-1, 0; 0, 1]$.
2. Let $x_0, \ldots, x_{n-1}$ by a list of all non-equivalent Manin symbols.
3. Form quotient by 2-term S and (possibly) I relations.
4. Create a sparse matrix A with m columns, whose rows encode the relations

$$[x_i] + [x_i T] + [x_i T^2] = 0.$$

There are about n such rows. The number of nonzero entries per row is at most 3*(k-1). Note that we must include rows for *all* i, since even if $[x_i] = [x_j]$, it need not be the case that $[x_i T] = [x_j T]$, since S and T do not commute. However, in many cases we have an a priori formula for the dimension of the quotient by all these relations, so we can omit many relations and just check that there are enough at the end–if there aren't, we add in more.

5. Compute the reduced row echelon form of A using sparse Gaussian elimination.

6. Use what we've done above to read off a sparse matrix R that uniquely expresses each of the n Manin symbols in terms of a subset of Manin symbols, modulo the relations. This subset of Manin symbols is a basis for the quotient by the relations.

EXAMPLE:

```
sage: L = sage.modular.modsym.manin_symbols.ManinSymbolList_gamma0(8,2)
sage: sage.modular.modsym.relation_matrix.compute_presentation(L, 1, GF(9,'a'), True)
([2 0 0]
[1 0 0]
[0 0 0]
[0 2 0]
[0 0 0]
[0 0 2]
[0 0 0]
[0 2 0]
[0 0 0]
[0 1 0]
[0 1 0]
[0 0 1], [1, 9, 11], [(1, 2), (1, 1), (0, 0), (9, 2), (0, 0), (11, 2), (0, 0), (9, 2), (0, 0), (
```

gens_to_basis_matrix(*syms, relation_matrix, mod, field, sparse*)

Compute echelon form of 3-term relation matrix, and read off each generator in terms of basis.

INPUT:

- `syms` - a ManinSymbols object
- `relation_matrix` - as output by `__compute_T_relation_matrix(self, mod)`
- `mod` - quotient of modular symbols modulo the 2-term S (and possibly I) relations
- `field` - base field
- `sparse` - (bool): whether or not matrix should be sparse

OUTPUT:

- `matrix` - a matrix whose ith row expresses the Manin symbol generators in terms of a basis of Manin symbols (modulo the S, (possibly I,) and T rels) Note that the entries of the matrix need not be integers.
- `list` - integers i, such that the Manin symbols x_i are a basis.

EXAMPLE:

```
sage: from sage.modular.modsym.relation_matrix import *
sage: L = sage.modular.modsym.manin_symbols.ManinSymbolList_gamma1(4, 3)
sage: modS = sparse_2term_quotient(modS_relations(L), 24, GF(3))
sage: gens_to_basis_matrix(L, T_relation_matrix_wtk_g0(L, modS, GF(3), 24), modS, GF(3), True)
(24 x 2 sparse matrix over Finite Field of size 3, [13, 23])
```

modI_relations(*syms, sign*)

Compute quotient of Manin symbols by the I relations.

INPUT:

- `syms` - ManinSymbols
- `sign` - int (either -1, 0, or 1)

OUTPUT:

- `rels` - set of pairs of pairs (j, s), where if mod[i] = (j,s), then x_i = s*x_j (mod S relations)

EXAMPLE:

```
sage: L = sage.modular.modsym.manin_symbols.ManinSymbolList_gamma1(4, 3)
sage: sage.modular.modsym.relation_matrix.modI_relations(L, 1)
set([((14, 1), (20, 1)), ((0, 1), (0, -1)), ((7, 1), (7, -1)), ((9, 1), (3, -1)), ((3, 1), (9, -
```

Warning: We quotient by the involution eta((u,v)) = (-u,v), which has the opposite sign as the involution in Merel's Springer LNM 1585 paper! Thus our +1 eigenspace is his -1 eigenspace, etc. We do this for consistency with MAGMA.

modS_relations (*syms*)

Compute quotient of Manin symbols by the S relations.

Here S is the 2x2 matrix [0, -1; 1, 0].

INPUT:

- `syms` - manin_symbols.ManinSymbols

OUTPUT:

- `rels` - set of pairs of pairs (j, s), where if mod[i] = (j,s), then x_i = s*x_j (mod S relations)

EXAMPLES:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma0
sage: from sage.modular.modsym.relation_matrix import modS_relations

sage: syms = ManinSymbolList_gamma0(2, 4); syms
Manin Symbol List of weight 4 for Gamma0(2)
sage: modS_relations(syms)
set([((3, -1), (4, 1)), ((5, -1), (5, 1)), ((1, 1), (6, 1)), ((0, 1), (7, 1)), ((3, 1), (4, -1))

sage: syms = ManinSymbolList_gamma0(7, 2); syms
Manin Symbol List of weight 2 for Gamma0(7)
sage: modS_relations(syms)
set([((3, 1), (4, 1)), ((2, 1), (7, 1)), ((5, 1), (6, 1)), ((0, 1), (1, 1))])
```

Next we do an example with Gamma1:

```
sage: from sage.modular.modsym.manin_symbols import ManinSymbolList_gamma1
sage: syms = ManinSymbolList_gamma1(3,2); syms
Manin Symbol List of weight 2 for Gamma1(3)
sage: modS_relations(syms)
set([((3, 1), (6, 1)), ((0, 1), (5, 1)), ((0, 1), (2, 1)), ((3, 1), (4, 1)), ((6, 1), (7, 1)), (
```

relation_matrix_wtk_g0 (*syms, sign, field, sparse*)

Compute the matrix of relations. Despite the name, this is used for all spaces (not just for Gamma0). For a description of the algorithm, see the docstring for `compute_presentation`.

INPUT:

- `syms`: sage.modular.modsym.manin_symbols.ManinSymbolList object
- `sign`: integer (0, 1 or -1)
- `field`: the base field (non-field base rings not supported at present)
- `sparse`: (True or False) whether to use sparse arithmetic.

Note that ManinSymbolList objects already have a specific weight, so there is no need for an extra `weight` parameter.

OUTPUT: a pair (R, mod) where

- R is a matrix as output by `T_relation_matrix_wtk_g0`
- mod is a set of 2-term relations as output by `sparse_2term_quotient`

EXAMPLE:

```
sage: L =  sage.modular.modsym.manin_symbols.ManinSymbolList_gamma0(8,2)
sage: A = sage.modular.modsym.relation_matrix.relation_matrix_wtk_g0(L, 0, GF(2), True); A
([0 0 0 0 0 0 0 0 1 0 0 0]
[0 0 0 0 0 0 0 0 1 1 1 0]
[0 0 0 0 0 0 1 0 0 1 1 0]
[0 0 0 0 0 0 1 0 0 0 0 0],
 [(1, 1),
  (1, 1),
  (8, 1),
  (10, 1),
  (6, 1),
  (11, 1),
  (6, 1),
  (9, 1),
  (8, 1),
  (9, 1),
  (10, 1),
  (11, 1)])
sage: A[0].is_sparse()
True
```

sparse_2term_quotient (*rels, n, F*)

Performs Sparse Gauss elimination on a matrix all of whose columns have at most 2 nonzero entries. We use an obvious algorithm, whichs runs fast enough. (Typically making the list of relations takes more time than computing this quotient.) This algorithm is more subtle than just "identify symbols in pairs", since complicated relations can cause generators to surprisingly equal 0.

INPUT:

- `rels` - set of pairs ((i,s), (j,t)). The pair represents the relation s*x_i + t*x_j = 0, where the i, j must be Python int's.
- `n` - int, the x_i are x_0, ..., x_n-1.
- `F` - base field

OUTPUT:

- `mod` - list such that mod[i] = (j,s), which means that x_i is equivalent to s*x_j, where the x_j are a basis for the quotient.

EXAMPLE: We quotient out by the relations

$$3 * x0 - x1 = 0, \qquad x1 + x3 = 0, \qquad x2 + x3 = 0, \qquad x4 - x5 = 0$$

to get

```
sage: v = [((int(0),3), (int(1),-1)), ((int(1),1), (int(3),1)), ((int(2),1),(int(3),1)), ((int(4
sage: rels = set(v)
sage: n = 6
sage: from sage.modular.modsym.relation_matrix import sparse_2term_quotient
sage: sparse_2term_quotient(rels, n, QQ)
[(3, -1/3), (3, -1), (3, -1), (3, 1), (5, 1), (5, 1)]
```

CHAPTER

FORTYFOUR

MODULAR FORMS

44.1 Creating Spaces of Modular Forms

EXAMPLES:

```
sage: m = ModularForms(Gamma1(4),11)
sage: m
Modular Forms space of dimension 6 for Congruence Subgroup Gamma1(4) of weight 11 over Rational Field
sage: m.basis()
[
q - 134*q^5 + O(q^6),
q^2 + 80*q^5 + O(q^6),
q^3 + 16*q^5 + O(q^6),
q^4 - 4*q^5 + O(q^6),
1 + 4092/50521*q^2 + 472384/50521*q^3 + 4194300/50521*q^4 + O(q^6),
q + 1024*q^2 + 59048*q^3 + 1048576*q^4 + 9765626*q^5 + O(q^6)
]
```

CuspForms(*group=1, weight=2, base_ring=None, use_cache=True, prec=6*)

Create a space of cuspidal modular forms.

See the documentation for the ModularForms command for a description of the input parameters.

EXAMPLES:

```
sage: CuspForms(11,2)
Cuspidal subspace of dimension 1 of Modular Forms space of dimension 2 for Congruence Subgroup G
```

EisensteinForms(*group=1, weight=2, base_ring=None, use_cache=True, prec=6*)

Create a space of eisenstein modular forms.

See the documentation for the ModularForms command for a description of the input parameters.

EXAMPLES:

```
sage: EisensteinForms(11,2)
Eisenstein subspace of dimension 1 of Modular Forms space of dimension 2 for Congruence Subgroup
```

ModularForms(*group=1, weight=2, base_ring=None, use_cache=True, prec=6*)

Create an ambient space of modular forms.

INPUT:

- `group` - A congruence subgroup or a Dirichlet character eps.
- `weight` - int, the weight, which must be an integer = 1.

- `base_ring` - the base ring (ignored if group is a Dirichlet character)

Create using the command ModularForms(group, weight, base_ring) where group could be either a congruence subgroup or a Dirichlet character.

EXAMPLES: First we create some spaces with trivial character:

```
sage: ModularForms(Gamma0(11),2).dimension()
2
sage: ModularForms(Gamma0(1),12).dimension()
2
```

If we give an integer N for the congruence subgroup, it defaults to $\Gamma_0(N)$:

```
sage: ModularForms(1,12).dimension()
2
sage: ModularForms(11,4)
Modular Forms space of dimension 4 for Congruence Subgroup Gamma0(11) of weight 4 over Rational
```

We create some spaces for $\Gamma_1(N)$.

```
sage: ModularForms(Gamma1(13),2)
Modular Forms space of dimension 13 for Congruence Subgroup Gamma1(13) of weight 2 over Rational
sage: ModularForms(Gamma1(13),2).dimension()
13
sage: [ModularForms(Gamma1(7),k).dimension() for k in [2,3,4,5]]
[5, 7, 9, 11]
sage: ModularForms(Gamma1(5),11).dimension()
12
```

We create a space with character:

```
sage: e = (DirichletGroup(13).0)^2
sage: e.order()
6
sage: M = ModularForms(e, 2); M
Modular Forms space of dimension 3, character [zeta6] and weight 2 over Cyclotomic Field of orde
sage: f = M.T(2).charpoly('x'); f
x^3 + (-2*zeta6 - 2)*x^2 - 2*zeta6*x + 14*zeta6 - 7
sage: f.factor()
(x - 2*zeta6 - 1) * (x - zeta6 - 2) * (x + zeta6 + 1)
```

More examples of spaces with character:

```
sage: e = DirichletGroup(5, RationalField()).gen(); e
[-1]
sage: m = ModularForms(e, 2); m
Modular Forms space of dimension 2, character [-1] and weight 2 over Rational Field
sage: m == loads(dumps(m))
True
sage: m.T(2).charpoly('x')
x^2 - 1
sage: m = ModularForms(e, 6); m.dimension()
4
sage: m.T(2).charpoly('x')
x^4 - 917*x^2 - 42284
```

This came up in a subtle bug (trac #5923):

```
sage: ModularForms(gp(1), gap(12))
Modular Forms space of dimension 2 for Modular Group SL(2,Z) of weight 12 over Rational Field
```

ModularForms_clear_cache()

Clear the cache of modular forms.

EXAMPLES:

```
sage: M = ModularForms(37,2)
sage: sage.modular.modform.constructor._cache == {}
False

sage: sage.modular.modform.constructor.ModularForms_clear_cache()
sage: sage.modular.modform.constructor._cache
{}
```

Newform(*identifier, group=None, weight=2, base_ring=Rational Field, names=None*)

INPUT:

- `identifier` - a canonical label, or the index of the specific newform desired
- `group` - the congruence subgroup of the newform
- `weight` - the weight of the newform (default 2)
- `base_ring` - the base ring
- `names` - if the newform has coefficients in a number field, a generator name must be specified

EXAMPLES:

```
sage: Newform('67a', names='a')
q + 2*q^2 - 2*q^3 + 2*q^4 + 2*q^5 + O(q^6)
sage: Newform('67b', names='a')
q + a1*q^2 + (-a1 - 3)*q^3 + (-3*a1 - 3)*q^4 - 3*q^5 + O(q^6)
```

Newforms(*group, weight=2, base_ring=Rational Field, names=None*)

INPUT:

- `group` - the congruence subgroup of the newform
- `weight` - the weight of the newform (default 2)
- `base_ring` - the base ring
- `names` - if the newform has coefficients in a number field, a generator name must be specified

EXAMPLES:

```
sage: Newforms(11, 2)
[q - 2*q^2 - q^3 + 2*q^4 + q^5 + O(q^6)]
sage: Newforms(65, names='a')
[q - q^2 - 2*q^3 - q^4 - q^5 + O(q^6),
 q + a1*q^2 + (a1 + 1)*q^3 + (-2*a1 - 1)*q^4 + q^5 + O(q^6),
 q + a2*q^2 + (-a2 + 1)*q^3 + q^4 - q^5 + O(q^6)]
```

canonical_parameters(*group, level, weight, base_ring*)

Given a group, level, weight, and base_ring as input by the user, return a canonicalized version of them, where level is a Sage integer, group really is a group, weight is a Sage integer, and base_ring a Sage ring. Note that we can't just get the level from the group, because we have the convention that the character for Gamma1(N) is None (which makes good sense).

INPUT:

- `group` - int, long, Sage integer, group, dirichlet character, or
- `level` - int, long, Sage integer, or group
- `weight` - coercible to Sage integer
- `base_ring` - commutative Sage ring

OUTPUT:

- `level` - Sage integer
- `group` - congruence subgroup
- `weight` - Sage integer
- `ring` - commutative Sage ring

EXAMPLES:

```
sage: from sage.modular.modform.constructor import canonical_parameters
sage: v = canonical_parameters(5, 5, int(7), ZZ); v
(5, Congruence Subgroup Gamma0(5), 7, Integer Ring)
sage: type(v[0]), type(v[1]), type(v[2]), type(v[3])
(<type 'sage.rings.integer.Integer'>,
 <class 'sage.modular.arithgroup.congroup_gamma0.Gamma0_class'>,
 <type 'sage.rings.integer.Integer'>,
 <type 'sage.rings.integer_ring.IntegerRing_class'>)
sage: canonical_parameters( 5, 7, 7, ZZ )
...
ValueError: group and level do not match.
```

parse_label(*s*)

Given a string s corresponding to a newform label, return the corresponding group and index.

EXAMPLES:

```
sage: sage.modular.modform.constructor.parse_label('11a')
(Congruence Subgroup Gamma0(11), 0)
sage: sage.modular.modform.constructor.parse_label('11aG1')
(Congruence Subgroup Gamma1(11), 0)
sage: sage.modular.modform.constructor.parse_label('11wG1')
(Congruence Subgroup Gamma1(11), 22)
```

44.2 Generic spaces of modular forms

EXAMPLES (computation of base ring): Return the base ring of this space of modular forms.

EXAMPLES: For spaces of modular forms for $\Gamma_0(N)$ or $\Gamma_1(N)$, the default base ring is $\mathbf{Q}$:

```
sage: ModularForms(11,2).base_ring()
Rational Field
sage: ModularForms(1,12).base_ring()
Rational Field
sage: CuspForms(Gamma1(13),3).base_ring()
Rational Field
```

The base ring can be explicitly specified in the constructor function.

```
sage: ModularForms(11,2,base_ring=GF(13)).base_ring()
Finite Field of size 13
```

For modular forms with character the default base ring is the field generated by the image of the character.

```
sage: ModularForms(DirichletGroup(13).0,3).base_ring()
Cyclotomic Field of order 12 and degree 4
```

For example, if the character is quadratic then the field is $\mathbf{Q}$ (if the characteristic is 0).

```
sage: ModularForms(DirichletGroup(13).0^6,3).base_ring()
Rational Field
```

An example in characteristic 7:

```
sage: ModularForms(13,3,base_ring=GF(7)).base_ring()
Finite Field of size 7
```

class ModularFormsSpace(*group, weight, character, base_ring*)

A generic space of modular forms.

base_extend(*base_ring*)

Return the base extension of self to base_ring.

EXAMPLES:

```
sage: M = ModularForms(11,2) ; M
Modular Forms space of dimension 2 for Congruence Subgroup Gamma0(11) of weight 2 over Ratio
sage: M.base_extend(CyclotomicField(5))
Modular Forms space of dimension 2 for Congruence Subgroup Gamma0(11) of weight 2 over Cyclo
```

basis()

Return a basis for self.

EXAMPLES:

```
sage: MM = ModularForms(11,2)
sage: MM.basis()
[
q - 2*q^2 - q^3 + 2*q^4 + q^5 + O(q^6),
1 + 12/5*q + 36/5*q^2 + 48/5*q^3 + 84/5*q^4 + 72/5*q^5 + O(q^6)
]
```

change_ring(*R*)

Change the base ring of this space of modular forms.

TODO: Write this function.

EXAMPLES:

```
sage: sage.modular.modform.space.ModularFormsSpace(Gamma0(11),2,DirichletGroup(1).0,QQ).char
...
NotImplementedError: This function has not yet been implemented.
```

character()

Return the Dirichlet character of this space.

EXAMPLES:

```
sage: M = ModularForms(DirichletGroup(11).0, 3)
sage: M.character()
[zeta10]
sage: s = M.cuspidal_submodule()
sage: s.character()
[zeta10]
```

```
sage: CuspForms(DirichletGroup(11).0,3).character()
[zeta10]
```

cuspidal_submodule()

Return the cuspidal submodule of self.

EXAMPLES:

```
sage: N = ModularForms(6,4) ; N
Modular Forms space of dimension 5 for Congruence Subgroup Gamma0(6) of weight 4 over Ration
sage: N.eisenstein_subspace().dimension()
4

sage: N.cuspidal_submodule()
Cuspidal subspace of dimension 1 of Modular Forms space of dimension 5 for Congruence Subgro

sage: N.cuspidal_submodule().dimension()
1
```

cuspidal_subspace()

Synonym for cuspidal_submodule.

EXAMPLES:

```
sage: N = ModularForms(6,4) ; N
Modular Forms space of dimension 5 for Congruence Subgroup Gamma0(6) of weight 4 over Ration
sage: N.eisenstein_subspace().dimension()
4

sage: N.cuspidal_subspace()
Cuspidal subspace of dimension 1 of Modular Forms space of dimension 5 for Congruence Subgro

sage: N.cuspidal_submodule().dimension()
1
```

decomposition()

This function returns a list of submodules $V(f_i, t)$ corresponding to newforms f_i of some level dividing the level of self, such that the direct sum of the submodules equals self, if possible. The space $V(f_i, t)$ is the image under $g(q)$ maps to $g(q^t)$ of the intersection with $R[[q]]$ of the space spanned by the conjugates of f_i, where R is the base ring of self.

TODO: Implement this function.

EXAMPLES:

```
sage: M = ModularForms(11,2); M.decomposition()
...
NotImplementedError
```

echelon_basis()

Return a basis for self in reduced echelon form. This means that if we view the q-expansions of the basis as defining rows of a matrix (with infinitely many columns), then this matrix is in reduced echelon form.

EXAMPLES:

```
sage: M = ModularForms(Gamma0(11),4)
sage: M.echelon_basis()
[
1 + O(q^6),
q - 9*q^4 - 10*q^5 + O(q^6),
q^2 + 6*q^4 + 12*q^5 + O(q^6),
q^3 + q^4 + q^5 + O(q^6)
]
```

```
sage: M.cuspidal_subspace().echelon_basis()
[
q + 3*q^3 - 6*q^4 - 7*q^5 + O(q^6),
q^2 - 4*q^3 + 2*q^4 + 8*q^5 + O(q^6)
]

sage: M = ModularForms(SL2Z, 12)
sage: M.echelon_basis()
[
1 + 196560*q^2 + 16773120*q^3 + 398034000*q^4 + 4629381120*q^5 + O(q^6),
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 + O(q^6)
]

sage: M = CuspForms(Gamma0(17),4, prec=10)
sage: M.echelon_basis()
[
q + 2*q^5 - 8*q^7 - 8*q^8 + 7*q^9 + O(q^10),
q^2 - 3/2*q^5 - 7/2*q^6 + 9/2*q^7 + q^8 - 4*q^9 + O(q^10),
q^3 - 2*q^6 + q^7 - 4*q^8 - 2*q^9 + O(q^10),
q^4 - 1/2*q^5 - 5/2*q^6 + 3/2*q^7 + 2*q^9 + O(q^10)
]
```

echelon_form()

Return a space of modular forms isomorphic to self but with basis of q-expansions in reduced echelon form.

This is useful, e.g., the default basis for spaces of modular forms is rarely in echelon form, but echelon form is useful for quickly recognizing whether a q-expansion is in the space.

EXAMPLES: We first illustrate two ambient spaces and their echelon forms.

```
sage: M = ModularForms(11)
sage: M.basis()
[
q - 2*q^2 - q^3 + 2*q^4 + q^5 + O(q^6),
1 + 12/5*q + 36/5*q^2 + 48/5*q^3 + 84/5*q^4 + 72/5*q^5 + O(q^6)
]
sage: M.echelon_form().basis()
[
1 + 12*q^2 + 12*q^3 + 12*q^4 + 12*q^5 + O(q^6),
q - 2*q^2 - q^3 + 2*q^4 + q^5 + O(q^6)
]

sage: M = ModularForms(Gamma1(6),4)
sage: M.basis()
[
q - 2*q^2 - 3*q^3 + 4*q^4 + 6*q^5 + O(q^6),
1 + O(q^6),
q - 8*q^4 + 126*q^5 + O(q^6),
q^2 + 9*q^4 + O(q^6),
q^3 + O(q^6)
]
sage: M.echelon_form().basis()
[
1 + O(q^6),
q + 94*q^5 + O(q^6),
q^2 + 36*q^5 + O(q^6),
q^3 + O(q^6),
q^4 - 4*q^5 + O(q^6)
]
```

We create a space with a funny basis then compute the corresponding echelon form.

```
sage: M = ModularForms(11,4)
sage: M.basis()
[
q + 3*q^3 - 6*q^4 - 7*q^5 + O(q^6),
q^2 - 4*q^3 + 2*q^4 + 8*q^5 + O(q^6),
1 + O(q^6),
q + 9*q^2 + 28*q^3 + 73*q^4 + 126*q^5 + O(q^6)
]
sage: F = M.span_of_basis([M.0 + 1/3*M.1, M.2 + M.3]); F.basis()
[
q + 1/3*q^2 + 5/3*q^3 - 16/3*q^4 - 13/3*q^5 + O(q^6),
1 + q + 9*q^2 + 28*q^3 + 73*q^4 + 126*q^5 + O(q^6)
]
sage: E = F.echelon_form(); E.basis()
[
1 + 26/3*q^2 + 79/3*q^3 + 235/3*q^4 + 391/3*q^5 + O(q^6),
q + 1/3*q^2 + 5/3*q^3 - 16/3*q^4 - 13/3*q^5 + O(q^6)
]
```

eisenstein_series()

Compute the Eisenstein series associated to this space.

Note: This function should be overridden by all derived classes.

EXAMPLES:

```
sage: M = sage.modular.modform.space.ModularFormsSpace(Gamma0(11),2,DirichletGroup(1).0,base
...
NotImplementedError: computation of Eisenstein series in this space not yet implemented
```

eisenstein_submodule()

Return the Eisenstein submodule for this space of modular forms.

EXAMPLES:

```
sage: M = ModularForms(11,2)
sage: M.eisenstein_submodule()
Eisenstein subspace of dimension 1 of Modular Forms space of dimension 2 for Congruence Subg
```

eisenstein_subspace()

Synonym for eisenstein_submodule.

EXAMPLES:

```
sage: M = ModularForms(11,2)
sage: M.eisenstein_subspace()
Eisenstein subspace of dimension 1 of Modular Forms space of dimension 2 for Congruence Subg
```

embedded_submodule()

Return the underlying module of self.

EXAMPLES:

```
sage: N = ModularForms(6,4)
sage: N.dimension()
5

sage: N.embedded_submodule()
Vector space of dimension 5 over Rational Field
```

find_in_space(*f, forms=None, prec=None, indep=True*)

INPUT:

- f - a modular form or power series
- forms - (default: None) a specific list of modular forms or q-expansions.
- prec - if forms are given, compute with them to the given precision
- indep - (default: True) whether the given list of forms are assumed to form a basis.

OUTPUT: A list of numbers that give f as a linear combination of the basis for this space or of the given forms if independent=True.

Note: If the list of forms is given, they do *not* have to be in self.

EXAMPLES:

```
sage: M = ModularForms(11,2)
sage: N = ModularForms(10,2)
sage: M.find_in_space( M.basis()[0] )
[1, 0]

sage: M.find_in_space( N.basis()[0], forms=N.basis() )
[1, 0, 0]

sage: M.find_in_space( N.basis()[0] )
...
ArithmeticError: vector is not in free module
```

gen(*n*)

Return the nth generator of self.

EXAMPLES:

```
sage: N = ModularForms(6,4)
sage: N.basis()
[
q - 2*q^2 - 3*q^3 + 4*q^4 + 6*q^5 + O(q^6),
1 + O(q^6),
q - 8*q^4 + 126*q^5 + O(q^6),
q^2 + 9*q^4 + O(q^6),
q^3 + O(q^6)
]

sage: N.gen(0)
q - 2*q^2 - 3*q^3 + 4*q^4 + 6*q^5 + O(q^6)

sage: N.gen(4)
q^3 + O(q^6)

sage: N.gen(5)
...
ValueError: Generator 5 not defined
```

gens()

Return a complete set of generators for self.

EXAMPLES:

```
sage: N = ModularForms(6,4)
sage: N.gens()
[
q - 2*q^2 - 3*q^3 + 4*q^4 + 6*q^5 + O(q^6),
1 + O(q^6),
q - 8*q^4 + 126*q^5 + O(q^6),
q^2 + 9*q^4 + O(q^6),
q^3 + O(q^6)
]
```

group()

Return the congruence subgroup associated to this space of modular forms.

EXAMPLES:

```
sage: ModularForms(Gamma0(12),4).group()
Congruence Subgroup Gamma0(12)

sage: CuspForms(Gamma1(113),2).group()
Congruence Subgroup Gamma1(113)
```

Note that $\Gamma_1(1)$ and $\Gamma_0(1)$ are replaced by $\mathrm{SL}_2(\mathbf{Z})$.

```
sage: CuspForms(Gamma1(1),12).group()
Modular Group SL(2,Z)
sage: CuspForms(SL2Z,12).group()
Modular Group SL(2,Z)
```

has_character()

Return True if this space of modular forms has a specific character.

This is True exactly when the character() function does not return None.

EXAMPLES: A space for $\Gamma_0(N)$ has trivial character, hence has a character.

```
sage: CuspForms(Gamma0(11),2).has_character()
True
```

A space for $\Gamma_1(N)$ (for $N \geq 2$) never has a specific character.

```
sage: CuspForms(Gamma1(11),2).has_character()
False
sage: CuspForms(DirichletGroup(11).0,3).has_character()
True
```

has_coerce_map_from_impl(*from_par*)

Code to make ModularFormsSpace work well with coercion framework.

EXAMPLES:

```
sage: M = ModularForms(22,2)
sage: M.has_coerce_map_from_impl(M.cuspidal_subspace())
True
sage: M.has_coerce_map_from(ModularForms(22,4))
False
```

integral_basis()

Return an integral basis for this space of modular forms.

EXAMPLES: In this example the integral and echelon bases are different.

```
sage: m = ModularForms(97,2,prec=10)
sage: s = m.cuspidal_subspace()
sage: s.integral_basis()
[
q + 2*q^7 + 4*q^8 - 2*q^9 + O(q^10),
q^2 + q^4 + q^7 + 3*q^8 - 3*q^9 + O(q^10),
q^3 + q^4 - 3*q^8 + q^9 + O(q^10),
2*q^4 - 2*q^8 + O(q^10),
q^5 - 2*q^8 + 2*q^9 + O(q^10),
q^6 + 2*q^7 + 5*q^8 - 5*q^9 + O(q^10),
3*q^7 + 6*q^8 - 4*q^9 + O(q^10)
]
sage: s.echelon_basis()
[
```

```
q + 2/3*q^9 + O(q^10),
q^2 + 2*q^8 - 5/3*q^9 + O(q^10),
q^3 - 2*q^8 + q^9 + O(q^10),
q^4 - q^8 + O(q^10),
q^5 - 2*q^8 + 2*q^9 + O(q^10),
q^6 + q^8 - 7/3*q^9 + O(q^10),
q^7 + 2*q^8 - 4/3*q^9 + O(q^10)
]
```

Here's another example where there is a big gap in the valuations:

```
sage: m = CuspForms(64,2)
sage: m.integral_basis()
[
q + O(q^6),
q^2 + O(q^6),
q^5 + O(q^6)
]
```

TESTS:

```
sage: m = CuspForms(11*2^4,2, prec=13); m
Cuspidal subspace of dimension 19 of Modular Forms space of dimension 30 for Congruence Subg
sage: m.integral_basis()          # takes a long time (3 or 4 seconds)
[
q + O(q^13),
q^2 + O(q^13),
q^3 + O(q^13),
q^4 + O(q^13),
q^5 + O(q^13),
q^6 + O(q^13),
q^7 + O(q^13),
q^8 + O(q^13),
q^9 + O(q^13),
q^10 + O(q^13),
q^11 + O(q^13),
q^12 + O(q^13),
O(q^13),
O(q^13),
O(q^13),
O(q^13),
O(q^13),
O(q^13),
O(q^13)
]
```

is_ambient()

Return True if this an ambient space of modular forms.

EXAMPLES:

```
sage: M = ModularForms(Gamma1(4),4)
sage: M.is_ambient()
True

sage: E = M.eisenstein_subspace()
sage: E.is_ambient()
False
```

level()

Return the level of self.

EXAMPLES:

```
sage: M = ModularForms(47,3)
sage: M.level()
47
```

modular_symbols(*sign=0*)

Return the space of modular symbols corresponding to self with the given sign.

EXAMPLES:

```
sage: M = sage.modular.modform.space.ModularFormsSpace(Gamma0(11),2,DirichletGroup(1).0,base
...
NotImplementedError: computation of associated modular symbols space not yet implemented
```

new_submodule(*p=None*)

Return the new submodule of self. If p is specified, return the p-new submodule of self.

Note: This function should be overridden by all derived classes.

EXAMPLES:

```
sage: M = sage.modular.modform.space.ModularFormsSpace(Gamma0(11),2,DirichletGroup(1).0,base
...
NotImplementedError: computation of new submodule not yet implemented
```

new_subspace(*p=None*)

Synonym for new_submodule.

EXAMPLES:

```
sage: M = sage.modular.modform.space.ModularFormsSpace(Gamma0(11),2,DirichletGroup(1).0,base
...
NotImplementedError: computation of new submodule not yet implemented
```

newforms(*names=None*)

Return all newforms in the cuspidal subspace of self.

EXAMPLES:

```
sage: CuspForms(18,4).newforms()
[q + 2*q^2 + 4*q^4 - 6*q^5 + O(q^6)]
sage: CuspForms(32,4).newforms()
[q - 8*q^3 - 10*q^5 + O(q^6), q + 22*q^5 + O(q^6), q + 8*q^3 - 10*q^5 + O(q^6)]
sage: CuspForms(23).newforms('b')
[q + b0*q^2 + (-2*b0 - 1)*q^3 + (-b0 - 1)*q^4 + 2*b0*q^5 + O(q^6)]
sage: CuspForms(23).newforms()
...
ValueError: Please specify a name to be used when generating names for generators of Hecke e
```

prec(*new_prec=None*)

Return or set the default precision used for displaying q-expansions of elements of this space.

INPUT:

- `new_prec` - positive integer (default: None)

OUTPUT: if new_prec is None, returns the current precision.

EXAMPLES:

```
sage: M = ModularForms(1,12)
sage: S = M.cuspidal_subspace()
sage: S.prec()
6
sage: S.basis()
[
```

```
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 + O(q^6)
]
sage: S.prec(8)
8
sage: S.basis()
[
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 - 6048*q^6 - 16744*q^7 + O(q^8)
]
```

q_echelon_basis(*prec=None*)

Return the echelon form of the basis of q-expansions of self up to precision prec.

The q-expansions are power series (not actual modular forms). The number of q-expansions returned equals the dimension.

EXAMPLES:

```
sage: M = ModularForms(11,2)
sage: M.q_expansion_basis()
[
q - 2*q^2 - q^3 + 2*q^4 + q^5 + O(q^6),
1 + 12/5*q + 36/5*q^2 + 48/5*q^3 + 84/5*q^4 + 72/5*q^5 + O(q^6)
]

sage: M.q_echelon_basis()
[
1 + 12*q^2 + 12*q^3 + 12*q^4 + 12*q^5 + O(q^6),
q - 2*q^2 - q^3 + 2*q^4 + q^5 + O(q^6)
]
```

q_expansion_basis(*prec=None*)

Return a sequence of q-expansions for the basis of this space computed to the given input precision.

INPUT:

- `prec` - integer (=0) or None

If prec is None, the prec is computed to be *at least* large enough so that each q-expansion determines the form as an element of this space.

Note: In fact, the q-expansion basis is always computed to *at least* `self.prec()`.

EXAMPLES:

```
sage: S = ModularForms(11,2).cuspidal_submodule()
sage: S.q_expansion_basis()
[
q - 2*q^2 - q^3 + 2*q^4 + q^5 + O(q^6)
]
sage: S.q_expansion_basis(5)
[
q - 2*q^2 - q^3 + 2*q^4 + O(q^5)
]
sage: S = ModularForms(1,24).cuspidal_submodule()
sage: S.q_expansion_basis(8)
[
q + 195660*q^3 + 12080128*q^4 + 44656110*q^5 - 982499328*q^6 - 147247240*q^7 + O(q^8),
q^2 - 48*q^3 + 1080*q^4 - 15040*q^5 + 143820*q^6 - 985824*q^7 + O(q^8)
]
```

q_integral_basis(*prec=None*)

Return a $\mathbf{Z}$-reduced echelon basis of q-expansions for self.

The q-expansions are power series with coefficients in $\mathbf{Z}$; they are *not* actual modular forms.

The base ring of self must be $\mathbf{Q}$. The number of q-expansions returned equals the dimension.

EXAMPLES:

```
sage: S = CuspForms(11,2)
sage: S.q_integral_basis(5)
[
q - 2*q^2 - q^3 + 2*q^4 + O(q^5)
]
```

set_precision(*new_prec*)

Set the default precision used for displaying q-expansions.

INPUT:

- new_prec - positive integer

EXAMPLES:

```
sage: M = ModularForms(Gamma0(37),2)
sage: M.set_precision(10)
sage: S = M.cuspidal_subspace()
sage: S.basis()
[
q + q^3 - 2*q^4 - q^7 - 2*q^9 + O(q^10),
q^2 + 2*q^3 - 2*q^4 + q^5 - 3*q^6 - 4*q^9 + O(q^10)
]

sage: S.set_precision(0)
sage: S.basis()
[
O(q^0),
O(q^0)
]
```

The precision of subspaces is the same as the precision of the ambient space.

```
sage: S.set_precision(2)
sage: M.basis()
[
q + O(q^2),
O(q^2),
1 + 2/3*q + O(q^2)
]
```

The precision must be nonnegative:

```
sage: S.set_precision(-1)
...
ValueError: n (=-1) must be >= 0
```

We do another example with nontrivial character.

```
sage: M = ModularForms(DirichletGroup(13).0^2)
sage: M.set_precision(10)
sage: M.cuspidal_subspace().0
q + (-zeta6 - 1)*q^2 + (2*zeta6 - 2)*q^3 + zeta6*q^4 + (-2*zeta6 + 1)*q^5 + (-2*zeta6 + 4)*q
```

span(*B*)

Take a set B of forms, and return the subspace of self with B as a basis.

EXAMPLES:

```
sage: N = ModularForms(6,4) ; N
Modular Forms space of dimension 5 for Congruence Subgroup Gamma0(6) of weight 4 over Ration
```

```
sage: N.span_of_basis([N.basis()[0]])
Modular Forms subspace of dimension 1 of Modular Forms space of dimension 5 for Congruence S

sage: N.span_of_basis([N.basis()[0], N.basis()[1]])
Modular Forms subspace of dimension 2 of Modular Forms space of dimension 5 for Congruence S

sage: N.span_of_basis( N.basis() )
Modular Forms subspace of dimension 5 of Modular Forms space of dimension 5 for Congruence S
```

span_of_basis(*B*)

Take a set B of forms, and return the subspace of self with B as a basis.

EXAMPLES:

```
sage: N = ModularForms(6,4) ; N
Modular Forms space of dimension 5 for Congruence Subgroup Gamma0(6) of weight 4 over Ration

sage: N.span_of_basis([N.basis()[0]])
Modular Forms subspace of dimension 1 of Modular Forms space of dimension 5 for Congruence S

sage: N.span_of_basis([N.basis()[0], N.basis()[1]])
Modular Forms subspace of dimension 2 of Modular Forms space of dimension 5 for Congruence S

sage: N.span_of_basis( N.basis() )
Modular Forms subspace of dimension 5 of Modular Forms space of dimension 5 for Congruence S
```

sturm_bound(*M=None*)

For a space M of modular forms, this function returns an integer B such that two modular forms in either self or M are equal if and only if their q-expansions are equal to precision B (note that this is 1+ the usual Sturm bound, since $O(q^{\text{prec}})$ has precision prec). If M is none, then M is set equal to self.

EXAMPLES:

```
sage: S37=CuspForms(37,2)
sage: S37.sturm_bound()
8
sage: M = ModularForms(11,2)
sage: M.sturm_bound()
3
sage: ModularForms(Gamma1(15),2).sturm_bound()
33
```

Note: Reference for the Sturm bound that we use in the definition of of this function:

J. Sturm, On the congruence of modular forms, Number theory (New York, 1984-1985), Springer, Berlin, 1987, pp. 275-280.

Useful Remark:

Kevin Buzzard pointed out to me (William Stein) in Fall 2002 that the above bound is fine for Gamma1 with character, as one sees by taking a power of f. More precisely, if $f \cong 0 \pmod{p}$ for first s coefficients, then $f^r = 0 \pmod{p}$ for first sr coefficents. Since the weight of f^r is $r$weight(f), it follows that if $s \geq$ the sturm bound for Γ_0 at weight(f), then f^r has valuation large enough to be forced to be 0 at $r\cdot$ weight(f) by Sturm bound (which is valid if we choose r right). Thus $f \cong 0 \pmod{p}$. Conclusion: For Γ_1 with fixed character, the Sturm bound is *exactly* the same as for Γ_0. A key point is that we are finding $\mathbf{Z}[\varepsilon]$ generators for the Hecke algebra here, not $\mathbf{Z}$-generators. So if one wants generators for the Hecke algebra over $\mathbf{Z}$, this bound is wrong.

This bound works over any base, even a finite field. There might be much better bounds over $\mathbf{Q}$, or for comparing two eigenforms.

weight()

Return the weight of this space of modular forms.

EXAMPLES:

```
sage: M = ModularForms(Gamma1(13),11)
sage: M.weight()
11

sage: M = ModularForms(Gamma0(997),100)
sage: M.weight()
100

sage: M = ModularForms(Gamma0(97),4)
sage: M.weight()
4
sage: M.eisenstein_submodule().weight()
4
```

contains_each(*V, B*)

Determine whether or not V contains every element of B. Used here for linear algebra, but works very generally.

EXAMPLES:

```
sage: contains_each = sage.modular.modform.space.contains_each
sage: contains_each( range(20), prime_range(20) )
True
sage: contains_each( range(20), range(30) )
False
```

is_ModularFormsSpace(*x*)

Return True if x is a `ModularFormsSpace`.

EXAMPLES:

```
sage: from sage.modular.modform.space import is_ModularFormsSpace
sage: is_ModularFormsSpace(ModularForms(11,2))
True
sage: is_ModularFormsSpace(CuspForms(11,2))
True
sage: is_ModularFormsSpace(3)
False
```

44.3 Ambient Spaces of Modular Forms.

EXAMPLES:

We compute a basis for the ambient space $M_2(\Gamma_1(25), \chi)$, where χ is quadratic.

```
sage: chi = DirichletGroup(25,QQ).0; chi
[-1]
sage: n = ModularForms(chi,2); n
Modular Forms space of dimension 6, character [-1] and weight 2 over Rational Field
sage: type(n)
<class 'sage.modular.modform.ambient_eps.ModularFormsAmbient_eps'>
```

Compute a basis:

```
sage: n.basis()
[
```

```
1 + O(q^6),
q + O(q^6),
q^2 + O(q^6),
q^3 + O(q^6),
q^4 + O(q^6),
q^5 + O(q^6)
]
```

Compute the same basis but to higher precision:

```
sage: n.set_precision(20)
sage: n.basis()
[
1 + 10*q^10 + 20*q^15 + O(q^20),
q + 5*q^6 + q^9 + 12*q^11 - 3*q^14 + 17*q^16 + 8*q^19 + O(q^20),
q^2 + 4*q^7 - q^8 + 8*q^12 + 2*q^13 + 10*q^17 - 5*q^18 + O(q^20),
q^3 + q^7 + 3*q^8 - q^12 + 5*q^13 + 3*q^17 + 6*q^18 + O(q^20),
q^4 - q^6 + 2*q^9 + 3*q^14 - 2*q^16 + 4*q^19 + O(q^20),
q^5 + q^10 + 2*q^15 + O(q^20)
]
```

TESTS:

```
sage: m = ModularForms(Gamma1(20),2,GF(7))
sage: loads(dumps(m)) == m
True
```

```
sage: m = ModularForms(GammaH(11,[2]), 2); m
Modular Forms space of dimension 2 for Congruence Subgroup Gamma_H(11) with H generated by [2] of wei
sage: type(m)
<class 'sage.modular.modform.ambient.ModularFormsAmbient'>
```

class ModularFormsAmbient(*group, weight, base_ring, character=None*)

An ambient space of modular forms.

ambient_space()

Return the ambient space that contains this ambient space. This is, of course, just this space again.

EXAMPLES:

```
sage: m = ModularForms(Gamma0(3),30)
sage: m.ambient_space() is m
True
```

change_ring(*base_ring*)

Change the base ring of this space of modular forms.

INPUT:

- R - ring

EXAMPLES:

```
sage: M = ModularForms(Gamma0(37),2)
sage: M.basis()
[
q + q^3 - 2*q^4 + O(q^6),
q^2 + 2*q^3 - 2*q^4 + q^5 + O(q^6),
1 + 2/3*q + 2*q^2 + 8/3*q^3 + 14/3*q^4 + 4*q^5 + O(q^6)
]
```

The basis after changing the base ring is the reduction modulo 3 of an integral basis.

```
sage: M3 = M.change_ring(GF(3))
sage: M3.basis()
[
1 + q^3 + q^4 + 2*q^5 + O(q^6),
q + q^3 + q^4 + O(q^6),
q^2 + 2*q^3 + q^4 + q^5 + O(q^6)
]
```

cuspidal_submodule()

Return the cuspidal submodule of this ambient module.

EXAMPLES:

```
sage: ModularForms(Gamma1(13)).cuspidal_submodule()
Cuspidal subspace of dimension 2 of Modular Forms space of dimension 13 for
Congruence Subgroup Gamma1(13) of weight 2 over Rational Field
```

dimension()

Return the dimension of this ambient space of modular forms, computed using a dimension formula (so it should be reasonably fast).

EXAMPLES:

```
sage: m = ModularForms(Gamma1(20),20)
sage: m.dimension()
238
```

eisenstein_params()

Return parameters that define all Eisenstein series in self.

OUTPUT: an immutable Sequence

EXAMPLES:

```
sage: m = ModularForms(Gamma0(22), 2)
sage: v = m.eisenstein_params(); v
[([1], [1], 2), ([1], [1], 11), ([1], [1], 22)]
sage: type(v)
<class 'sage.structure.sequence.Sequence'>
```

eisenstein_series()

Return all Eisenstein series associated to this space.

```
sage: ModularForms(27,2).eisenstein_series()
[
q^3 + O(q^6),
q - 3*q^2 + 7*q^4 - 6*q^5 + O(q^6),
1/12 + q + 3*q^2 + q^3 + 7*q^4 + 6*q^5 + O(q^6),
1/3 + q + 3*q^2 + 4*q^3 + 7*q^4 + 6*q^5 + O(q^6),
13/12 + q + 3*q^2 + 4*q^3 + 7*q^4 + 6*q^5 + O(q^6)
]
```

```
sage: ModularForms(Gamma1(5),3).eisenstein_series()
[
-1/5*zeta4 - 2/5 + q + (4*zeta4 + 1)*q^2 + (-9*zeta4 + 1)*q^3 + (4*zeta4 - 15)*q^4 + q^5 + O
q + (zeta4 + 4)*q^2 + (-zeta4 + 9)*q^3 + (4*zeta4 + 15)*q^4 + 25*q^5 + O(q^6),
1/5*zeta4 - 2/5 + q + (-4*zeta4 + 1)*q^2 + (9*zeta4 + 1)*q^3 + (-4*zeta4 - 15)*q^4 + q^5 + O
q + (-zeta4 + 4)*q^2 + (zeta4 + 9)*q^3 + (-4*zeta4 + 15)*q^4 + 25*q^5 + O(q^6)
]
```

```
sage: eps = DirichletGroup(13).0^2
sage: ModularForms(eps,2).eisenstein_series()
[
-7/13*zeta6 - 11/13 + q + (2*zeta6 + 1)*q^2 + (-3*zeta6 + 1)*q^3 + (6*zeta6 - 3)*q^4 - 4*q^5
q + (zeta6 + 2)*q^2 + (-zeta6 + 3)*q^3 + (3*zeta6 + 3)*q^4 + 4*q^5 + O(q^6)
]
```

eisenstein_submodule()

Return the Eisenstein submodule of this ambient module.

EXAMPLES:

```
sage: m = ModularForms(Gamma1(13),2); m
Modular Forms space of dimension 13 for Congruence Subgroup Gamma1(13) of weight 2 over Rati
sage: m.eisenstein_submodule()
Eisenstein subspace of dimension 11 of Modular Forms space of dimension 13 for Congruence Su
```

hecke_module_of_level(*N*)

Return the Hecke module of level N corresponding to self, which is the domain or codomain of a degeneracy map from self. Here N must be either a divisor or a multiple of the level of self.

EXAMPLES:

```
sage: ModularForms(25, 6).hecke_module_of_level(5)
Modular Forms space of dimension 3 for Congruence Subgroup Gamma0(5) of weight 6 over Ration
sage: ModularForms(Gamma1(4), 3).hecke_module_of_level(8)
Modular Forms space of dimension 7 for Congruence Subgroup Gamma1(8) of weight 3 over Ration
sage: ModularForms(Gamma1(4), 3).hecke_module_of_level(9)
...
ValueError: N (=9) must be a divisor or a multiple of the level of self (=4)
```

is_ambient()

Return True if this an ambient space of modular forms.

This is an ambient space, so this function always returns True.

EXAMPLES:

```
sage: ModularForms(11).is_ambient()
True
sage: CuspForms(11).is_ambient()
False
```

modular_symbols(*sign=0*)

Return the corresponding space of modular symbols with the given sign.

EXAMPLES:

```
sage: S = ModularForms(11,2)
sage: S.modular_symbols()
Modular Symbols space of dimension 3 for Gamma_0(11) of weight 2 with sign 0 over Rational F
sage: S.modular_symbols(sign=1)
Modular Symbols space of dimension 2 for Gamma_0(11) of weight 2 with sign 1 over Rational F
sage: S.modular_symbols(sign=-1)
Modular Symbols space of dimension 1 for Gamma_0(11) of weight 2 with sign -1 over Rational

sage: ModularForms(1,12).modular_symbols()
Modular Symbols space of dimension 3 for Gamma_0(1) of weight 12 with sign 0 over Rational F
```

module()

Return the underlying free module corresponding to this space of modular forms. This is a free module (viewed as a tuple space) of the same dimension as this space over the same base ring.

EXAMPLES:

```
sage: m = ModularForms(Gamma1(13),10)
sage: m.free_module()
Vector space of dimension 69 over Rational Field
sage: ModularForms(Gamma1(13),4, GF(49,'b')).free_module()
Vector space of dimension 27 over Finite Field in b of size 7^2
```

new_submodule(*p=None*)

Return the new or p-new submodule of this ambient module.

INPUT:

- p - (default: None), if specified return only the p-new submodule.

EXAMPLES:

```
sage: m = ModularForms(Gamma0(33),2); m
Modular Forms space of dimension 6 for Congruence Subgroup Gamma0(33) of weight 2 over Ratio
sage: m.new_submodule()
Modular Forms subspace of dimension 1 of Modular Forms space of dimension 6 for Congruence S
```

Another example:

```
sage: M = ModularForms(17,4)
sage: N = M.new_subspace(); N
Modular Forms subspace of dimension 4 of Modular Forms space of dimension 6 for Congruence S
sage: N.basis()
[
q + 2*q^5 + O(q^6),
q^2 - 3/2*q^5 + O(q^6),
q^3 + O(q^6),
q^4 - 1/2*q^5 + O(q^6)
]

sage: ModularForms(12,4).new_submodule()
Modular Forms subspace of dimension 1 of Modular Forms space of dimension 9 for Congruence S
```

Unfortunately (TODO) - p-new submodules aren't yet implemented:

```
sage: m.new_submodule(3)            # not implemented
...
NotImplementedError
sage: m.new_submodule(11)           # not implemented
...
NotImplementedError
```

prec(*new_prec=None*)

Set or get default initial precision for printing modular forms.

INPUT:

- new_prec - positive integer (default: None)

OUTPUT: if new_prec is None, returns the current precision.

EXAMPLES:

```
sage: M = ModularForms(1,12, prec=3)
sage: M.prec()
3

sage: M.basis()
[
q - 24*q^2 + O(q^3),
1 + 65520/691*q + 134250480/691*q^2 + O(q^3)
]
```

```
sage: M.prec(5)
5
sage: M.basis()
[
q - 24*q^2 + 252*q^3 - 1472*q^4 + O(q^5),
1 + 65520/691*q + 134250480/691*q^2 + 11606736960/691*q^3 + 274945048560/691*q^4 + O(q^5)
]
```

rank()

This is a synonym for `self.dimension()`.

EXAMPLES:

```
sage: m = ModularForms(Gamma0(20),4)
sage: m.rank()
12
sage: m.dimension()
12
```

set_precision(*n*)

Set the default precision for displaying elements of this space.

EXAMPLES:

```
sage: m = ModularForms(Gamma1(5),2)
sage: m.set_precision(10)
sage: m.basis()
[
1 + 60*q^3 - 120*q^4 + 240*q^5 - 300*q^6 + 300*q^7 - 180*q^9 + O(q^10),
q + 6*q^3 - 9*q^4 + 27*q^5 - 28*q^6 + 30*q^7 - 11*q^9 + O(q^10),
q^2 - 4*q^3 + 12*q^4 - 22*q^5 + 30*q^6 - 24*q^7 + 5*q^8 + 18*q^9 + O(q^10)
]
sage: m.set_precision(5)
sage: m.basis()
[
1 + 60*q^3 - 120*q^4 + O(q^5),
q + 6*q^3 - 9*q^4 + O(q^5),
q^2 - 4*q^3 + 12*q^4 + O(q^5)
]
```

44.4 Modular Forms with Character

EXAMPLES:

```
sage: eps = DirichletGroup(13).0
sage: M = ModularForms(eps^2, 2); M
Modular Forms space of dimension 3, character [zeta6] and weight 2 over Cyclotomic Field of order 6 a

sage: S = M.cuspidal_submodule(); S
Cuspidal subspace of dimension 1 of Modular Forms space of dimension 3, character [zeta6] and weight
sage: S.modular_symbols()
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 4 and level 13, weight
```

We create a spaces associated to Dirichlet characters of modulus 225:

```
sage: e = DirichletGroup(225).0
sage: e.order()
```

```
6
sage: e.base_ring()
Cyclotomic Field of order 60 and degree 16
sage: M = ModularForms(e,3)
```

Notice that the base ring is "minimized":

```
sage: M
Modular Forms space of dimension 66, character [zeta6, 1] and weight 3
over Cyclotomic Field of order 6 and degree 2
```

If we don't want the base ring to change, we can explicitly specify it:

```
sage: ModularForms(e, 3, e.base_ring())
Modular Forms space of dimension 66, character [zeta6, 1] and weight 3
over Cyclotomic Field of order 60 and degree 16
```

Next we create a space associated to a Dirichlet character of order 20:

```
sage: e = DirichletGroup(225).1
sage: e.order()
20
sage: e.base_ring()
Cyclotomic Field of order 60 and degree 16
sage: M = ModularForms(e,17); M
Modular Forms space of dimension 484, character [1, zeta20] and
weight 17 over Cyclotomic Field of order 20 and degree 8
```

We compute the Eisenstein subspace, which is fast even though the dimension of the space is large (since an explicit basis of q-expansions has not been computed yet).

```
sage: M.eisenstein_submodule()
Eisenstein subspace of dimension 8 of Modular Forms space of
dimension 484, character [1, zeta20] and weight 17 over Cyclotomic Field of order 20 and degree 8

sage: M.cuspidal_submodule()
Cuspidal subspace of dimension 476 of Modular Forms space of dimension 484, character [1, zeta20] and
```

TESTS:

```
sage: m = ModularForms(DirichletGroup(20).1,5)
sage: m == loads(dumps(m))
True
sage: type(m)
<class 'sage.modular.modform.ambient_eps.ModularFormsAmbient_eps'>
```

class ModularFormsAmbient_eps(*character, weight=2, base_ring=None*)

A space of modular forms with character.

base_extend(*R*)

Return space with same defining parameters as this ambient space of modular symbols, but with scalars extended to a different base ring. This differs from change_ring in that it is always possible to coerce elements of the original space to elements of the new one.

EXAMPLES:

```
sage: m = ModularForms(DirichletGroup(13).0^2,2); m
Modular Forms space of dimension 3, character [zeta6] and weight 2 over Cyclotomic Field of
sage: m.base_extend(CyclotomicField(12))
Modular Forms space of dimension 3, character [zeta12^2] and weight 2 over Cyclotomic Field
```

change_ring(*base_ring*)

Return space with same defining parameters as this ambient space of modular symbols, but defined over a different base ring.

EXAMPLES:

```
sage: m = ModularForms(DirichletGroup(13).0^2,2); m
Modular Forms space of dimension 3, character [zeta6] and weight 2 over Cyclotomic Field of
sage: m.change_ring(CyclotomicField(12))
Modular Forms space of dimension 3, character [zeta12^2] and weight 2 over Cyclotomic Field
```

It must be possible to change the ring of the underlying Dirichlet character:

```
sage: m.change_ring(QQ)
...
ValueError: cannot coerce element of order 6 into self
```

cuspidal_submodule()

Return the cuspidal submodule of this ambient space of modular forms.

EXAMPLES:

```
sage: eps = DirichletGroup(4).0
sage: M = ModularForms(eps, 5); M
Modular Forms space of dimension 3, character [-1] and weight 5 over Rational Field
sage: M.cuspidal_submodule()
Cuspidal subspace of dimension 1 of Modular Forms space of dimension 3, character [-1] and w
```

eisenstein_submodule()

Return the submodule of this ambient module with character that is spanned by Eisenstein series. This is the Hecke stable complement of the cuspidal submodule.

EXAMPLES:

```
sage: m = ModularForms(DirichletGroup(13).0^2,2); m
Modular Forms space of dimension 3, character [zeta6] and weight 2 over Cyclotomic Field of
sage: m.eisenstein_submodule()
Eisenstein subspace of dimension 2 of Modular Forms space of dimension 3, character [zeta6]
```

hecke_module_of_level(*N*)

Return the Hecke module of level N corresponding to self, which is the domain or codomain of a degeneracy map from self. Here N must be either a divisor or a multiple of the level of self, and a multiple of the conductor of the character of self.

EXAMPLES:

```
sage: M = ModularForms(DirichletGroup(15).0, 3); M.character().conductor()
3
sage: M.hecke_module_of_level(3)
Modular Forms space of dimension 2, character [-1] and weight 3 over Rational Field
sage: M.hecke_module_of_level(5)
...
ValueError: conductor(=3) must divide M(=5)
sage: M.hecke_module_of_level(30)
Modular Forms space of dimension 16, character [-1, 1] and weight 3 over Rational Field
```

modular_symbols(*sign=0*)

Return corresponding space of modular symbols with given sign.

EXAMPLES:

```
sage: eps = DirichletGroup(13).0
sage: M = ModularForms(eps^2, 2)
sage: M.modular_symbols()
Modular Symbols space of dimension 4 and level 13, weight 2, character [zeta6], sign 0, over
sage: M.modular_symbols(1)
Modular Symbols space of dimension 3 and level 13, weight 2, character [zeta6], sign 1, over
sage: M.modular_symbols(-1)
Modular Symbols space of dimension 1 and level 13, weight 2, character [zeta6], sign -1, ove
sage: M.modular_symbols(2)
...
ValueError: sign must be -1, 0, or 1
```

44.5 Modular Forms for $Gamma_0(N)$ over Q.

TESTS: sage: m = ModularForms(Gamma0(389),6) sage: loads(dumps(m)) == m True

class ModularFormsAmbient_g0_Q (*level, weight*)

A space of modular forms for Gamma_0(N) over QQ.

cuspidal_submodule ()

Return the cuspidal submodule of this space of modular forms for $Gamma_0(N)$.

EXAMPLES: sage: m = ModularForms(Gamma0(33),4) sage: s = m.cuspidal_submodule(); s Cuspidal subspace of dimension 10 of Modular Forms space of dimension 14 for Congruence Subgroup Gamma0(33) of weight 4 over Rational Field sage: type(s) <class 'sage.modular.modform.cuspidal_submodule.CuspidalSubmodule_g0_Q'>

eisenstein_submodule ()

Return the Eisenstein submodule of this space of modular forms for $Gamma_0(N)$.

EXAMPLES: sage: m = ModularForms(Gamma0(389),6) sage: m.eisenstein_submodule() Eisenstein subspace of dimension 2 of Modular Forms space of dimension 163 for Congruence Subgroup Gamma0(389) of weight 6 over Rational Field

44.6 Modular Forms for $\Gamma_1(N)$ over Q.

EXAMPLES:

```
sage: M = ModularForms(Gamma1(13),2); M
Modular Forms space of dimension 13 for Congruence Subgroup Gamma1(13) of weight 2 over Rational Fiel
sage: S = M.cuspidal_submodule(); S
Cuspidal subspace of dimension 2 of Modular Forms space of dimension 13 for Congruence Subgroup Gamma
sage: S.basis()
[
q - 4*q^3 - q^4 + 3*q^5 + O(q^6),
q^2 - 2*q^3 - q^4 + 2*q^5 + O(q^6)
]
```

TESTS:

```
sage: m = ModularForms(Gamma1(20),2)
sage: loads(dumps(m)) == m
True
```

class ModularFormsAmbient_g1_Q(*level, weight*)
A space of modular forms for the group $\Gamma_1(N)$ over the rational numbers.

cuspidal_submodule()
Return the cuspidal submodule of this modular forms space.
EXAMPLES:

```
sage: m = ModularForms(Gamma1(17),2); m
Modular Forms space of dimension 20 for Congruence Subgroup Gamma1(17) of weight 2 over Rati
sage: m.cuspidal_submodule()
Cuspidal subspace of dimension 5 of Modular Forms space of dimension 20 for Congruence Subgr
```

eisenstein_submodule()
Return the Eisenstein submodule of this modular forms space.
EXAMPLES:

```
sage: ModularForms(Gamma1(13),2).eisenstein_submodule()
Eisenstein subspace of dimension 11 of Modular Forms space of dimension 13 for Congruence Su
sage: ModularForms(Gamma1(13),10).eisenstein_submodule()
Eisenstein subspace of dimension 12 of Modular Forms space of dimension 69 for Congruence Su
```

44.7 Modular Forms over a Non-minimal Base Ring

class ModularFormsAmbient_R(*M, base_ring*)

cuspidal_submodule()
Return the cuspidal subspace of this space.
EXAMPLE:

```
sage: C = CuspForms(7, 4, base_ring=CyclotomicField(5)) # indirect doctest
sage: type(C)
<class 'sage.modular.modform.cuspidal_submodule.CuspidalSubmodule_R'>
```

44.8 Submodules of spaces of modular forms

EXAMPLES: sage: M = ModularForms(Gamma1(13),2); M Modular Forms space of dimension 13 for Congruence Subgroup Gamma1(13) of weight 2 over Rational Field sage: M.eisenstein_subspace() Eisenstein subspace of dimension 11 of Modular Forms space of dimension 13 for Congruence Subgroup Gamma1(13) of weight 2 over Rational Field sage: M == loads(dumps(M)) True sage: M.cuspidal_subspace() Cuspidal subspace of dimension 2 of Modular Forms space of dimension 13 for Congruence Subgroup Gamma1(13) of weight 2 over Rational Field

class ModularFormsSubmodule(*ambient_module, submodule, dual=None, check=False*)
A submodule of an ambient space of modular forms.

change_ring(*base_ring*)
Return the base change of this subspace of modular forms to base_ring.

EXAMPLES: sage: M = ModularForms(6,4) ; M.cuspidal_subspace().change_ring(GF(3)) Traceback (most recent call last): ... NotImplementedError: Base change only currently implemented for ambient spaces.

class ModularFormsSubmoduleWithBasis(*ambient_module, submodule, dual=None, check=False*)

44.9 The Cuspidal Subspace

EXAMPLES:

```
sage: S = CuspForms(SL2Z,12); S
Cuspidal subspace of dimension 1 of Modular Forms space of dimension 2 for
Modular Group SL(2,Z) of weight 12 over Rational Field
sage: S.basis()
[
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 + O(q^6)
]

sage: S = CuspForms(Gamma0(33),2); S
Cuspidal subspace of dimension 3 of Modular Forms space of dimension 6 for
Congruence Subgroup Gamma0(33) of weight 2 over Rational Field
sage: S.basis()
[
q - q^5 + O(q^6),
q^2 - q^4 - q^5 + O(q^6),
q^3 + O(q^6)
]

sage: S = CuspForms(Gamma1(3),6); S
Cuspidal subspace of dimension 1 of Modular Forms space of dimension 3 for
Congruence Subgroup Gamma1(3) of weight 6 over Rational Field
sage: S.basis()
[
q - 6*q^2 + 9*q^3 + 4*q^4 + 6*q^5 + O(q^6)
]
```

class **CuspidalSubmodule** (*ambient_space*)

Base class for cuspidal submodules of ambient spaces of modular forms.

modular_symbols (*sign=0*)

Return the corresponding space of modular symbols with the given sign.

EXAMPLES:

```
sage: S = ModularForms(11,2).cuspidal_submodule()
sage: S.modular_symbols()
Modular Symbols subspace of dimension 2 of Modular Symbols space
of dimension 3 for Gamma_0(11) of weight 2 with sign 0 over Rational Field

sage: S.modular_symbols(sign=-1)
Modular Symbols subspace of dimension 1 of Modular Symbols space
of dimension 1 for Gamma_0(11) of weight 2 with sign -1 over Rational Field

sage: M = S.modular_symbols(sign=1); M
Modular Symbols subspace of dimension 1 of Modular Symbols space of
dimension 2 for Gamma_0(11) of weight 2 with sign 1 over Rational Field
sage: M.sign()
1

sage: S = ModularForms(1,12).cuspidal_submodule()
sage: S.modular_symbols()
Modular Symbols subspace of dimension 2 of Modular Symbols space of
dimension 3 for Gamma_0(1) of weight 12 with sign 0 over Rational Field

sage: eps = DirichletGroup(13).0
```

```
sage: S = CuspForms(eps^2, 2)

sage: S.modular_symbols(sign=0)
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 4 and level 13

sage: S.modular_symbols(sign=1)
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 3 and level 13

sage: S.modular_symbols(sign=-1)
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 1 and level 13
```

class CuspidalSubmodule_R(*ambient_space*)
Cuspidal submodule over a non-minimal base ring.

class CuspidalSubmodule_eps(*ambient_space*)
Space of cusp forms with given Dirichlet character.

EXAMPLES:

```
sage: S = CuspForms(DirichletGroup(5).0,5); S
Cuspidal subspace of dimension 1 of Modular Forms space of dimension 3, character [zeta4] and we

sage: S.basis()
[
q + (-zeta4 - 1)*q^2 + (6*zeta4 - 6)*q^3 - 14*zeta4*q^4 + (15*zeta4 + 20)*q^5 + O(q^6)
]
sage: f = S.0
sage: f.qexp()
q + (-zeta4 - 1)*q^2 + (6*zeta4 - 6)*q^3 - 14*zeta4*q^4 + (15*zeta4 + 20)*q^5 + O(q^6)
sage: f.qexp(7)
q + (-zeta4 - 1)*q^2 + (6*zeta4 - 6)*q^3 - 14*zeta4*q^4 + (15*zeta4 + 20)*q^5 + 12*q^6 + O(q^7)
sage: f.qexp(3)
q + (-zeta4 - 1)*q^2 + O(q^3)
sage: f.qexp(2)
q + O(q^2)
sage: f.qexp(1)
O(q^1)
```

class CuspidalSubmodule_g0_Q(*ambient_space*)
Space of cusp forms for $\Gamma_0(N)$ over $\mathbf{Q}$.

class CuspidalSubmodule_g1_Q(*ambient_space*)
Space of cusp forms for $\Gamma_1(N)$ over $\mathbf{Q}$.

class CuspidalSubmodule_level1_Q(*ambient_space*)
Space of cusp forms of level 1 over $\mathbf{Q}$.

class CuspidalSubmodule_modsym_qexp(*ambient_space*)
Cuspidal submodule with q-expansions calculated via modular symbols.

new_submodule(*p=None*)
Return the new subspace of this space of cusp forms. This is computed using modular symbols.

EXAMPLE:

```
sage: CuspForms(55).new_submodule()
Modular Forms subspace of dimension 3 of Modular Forms space of dimension 8 for Congruence S
```

44.10 The Eisenstein Subspace

class EisensteinSubmodule(*ambient_space*)

The Eisenstein submodule of an ambient space of modular forms.

eisenstein_submodule()

Return the Eisenstein submodule of self. (Yes, this is just self.)

EXAMPLES:

```
sage: E = ModularForms(23,4).eisenstein_subspace()
sage: E == E.eisenstein_submodule()
True
```

modular_symbols(*sign=0*)

Return the corresponding space of modular symbols with given sign.

> **Warning:** If sign != 0, then the space of modular symbols will, in general, only correspond to a *subspace* of this space of modular forms. This can be the case for both sign +1 or -1.

EXAMPLES:

```
sage: E = ModularForms(11,2).eisenstein_submodule()
sage: M = E.modular_symbols(); M
Modular Symbols subspace of dimension 1 of Modular Symbols space
of dimension 3 for Gamma_0(11) of weight 2 with sign 0 over Rational Field
sage: M.sign()
0

sage: M = E.modular_symbols(sign=-1); M
Modular Symbols subspace of dimension 0 of Modular Symbols space of
dimension 1 for Gamma_0(11) of weight 2 with sign -1 over Rational Field

sage: E = ModularForms(1,12).eisenstein_submodule()
sage: E.modular_symbols()
Modular Symbols subspace of dimension 1 of Modular Symbols space of
dimension 3 for Gamma_0(1) of weight 12 with sign 0 over Rational Field

sage: eps = DirichletGroup(13).0
sage: E = EisensteinForms(eps^2, 2)
sage: E.modular_symbols()
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 4 and level 13
```

class EisensteinSubmodule_eps(*ambient_space*)

Space of Eisenstein forms with given Dirichlet character.

EXAMPLES:

```
sage: e = DirichletGroup(27,CyclotomicField(3)).0**2
sage: M = ModularForms(e,2,prec=10).eisenstein_subspace()
sage: M.dimension()
6

sage: M.eisenstein_series()
[
-1/3*zeta6 - 1/3 + q + (2*zeta6 - 1)*q^2 + q^3 + (-2*zeta6 - 1)*q^4 + (-5*zeta6 + 1)*q^5 + O(q^6
-1/3*zeta6 - 1/3 + q^3 + O(q^6),
q + (-2*zeta6 + 1)*q^2 + (-2*zeta6 - 1)*q^4 + (5*zeta6 - 1)*q^5 + O(q^6),
q + (zeta6 + 1)*q^2 + 3*q^3 + (zeta6 + 2)*q^4 + (-zeta6 + 5)*q^5 + O(q^6),
q^3 + O(q^6),
```

```
q + (-zeta6 - 1)*q^2 + (zeta6 + 2)*q^4 + (zeta6 - 5)*q^5 + O(q^6)
]
sage: M.eisenstein_subspace().T(2).matrix().fcp()
(x + zeta3 + 2) * (x + 2*zeta3 + 1) * (x - 2*zeta3 - 1)^2 * (x - zeta3 - 2)^2
sage: ModularSymbols(e,2).eisenstein_subspace().T(2).matrix().fcp()
(x + zeta3 + 2) * (x + 2*zeta3 + 1) * (x - 2*zeta3 - 1)^2 * (x - zeta3 - 2)^2

sage: M.basis()
[
1 - 3*zeta3*q^6 + (-2*zeta3 + 2)*q^9 + O(q^10),
q + (5*zeta3 + 5)*q^7 + O(q^10),
q^2 - 2*zeta3*q^8 + O(q^10),
q^3 + (zeta3 + 2)*q^6 + 3*q^9 + O(q^10),
q^4 - 2*zeta3*q^7 + O(q^10),
q^5 + (zeta3 + 1)*q^8 + O(q^10)
]
```

class **EisensteinSubmodule_g0_Q**(*ambient_space*)
Space of Eisenstein forms for $\Gamma_0(N)$.

class **EisensteinSubmodule_g1_Q**(*ambient_space*)
Space of Eisenstein forms for $\Gamma_1(N)$.

class **EisensteinSubmodule_params**(*ambient_space*)

change_ring(*base_ring*)
Return self as a module over base_ring.
EXAMPLES:

```
sage: E = EisensteinForms(12,2) ; E
Eisenstein subspace of dimension 5 of Modular Forms space of dimension 5 for Congruence Subg
sage: E.basis()
[
1 + O(q^6),
q + 6*q^5 + O(q^6),
q^2 + O(q^6),
q^3 + O(q^6),
q^4 + O(q^6)
]
sage: E.change_ring(GF(5))
Eisenstein subspace of dimension 5 of Modular Forms space of dimension 5 for Congruence Subg
sage: E.change_ring(GF(5)).basis()
[
1 + O(q^6),
q + q^5 + O(q^6),
q^2 + O(q^6),
q^3 + O(q^6),
q^4 + O(q^6)
]
```

eisenstein_series()
Return the Eisenstein series that span this space (over the algebraic closure).
EXAMPLES:

```
sage: EisensteinForms(11,2).eisenstein_series()
[
5/12 + q + 3*q^2 + 4*q^3 + 7*q^4 + 6*q^5 + O(q^6)
]
```

```
sage: EisensteinForms(1,4).eisenstein_series()
[
1/240 + q + 9*q^2 + 28*q^3 + 73*q^4 + 126*q^5 + O(q^6)
]
sage: EisensteinForms(1,24).eisenstein_series()
[
236364091/131040 + q + 8388609*q^2 + 94143178828*q^3 + 70368752566273*q^4 + 1192092895507812
]
sage: EisensteinForms(5,4).eisenstein_series()
[
1/240 + q + 9*q^2 + 28*q^3 + 73*q^4 + 126*q^5 + O(q^6),
1/240 + q^5 + O(q^6)
]
sage: EisensteinForms(13,2).eisenstein_series()
[
1/2 + q + 3*q^2 + 4*q^3 + 7*q^4 + 6*q^5 + O(q^6)
]

sage: E = EisensteinForms(Gamma1(7),2)
sage: E.set_precision(4)
sage: E.eisenstein_series()
[
1/4 + q + 3*q^2 + 4*q^3 + O(q^4),
1/7*zeta6 - 3/7 + q + (-2*zeta6 + 1)*q^2 + (3*zeta6 - 2)*q^3 + O(q^4),
q + (-zeta6 + 2)*q^2 + (zeta6 + 2)*q^3 + O(q^4),
-1/7*zeta6 - 2/7 + q + (2*zeta6 - 1)*q^2 + (-3*zeta6 + 1)*q^3 + O(q^4),
q + (zeta6 + 1)*q^2 + (-zeta6 + 3)*q^3 + O(q^4)
]

sage: eps = DirichletGroup(13).0^2
sage: ModularForms(eps,2).eisenstein_series()
[
-7/13*zeta6 - 11/13 + q + (2*zeta6 + 1)*q^2 + (-3*zeta6 + 1)*q^3 + (6*zeta6 - 3)*q^4 - 4*q^5
q + (zeta6 + 2)*q^2 + (-zeta6 + 3)*q^3 + (3*zeta6 + 3)*q^4 + 4*q^5 + O(q^6)
]

sage: M = ModularForms(19,3).eisenstein_subspace()
sage: M.eisenstein_series()
[
]
```

new_eisenstein_series()

Return a list of the Eisenstein series in this space that are new.

EXAMPLE:

```
sage: E = EisensteinForms(25, 4)
sage: E.new_eisenstein_series()
[q + 7*zeta4*q^2 - 26*zeta4*q^3 - 57*q^4 + O(q^6),
 q - 9*q^2 - 28*q^3 + 73*q^4 + O(q^6),
 q - 7*zeta4*q^2 + 26*zeta4*q^3 - 57*q^4 + O(q^6)]
```

new_submodule(*p=None*)

Return the new submodule of self.

EXAMPLE:

```
sage: e = EisensteinForms(Gamma0(225), 2).new_submodule(); e
Modular Forms subspace of dimension 3 of Modular Forms space of dimension 42 for Congruence
sage: e.basis()
```

```
[
q + O(q^6),
q^2 + O(q^6),
q^4 + O(q^6)
]
```

parameters()

Return a list of parameters for each Eisenstein series spanning self. That is, for each such series, return a triple of the form (ψ, χ, level), where ψ and χ are the characters defining the Eisenstein series, and level is the smallest level at which this series occurs.

EXAMPLES:

```
sage: ModularForms(24,2).eisenstein_submodule().parameters()
[([1, 1, 1], [1, 1, 1], 2),
([1, 1, 1], [1, 1, 1], 3),
([1, 1, 1], [1, 1, 1], 4),
([1, 1, 1], [1, 1, 1], 6),
([1, 1, 1], [1, 1, 1], 8),
([1, 1, 1], [1, 1, 1], 12),
([1, 1, 1], [1, 1, 1], 24)]
sage: EisensteinForms(12,6).parameters()
[([1, 1], [1, 1], 1),
([1, 1], [1, 1], 2),
([1, 1], [1, 1], 3),
([1, 1], [1, 1], 4),
([1, 1], [1, 1], 6),
([1, 1], [1, 1], 12)]
sage: ModularForms(DirichletGroup(24).0,3).eisenstein_submodule().parameters()
[([1, 1, 1], [-1, 1, 1], 1),
([1, 1, 1], [-1, 1, 1], 2),
([1, 1, 1], [-1, 1, 1], 3),
([1, 1, 1], [-1, 1, 1], 6),
([-1, 1, 1], [1, 1, 1], 1),
([-1, 1, 1], [1, 1, 1], 2),
([-1, 1, 1], [1, 1, 1], 3),
([-1, 1, 1], [1, 1, 1], 6)]
```

cyclotomic_restriction(*L*, *K*)

Given two cyclotomic fields L and K, compute the compositum M of K and L, and return a function and the index [M:K]. The function is a map that acts as follows (here $M = Q(\zeta_m)$):

INPUT:

element alpha in L

OUTPUT:

a polynomial $f(x)$ in $K[x]$ such that $f(\zeta_m) = \alpha$, where we view alpha as living in M. (Note that ζ_m generates M, not L.)

EXAMPLES:

```
sage: L = CyclotomicField(12) ; N = CyclotomicField(33) ; M = CyclotomicField(132)
sage: z, n = sage.modular.modform.eisenstein_submodule.cyclotomic_restriction(L,N)
sage: n
2

sage: z(L.0)
-zeta33^19*x
sage: z(L.0)(M.0)
zeta132^11
```

```
sage: z(L.0^3-L.0+1)
(zeta33^19 + zeta33^8)*x + 1
sage: z(L.0^3-L.0+1)(M.0)
zeta132^33 - zeta132^11 + 1
sage: z(L.0^3-L.0+1)(M.0) - M(L.0^3-L.0+1)
0
```

cyclotomic_restriction_tower(*L, K*)

Suppose L/K is an extension of cyclotomic fields and L=Q(zeta_m). This function computes a map with the following property:

INPUT:

an element alpha in L

OUTPUT:

a polynomial $f(x)$ in $K[x]$ such that $f(zeta_m) = alpha$.

EXAMPLES:

```
sage: L = CyclotomicField(12) ; K = CyclotomicField(6)
sage: z = sage.modular.modform.eisenstein_submodule.cyclotomic_restriction_tower(L,K)
sage: z(L.0)
x
sage: z(L.0^2+L.0)
x + zeta6
```

44.11 Eisenstein Series

compute_eisenstein_params(*character, k*)

Compute and return a list of all parameters (χ, ψ, t) that define the Eisenstein series with given character and weight k.

Only the parity of k is relevant.

If character is an integer N, then the parameters for $\Gamma_1(N)$ are computed instead. Then the condition is that $\chi(-1) * \psi(-1) = (-1)^k$.

EXAMPLES:

```
sage: sage.modular.modform.eis_series.compute_eisenstein_params(DirichletGroup(30)(1), 3)
[]

sage: sage.modular.modform.eis_series.compute_eisenstein_params(DirichletGroup(30)(1), 4)
[([1, 1], [1, 1], 1),
([1, 1], [1, 1], 2),
([1, 1], [1, 1], 3),
([1, 1], [1, 1], 5),
([1, 1], [1, 1], 6),
([1, 1], [1, 1], 10),
([1, 1], [1, 1], 15),
([1, 1], [1, 1], 30)]
```

eisenstein_series_lseries(*weight, prec=53, max_imaginary_part=0, max_asymp_coeffs=40*)

Return the L-series of the weight $2k$ Eisenstein series on $\mathrm{SL}_2(\mathbf{Z})$.

This actually returns an interface to Tim Dokchitser's program for computing with the L-series of the Eisenstein series

INPUT:

- weight - even integer
- prec - integer (bits precision)
- max_imaginary_part - real number
- max_asymp_coeffs - integer

OUTPUT:

The L-series of the Eisenstein series.

EXAMPLES:

We compute with the L-series of E_{16} and then E_{20}:

```
sage: L = eisenstein_series_lseries(16)
sage: L(1)
-0.291657724743873
sage: L = eisenstein_series_lseries(20)
sage: L(2)
-5.02355351645987
```

eisenstein_series_qexp(*k, prec=10, K=Rational Field, var='q'*)

Return the q-expansion of the normalized weight k Eisenstein series to precision prec in the ring K. (The normalization chosen here is the one that forces the coefficient of q to be 1.)

Here's a rough description of how the algorithm works: we know $E_k = const + \sum_n sigma(n, k-1)q^n$. Now, we basically just compute all the $\sigma(n, k-1)$ simultaneously, as σ is multiplicative.

INPUT:

- k - an even positive integer
- prec - (default: 10) a nonnegative integer
- K - (default: QQ) a ring in which -(2*k)/B_k is invertible
- var - (default: 'q') variable name to use for q-expansion

EXAMPLES:

```
sage: eisenstein_series_qexp(2,5)
-1/24 + q + 3*q^2 + 4*q^3 + 7*q^4 + O(q^5)
sage: eisenstein_series_qexp(2,0)
O(q^0)
sage: eisenstein_series_qexp(2,5,GF(7))
2 + q + 3*q^2 + 4*q^3 + O(q^5)
sage: eisenstein_series_qexp(2,5,GF(7),var='T')
2 + T + 3*T^2 + 4*T^3 + O(T^5)

sage: eisenstein_series_qexp(10, 30, GF(17))
15 + q + 3*q^2 + 15*q^3 + 7*q^4 + 13*q^5 + 11*q^6 + 11*q^7 + 15*q^8 + 7*q^9 + 5*q^10 + 7*q^11 +
```

AUTHORS:

- Craig Citro (2007-06-01): rewrote for massive speedup

44.12 Elements of modular forms spaces.

class **EisensteinSeries** (*parent, vector, t, chi, psi*)

An Eisenstein series.

EXAMPLES:

```
sage: E = EisensteinForms(1,12)
sage: E.eisenstein_series()
[
691/65520 + q + 2049*q^2 + 177148*q^3 + 4196353*q^4 + 48828126*q^5 + O(q^6)
]
sage: E = EisensteinForms(11,2)
sage: E.eisenstein_series()
[
5/12 + q + 3*q^2 + 4*q^3 + 7*q^4 + 6*q^5 + O(q^6)
]
sage: E = EisensteinForms(Gamma1(7),2)
sage: E.set_precision(4)
sage: E.eisenstein_series()
[
1/4 + q + 3*q^2 + 4*q^3 + O(q^4),
1/7*zeta6 - 3/7 + q + (-2*zeta6 + 1)*q^2 + (3*zeta6 - 2)*q^3 + O(q^4),
q + (-zeta6 + 2)*q^2 + (zeta6 + 2)*q^3 + O(q^4),
-1/7*zeta6 - 2/7 + q + (2*zeta6 - 1)*q^2 + (-3*zeta6 + 1)*q^3 + O(q^4),
q + (zeta6 + 1)*q^2 + (-zeta6 + 3)*q^3 + O(q^4)
]
```

L()

Return the conductor of self.chi().

EXAMPLES:

```
sage: EisensteinForms(DirichletGroup(17).0,99).eisenstein_series()[1].L()
17
```

M()

Return the conductor of self.psi().

EXAMPLES:

```
sage: EisensteinForms(DirichletGroup(17).0,99).eisenstein_series()[1].M()
1
```

character()

Return the character associated to self.

EXAMPLES:

```
sage: EisensteinForms(DirichletGroup(17).0,99).eisenstein_series()[1].character()
[zeta16]

sage: chi = DirichletGroup(7)[4]
sage: E = EisensteinForms(chi).eisenstein_series() ; E
[
-1/7*zeta6 - 2/7 + q + (2*zeta6 - 1)*q^2 + (-3*zeta6 + 1)*q^3 + (-2*zeta6 - 1)*q^4 + (5*zeta
q + (zeta6 + 1)*q^2 + (-zeta6 + 3)*q^3 + (zeta6 + 2)*q^4 + (zeta6 + 4)*q^5 + O(q^6)
]
sage: E[0].character() == chi
True
sage: E[1].character() == chi
True
```

TESTS:

```
sage: [ [ f.character() == chi for f in EisensteinForms(chi).eisenstein_series() ] for chi i
[[True], [], [True, True], [], [True, True], [], [True, True], [], [True, True], [], [True,

sage: [ [ f.character() == chi for f in EisensteinForms(chi).eisenstein_series() ] for chi i
[[True, True, True, True, True], [], [True, True], [], [True, True, True, True], [], [True,
```

chi()

Return the parameter chi associated to self.

EXAMPLES:

```
sage: EisensteinForms(DirichletGroup(17).0,99).eisenstein_series()[1].chi()
[zeta16]
```

new_level()

Return level at which self is new.

EXAMPLES:

```
sage: EisensteinForms(DirichletGroup(17).0,99).eisenstein_series()[1].level()
17
sage: EisensteinForms(DirichletGroup(17).0,99).eisenstein_series()[1].new_level()
17
sage: [ [x.level(), x.new_level()] for x in EisensteinForms(DirichletGroup(60).0^2,2).eisens
[[60, 2], [60, 3], [60, 2], [60, 5], [60, 2], [60, 2], [60, 2], [60, 3], [60, 2], [60, 2], [
```

parameters()

Return chi, psi, and t, which are the defining parameters of self.

EXAMPLES:

```
sage: EisensteinForms(DirichletGroup(17).0,99).eisenstein_series()[1].parameters()
([zeta16], [1], 1)
```

psi()

Return the parameter psi associated to self.

EXAMPLES:

```
sage: EisensteinForms(DirichletGroup(17).0,99).eisenstein_series()[1].psi()
[1]
```

t()

Return the parameter t associated to self.

EXAMPLES:

```
sage: EisensteinForms(DirichletGroup(17).0,99).eisenstein_series()[1].t()
1
```

class **ModularFormElement**(*parent, x, check=True*)

atkin_lehner_eigenvalue(*d=None*)

Return the eigenvalue of the Atkin-Lehner operator W_d acting on this modular form (which is either 1 or -1), or None if this form is not an eigenvector for this operator.

EXAMPLE:

```
sage: CuspForms(1, 30).0.atkin_lehner_eigenvalue()
1
sage: CuspForms(2, 8).0.atkin_lehner_eigenvalue()
...
NotImplementedError: Don't know how to compute Atkin-Lehner matrix acting on this space (try
```

modform_lseries (*prec=53, max_imaginary_part=0, max_asymp_coeffs=40*)

Return the L-series of the weight k modular form f on $\mathrm{SL}_2(\mathbf{Z})$.

This actually returns an interface to Tim Dokchitser's program for computing with the L-series of the modular form.

INPUT:

- `prec` - integer (bits precision)
- `max_imaginary_part` - real number
- `max_asymp_coeffs` - integer

OUTPUT:

The L-series of the modular form.

EXAMPLES:

We commpute with the L-series of the Eisenstein series E_4:

```
sage: f = ModularForms(1,4).0
sage: L = f.modform_lseries()
sage: L(1)
-0.0304484570583933
```

class **ModularFormElement_elliptic_curve** (*parent, E*)

A modular form attached to an elliptic curve.

atkin_lehner_eigenvalue (*d=None*)

Calculate the eigenvalue of the Atkin-Lehner operator W_d acting on this form. If d is None, default to the level of the form. As this form is attached to an elliptic curve, we can read this off from the root number of the curve if d is the level.

EXAMPLE:

```
sage: EllipticCurve('57a1').newform().atkin_lehner_eigenvalue()
1
sage: EllipticCurve('57b1').newform().atkin_lehner_eigenvalue()
-1
sage: EllipticCurve('57b1').newform().atkin_lehner_eigenvalue(19)
1
```

elliptic_curve ()

Return elliptic curve associated to self.

EXAMPLES:

```
sage: E = EllipticCurve('11a')
sage: f = E.modular_form()
sage: f.elliptic_curve()
Elliptic Curve defined by y^2 + y = x^3 - x^2 - 10*x - 20 over Rational Field
sage: f.elliptic_curve() is E
True
```

class **ModularForm_abstract** ()

Constructor for generic class of a modular form. This should never be called directly; instead one should instantiate one of the derived classes of this class.

atkin_lehner_eigenvalue (*d=None*)

Return the eigenvalue of the Atkin-Lehner operator W_d acting on self (which is either 1 or -1), or None if this form is not an eigenvector for this operator. If d is not given or is None, use d = the level.

EXAMPLES:

```
sage: sage.modular.modform.element.ModularForm_abstract.atkin_lehner_eigenvalue(CuspForms(2,
...
NotImplementedError
```

base_ring()

Return the base_ring of self.

EXAMPLES:

```
sage: (ModularForms(117, 2).13).base_ring()
Rational Field
sage: (ModularForms(119, 2, base_ring=GF(7)).12).base_ring()
Finite Field of size 7
```

character()

Return the character of self.

EXAMPLES:

```
sage: ModularForms(DirichletGroup(17).0^2,2).2.character()
[zeta8]
```

coefficients(*X*)

The coefficients a_n of self, for integers n>=0 in the list X. If X is an Integer, return coefficients for indices from 1 to X.

This function caches the results of the compute function.

TESTS:

```
sage: e = DirichletGroup(11).gen()
sage: f = EisensteinForms(e, 3).eisenstein_series()[0]
sage: f.coefficients([0,1])
[15/11*zeta10^3 - 9/11*zeta10^2 - 26/11*zeta10 - 10/11,
1]
sage: f.coefficients([0,1,2,3])
[15/11*zeta10^3 - 9/11*zeta10^2 - 26/11*zeta10 - 10/11,
1,
4*zeta10 + 1,
-9*zeta10^3 + 1]
sage: f.coefficients([2,3])
[4*zeta10 + 1,
-9*zeta10^3 + 1]
```

Running this twice once revealed a bug, so we test it:

```
sage: f.coefficients([0,1,2,3])
[15/11*zeta10^3 - 9/11*zeta10^2 - 26/11*zeta10 - 10/11,
1,
4*zeta10 + 1,
-9*zeta10^3 + 1]
```

cuspform_lseries(*prec=53, max_imaginary_part=0, max_asymp_coeffs=40*)

Return the L-series of the weight k cusp form f on $\Gamma_0(N)$.

This actually returns an interface to Tim Dokchitser's program for computing with the L-series of the cusp form.

INPUT:

- `prec` - integer (bits precision)
- `max_imaginary_part` - real number
- `max_asymp_coeffs` - integer

OUTPUT:

The L-series of the cusp form.

EXAMPLES:

```
sage: f = CuspForms(2,8).newforms()[0]
sage: L = f.cuspform_lseries()
sage: L(1)
0.0884317737041015
sage: L(0.5)
0.0296568512531983
```

Consistency check with delta_lseries (which computes coefficients in pari):

```
sage: delta = CuspForms(1,12).0
sage: L = delta.cuspform_lseries()
sage: L(1)
0.0374412812685155
sage: L = delta_lseries()
sage: L(1)
0.0374412812685155
```

We check that #5262 is fixed:

```
sage: E=EllipticCurve('37b2')
sage: h=Newforms(37)[1]
sage: Lh = h.cuspform_lseries()
sage: LE=E.lseries()
sage: Lh(1), LE(1)
(0.725681061936153, 0.725681061936153)
sage: CuspForms(1, 30).0.cuspform_lseries().eps
-1
```

group()

Return the group for which self is a modular form.

EXAMPLES:

```
sage: ModularForms(Gamma1(11), 2).gen(0).group()
Congruence Subgroup Gamma1(11)
```

level()

Return the level of self.

EXAMPLES:

```
sage: ModularForms(25,4).0.level()
25
```

padded_list(*n*)

Return a list of length n whose entries are the first n coefficients of the q-expansion of self.

EXAMPLES:

```
sage: CuspForms(1,12).0.padded_list(20)
[0, 1, -24, 252, -1472, 4830, -6048, -16744, 84480, -113643, -115920, 534612, -370944, -5777
```

prec()

Return the precision to which self.q_expansion() is currently known. Note that this may be 0.

EXAMPLES:

```
sage: M = ModularForms(2,14)
sage: f = M.0
sage: f.prec()
0

sage: M.prec(20)
20
```

```
sage: f.prec()
0
sage: x = f.q_expansion() ; f.prec()
20
```

q_expansion(*prec=None*)

The q-expansion of the modular form to precision $O(q^{\text{prec}})$. This function takes one argument, which is the integer prec.

EXAMPLES:

We compute the cusp form Δ:

```
sage: delta = CuspForms(1,12).0
sage: delta.q_expansion()
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 + O(q^6)
```

We compute the q-expansion of one of the cusp forms of level 23:

```
sage: f = CuspForms(23,2).0
sage: f.q_expansion()
q - q^3 - q^4 + O(q^6)
sage: f.q_expansion(10)
q - q^3 - q^4 - 2*q^6 + 2*q^7 - q^8 + 2*q^9 + O(q^10)
sage: f.q_expansion(2)
q + O(q^2)
sage: f.q_expansion(1)
O(q^1)
sage: f.q_expansion(0)
O(q^0)
```

qexp(*prec=None*)

Same as self.q_expansion(prec).

EXAMPLES:

```
sage: CuspForms(1,12).0.qexp()
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 + O(q^6)
```

valuation()

Return the valuation of self (i.e. as an element of the power series ring in q).

EXAMPLES:

```
sage: ModularForms(11,2).0.valuation()
1
sage: ModularForms(11,2).1.valuation()
0
sage: ModularForms(25,6).1.valuation()
2
sage: ModularForms(25,6).6.valuation()
7
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: (ModularForms(Gamma1(9),2).6).weight()
2
```

class **Newform**(*parent, component, names, check=True*)

abelian_variety()

Return the abelian variety associated to self.

EXAMPLES:

```
sage: Newforms(14,2)[0]
q - q^2 - 2*q^3 + q^4 + O(q^6)
sage: Newforms(14,2)[0].abelian_variety()
Newform abelian subvariety 14a of dimension 1 of J0(14)
```

atkin_lehner_eigenvalue(*d=None*)

Return the eigenvalue of the Atkin-Lehner operator W_d acting on this newform (which is either 1 or -1). A ValueError will be raised if the character of this form is not either trivial or quadratic. If d is not given or is None, then d defaults to the level of self.

EXAMPLE:

```
sage: [x.atkin_lehner_eigenvalue() for x in ModularForms(53).newforms('a')]
[1, -1]
sage: CuspForms(DirichletGroup(5).0, 5).newforms()[0].atkin_lehner_eigenvalue()
...
ValueError: Atkin-Lehner only leaves space invariant when character is trivial or quadratic.
```

element()

Find an element of the ambient space of modular forms which represents this newform.

Note: This can be quite expensive. Also, the polynomial defining the field of Hecke eigenvalues should be considered random, since it is generated by a random sum of Hecke operators. (The field itself is not random, of course.)

EXAMPLES:

```
sage: ls = Newforms(38,4,names='a')
sage: ls[0]
q - 2*q^2 - 2*q^3 + 4*q^4 - 9*q^5 + O(q^6)
sage: ls # random
[q - 2*q^2 - 2*q^3 + 4*q^4 - 9*q^5 + O(q^6),
q - 2*q^2 + (-a1 - 2)*q^3 + 4*q^4 + (2*a1 + 10)*q^5 + O(q^6),
q + 2*q^2 + (1/2*a2 - 1)*q^3 + 4*q^4 + (-3/2*a2 + 12)*q^5 + O(q^6)]
sage: type(ls[0])
<class 'sage.modular.modform.element.Newform'>
sage: ls[2][3].minpoly()
x^2 - 9*x + 2
sage: ls2 = [ x.element() for x in ls ]
sage: ls2 # random
[q - 2*q^2 - 2*q^3 + 4*q^4 - 9*q^5 + O(q^6),
q - 2*q^2 + (-a1 - 2)*q^3 + 4*q^4 + (2*a1 + 10)*q^5 + O(q^6),
q + 2*q^2 + (1/2*a2 - 1)*q^3 + 4*q^4 + (-3/2*a2 + 12)*q^5 + O(q^6)]
sage: type(ls2[0])
<class 'sage.modular.modform.element.ModularFormElement'>
sage: ls2[2][3].minpoly()
x^2 - 9*x + 2
```

hecke_eigenvalue_field()

Return the field generated over the rationals by the coefficients of this newform.

EXAMPLES:

```
sage: ls = Newforms(35, 2, names='a') ; ls
[q + q^3 - 2*q^4 - q^5 + O(q^6),
q + a1*q^2 + (-a1 - 1)*q^3 + (-a1 + 2)*q^4 + q^5 + O(q^6)]
sage: ls[0].hecke_eigenvalue_field()
Rational Field
sage: ls[1].hecke_eigenvalue_field()
Number Field in a1 with defining polynomial x^2 + x - 4
```

modular_symbols(*sign=0*)

Return the subspace with the specified sign of the space of modular symbols corresponding to this newform.

EXAMPLES:

```
sage: f = Newforms(18,4)[0]
sage: f.modular_symbols()
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 18 for Gamma_0
sage: f.modular_symbols(1)
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 11 for Gamma_0
```

number()

Return the index of this space in the list of simple, new, cuspidal subspaces of the full space of modular symbols for this weight and level.

EXAMPLES:

```
sage: Newforms(43, 2, names='a')[1].number()
1
```

delta_lseries(*prec=53, max_imaginary_part=0, max_asymp_coeffs=40*)

Return the L-series of the modular form Delta.

This actually returns an interface to Tim Dokchitser's program for computing with the L-series of the modular form Δ.

INPUT:

- `prec` - integer (bits precision)
- `max_imaginary_part` - real number
- `max_asymp_coeffs` - integer

OUTPUT:

The L-series of Δ.

EXAMPLES:

```
sage: L = delta_lseries()
sage: L(1)
0.0374412812685155
```

is_ModularFormElement(*x*)

Return True if x is a modular form.

EXAMPLES:

```
sage: from sage.modular.modform.element import is_ModularFormElement
sage: is_ModularFormElement(5)
False
sage: is_ModularFormElement(ModularForms(11).0)
True
```

44.13 Hecke Operators on q-expansions.

hecke_operator_on_basis(*B, n, k, eps=None, already_echelonized=False*)

Given a basis B of q-expansions for a space of modular forms with character ε to precision at least $\#B \cdot n + 1$, this function computes the matrix of T_n relative to B.

Note: If the elements of B are not known to sufficient precision, this function will report that the vectors are linearly dependent (since they are to the specified precision).

INPUT:

- `B` - list of q-expansions
- `n` - an integer >= 1
- `k` - an integer
- `eps` - Dirichlet character
- `already_echelonized` – bool (default: False); if True, use that the basis is already in Echelon form, which saves a lot of time.

EXAMPLES:

```
sage: sage.modular.modform.constructor.ModularForms_clear_cache()
sage: ModularForms(1,12).q_expansion_basis()
[
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 + O(q^6),
1 + 65520/691*q + 134250480/691*q^2 + 11606736960/691*q^3 + 274945048560/691*q^4 + 3199218815520
]
sage: hecke_operator_on_basis(ModularForms(1,12).q_expansion_basis(), 3, 12)
...
ValueError: The given basis vectors must be linearly independent.

sage: hecke_operator_on_basis(ModularForms(1,12).q_expansion_basis(30), 3, 12)
[   252      0]
[     0 177148]
```

hecke_operator_on_qexp (*f, n, k, eps=None, prec=None, check=True, _return_list=False*)

Given the q-expansion f of a modular form with character ε, this function computes the image of f under the Hecke operator $T_{n,k}$ of weight k.

EXAMPLES:

```
sage: M = ModularForms(1,12)
sage: hecke_operator_on_qexp(M.basis()[0], 3, 12)
252*q - 6048*q^2 + 63504*q^3 - 370944*q^4 + O(q^5)
sage: hecke_operator_on_qexp(M.basis()[0], 1, 12, prec=7)
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 - 6048*q^6 + O(q^7)
sage: hecke_operator_on_qexp(M.basis()[0], 1, 12)
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 - 6048*q^6 - 16744*q^7 + 84480*q^8 - 113643*q^9 - 115

sage: M.prec(20)
20
sage: hecke_operator_on_qexp(M.basis()[0], 3, 12)
252*q - 6048*q^2 + 63504*q^3 - 370944*q^4 + 1217160*q^5 - 1524096*q^6 + O(q^7)
sage: hecke_operator_on_qexp(M.basis()[0], 1, 12)
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 - 6048*q^6 - 16744*q^7 + 84480*q^8 - 113643*q^9 - 115

sage: (hecke_operator_on_qexp(M.basis()[0], 1, 12)*252).add_bigoh(7)
252*q - 6048*q^2 + 63504*q^3 - 370944*q^4 + 1217160*q^5 - 1524096*q^6 + O(q^7)

sage: hecke_operator_on_qexp(M.basis()[0], 6, 12)
-6048*q + 145152*q^2 - 1524096*q^3 + O(q^4)
```

An example on a formal power series:

```
sage: R.<q> = QQ[[]]
sage: f = q + q^2 + q^3 + q^7 + O(q^8)
sage: hecke_operator_on_qexp(f, 3, 12)
q + O(q^3)
sage: hecke_operator_on_qexp(delta_qexp(24), 3, 12).prec()
8
sage: hecke_operator_on_qexp(delta_qexp(25), 3, 12).prec()
9
```

44.14 Numerical computation of newforms

class **NumericalEigenforms** (*group, weight=2, eps=9.9999999999999995e-21, delta=0.01, tp=, [2, 3, 5]*)

numerical_eigenforms(group, weight=2, eps=1e-20, delta=1e-2, tp=[2,3,5])

INPUT:

- `group` - a congruence subgroup of a Dirichlet character of order 1 or 2
- `weight` - an integer >= 2
- `eps` - a small float; abs( ) < eps is what "equal to zero" is interpreted as for floating point numbers.
- `delta` - a small-ish float; eigenvalues are considered distinct if their difference has absolute value at least delta
- `tp` - use the Hecke operators T_p for p in tp when searching for a random Hecke operator with distinct Hecke eigenvalues.

OUTPUT:

A numerical eigenforms object, with the following useful methods:

- `ap()` - return all eigenvalues of T_p
- `eigenvalues()` - list of eigenvalues corresponding to the given list of primes, e.g.,:

```
[[eigenvalues of T_2],
 [eigenvalues of T_3],
 [eigenvalues of T_5], ...]
```

- `systems_of_eigenvalues()` - a list of the systems of eigenvalues of eigenforms such that the chosen random linear combination of Hecke operators has multiplicity 1 eigenvalues.

EXAMPLES:

```
sage: n = numerical_eigenforms(23)
sage: n == loads(dumps(n))
True
sage: n.ap(2)
[3.0, 0.61803398875, -1.61803398875]
sage: n.systems_of_eigenvalues(7)
[
[-1.61803398875, 2.2360679775, -3.2360679775],
[0.61803398875, -2.2360679775, 1.2360679775],
[3.0, 4.0, 6.0]
]
sage: n.systems_of_abs(7)
[
[0.6180339887..., 2.236067977..., 1.236067977...],
```

```
[1.6180339887..., 2.236067977..., 3.236067977...],
[3.0, 4.0, 6.0]
]
sage: n.eigenvalues([2,3,5])
[[3.0, 0.61803398875, -1.61803398875],
 [4.0, -2.2360679775, 2.2360679775],
 [6.0, 1.2360679775, -3.2360679775]]
```

ap(*p*)

Return a list of the eigenvalues of the Hecke operator T_p on all the computed eigenforms. The eigenvalues match up between one prime and the next.

INPUT:

- `p` - integer, a prime number

OUTPUT:

- `list` - a list of double precision complex numbers

EXAMPLES:

```
sage: n = numerical_eigenforms(11,4)
sage: n.ap(2) # random order
[9.0, 9.0, 2.73205080757, -0.732050807569]
sage: n.ap(3) # random order
[28.0, 28.0, -7.92820323028, 5.92820323028]
sage: m = n.modular_symbols()
sage: x = polygen(QQ, 'x')
sage: m.T(2).charpoly(x).factor()
(x - 9)^2 * (x^2 - 2*x - 2)
sage: m.T(3).charpoly(x).factor()
(x - 28)^2 * (x^2 + 2*x - 47)
```

eigenvalues(*primes*)

Return the eigenvalues of the Hecke operators corresponding to the primes in the input list of primes. The eigenvalues match up between one prime and the next.

INPUT:

- `primes` - a list of primes

OUTPUT:

list of lists of eigenvalues.

EXAMPLES:

```
sage: n = numerical_eigenforms(1,12)
sage: n.eigenvalues([3,5,13])
[[177148.0, 252.0], [48828126.0, 4830.0], [1.79216039404e+12, -577737.999...]]
```

level()

Return the level of this set of modular eigenforms.

EXAMPLES:

```
sage: n = numerical_eigenforms(61) ; n.level()
61
```

modular_symbols()

Return the space of modular symbols used for computing this set of modular eigenforms.

EXAMPLES:

```
sage: n = numerical_eigenforms(61) ; n.modular_symbols()
Modular Symbols space of dimension 5 for Gamma_0(61) of weight 2 with sign 1 over Rational F
```

systems_of_abs(*bound*)

Return the absolute values of all systems of eigenvalues for self for primes up to bound.

EXAMPLES:

```
sage: numerical_eigenforms(61).systems_of_abs(10)
[
[0.311107817466, 2.90321192591, 2.52542756084, 3.21431974338],
[1.0, 2.0, 3.0, 1.0],
[1.48119430409, 0.806063433525, 3.15632517466, 0.675130870567],
[2.17008648663, 1.70927535944, 1.63089761382, 0.460811127189],
[3.0, 4.0, 6.0, 8.0]
]
```

systems_of_eigenvalues(*bound*)

Return all systems of eigenvalues for self for primes up to bound.

EXAMPLES:

```
sage: numerical_eigenforms(61).systems_of_eigenvalues(10)
[
[-1.48119430409..., 0.806063433525..., 3.15632517466..., 0.675130870567...],
[-1.0..., -2.0..., -3.0..., 1.0...],
[0.311107817466..., 2.90321192591..., -2.52542756084..., -3.21431974338...],
[2.17008648663..., -1.70927535944..., -1.63089761382..., -0.460811127189...],
[3.0, 4.0, 6.0, 8.0]
]
```

weight()

Return the weight of this set of modular eigenforms.

EXAMPLES:

```
sage: n = numerical_eigenforms(61) ; n.weight()
2
```

support(*v, eps*)

Given a vector v and a threshold eps, return all indices where $|v|$ is larger than eps.

EXAMPLES:

```
sage: sage.modular.modform.numerical.support( numerical_eigenforms(61)._easy_vector(), 1.0 )
[]

sage: sage.modular.modform.numerical.support( numerical_eigenforms(61)._easy_vector(), 0.5 )
[0, 1]
```

44.15 The Victor Miller Basis

delta_qexp(*prec=10, var='q', K=Integer Ring*)

Return the q-expansion of Delta as a power series with coefficients in K (=ZZ by default).

INPUT:

- `prec` – integer; the absolute precision of the output
- `var` – (default: 'q') variable name
- `K` – (default: ZZ) base ring of answer

OUTPUT: a power series over K

ALGORITHM: Compute a simple very explicit modular form whose 8th power is Delta. Then compute the 8th power using NTL polynomial arithmetic, which is VERY fast. This function computes a *million* terms of Delta in under a minute.

EXAMPLES:

```
sage: delta_qexp(7)
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 - 6048*q^6 + O(q^7)
sage: delta_qexp(7,'z')
z - 24*z^2 + 252*z^3 - 1472*z^4 + 4830*z^5 - 6048*z^6 + O(z^7)
sage: delta_qexp(-3)
...
ValueError: prec must be positive
```

AUTHORS:

- William Stein: original code
- David Harvey (2007-05): sped up first squaring step

victor_miller_basis(*k, prec=10, cusp_only=False, var='q'*)

Compute and return the Victor-Miller basis for modular forms of weight k and level 1 to precision $O(q^{prec})$. If `cusp_only` is True, return only a basis for the cuspidal subspace.

INPUT:

- `k` – an integer
- `prec` – (default: 10) a positive integer
- `cusp_only` – bool (default: False)
- `var` – string (default: 'q'

OUTPUT: A sequence whose entries are power series in ZZ[[var]].

EXAMPLES:

```
sage: victor_miller_basis(1, 6)
[]
sage: victor_miller_basis(0, 6)
[
1 + O(q^6)
]
sage: victor_miller_basis(2, 6)
[]
sage: victor_miller_basis(4, 6)
[
1 + 240*q + 2160*q^2 + 6720*q^3 + 17520*q^4 + 30240*q^5 + O(q^6)
]

sage: victor_miller_basis(6, 6, var='w')
[
1 - 504*w - 16632*w^2 - 122976*w^3 - 532728*w^4 - 1575504*w^5 + O(w^6)
]

sage: victor_miller_basis(6, 6)
[
1 - 504*q - 16632*q^2 - 122976*q^3 - 532728*q^4 - 1575504*q^5 + O(q^6)
]
sage: victor_miller_basis(12, 6)
```

```
[
1 + 196560*q^2 + 16773120*q^3 + 398034000*q^4 + 4629381120*q^5 + O(q^6),
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 + O(q^6)
]

sage: victor_miller_basis(12, 6, cusp_only=True)
[
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 + O(q^6)
]
sage: victor_miller_basis(24, 6, cusp_only=True)
[
q + 195660*q^3 + 12080128*q^4 + 44656110*q^5 + O(q^6),
q^2 - 48*q^3 + 1080*q^4 - 15040*q^5 + O(q^6)
]
sage: victor_miller_basis(24, 6)
[
1 + 52416000*q^3 + 39007332000*q^4 + 6609020221440*q^5 + O(q^6),
q + 195660*q^3 + 12080128*q^4 + 44656110*q^5 + O(q^6),
q^2 - 48*q^3 + 1080*q^4 - 15040*q^5 + O(q^6)
]
sage: victor_miller_basis(32, 6)
[
1 + 2611200*q^3 + 19524758400*q^4 + 19715347537920*q^5 + O(q^6),
q + 50220*q^3 + 87866368*q^4 + 18647219790*q^5 + O(q^6),
q^2 + 432*q^3 + 39960*q^4 - 1418560*q^5 + O(q^6)
]

sage: victor_miller_basis(40,200)[1:] == victor_miller_basis(40,200,cusp_only=True)
True
sage: victor_miller_basis(200,40)[1:] == victor_miller_basis(200,40,cusp_only=True)
True
```

44.16 Ambient Spaces of Modular Forms.

EXAMPLES:

We compute a basis for the ambient space $M_2(\Gamma_1(25), \chi)$, where χ is quadratic.

```
sage: chi = DirichletGroup(25,QQ).0; chi
[-1]
sage: n = ModularForms(chi,2); n
Modular Forms space of dimension 6, character [-1] and weight 2 over Rational Field
sage: type(n)
<class 'sage.modular.modform.ambient_eps.ModularFormsAmbient_eps'>
```

Compute a basis:

```
sage: n.basis()
[
1 + O(q^6),
q + O(q^6),
q^2 + O(q^6),
q^3 + O(q^6),
q^4 + O(q^6),
```

```
q^5 + O(q^6)
]
```

Compute the same basis but to higher precision:

```
sage: n.set_precision(20)
sage: n.basis()
[
1 + 10*q^10 + 20*q^15 + O(q^20),
q + 5*q^6 + q^9 + 12*q^11 - 3*q^14 + 17*q^16 + 8*q^19 + O(q^20),
q^2 + 4*q^7 - q^8 + 8*q^12 + 2*q^13 + 10*q^17 - 5*q^18 + O(q^20),
q^3 + q^7 + 3*q^8 - q^12 + 5*q^13 + 3*q^17 + 6*q^18 + O(q^20),
q^4 - q^6 + 2*q^9 + 3*q^14 - 2*q^16 + 4*q^19 + O(q^20),
q^5 + q^10 + 2*q^15 + O(q^20)
]
```

TESTS:

```
sage: m = ModularForms(Gamma1(20),2,GF(7))
sage: loads(dumps(m)) == m
True
```

```
sage: m = ModularForms(GammaH(11,[2]), 2); m
Modular Forms space of dimension 2 for Congruence Subgroup Gamma_H(11) with H generated by [2] of wei
sage: type(m)
<class 'sage.modular.modform.ambient.ModularFormsAmbient'>
```

class ModularFormsAmbient (*group, weight, base_ring, character=None*)

An ambient space of modular forms.

ambient_space()

Return the ambient space that contains this ambient space. This is, of course, just this space again.

EXAMPLES:

```
sage: m = ModularForms(Gamma0(3),30)
sage: m.ambient_space() is m
True
```

change_ring(*base_ring*)

Change the base ring of this space of modular forms.

INPUT:

- R - ring

EXAMPLES:

```
sage: M = ModularForms(Gamma0(37),2)
sage: M.basis()
[
q + q^3 - 2*q^4 + O(q^6),
q^2 + 2*q^3 - 2*q^4 + q^5 + O(q^6),
1 + 2/3*q + 2*q^2 + 8/3*q^3 + 14/3*q^4 + 4*q^5 + O(q^6)
]
```

The basis after changing the base ring is the reduction modulo 3 of an integral basis.

```
sage: M3 = M.change_ring(GF(3))
sage: M3.basis()
[
```

```
1 + q^3 + q^4 + 2*q^5 + O(q^6),
q + q^3 + q^4 + O(q^6),
q^2 + 2*q^3 + q^4 + q^5 + O(q^6)
]
```

cuspidal_submodule()

Return the cuspidal submodule of this ambient module.

EXAMPLES:

```
sage: ModularForms(Gamma1(13)).cuspidal_submodule()
Cuspidal subspace of dimension 2 of Modular Forms space of dimension 13 for
Congruence Subgroup Gamma1(13) of weight 2 over Rational Field
```

dimension()

Return the dimension of this ambient space of modular forms, computed using a dimension formula (so it should be reasonably fast).

EXAMPLES:

```
sage: m = ModularForms(Gamma1(20),20)
sage: m.dimension()
238
```

eisenstein_params()

Return parameters that define all Eisenstein series in self.

OUTPUT: an immutable Sequence

EXAMPLES:

```
sage: m = ModularForms(Gamma0(22), 2)
sage: v = m.eisenstein_params(); v
[([1], [1], 2), ([1], [1], 11), ([1], [1], 22)]
sage: type(v)
<class 'sage.structure.sequence.Sequence'>
```

eisenstein_series()

Return all Eisenstein series associated to this space.

```
sage: ModularForms(27,2).eisenstein_series()
[
q^3 + O(q^6),
q - 3*q^2 + 7*q^4 - 6*q^5 + O(q^6),
1/12 + q + 3*q^2 + q^3 + 7*q^4 + 6*q^5 + O(q^6),
1/3 + q + 3*q^2 + 4*q^3 + 7*q^4 + 6*q^5 + O(q^6),
13/12 + q + 3*q^2 + 4*q^3 + 7*q^4 + 6*q^5 + O(q^6)
]

sage: ModularForms(Gamma1(5),3).eisenstein_series()
[
-1/5*zeta4 - 2/5 + q + (4*zeta4 + 1)*q^2 + (-9*zeta4 + 1)*q^3 + (4*zeta4 - 15)*q^4 + q^5 + O
q + (zeta4 + 4)*q^2 + (-zeta4 + 9)*q^3 + (4*zeta4 + 15)*q^4 + 25*q^5 + O(q^6),
1/5*zeta4 - 2/5 + q + (-4*zeta4 + 1)*q^2 + (9*zeta4 + 1)*q^3 + (-4*zeta4 - 15)*q^4 + q^5 + O
q + (-zeta4 + 4)*q^2 + (zeta4 + 9)*q^3 + (-4*zeta4 + 15)*q^4 + 25*q^5 + O(q^6)
]

sage: eps = DirichletGroup(13).0^2
sage: ModularForms(eps,2).eisenstein_series()
[
-7/13*zeta6 - 11/13 + q + (2*zeta6 + 1)*q^2 + (-3*zeta6 + 1)*q^3 + (6*zeta6 - 3)*q^4 - 4*q^5
q + (zeta6 + 2)*q^2 + (-zeta6 + 3)*q^3 + (3*zeta6 + 3)*q^4 + 4*q^5 + O(q^6)
]
```

eisenstein_submodule()
Return the Eisenstein submodule of this ambient module.
EXAMPLES:

```
sage: m = ModularForms(Gamma1(13),2); m
Modular Forms space of dimension 13 for Congruence Subgroup Gamma1(13) of weight 2 over Rati
sage: m.eisenstein_submodule()
Eisenstein subspace of dimension 11 of Modular Forms space of dimension 13 for Congruence Su
```

hecke_module_of_level(*N*)
Return the Hecke module of level N corresponding to self, which is the domain or codomain of a degeneracy map from self. Here N must be either a divisor or a multiple of the level of self.
EXAMPLES:

```
sage: ModularForms(25, 6).hecke_module_of_level(5)
Modular Forms space of dimension 3 for Congruence Subgroup Gamma0(5) of weight 6 over Ration
sage: ModularForms(Gamma1(4), 3).hecke_module_of_level(8)
Modular Forms space of dimension 7 for Congruence Subgroup Gamma1(8) of weight 3 over Ration
sage: ModularForms(Gamma1(4), 3).hecke_module_of_level(9)
...
ValueError: N (=9) must be a divisor or a multiple of the level of self (=4)
```

is_ambient()
Return True if this an ambient space of modular forms.
This is an ambient space, so this function always returns True.
EXAMPLES:

```
sage: ModularForms(11).is_ambient()
True
sage: CuspForms(11).is_ambient()
False
```

modular_symbols(*sign=0*)
Return the corresponding space of modular symbols with the given sign.
EXAMPLES:

```
sage: S = ModularForms(11,2)
sage: S.modular_symbols()
Modular Symbols space of dimension 3 for Gamma_0(11) of weight 2 with sign 0 over Rational F
sage: S.modular_symbols(sign=1)
Modular Symbols space of dimension 2 for Gamma_0(11) of weight 2 with sign 1 over Rational F
sage: S.modular_symbols(sign=-1)
Modular Symbols space of dimension 1 for Gamma_0(11) of weight 2 with sign -1 over Rational

sage: ModularForms(1,12).modular_symbols()
Modular Symbols space of dimension 3 for Gamma_0(1) of weight 12 with sign 0 over Rational F
```

module()
Return the underlying free module corresponding to this space of modular forms. This is a free module (viewed as a tuple space) of the same dimension as this space over the same base ring.
EXAMPLES:

```
sage: m = ModularForms(Gamma1(13),10)
sage: m.free_module()
Vector space of dimension 69 over Rational Field
sage: ModularForms(Gamma1(13),4, GF(49,'b')).free_module()
Vector space of dimension 27 over Finite Field in b of size 7^2
```

new_submodule(*p=None*)
Return the new or p-new submodule of this ambient module.

INPUT:

- p - (default: None), if specified return only the p-new submodule.

EXAMPLES:

```
sage: m = ModularForms(Gamma0(33),2); m
Modular Forms space of dimension 6 for Congruence Subgroup Gamma0(33) of weight 2 over Ratio
sage: m.new_submodule()
Modular Forms subspace of dimension 1 of Modular Forms space of dimension 6 for Congruence S
```

Another example:

```
sage: M = ModularForms(17,4)
sage: N = M.new_subspace(); N
Modular Forms subspace of dimension 4 of Modular Forms space of dimension 6 for Congruence S
sage: N.basis()
[
q + 2*q^5 + O(q^6),
q^2 - 3/2*q^5 + O(q^6),
q^3 + O(q^6),
q^4 - 1/2*q^5 + O(q^6)
]

sage: ModularForms(12,4).new_submodule()
Modular Forms subspace of dimension 1 of Modular Forms space of dimension 9 for Congruence S
```

Unfortunately (TODO) - p-new submodules aren't yet implemented:

```
sage: m.new_submodule(3)            # not implemented
...
NotImplementedError
sage: m.new_submodule(11)           # not implemented
...
NotImplementedError
```

prec(*new_prec=None*)

Set or get default initial precision for printing modular forms.

INPUT:

- new_prec - positive integer (default: None)

OUTPUT: if new_prec is None, returns the current precision.

EXAMPLES:

```
sage: M = ModularForms(1,12, prec=3)
sage: M.prec()
3

sage: M.basis()
[
q - 24*q^2 + O(q^3),
1 + 65520/691*q + 134250480/691*q^2 + O(q^3)
]

sage: M.prec(5)
5
sage: M.basis()
[
q - 24*q^2 + 252*q^3 - 1472*q^4 + O(q^5),
1 + 65520/691*q + 134250480/691*q^2 + 11606736960/691*q^3 + 274945048560/691*q^4 + O(q^5)
]
```

rank()
This is a synonym for `self.dimension()`.
EXAMPLES:

```
sage: m = ModularForms(Gamma0(20),4)
sage: m.rank()
12
sage: m.dimension()
12
```

set_precision(*n*)
Set the default precision for displaying elements of this space.
EXAMPLES:

```
sage: m = ModularForms(Gamma1(5),2)
sage: m.set_precision(10)
sage: m.basis()
[
1 + 60*q^3 - 120*q^4 + 240*q^5 - 300*q^6 + 300*q^7 - 180*q^9 + O(q^10),
q + 6*q^3 - 9*q^4 + 27*q^5 - 28*q^6 + 30*q^7 - 11*q^9 + O(q^10),
q^2 - 4*q^3 + 12*q^4 - 22*q^5 + 30*q^6 - 24*q^7 + 5*q^8 + 18*q^9 + O(q^10)
]
sage: m.set_precision(5)
sage: m.basis()
[
1 + 60*q^3 - 120*q^4 + O(q^5),
q + 6*q^3 - 9*q^4 + O(q^5),
q^2 - 4*q^3 + 12*q^4 + O(q^5)
]
```

44.17 Compute spaces of half-integral weight modular forms.

Based on an algorithm in Basmaji's thesis.

AUTHORS:

- William Stein (2007-08)

half_integral_weight_modform_basis(*chi, k, prec*)
A basis for the space of weight $k/2$ forms with character χ. The modulus of χ must be divisible by 16 and k must be odd and > 1.
INPUT:

- `chi` - a Dirichlet character with modulus divisible by 16
- `k` - an odd integer = 1
- `prec` - a positive integer

OUTPUT: a list of power series

Warning:

1. This code is very slow because it requests computation of a basis of modular forms for integral weight spaces, and that computation is still very slow.
2. If you give an input prec that is too small, then the output list of power series may be larger than the dimension of the space of half-integral forms.

EXAMPLES:

We compute some half-integral weight forms of level 16*7

```
sage: half_integral_weight_modform_basis(DirichletGroup(16*7).0^2,3,30)
[q - 2*q^2 - q^9 + 2*q^14 + 6*q^18 - 2*q^21 - 4*q^22 - q^25 + O(q^30),
 q^2 - q^14 - 3*q^18 + 2*q^22 + O(q^30),
 q^4 - q^8 - q^16 + q^28 + O(q^30),
 q^7 - 2*q^15 + O(q^30)]
```

The following illustrates that choosing too low of a precision can give an incorrect answer.

```
sage: half_integral_weight_modform_basis(DirichletGroup(16*7).0^2,3,20)
[q - 2*q^2 - q^9 + 2*q^14 + 6*q^18 + O(q^20),
 q^2 - q^14 - 3*q^18 + O(q^20),
 q^4 - 2*q^8 + 2*q^12 - 4*q^16 + O(q^20),
 q^7 - 2*q^8 + 4*q^12 - 2*q^15 - 6*q^16 + O(q^20),
 q^8 - 2*q^12 + 3*q^16 + O(q^20)]
```

We compute some spaces of low level and the first few possible weights.

```
sage: half_integral_weight_modform_basis(DirichletGroup(16,QQ).1, 3, 10)
[]
sage: half_integral_weight_modform_basis(DirichletGroup(16,QQ).1, 5, 10)
[q - 2*q^3 - 2*q^5 + 4*q^7 - q^9 + O(q^10)]
sage: half_integral_weight_modform_basis(DirichletGroup(16,QQ).1, 7, 10)
[q - 2*q^2 + 4*q^3 + 4*q^4 - 10*q^5 - 16*q^7 + 19*q^9 + O(q^10),
 q^2 - 2*q^3 - 2*q^4 + 4*q^5 + 4*q^7 - 8*q^9 + O(q^10),
 q^3 - 2*q^5 - 2*q^7 + 4*q^9 + O(q^10)]
sage: half_integral_weight_modform_basis(DirichletGroup(16,QQ).1, 9, 10)
[q - 2*q^2 + 4*q^3 - 8*q^4 + 14*q^5 + 16*q^6 - 40*q^7 + 16*q^8 - 57*q^9 + O(q^10),
 q^2 - 2*q^3 + 4*q^4 - 8*q^5 - 8*q^6 + 20*q^7 - 8*q^8 + 32*q^9 + O(q^10),
 q^3 - 2*q^4 + 4*q^5 + 4*q^6 - 10*q^7 - 16*q^9 + O(q^10),
 q^4 - 2*q^5 - 2*q^6 + 4*q^7 + 4*q^9 + O(q^10),
 q^5 - 2*q^7 - 2*q^9 + O(q^10)]
```

This example once raised an error (see trac #5792).

```
sage: half_integral_weight_modform_basis(trivial_character(16),9,10)
[q - 2*q^2 + 4*q^3 - 8*q^4 + 4*q^6 - 16*q^7 + 48*q^8 - 15*q^9 + O(q^10),
 q^2 - 2*q^3 + 4*q^4 - 2*q^6 + 8*q^7 - 24*q^8 + O(q^10),
 q^3 - 2*q^4 - 4*q^7 + 12*q^8 + O(q^10),
 q^4 - 6*q^8 + O(q^10)]
```

ALGORITHM: Basmaji (page 55 of his Essen thesis, "Ein Algorithmus zur Berechnung von Hecke-Operatoren und Anwendungen auf modulare Kurven", http://wstein.org/scans/papers/basmaji/).

Let $S = S_{k+1}(\epsilon)$ be the space of cusp forms of even integer weight $k+1$ and character $\varepsilon = \chi\psi^{(k+1)/2}$, where ψ is the nontrivial mod-4 Dirichlet character. Let U be the subspace of $S \times S$ of elements (a, b) such that $\Theta_2 a = \Theta_3 b$. Then U is isomorphic to $S_{k/2}(\chi)$ via the map $(a, b) \mapsto a/\Theta_3$.

44.18 Graded Rings of Modular Forms

This module contains functions to find generators for the graded ring of modular forms of given level.

AUTHORS:

- William Stein (2007-08-24): first version

class ModularFormsRing(*group*)

The ring of modular forms (of weights 0 or at least 2) for a congruence subgroup of $\mathrm{SL}_2(\mathbf{Z})$.

EXAMPLES:

```
sage: ModularFormsRing(Gamma1(13))
Ring of modular forms for Congruence Subgroup Gamma1(13) of weights 0 and at least 2
sage: m = ModularFormsRing(4); m
Ring of modular forms for Congruence Subgroup Gamma0(4)
sage: m.modular_forms_of_weight(2)
Modular Forms space of dimension 2 for Congruence Subgroup Gamma0(4) of weight 2 over Rational F
sage: m.modular_forms_of_weight(10)
Modular Forms space of dimension 6 for Congruence Subgroup Gamma0(4) of weight 10 over Rational
sage: m == loads(dumps(m))
True
sage: m.generators()
[(2, 1 + 24*q^2 + 24*q^4 + 96*q^6 + 24*q^8 + O(q^10)),
(2, q + 4*q^3 + 6*q^5 + 8*q^7 + 13*q^9 + O(q^10))]
sage: m.q_expansion_basis(2,10)
[1 + 24*q^2 + 24*q^4 + 96*q^6 + 24*q^8 + O(q^10),
 q + 4*q^3 + 6*q^5 + 8*q^7 + 13*q^9 + O(q^10)]
sage: m.q_expansion_basis(3,10)
[]
sage: m.q_expansion_basis(10,10)
[1 + 10560*q^6 + 3960*q^8 + O(q^10),
 q - 8056*q^7 - 30855*q^9 + O(q^10),
 q^2 - 796*q^6 - 8192*q^8 + O(q^10),
 q^3 + 66*q^7 + 832*q^9 + O(q^10),
 q^4 + 40*q^6 + 528*q^8 + O(q^10),
 q^5 + 20*q^7 + 190*q^9 + O(q^10)]
```

generators(*prec=10, maxweight=20*)

Calculate modular forms generating a subring that contains all forms of weight up to maxweight (default 20).

EXAMPLES:

```
sage: ModularFormsRing(SL2Z).generators()
[(4, 1 + 240*q + 2160*q^2 + 6720*q^3 + 17520*q^4 + 30240*q^5 + 60480*q^6 + 82560*q^7 + 14040
sage: ModularFormsRing(SL2Z).generators(maxweight=5)
[(4, 1 + 240*q + 2160*q^2 + 6720*q^3 + 17520*q^4 + 30240*q^5 + 60480*q^6 + 82560*q^7 + 14040
```

modular_forms_of_weight(*weight*)

Return the space of modular forms on this group of the given weight.

EXAMPLES:

```
sage: R = ModularFormsRing(13)
sage: R.modular_forms_of_weight(10)
Modular Forms space of dimension 11 for Congruence Subgroup Gamma0(13) of weight 10 over Rat
sage: ModularFormsRing(Gamma1(13)).modular_forms_of_weight(3)
Modular Forms space of dimension 20 for Congruence Subgroup Gamma1(13) of weight 3 over Rati
```

q_expansion_basis(*weight, prec=None*)

Calculate a basis of q-expansions for the space of modular forms of the given weight for this group, calculated using the ring generators given by `find_generators`.

EXAMPLES:

```
sage: m = ModularFormsRing(Gamma0(4))
sage: m.q_expansion_basis(2,10)
[1 + 24*q^2 + 24*q^4 + 96*q^6 + 24*q^8 + O(q^10),
```

```
q + 4*q^3 + 6*q^5 + 8*q^7 + 13*q^9 + O(q^10)]
sage: m.q_expansion_basis(3,10)
[]
```

basis_for_modform_space(*gens, group, weight*)

Given a list of pairs `(k,f)` of a weight and a modular form of that weight, and a target weight l, return a basis of q-expansions for the weight l part of the graded algebra generated by those forms (which may or may not be the whole space of weight l forms for the given group).

EXAMPLES:

```
sage: X = ModularFormsRing(SL2Z).generators()
sage: sage.modular.modform.find_generators.basis_for_modform_space(X, SL2Z, 12)
[1 + 196560*q^2 + 16773120*q^3 + 398034000*q^4 + 4629381120*q^5 + 34417656000*q^6 + 187489935360
q - 24*q^2 + 252*q^3 - 1472*q^4 + 4830*q^5 - 6048*q^6 - 16744*q^7 + 84480*q^8 - 113643*q^9 + O(q
```

modform_generators(*group, maxweight=20, prec=None, start_gens=, [], start_weight=2*)

Find modular forms in $M_k(group)$ for $k \leq maxweight$, such that these forms generate – as an algebra – all forms on group of weight up to maxweight, where all forms are computed as q-expansions to precision prec.

INPUT:

- `group` – a level or a congruence subgroup
- `maxweight` – integer
- `prec` – integer (default: twice largest dimension)
- `start_gens` – list of pairs (k,f) where k is an integer and f is a power seris (default: []); if given, we assume the given pairs (k,f) are q-expansions of modular form of the given weight, and start creating modular forms generators using them.
- `start_weight` – an integer (default: 2)

OUTPUT:

a list of pairs (k, f), where f is the q-expansion of a modular form of weight k.

EXAMPLES:

```
sage: import sage.modular.modform.find_generators as fg
sage: forms = [(4, 240*eisenstein_series_qexp(4,5)), (6,504*eisenstein_series_qexp(6,5))]
sage: fg.multiply_forms_to_weight(forms, 12)
[(12, 1 - 1008*q + 220752*q^2 + 16519104*q^3 + 399517776*q^4 + O(q^5)), (12, 1 + 720*q + 179280*
sage: fg.multiply_forms_to_weight(forms, 24)
[(24, 1 - 2016*q + 1457568*q^2 - 411997824*q^3 + 16227967392*q^4 + O(q^5)), (24, 1 - 288*q - 325
sage: dimension_modular_forms(SL2Z,24)
3

sage: fg.modform_generators(1)
[(4, 1 + 240*q + 2160*q^2 + 6720*q^3 + O(q^4)), (6, 1 - 504*q - 16632*q^2 - 122976*q^3 + O(q^4))
sage: fg.modform_generators(2)
[(2, 1 + 24*q + 24*q^2 + 96*q^3 + 24*q^4 + 144*q^5 + 96*q^6 + 192*q^7 + 24*q^8 + 312*q^9 + 144*q
sage: fg.modform_generators(4, 12, 20)
[(2, 1 + 24*q^2 + 24*q^4 + 96*q^6 + 24*q^8 + 144*q^10 + 96*q^12 + 192*q^14 + 24*q^16 + 312*q^18
```

Here we see that for `\Gamma_0(11)` taking a basis of forms in weights 2 and 4 is enough to generate everything up to weight 12 (and probably everything else).:

```
sage: v = fg.modform_generators(11, 12)
sage: len(v)
3
```

```
sage: [k for k, _ in v]
[2, 2, 4]
sage: dimension_modular_forms(11,2)
2
sage: dimension_modular_forms(11,4)
4
```

For congruence subgroups not -1, we miss out some forms since we can't calculate weight 1 forms at present, but we can still find generators for the ring of forms of weight ≥ 2:

```
sage: fg.modform_generators(Gamma1(4), prec=10, maxweight=10)
[(2, 1 + 24*q^2 + 24*q^4 + 96*q^6 + 24*q^8 + O(q^10)),
(2, q + 4*q^3 + 6*q^5 + 8*q^7 + 13*q^9 + O(q^10)),
(3, 1 + 12*q^2 + 64*q^3 + 60*q^4 + 160*q^6 + 384*q^7 + 252*q^8 + O(q^10)),
(3, q + 4*q^2 + 8*q^3 + 16*q^4 + 26*q^5 + 32*q^6 + 48*q^7 + 64*q^8 + 73*q^9 + O(q^10))]
```

multiply_forms_to_weight(*forms, weight, stop_dim=None*)

Given a list of pairs `(k,f)`, where k is an integer and f is a power series, and a weight l, return all weight l forms obtained by multiplying together the given forms.

INPUT:

- forms – list of pairs (k, f) with k an integer and f a power series
- weight – an integer
- stop_dim – integer (optional): if set to an integer and we find that the series so far span a space of at least this dimension, then stop multiplying more forms together.

EXAMPLES:

```
sage: import sage.modular.modform.find_generators as f
sage: forms = [(4, 240*eisenstein_series_qexp(4,5)), (6,504*eisenstein_series_qexp(6,5))]
sage: f.multiply_forms_to_weight(forms, 12)
[(12, 1 - 1008*q + 220752*q^2 + 16519104*q^3 + 399517776*q^4 + O(q^5)), (12, 1 + 720*q + 179280*
sage: f.multiply_forms_to_weight(forms, 24)
[(24, 1 - 2016*q + 1457568*q^2 - 411997824*q^3 + 16227967392*q^4 + O(q^5)), (24, 1 - 288*q - 325
sage: dimension_modular_forms(SL2Z,24)
3
```

span_of_series(*v, prec=None, basis=False*)

Return the free module spanned by the given list of power series or objects with a padded_list method. If prec is not given, the precision used is the minimum of the precisions of the elements in the list (as determined by a prec method).

INPUT:

- v – a list of power series
- prec – optional; if given then the series do not have to be of finite precision, and will be considered to have precision prec.
- basis – (default: False) if True the input is assumed to determine linearly independent vectors, and the resulting free module has that as basis.

OUTPUT:

A free module of rank prec over the base ring of the forms (actually, of the first form in the list). If the list is empty, the free module is over QQ.

EXAMPLES:

An example involving modular forms:

```
sage: from sage.modular.modform.find_generators import span_of_series
sage: v = ModularForms(11,2, prec=5).basis(); v
[
q - 2*q^2 - q^3 + 2*q^4 + O(q^5),
1 + 12/5*q + 36/5*q^2 + 48/5*q^3 + 84/5*q^4 + O(q^5)
]
sage: span_of_series(v)
Vector space of degree 5 and dimension 2 over Rational Field
Basis matrix:
[ 1  0 12 12 12]
[ 0  1 -2 -1  2]
```

Next we make sure the vectors give a basis:

```
sage: span_of_series(v,basis=True)
Vector space of degree 5 and dimension 2 over Rational Field
User basis matrix:
[   0    1   -2   -1    2]
[   1 12/5 36/5 48/5 84/5]
```

An example involving power series.:

```
sage: R.<x> = PowerSeriesRing(QQ, default_prec=5)
sage: v = [1/(1-x), 1/(1+x), 2/(1+x), 2/(1-x)]; v
[1 + x + x^2 + x^3 + x^4 + O(x^5),
 1 - x + x^2 - x^3 + x^4 + O(x^5),
 2 - 2*x + 2*x^2 - 2*x^3 + 2*x^4 + O(x^5),
 2 + 2*x + 2*x^2 + 2*x^3 + 2*x^4 + O(x^5)]
sage: span_of_series(v)
Vector space of degree 5 and dimension 2 over Rational Field
Basis matrix:
[1 0 1 0 1]
[0 1 0 1 0]
sage: span_of_series(v,10)
Vector space of degree 10 and dimension 2 over Rational Field
Basis matrix:
[1 0 1 0 1 0 0 0 0 0]
[0 1 0 1 0 0 0 0 0 0]
```

An example involving polynomials.:

```
sage: x = polygen(QQ)
sage: span_of_series([x^3, 2*x^2 + 17*x^3, x^2])
...
ValueError: please specify a precision
sage: span_of_series([x^3, 2*x^2 + 17*x^3, x^2],5)
Vector space of degree 5 and dimension 2 over Rational Field
Basis matrix:
[0 0 1 0 0]
[0 0 0 1 0]
sage: span_of_series([x^3, 2*x^2 + 17*x^3, x^2],3)
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[0 0 1]
```

CHAPTER

FORTYFIVE

MODULAR ABELIAN VARIETIES

45.1 Constructors for certain modular abelian varieties.

AUTHORS:

- William Stein (2007-03)

AbelianVariety(*X*)

Create the abelian variety corresponding to the given definining data.

INPUT:

- X - an integer, string, newform, modsym space, congruence subgroup or tuple of congruence subgroups

OUTPUT: a modular abelian variety

EXAMPLES:

```
sage: AbelianVariety(Gamma0(37))
Abelian variety J0(37) of dimension 2
sage: AbelianVariety('37a')
Newform abelian subvariety 37a of dimension 1 of J0(37)
sage: AbelianVariety(Newform('37a'))
Newform abelian subvariety 37a of dimension 1 of J0(37)
sage: AbelianVariety(ModularSymbols(37).cuspidal_submodule())
Abelian variety J0(37) of dimension 2
sage: AbelianVariety((Gamma0(37), Gamma0(11)))
Abelian variety J0(37) x J0(11) of dimension 3
sage: AbelianVariety(37)
Abelian variety J0(37) of dimension 2
sage: AbelianVariety([1,2,3])
...
TypeError: X must be an integer, string, newform, modsym space, congruence subgroup or tuple of
```

J0(*N*)

Return the Jacobian $J_0(N)$ of the modular curve $X_0(N)$.

EXAMPLES:

```
sage: J0(389)
Abelian variety J0(389) of dimension 32
```

The result is cached:

```
sage: J0(33) is J0(33)
True
```

J1(*N*)
Return the Jacobian $J_1(N)$ of the modular curve $X_1(N)$.

EXAMPLES:

```
sage: J1(389)
Abelian variety J1(389) of dimension 6112
```

JH(*N*, *H*)
Return the Jacobian $J_H(N)$ of the modular curve $X_H(N)$.

EXAMPLES:

```
sage: JH(389,[2])
Abelian variety JH(389,[2]) of dimension 32
```

45.2 Base class for modular abelian varieties

AUTHORS:

- William Stein (2007-03)

TESTS:

```
sage: A = J0(33)
sage: D = A.decomposition(); D
[
Simple abelian subvariety 11a(1,33) of dimension 1 of J0(33),
Simple abelian subvariety 11a(3,33) of dimension 1 of J0(33),
Simple abelian subvariety 33a(1,33) of dimension 1 of J0(33)
]
sage: loads(dumps(D)) == D
True
sage: loads(dumps(A)) == A
True
```

class ModularAbelianVariety(*groups, lattice=None, base_field=Rational Field, is_simple=None, newform_level=None, isogeny_number=None, number=None, check=True*)

lattice()
Return the lattice that defines this abelan variety.

OUTPUT:

•`lattice` - a lattice embedded in the rational homology of the ambient product Jacobian

EXAMPLES:

```
sage: A = (J0(11) * J0(37))[1]; A
Simple abelian subvariety 37a(1,37) of dimension 1 of J0(11) x J0(37)
sage: type(A)
<class 'sage.modular.abvar.abvar.ModularAbelianVariety'>
sage: A.lattice()
Free module of degree 6 and rank 2 over Integer Ring
```

```
Echelon basis matrix:
[ 0  0  1 -1  1  0]
[ 0  0  0  0  2 -1]
```

class ModularAbelianVariety_abstract(*groups, base_field, is_simple=None, newform_level=None, isogeny_number=None, number=None, check=True*)

ambient_morphism()

Return the morphism from self to the ambient variety. This is injective if self is natural a subvariety of the ambient product Jacobian.

OUTPUT: morphism

The output is cached.

EXAMPLES: We compute the ambient structure morphism for an abelian subvariety of $J_0(33)$:

```
sage: A,B,C = J0(33)
sage: phi = A.ambient_morphism()
sage: phi.domain()
Simple abelian subvariety 11a(1,33) of dimension 1 of J0(33)
sage: phi.codomain()
Abelian variety J0(33) of dimension 3
sage: phi.matrix()
[ 1  1 -2  0  2 -1]
[ 0  3 -2 -1  2  0]
```

phi is of course injective

```
sage: phi.kernel()
(Finite subgroup with invariants [] over QQ of Simple abelian subvariety 11a(1,33) of dimens
 Abelian subvariety of dimension 0 of J0(33))
```

This is the same as the basis matrix for the lattice corresponding to self:

```
sage: A.lattice()
Free module of degree 6 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1  1 -2  0  2 -1]
[ 0  3 -2 -1  2  0]
```

We compute a non-injecture map to an ambient space:

```
sage: Q,pi = J0(33)/A
sage: phi = Q.ambient_morphism()
sage: phi.matrix()
[  1   4   1   9  -1  -1]
[  0  15   0   0  30 -75]
[  0   0   5  10  -5  15]
[  0   0   0  15 -15  30]
sage: phi.kernel()[0]
Finite subgroup with invariants [5, 15, 15] over QQ of Abelian variety factor of dimension 2
```

ambient_variety()

Return the ambient modular abelian variety that contains this abelian variety. The ambient variety is always a product of Jacobians of modular curves.

OUTPUT: abelian variety

EXAMPLES:

```
sage: A = J0(33)[0]; A
Simple abelian subvariety 11a(1,33) of dimension 1 of J0(33)
sage: A.ambient_variety()
Abelian variety J0(33) of dimension 3
```

base_extend(*K*)

EXAMPLES:

```
sage: A = J0(37); A
Abelian variety J0(37) of dimension 2
sage: A.base_extend(QQbar)
Abelian variety J0(37) over Algebraic Field of dimension 2
sage: A.base_extend(GF(7))
Abelian variety J0(37) over Finite Field of size 7 of dimension 2
```

base_field()

Synonym for `self.base_ring()`.

EXAMPLES:

```
sage: J0(11).base_field()
Rational Field
```

category()

Return the category of modular abelian varieties that contains this modular abelian variety.

EXAMPLES:

```
sage: J0(23).category()
Category of modular abelian varieties over Rational Field
```

change_ring(*R*)

Change the base ring of this modular abelian variety.

EXAMPLES:

```
sage: A = J0(23)
sage: A.change_ring(QQ)
Abelian variety J0(23) of dimension 2
```

complement(*A=None*)

Return a complement of this abelian variety.

INPUT:

- `A` - (default: None); if given, A must be an abelian variety that contains self, in which case the complement of self is taken inside A. Otherwise the complement is taken in the ambient product Jacobian.

OUTPUT: abelian variety

EXAMPLES:

```
sage: a,b,c = J0(33)
sage: (a+b).complement()
Simple abelian subvariety 33a(1,33) of dimension 1 of J0(33)
sage: (a+b).complement() == c
True
sage: a.complement(a+b)
Abelian subvariety of dimension 1 of J0(33)
```

cuspidal_subgroup()

Return the cuspidal subgroup of this modular abelian variety. This is the subgroup generated by rational cusps.

EXAMPLES:

```
sage: J = J0(54)
sage: C = J.cuspidal_subgroup()
sage: C.gens()
[[(1/3, 0, 0, 0, 0, 1/3, 0, 2/3)], [(0, 1/3, 0, 0, 0, 2/3, 0, 1/3)], [(0, 0, 1/9, 1/9, 1/9,
```

```
sage: C.invariants()
[3, 3, 3, 3, 3, 9]
sage: J1(13).cuspidal_subgroup()
Finite subgroup with invariants [19, 19] over QQ of Abelian variety J1(13) of dimension 2
sage: A = J0(33)[0]
sage: A.cuspidal_subgroup()
Finite subgroup with invariants [5] over QQ of Simple abelian subvariety 11a(1,33) of dimens
```

decomposition(*simple=True, bound=None*)

Return a sequence of abelian subvarieties of self that are all simple, have finite intersection and sum to self.

INPUT: simple- bool (default: True) if True, all factors are simple. If False, each factor returned is isogenous to a power of a simple and the simples in each factor are distinct.

- `bound` - int (default: None) if given, only use Hecke operators up to this bound when decomposing. This can give wrong answers, so use with caution!

EXAMPLES:

```
sage: m = ModularSymbols(11).cuspidal_submodule()
sage: d1 = m.degeneracy_map(33,1).matrix(); d3=m.degeneracy_map(33,3).matrix()
sage: w = ModularSymbols(33).submodule((d1 + d3).image(), check=False)
sage: A = w.abelian_variety(); A
Abelian subvariety of dimension 1 of J0(33)
sage: D = A.decomposition(); D
[
Simple abelian subvariety 11a(3,33) of dimension 1 of J0(33)
]
sage: D[0] == A
True
sage: B = A + J0(33)[0]; B
Abelian subvariety of dimension 2 of J0(33)
sage: dd = B.decomposition(simple=False); dd
[
Abelian subvariety of dimension 2 of J0(33)
]
sage: dd[0] == B
True
sage: dd = B.decomposition(); dd
[
Simple abelian subvariety 11a(1,33) of dimension 1 of J0(33),
Simple abelian subvariety 11a(3,33) of dimension 1 of J0(33)
]
sage: sum(dd) == B
True
```

We decompose a product of two Jacobians:

```
sage: (J0(33) * J0(11)).decomposition()
[
Simple abelian subvariety 11a(1,11) of dimension 1 of J0(33) x J0(11),
Simple abelian subvariety 11a(1,33) of dimension 1 of J0(33) x J0(11),
Simple abelian subvariety 11a(3,33) of dimension 1 of J0(33) x J0(11),
Simple abelian subvariety 33a(1,33) of dimension 1 of J0(33) x J0(11)
]
```

degen_t(*none_if_not_known=False*)

If this abelian variety is obtained via decomposition then it gets labeled with the newform label along with some information about degeneracy maps. In particular, the label ends in a pair (t, N), where N is the ambient level and t is an integer that divides the quotient of N by the newform level. This function returns

the tuple (t, N), or raises a ValueError if self isn't simple.

Note: It need not be the case that self is literally equal to the image of the newform abelian variety under the t^{th} degeneracy map. See the documentation for the label method for more details.

INPUT:

- `none_if_not_known` - (default: False) - if True, return None instead of attempting to compute the degen map's t, if it isn't known. This None result is not cached.

OUTPUT: a pair (integer, integer)

EXAMPLES:

```
sage: D = J0(33).decomposition(); D
[
Simple abelian subvariety 11a(1,33) of dimension 1 of J0(33),
Simple abelian subvariety 11a(3,33) of dimension 1 of J0(33),
Simple abelian subvariety 33a(1,33) of dimension 1 of J0(33)
]
sage: D[0].degen_t()
(1, 33)
sage: D[1].degen_t()
(3, 33)
sage: D[2].degen_t()
(1, 33)
sage: J0(33).degen_t()
...
ValueError: self must be simple
```

degeneracy_map (*M_ls, t_ls*)

Return the degeneracy map with domain self and given level/parameter. If self.ambient_variety() is a product of Jacobians (as opposed to a single Jacobian), then one can provide a list of new levels and parameters, corresponding to the ambient Jacobians in order. (See the examples below.)

INPUT:

- `M, t` - integers level and t, or
- `Mlist, tlist` - if self is in a nontrivial product ambient Jacobian, input consists of a list of levels and corresponding list of t's.

OUTPUT: a degeneracy map

EXAMPLES: We make several degenerancy maps related to $J_0(11)$ and $J_0(33)$ and compute their matrices.

```
sage: d1 = J0(11).degeneracy_map(33, 1); d1
Degeneracy map from Abelian variety J0(11) of dimension 1 to Abelian variety J0(33) of dimen
sage: d1.matrix()
[ 0 -3  2  1 -2  0]
[ 1 -2  0  1  0 -1]
sage: d2 = J0(11).degeneracy_map(33, 3); d2
Degeneracy map from Abelian variety J0(11) of dimension 1 to Abelian variety J0(33) of dimen
sage: d2.matrix()
[-1  0  0  0  1 -2]
[-1 -1  1 -1  1  0]
sage: d3 = J0(33).degeneracy_map(11, 1); d3
Degeneracy map from Abelian variety J0(33) of dimension 3 to Abelian variety J0(11) of dimen
```

He we verify that first mapping from level 11 to level 33, then back is multiplication by 4:

```
sage: d1.matrix() * d3.matrix()
[4 0]
[0 4]
```

We compute a more complciated degeneracy map involving nontrivial product ambient Jacobians; note that this is just the block direct sum of the two matrices at the beginning of this example:

```
sage: d = (J0(11)*J0(11)).degeneracy_map([33,33], [1,3]); d
Degeneracy map from Abelian variety J0(11) x J0(11) of dimension 2 to Abelian variety J0(33)
sage: d.matrix()
[ 0 -3  2  1 -2  0  0  0  0  0  0  0]
[ 1 -2  0  1  0 -1  0  0  0  0  0  0]
[ 0  0  0  0  0  0 -1  0  0  0  1 -2]
[ 0  0  0  0  0  0 -1 -1  1 -1  1  0]
```

degree()

Return the degree of this abelian variety, which is the dimension of the ambient Jacobian product.

EXAMPLES:

```
sage: A = J0(23)
sage: A.dimension()
2
```

dimension()

Return the dimension of this abelian variety.

EXAMPLES:

```
sage: A = J0(23)
sage: A.dimension()
2
```

direct_product(*other*)

Compute the direct product of self and other.

INPUT:

- `self, other` - modular abelian varieties

OUTPUT: abelian variety

EXAMPLES:

```
sage: J0(11).direct_product(J1(13))
Abelian variety J0(11) x J1(13) of dimension 3
sage: A = J0(33)[0].direct_product(J0(33)[1]); A
Abelian subvariety of dimension 2 of J0(33) x J0(33)
sage: A.lattice()
Free module of degree 12 and rank 4 over Integer Ring
Echelon basis matrix:
[ 1  1 -2  0  2 -1  0  0  0  0  0  0]
[ 0  3 -2 -1  2  0  0  0  0  0  0  0]
[ 0  0  0  0  0  0  1  0  0  0 -1  2]
[ 0  0  0  0  0  0  0  1 -1  1  0 -2]
```

dual()

Return the dual of this abelian variety.

OUTPUT: abelian variety

Warning: This is currently only implemented when self is an abelian subvariety of the ambient Jacobian product, and the complement of self in the ambient product Jacobian share no common factors. A more general implementation will require implementing computation of the intersection pairing on integral homology and the resulting Weil pairing on torsion.

EXAMPLES: We compute the dual of the elliptic curve newform abelian variety of level 33, and find the kernel of the modular map, which has structure $(\mathbf{Z}/3)^2$.

```
sage: A,B,C = J0(33)
sage: C
```

```
Simple abelian subvariety 33a(1,33) of dimension 1 of J0(33)
sage: Cd, f = C.dual()
sage: f.matrix()
[3 0]
[0 3]
sage: f.kernel()[0]
Finite subgroup with invariants [3, 3] over QQ of Simple abelian subvariety 33a(1,33) of dim
```

By a theorem the modular degree must thus be 3:

```
sage: E = EllipticCurve('33a')
sage: E.modular_degree()
3
```

Next we compute the dual of a 2-dimensional new simple abelian subvariety of $J_0(43)$.

```
sage: A = AbelianVariety('43b'); A
Newform abelian subvariety 43b of dimension 2 of J0(43)
sage: Ad, f = A.dual()
```

The kernel shows that the modular degree is 2:

```
sage: f.kernel()[0]
Finite subgroup with invariants [2, 2] over QQ of Newform abelian subvariety 43b of dimensio
```

Unfortunately, the dual is not implemented in general:

```
sage: A = J0(22)[0]; A
Simple abelian subvariety 11a(1,22) of dimension 1 of J0(22)
sage: A.dual()
...
NotImplementedError: dual not implemented unless complement shares no simple factors with se
```

endomorphism_ring()

Return the endomorphism ring of self.

OUTPUT: b = self.sturm_bound()

EXAMPLES: We compute a few endomorphism rings:

```
sage: J0(11).endomorphism_ring()
Endomorphism ring of Abelian variety J0(11) of dimension 1
sage: J0(37).endomorphism_ring()
Endomorphism ring of Abelian variety J0(37) of dimension 2
sage: J0(33)[2].endomorphism_ring()
Endomorphism ring of Simple abelian subvariety 33a(1,33) of dimension 1 of J0(33)
```

No real computation is done:

```
sage: J1(123456).endomorphism_ring()
Endomorphism ring of Abelian variety J1(123456) of dimension 423185857
```

finite_subgroup(*X, field_of_definition=None, check=True*)

Return a finite subgroup of this modular abelian variety.

INPUT:

- `X` - list of elements of other finite subgroups of this modular abelian variety or elements that coerce into the rational homology (viewed as a rational vector space); also X could be a finite subgroup itself that is contained in this abelian variety.
- `field_of_definition` - (default: None) field over which this group is defined. If None try to figure out the best base field.

OUTPUT: a finite subgroup of a modular abelian variety

EXAMPLES:

```
sage: J = J0(11)
sage: J.finite_subgroup([[1/5,0], [0,1/3]])
Finite subgroup with invariants [15] over QQbar of Abelian variety J0(11) of dimension 1

sage: J = J0(33); C = J[0].cuspidal_subgroup(); C
Finite subgroup with invariants [5] over QQ of Simple abelian subvariety 11a(1,33) of dimens
sage: J.finite_subgroup([[0,0,0,0,0,1/6]])
Finite subgroup with invariants [6] over QQbar of Abelian variety J0(33) of dimension 3
sage: J.finite_subgroup(C)
Finite subgroup with invariants [5] over QQ of Abelian variety J0(33) of dimension 3
```

free_module()

Synonym for `self.lattice()`.

OUTPUT: a free module over $\mathbf{Z}$

EXAMPLES:

```
sage: J0(37).free_module()
Ambient free module of rank 4 over the principal ideal domain Integer Ring
sage: J0(37)[0].free_module()
Free module of degree 4 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1 -1  1  0]
[ 0  0  2 -1]
```

groups()

Return an ordered tuple of the congruence subgroups that the ambient product Jacobian is attached to.

Every modular abelian variety is a finite quotient of an abelian subvariety of a product of modular Jacobians J_Γ. This function returns a tuple containing the groups Γ.

EXAMPLES:

```
sage: A = (J0(37) * J1(13))[0]; A
Simple abelian subvariety 13aG1(1,13) of dimension 2 of J0(37) x J1(13)
sage: A.groups()
(Congruence Subgroup Gamma0(37), Congruence Subgroup Gamma1(13))
```

hecke_operator(*n*)

Return the n^{th} Hecke operator on the modular abelian variety, if this makes sense [[elaborate]]. Otherwise raise a ValueError.

EXAMPLES: We compute T_2 on $J_0(37)$.

```
sage: t2 = J0(37).hecke_operator(2); t2
Hecke operator T_2 on Abelian variety J0(37) of dimension 2
sage: t2.charpoly().factor()
x * (x + 2)
sage: t2.index()
2
```

Note that there is no matrix associated to Hecke operators on modular abelian varieties. For a matrix, instead consider, e.g., the Hecke operator on integral or rational homology.

```
sage: t2.action_on_homology().matrix()
[-1  1  1 -1]
[ 1 -1  1  0]
[ 0  0 -2  1]
[ 0  0  0  0]
```

hecke_polynomial(*n, var='x'*)

Return the characteristic polynomial of the n^{th} Hecke operator T_n acting on self. Raises an ArithmeticError if self is not Hecke equivariant.

INPUT:

- n - integer ≥ 1
- var - string (default: 'x'); valid variable name

EXAMPLES:

```
sage: J0(33).hecke_polynomial(2)
x^3 + 3*x^2 - 4
sage: f = J0(33).hecke_polynomial(2, 'y'); f
y^3 + 3*y^2 - 4
sage: f.parent()
Univariate Polynomial Ring in y over Rational Field
sage: J0(33)[2].hecke_polynomial(3)
x + 1
sage: J0(33)[0].hecke_polynomial(5)
x - 1
sage: J0(33)[0].hecke_polynomial(11)
x - 1
sage: J0(33)[0].hecke_polynomial(3)
...
ArithmeticError: subspace is not invariant under matrix
```

homology(*base_ring=Integer Ring*)

Return the homology of this modular abelian variety.

Warning: For efficiency reasons the basis of the integral homology need not be the same as the basis for the rational homology.

EXAMPLES:

```
sage: J0(389).homology(GF(7))
Homology with coefficients in Finite Field of size 7 of Abelian variety J0(389) of dimension
sage: J0(389).homology(QQ)
Rational Homology of Abelian variety J0(389) of dimension 32
sage: J0(389).homology(ZZ)
Integral Homology of Abelian variety J0(389) of dimension 32
```

in_same_ambient_variety(*other*)

Return True if self and other are abelian subvarieties of the same ambient product Jacobian.

EXAMPLES:

```
sage: A,B,C = J0(33)
sage: A.in_same_ambient_variety(B)
True
sage: A.in_same_ambient_variety(J0(11))
False
```

integral_homology()

Return the integral homology of this modular abelian variety.

EXAMPLES:

```
sage: H = J0(43).integral_homology(); H
Integral Homology of Abelian variety J0(43) of dimension 3
sage: H.rank()
6
sage: H = J1(17).integral_homology(); H
Integral Homology of Abelian variety J1(17) of dimension 5
sage: H.rank()
10
```

If you just ask for the rank of the homology, no serious calculations are done, so the following is fast:

```
sage: H = J0(50000).integral_homology(); H
Integral Homology of Abelian variety J0(50000) of dimension 7351
sage: H.rank()
14702
```

A product:

```
sage: H = (J0(11) * J1(13)).integral_homology()
sage: H.hecke_operator(2)
Hecke operator T_2 on Integral Homology of Abelian variety J0(11) x J1(13) of dimension 3
sage: H.hecke_operator(2).matrix()
[-2  0  0  0  0  0]
[ 0 -2  0  0  0  0]
[ 0  0 -2  0 -1  1]
[ 0  0  1 -1  0 -1]
[ 0  0  1  1 -2  0]
[ 0  0  0  1 -1 -1]
```

intersection(*other*)

Returns the intersection of self and other inside a common ambient Jacobian product.

INPUT:

- `other` - a modular abelian variety or a finite group

OUTPUT: If other is a modular abelian variety:

- `G` - finite subgroup of self
- `A` - abelian variety (identity component of intersection) If other is a finite group:
- `G` - a finite group

EXAMPLES: We intersect some abelian varieties with finite intersection.

```
sage: J = J0(37)
sage: J[0].intersection(J[1])
(Finite subgroup with invariants [2, 2] over QQ of Simple abelian subvariety 37a(1,37) of di

sage: D = list(J0(65)); D
[Simple abelian subvariety 65a(1,65) of dimension 1 of J0(65), Simple abelian subvariety 65b
sage: D[0].intersection(D[1])
(Finite subgroup with invariants [2] over QQ of Simple abelian subvariety 65a(1,65) of dimen
sage: (D[0]+D[1]).intersection(D[1]+D[2])
(Finite subgroup with invariants [2] over QQbar of Abelian subvariety of dimension 3 of J0(6

sage: J = J0(33)
sage: J[0].intersection(J[1])
(Finite subgroup with invariants [5] over QQ of Simple abelian subvariety 11a(1,33) of dimen
```

Next we intersect two abelian varieties with non-finite intersection:

```
sage: J = J0(67); D = J.decomposition(); D
[
Simple abelian subvariety 67a(1,67) of dimension 1 of J0(67),
Simple abelian subvariety 67b(1,67) of dimension 2 of J0(67),
Simple abelian subvariety 67c(1,67) of dimension 2 of J0(67)
]
sage: (D[0] + D[1]).intersection(D[1] + D[2])
(Finite subgroup with invariants [5, 10] over QQbar of Abelian subvariety of dimension 3 of
```

is_ambient()

Return True if self equals the ambient product Jacobian.

OUTPUT: bool

EXAMPLES:

```
sage: A,B,C = J0(33)
sage: A.is_ambient()
False
sage: J0(33).is_ambient()
True
sage: (A+B).is_ambient()
False
sage: (A+B+C).is_ambient()
True
```

is_hecke_stable()

Return True if self is stable under the Hecke operators of its ambient Jacobian.

OUTPUT: bool

EXAMPLES:

```
sage: J0(11).is_hecke_stable()
True
sage: J0(33)[2].is_hecke_stable()
True
sage: J0(33)[0].is_hecke_stable()
False
sage: (J0(33)[0] + J0(33)[1]).is_hecke_stable()
True
```

is_simple(*none_if_not_known=False*)

Return whether or not this modular abelian variety is simple, i.e., has no proper nonzero abelian subvarieties.

INPUT:

- `none_if_not_known` - bool (default: False); if True then this function may return None instead of True of False if we don't already know whether or not self is simple.

EXAMPLES:

```
sage: J0(5).is_simple(none_if_not_known=True) is None  # this may fail if J0(5) comes up els
True
sage: J0(33).is_simple()
False
sage: J0(33).is_simple(none_if_not_known=True)
False
sage: J0(33)[1].is_simple()
True
sage: J1(17).is_simple()
False
```

is_subvariety(*other*)

Return True if self is a subvariety of other as they sit in a common ambient modular Jacobian. In particular, this function will only return True if self and other have exactly the same ambient Jacobians.

EXAMPLES:

```
sage: J = J0(37); J
Abelian variety J0(37) of dimension 2
sage: A = J[0]; A
Simple abelian subvariety 37a(1,37) of dimension 1 of J0(37)
sage: A.is_subvariety(A)
True
sage: A.is_subvariety(J)
True
```

is_subvariety_of_ambient_jacobian()

Return True if self is (presented as) a subvariety of the ambient product Jacobian.

Every abelian variety in Sage is a quotient of a subvariety of an ambient Jacobian product by a finite subgroup.

EXAMPLES:

```
sage: J0(33).is_subvariety_of_ambient_jacobian()
True
sage: A = J0(33)[0]; A
Simple abelian subvariety 11a(1,33) of dimension 1 of J0(33)
sage: A.is_subvariety_of_ambient_jacobian()
True
sage: B, phi = A / A.torsion_subgroup(2)
sage: B
Abelian variety factor of dimension 1 of J0(33)
sage: phi.matrix()
[2 0]
[0 2]
sage: B.is_subvariety_of_ambient_jacobian()
False
```

isogeny_number(*none_if_not_known=False*)

Return the number (starting at 0) of the isogeny class of new simple abelian varieties that self is in. If self is not simple, raises a ValueError exception.

INPUT:

- `none_if_not_known` - bool (default: False); if True then this function may return None instead of True of False if we don't already know the isogeny number of self.

EXAMPLES: We test the none_if_not_known flag first:

```
sage: J0(33).isogeny_number(none_if_not_known=True) is None
True
```

Of course, $J_0(33)$ is not simple, so this function raises a ValueError:

```
sage: J0(33).isogeny_number()
...
ValueError: self must be simple
```

Each simple factor has isogeny number 1, since that's the number at which the factor is new.

```
sage: J0(33)[1].isogeny_number()
0
sage: J0(33)[2].isogeny_number()
0
```

Next consider $J_0(37)$ where there are two distinct newform factors:

```
sage: J0(37)[1].isogeny_number()
1
```

label()

Return the label associated to this modular abelian variety.

The format of the label is [level][isogeny class][group](t, ambient level)

If this abelian variety B has the above label, this implies only that B is isogenous to the newform abelan variety A_f associated to the newform with label [level][isogeny class][group]. The [group] is empty for $\Gamma_0(N)$, is G1 for $\Gamma_1(N)$ and is GH[...] for $\Gamma_H(N)$.

Warning: The sum of $\delta_s(A_f)$ for all $s \mid t$ contains A, but no sum for a proper divisor of t contains A. It need *not* be the case that B is equal to $\delta_t(A_f)$!!!

OUTPUT: string

EXAMPLES:

```
sage: J0(11).label()
'11a(1,11)'
sage: J0(11)[0].label()
'11a(1,11)'
sage: J0(33)[2].label()
'33a(1,33)'
sage: J0(22).label()
...
ValueError: self must be simple
```

We illustrate that self need not equal $\delta_t(A_f)$:

```
sage: J = J0(11); phi = J.degeneracy_map(33, 1) + J.degeneracy_map(33,3)
sage: B = phi.image(); B
Abelian subvariety of dimension 1 of J0(33)
sage: B.decomposition()
[
Simple abelian subvariety 11a(3,33) of dimension 1 of J0(33)
]
sage: C = J.degeneracy_map(33,3).image(); C
Abelian subvariety of dimension 1 of J0(33)
sage: C == B
False
```

lattice()

Return lattice in ambient cuspidal modular symbols product that defines this modular abelian variety.

This must be defined in each derived class.

OUTPUT: a free module over $\mathbf{Z}$

EXAMPLES:

```
sage: A = sage.modular.abvar.abvar.ModularAbelianVariety_abstract((Gamma0(37),), QQ)
sage: A
...
NotImplementedError: BUG -- lattice method must be defined in derived class
```

level()

Return the level of this modular abelian variety, which is an integer N (usually minimal) such that this modular abelian variety is a quotient of $J_1(N)$. In the case that the ambient variety of self is a product of Jacobians, return the LCM of their levels.

EXAMPLES:

```
sage: J1(5077).level()
5077
sage: JH(389,[4]).level()
389
sage: (J0(11)*J0(17)).level()
187
```

lseries()

Return the complex L-series of this modular abelian variety.

EXAMPLES:

```
sage: A = J0(37)
sage: A.lseries()
Complex L-series attached to Abelian variety J0(37) of dimension 2
```

modular_degree()
Return the modular degree of this abelian variety, which is the square root of the degree of the modular kernel.

EXAMPLES:

```
sage: A = AbelianVariety('37a')
sage: A.modular_degree()
2
```

modular_kernel()
Return the modular kernel of this abelian variety, which is the kernel of the canonical polarization of self.

EXAMPLES:

```
sage: A = AbelianVariety('33a'); A
Newform abelian subvariety 33a of dimension 1 of J0(33)
sage: A.modular_kernel()
Finite subgroup with invariants [3, 3] over QQ of Newform abelian subvariety 33a of dimensio
```

newform_label()
Return the label [level][isogeny class][group] of the newform f such that this abelian variety is isogenous to the newform abelian variety A_f. If this abelian variety is not simple, raise a ValueError.

OUTPUT: string

EXAMPLES:

```
sage: J0(11).newform_label()
'11a'
sage: J0(33)[2].newform_label()
'33a'
```

The following fails since $J_0(33)$ is not simple:

```
sage: J0(33).newform_label()
...
ValueError: self must be simple
```

newform_level(*none_if_not_known=False*)
Write self as a product (up to isogeny) of newform abelian varieties A_f. Then this function return the least common multiple of the levels of the newforms f, along with the corresponding group or list of groups (the groups do not appear with multiplicity).

INPUT:

- `none_if_not_known` - (default: False) if True, return None instead of attempting to compute the newform level, if it isn't already known. This None result is not cached.

OUTPUT: integer group or list of distinct groups

EXAMPLES:

```
sage: J0(33)[0].newform_level()
(11, Congruence Subgroup Gamma0(33))
sage: J0(33)[0].newform_level(none_if_not_known=True)
(11, Congruence Subgroup Gamma0(33))
```

Here there are multiple groups since there are in fact multiple newforms:

```
sage: (J0(11) * J1(13)).newform_level()
(143, [Congruence Subgroup Gamma0(11), Congruence Subgroup Gamma1(13)])
```

padic_lseries(p)
Return the p-adic L-series of this modular abelian variety.

EXAMPLES:

```
sage: A = J0(37)
sage: A.padic_lseries(7)
7-adic L-series attached to Abelian variety J0(37) of dimension 2
```

project_to_factor(*n*)

If self is an ambient product of Jacobians, return a projection from self to the nth such Jacobian.

EXAMPLES:

```
sage: J = J0(33)
sage: J.project_to_factor(0)
Abelian variety endomorphism of Abelian variety J0(33) of dimension 3

sage: J = J0(33) * J0(37) * J0(11)
sage: J.project_to_factor(2)
Abelian variety morphism:
  From: Abelian variety J0(33) x J0(37) x J0(11) of dimension 6
  To:   Abelian variety J0(11) of dimension 1
sage: J.project_to_factor(2).matrix()
[0 0]
[0 0]
[0 0]
[0 0]
[0 0]
[0 0]
[0 0]
[0 0]
[0 0]
[0 0]
[1 0]
[0 1]
```

projection(*A, check=True*)

Given an abelian subvariety A of self, return a projection morphism from self to A. Note that this morphism need not be unique.

INPUT:

- A - an abelian variety

OUTPUT: a morphism

EXAMPLES:

```
sage: a,b,c = J0(33)
sage: pi = J0(33).projection(a); pi.matrix()
[ 3 -2]
[-5  5]
[-4  1]
[ 3 -2]
[ 5  0]
[ 1  1]
sage: pi = (a+b).projection(a); pi.matrix()
[ 0  0]
[-3  2]
[-4  1]
[-1 -1]
sage: pi = a.projection(a); pi.matrix()
[1 0]
[0 1]
```

We project onto a factor in a product of two Jacobians:

```
sage: A = J0(11)*J0(11); A
Abelian variety J0(11) x J0(11) of dimension 2
sage: A[0]
Simple abelian subvariety 11a(1,11) of dimension 1 of J0(11) x J0(11)
sage: A.projection(A[0])
Abelian variety morphism:
  From: Abelian variety J0(11) x J0(11) of dimension 2
  To:   Simple abelian subvariety 11a(1,11) of dimension 1 of J0(11) x J0(11)
sage: A.projection(A[0]).matrix()
[0 0]
[0 0]
[1 0]
[0 1]
sage: A.projection(A[1]).matrix()
[1 0]
[0 1]
[0 0]
[0 0]
```

qbar_torsion_subgroup()

Return the group of all points of finite order in the algebraic closure of this abelian variety.

EXAMPLES:

```
sage: T = J0(33).qbar_torsion_subgroup(); T
Group of all torsion points in QQbar on Abelian variety J0(33) of dimension 3
```

The field of definition is the same as the base field of the abelian variety.

```
sage: T.field_of_definition()
Rational Field
```

On the other hand, T is a module over $\mathbf{Z}$.

```
sage: T.base_ring()
Integer Ring
```

quotient(*other*)

Compute the quotient of self and other, where other is either an abelian subvariety of self or a finite subgroup of self.

INPUT:

- `other` - a finite subgroup or subvariety

OUTPUT: a pair (A, phi) with phi the quotient map from self to A

EXAMPLES: We quotient $J_0(33)$ out by an abelian subvariety:

```
sage: Q, f = J0(33).quotient(J0(33)[0])
sage: Q
Abelian variety factor of dimension 2 of J0(33)
sage: f
Abelian variety morphism:
  From: Abelian variety J0(33) of dimension 3
  To:   Abelian variety factor of dimension 2 of J0(33)
```

We quotient $J_0(33)$ by the cuspidal subgroup:

```
sage: C = J0(33).cuspidal_subgroup()
sage: Q, f = J0(33).quotient(C)
sage: Q
Abelian variety factor of dimension 3 of J0(33)
sage: f.kernel()[0]
```

```
Finite subgroup with invariants [10, 10] over QQ of Abelian variety J0(33) of dimension 3
sage: C
Finite subgroup with invariants [10, 10] over QQ of Abelian variety J0(33) of dimension 3
sage: J0(11).direct_product(J1(13))
Abelian variety J0(11) x J1(13) of dimension 3
```

rank()

Return the rank of the underlying lattice of self.

EXAMPLES:

```
sage: J = J0(33)
sage: J.rank()
6
sage: J[1]
Simple abelian subvariety 11a(3,33) of dimension 1 of J0(33)
sage: (J[1] * J[1]).rank()
4
```

rational_cusp_subgroup()

Return the subgroup of this modular abelian variety generated by rational cusps.

This is a subgroup of the group of rational points in the cuspidal subgroup.

Warning: This is only currently implemented for $\Gamma_0(N)$.

EXAMPLES:

```
sage: J = J0(54)
sage: CQ = J.rational_cusp_subgroup(); CQ
Finite subgroup with invariants [3, 3, 9] over QQ of Abelian variety J0(54) of dimension 4
sage: CQ.gens()
[[(1/3, 0, 0, 1/3, 2/3, 1/3, 0, 1/3)], [(0, 0, 1/9, 1/9, 7/9, 7/9, 1/9, 8/9)], [(0, 0, 0, 0,
sage: factor(CQ.order())
3^4
sage: CQ.invariants()
[3, 3, 9]
```

In this example the rational cuspidal subgroup and the cuspidal subgroup differ by a lot.

```
sage: J = J0(49)
sage: J.cuspidal_subgroup()
Finite subgroup with invariants [2, 14] over QQ of Abelian variety J0(49) of dimension 1
sage: J.rational_cusp_subgroup()
Finite subgroup with invariants [2] over QQ of Abelian variety J0(49) of dimension 1
```

Note that computation of the rational cusp subgroup isn't implemented for Γ_1.

```
sage: J = J1(13)
sage: J.cuspidal_subgroup()
Finite subgroup with invariants [19, 19] over QQ of Abelian variety J1(13) of dimension 2
sage: J.rational_cusp_subgroup()
...
NotImplementedError: computation of rational cusps only implemented in Gamma0 case.
```

rational_homology()

Return the rational homology of this modular abelian variety.

EXAMPLES:

```
sage: H = J0(37).rational_homology(); H
Rational Homology of Abelian variety J0(37) of dimension 2
sage: H.rank()
```

```
4
sage: H.base_ring()
Rational Field
sage: H = J1(17).rational_homology(); H
Rational Homology of Abelian variety J1(17) of dimension 5
sage: H.rank()
10
sage: H.base_ring()
Rational Field
```

rational_torsion_subgroup()

Return the maximal torsion subgroup of self defined over QQ.

EXAMPLES:

```
sage: J = J0(33)
sage: A = J.new_subvariety()
sage: A
Abelian subvariety of dimension 1 of J0(33)
sage: t = A.rational_torsion_subgroup()
sage: t.multiple_of_order()
4
sage: t.divisor_of_order()
4
sage: t.order()
4
sage: t.gens()
[[(1/2, 0, 0, -1/2, 0, 0)], [(0, 0, 1/2, 0, 1/2, -1/2)]]
sage: t
Torsion subgroup of Abelian subvariety of dimension 1 of J0(33)
```

sturm_bound()

Return a bound B such that all Hecke operators T_n for $n \leq B$ generate the Hecke algebra.

OUTPUT: integer

EXAMPLES:

```
sage: J0(11).sturm_bound()
2
sage: J0(33).sturm_bound()
8
sage: J1(17).sturm_bound()
48
sage: J1(123456).sturm_bound()
1693483008
sage: JH(37,[2,3]).sturm_bound()
7
sage: J1(37).sturm_bound()
228
```

torsion_subgroup(n)

If n is an integer, return the subgroup of points of order n. Return the n-torsion subgroup of elements of order dividing n of this modular abelian variety A, i.e., the group $A[n]$.

EXAMPLES:

```
sage: J1(13).torsion_subgroup(19)
Finite subgroup with invariants [19, 19, 19, 19] over QQ of Abelian variety J1(13) of dimens
```

```
sage: A = J0(23)
sage: G = A.torsion_subgroup(5); G
```

```
Finite subgroup with invariants [5, 5, 5, 5] over QQ of Abelian variety J0(23) of dimension
sage: G.order()
625
sage: G.gens()
[[(1/5, 0, 0, 0)], [(0, 1/5, 0, 0)], [(0, 0, 1/5, 0)], [(0, 0, 0, 1/5)]]
sage: A = J0(23)
sage: A.torsion_subgroup(2).order()
16
```

vector_space()

Return vector space corresponding to the modular abelian variety.

This is the lattice tensored with $\mathbf{Q}$.

EXAMPLES:

```
sage: J0(37).vector_space()
Vector space of dimension 4 over Rational Field
sage: J0(37)[0].vector_space()
Vector space of degree 4 and dimension 2 over Rational Field
Basis matrix:
[   1   -1    0  1/2]
[   0    0    1 -1/2]
```

zero_subgroup()

Return the zero subgroup of this modular abelian variety, as a finite group.

EXAMPLES:

```
sage: A =J0(54); G = A.zero_subgroup(); G
Finite subgroup with invariants [] over QQ of Abelian variety J0(54) of dimension 4
sage: G.is_subgroup(A)
True
```

zero_subvariety()

Return the zero subvariety of self.

EXAMPLES:

```
sage: J = J0(37)
sage: J.zero_subvariety()
Simple abelian subvariety of dimension 0 of J0(37)
sage: J.zero_subvariety().level()
37
sage: J.zero_subvariety().newform_level()
(1, [])
```

class **ModularAbelianVariety_modsym**(*modsym, lattice=None, newform_level=None, is_simple=None, isogeny_number=None, number=None, check=True*)

brandt_module(*p*)

Return the Brandt module at p that corresponds to self. This is the factor of the vector space on the ideal class set in an order of level N in the quaternion algebra ramified at p and infinity.

INPUT: • p – prime that exactly divides the level

OUTPUT: • Brandt module space that corresponds to self.

EXAMPLES:

```
sage: J0(43)[1].brandt_module(43)
Subspace of dimension 2 of Brandt module of dimension 4 of level 43 of weight 2 over Rationa
sage: J0(43)[1].brandt_module(43).basis()
((1, 0, -1/2, -1/2), (0, 1, -1/2, -1/2))
sage: J0(43)[0].brandt_module(43).basis()
```

```
((0, 0, 1, -1),)
sage: J0(35)[0].brandt_module(5).basis()
((1, 0, -1, 0),)
sage: J0(35)[0].brandt_module(7).basis()
((1, -1, 1, -1),)
```

component_group_order(*p*)

Return the order of the component group of the special fiber at p of the Neron model of self.

NOTE: For bad primes, this is only implemented when the group if Gamma0 and p exactly divides the level.

NOTE: the input abelian variety must be simple

ALGORITHM: See "Component Groups of Quotients of J0(N)" by Kohel and Stein. That paper is about optimal quotients; however, section 4.1 of Conrad-Stein "Component Groups of Purely Toric Quotients", one sees that the component group of an optimal quotient is the same as the component group of its dual (which is the subvariety).

INPUT: • p – a prime number

OUTPUT: • Integer

EXAMPLES:

```
sage: A = J0(37)[1]
sage: A.component_group_order(37)
3
sage: A = J0(43)[1]
sage: A.component_group_order(37)
1
sage: A.component_group_order(43)
7
sage: A = J0(23)[0]
sage: A.component_group_order(23)
11
```

tamagawa_number(*p*)

Return the Tamagawa number of this abelianv variety at p.

NOTE: For bad primes, this is only implemented when the group if Gamma0 and p exactly divides the level and Atkin-Lehner acts diagonally on this abelian variety (e.g., if this variety is new and simple). See the self.component_group command for more information.

NOTE: the input abelian variety must be simple

In cases where this function doesn't work, consider using the self.tamagawa_number_bounds functions.

INPUT: • p – a prime number

OUTPUT: • Integer

EXAMPLES:

```
sage: A = J0(37)[1]
sage: A.tamagawa_number(37)
3
sage: A = J0(43)[1]
sage: A.tamagawa_number(37)
1
sage: A.tamagawa_number(43)
7
sage: A = J0(23)[0]
sage: A.tamagawa_number(23)
11
```

tamagawa_number_bounds(*p*)

Return a divisor and multiple of the Tamagawa number of self at p.

NOTE: the input abelian variety must be simple

INPUT: • p – a prime number

OUTPUT: • div – integer; divisor of Tamagawa number at p
- mul – integer; multiple of Tamagawa number at p
- mul_primes – tuple; in case mul==0, a list of all primes that can possibly divide the Tamagawa number at p.

EXAMPLES:

```
sage: A = J0(63).new_subvariety()[1]; A
Simple abelian subvariety 63b(1,63) of dimension 2 of J0(63)
sage: A.tamagawa_number_bounds(7)
(3, 3, ())
sage: A.tamagawa_number_bounds(3)
(1, 0, (2, 3, 5))
```

class ModularAbelianVariety_modsym_abstract(*groups, base_field, is_simple=None, newform_level=None, isogeny_number=None, number=None, check=True*)

decomposition(*simple=True, bound=None*)

Decompose this modular abelian variety as a product of abelian subvarieties, up to isogeny.

INPUT: simple- bool (default: True) if True, all factors are simple. If False, each factor returned is isogenous to a power of a simple and the simples in each factor are distinct.

•`bound` - int (default: None) if given, only use Hecke operators up to this bound when decomposing. This can give wrong answers, so use with caution!

EXAMPLES:

```
sage: J = J0(33)
sage: J.decomposition()
[
Simple abelian subvariety 11a(1,33) of dimension 1 of J0(33),
Simple abelian subvariety 11a(3,33) of dimension 1 of J0(33),
Simple abelian subvariety 33a(1,33) of dimension 1 of J0(33)
]
sage: J1(17).decomposition()
[
Simple abelian subvariety 17aG1(1,17) of dimension 1 of J1(17),
Simple abelian subvariety 17bG1(1,17) of dimension 4 of J1(17)
]
```

dimension()

Return the dimension of this modular abelian variety.

EXAMPLES:

```
sage: J0(37)[0].dimension()
1
sage: J0(43)[1].dimension()
2
sage: J1(17)[1].dimension()
4
```

group()

Return the congruence subgroup associated that this modular abelian variety is associated to.

EXAMPLES:

```
sage: J0(13).group()
Congruence Subgroup Gamma0(13)
```

```
sage: J1(997).group()
Congruence Subgroup Gamma1(997)
sage: JH(37,[3]).group()
Congruence Subgroup Gamma_H(37) with H generated by [3]
sage: J0(37)[1].groups()
(Congruence Subgroup Gamma0(37),)
```

groups()

Return the tuple of groups associated to the modular symbols abelian variety. This is always a 1-tuple.

OUTPUT: tuple

EXAMPLES:

```
sage: A = ModularSymbols(33).cuspidal_submodule().abelian_variety(); A
Abelian variety J0(33) of dimension 3
sage: A.groups()
(Congruence Subgroup Gamma0(33),)
sage: type(A)
<class 'sage.modular.abvar.abvar.ModularAbelianVariety_modsym'>
```

is_ambient()

Return True if this abelian variety attached to a modular symbols space space is attached to the cuspidal subspace of the ambient modular symbols space.

OUTPUT: bool

EXAMPLES:

```
sage: A = ModularSymbols(43).cuspidal_subspace().abelian_variety(); A
Abelian variety J0(43) of dimension 3
sage: A.is_ambient()
True
sage: type(A)
<class 'sage.modular.abvar.abvar.ModularAbelianVariety_modsym'>
sage: A = ModularSymbols(43).cuspidal_subspace()[1].abelian_variety(); A
Abelian subvariety of dimension 2 of J0(43)
sage: A.is_ambient()
False
```

is_subvariety(*other*)

Return True if self is a subvariety of other.

EXAMPLES:

```
sage: J = J0(37); J
Abelian variety J0(37) of dimension 2
sage: A = J[0]; A
Simple abelian subvariety 37a(1,37) of dimension 1 of J0(37)
sage: A.is_subvariety(J)
True
sage: A.is_subvariety(J0(11))
False
```

There may be a way to map A into $J_0(74)$, but A is not equipped with any special structure of an embedding.

```
sage: A.is_subvariety(J0(74))
False
```

Some ambient examples:

```
sage: J = J0(37)
sage: J.is_subvariety(J)
```

```
True
sage: J.is_subvariety(25)
False
```

More examples:

```
sage: A = J0(42); D = A.decomposition(); D
[
Simple abelian subvariety 14a(1,42) of dimension 1 of J0(42),
Simple abelian subvariety 14a(3,42) of dimension 1 of J0(42),
Simple abelian subvariety 21a(1,42) of dimension 1 of J0(42),
Simple abelian subvariety 21a(2,42) of dimension 1 of J0(42),
Simple abelian subvariety 42a(1,42) of dimension 1 of J0(42)
]
sage: D[0].is_subvariety(A)
True
sage: D[1].is_subvariety(D[0] + D[1])
True
sage: D[2].is_subvariety(D[0] + D[1])
False
```

lattice()

Return the lattice the defines this modular symbols modular abelian variety.

OUTPUT: a free $\mathbf{Z}$-module embedded in an ambient $\mathbf{Q}$-vector space

EXAMPLES:

```
sage: A = ModularSymbols(33).cuspidal_submodule()[0].abelian_variety(); A
Abelian subvariety of dimension 1 of J0(33)
sage: A.lattice()
Free module of degree 6 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1  0  0 -1  0  0]
[ 0  0  1  0  1 -1]
sage: type(A)
<class 'sage.modular.abvar.abvar.ModularAbelianVariety_modsym'>
```

modular_symbols(*sign=0*)

Return space of modular symbols (with given sign) associated to this modular abelian variety, if it can be found by cutting down using Hecke operators. Otherwise raise a RuntimeError exception.

EXAMPLES:

```
sage: A = J0(37)
sage: A.modular_symbols()
Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 5 for Gamma_0(
sage: A.modular_symbols(1)
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 3 for Gamma_0(
```

More examples:

```
sage: J0(11).modular_symbols()
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 3 for Gamma_0(
sage: J0(11).modular_symbols(sign=1)
Modular Symbols subspace of dimension 1 of Modular Symbols space of dimension 2 for Gamma_0(
sage: J0(11).modular_symbols(sign=0)
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 3 for Gamma_0(
sage: J0(11).modular_symbols(sign=-1)
Modular Symbols space of dimension 1 for Gamma_0(11) of weight 2 with sign -1 over Rational
```

Even more examples:

```
sage: A = J0(33)[1]; A
Simple abelian subvariety 11a(3,33) of dimension 1 of J0(33)
sage: A.modular_symbols()
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 9 for Gamma_0(
```

It is not always possible to determine the sign subspaces:

```
sage: A.modular_symbols(1)
...
RuntimeError: unable to determine sign (=1) space of modular symbols

sage: A.modular_symbols(-1)
...
RuntimeError: unable to determine sign (=-1) space of modular symbols
```

new_subvariety(*p=None*)

Return the new or p-new subvariety of self.

INPUT:

- `self` - a modular abelian variety
- `p` - prime number or None (default); if p is a prime, return the p-new subvariety. Otherwise return the full new subvariety.

EXAMPLES:

```
sage: J0(33).new_subvariety()
Abelian subvariety of dimension 1 of J0(33)
sage: J0(100).new_subvariety()
Abelian subvariety of dimension 1 of J0(100)
sage: J1(13).new_subvariety()
Abelian variety J1(13) of dimension 2
```

old_subvariety(*p=None*)

Return the old or p-old abelian variety of self.

INPUT:

- `self` - a modular abelian variety
- `p` - prime number or None (default); if p is a prime, return the p-old subvariety. Otherwise return the full old subvariety.

EXAMPLES:

```
sage: J0(33).old_subvariety()
Abelian subvariety of dimension 2 of J0(33)
sage: J0(100).old_subvariety()
Abelian subvariety of dimension 6 of J0(100)
sage: J1(13).old_subvariety()
Abelian subvariety of dimension 0 of J1(13)
```

factor_modsym_space_new_factors(*M*)

Given an ambient modular symbols space, return complete factorization of it.

INPUT:

- `M` - modular symbols space

OUTPUT: list of decompositions corresponding to each new space.

EXAMPLES:

```
sage: M = ModularSymbols(33)
sage: sage.modular.abvar.abvar.factor_modsym_space_new_factors(M)
[[
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 3 for Gamma_0(11)
],
 [
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 9 for Gamma_0(33)
]]
```

factor_new_space(*M*)

Given a new space M of modular symbols, return the decomposition into simple of M under the Hecke operators.

INPUT:

- M - modular symbols space

OUTPUT: list of factors

EXAMPLES:

```
sage: M = ModularSymbols(37).cuspidal_subspace()
sage: sage.modular.abvar.abvar.factor_new_space(M)
[
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 5 for Gamma_0(37)
Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 5 for Gamma_0(37)
]
```

is_ModularAbelianVariety(*x*)

Return True if x is a modular abelian variety.

INPUT:

- x - object

EXAMPLES:

```
sage: from sage.modular.abvar.abvar import is_ModularAbelianVariety
sage: is_ModularAbelianVariety(5)
False
sage: is_ModularAbelianVariety(J0(37))
True
```

Returning True is a statement about the data type not whether or not some abelian variety is modular:

```
sage: is_ModularAbelianVariety(EllipticCurve('37a'))
False
```

modsym_lattices(*M, factors*)

Append lattice information to the output of simple_factorization_of_modsym_space.

INPUT:

- M - modular symbols spaces
- factors - Sequence (simple_factorization_of_modsym_space)

OUTPUT: sequence with more information for each factor (the lattice)

EXAMPLES:

```
sage: M = ModularSymbols(33)
sage: factors = sage.modular.abvar.abvar.simple_factorization_of_modsym_space(M, simple=False)
sage: sage.modular.abvar.abvar.modsym_lattices(M, factors)
[
(11, 0, None, Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 9 fo
Echelon basis matrix:
[ 1  0  0  0 -1  2]
[ 0  1  0  0 -1  1]
[ 0  0  1  0 -2  2]
[ 0  0  0  1 -1 -1]),
(33, 0, None, Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 9 fo
Echelon basis matrix:
[ 1  0  0 -1  0  0]
[ 0  0  1  0  1 -1])
]
```

random_hecke_operator(*M, t=None, p=2*)

Return a random Hecke operator acting on M, got by adding to t a random multiple of T_p

INPUT:

- `M` - modular symbols space
- `t` - None or a Hecke operator
- `p` - a prime

OUTPUT: Hecke operator prime

EXAMPLES:

```
sage: M = ModularSymbols(11).cuspidal_subspace()
sage: t, p = sage.modular.abvar.abvar.random_hecke_operator(M)
sage: p
3
sage: t, p = sage.modular.abvar.abvar.random_hecke_operator(M, t, p)
sage: p
5
```

simple_factorization_of_modsym_space(*M, simple=True*)

Return factorization of M. If simple is False, return powers of simples.

INPUT:

- `M` - modular symbols space
- `simple` - bool (default: True)

OUTPUT: sequence

EXAMPLES:

```
sage: M = ModularSymbols(33)
sage: sage.modular.abvar.abvar.simple_factorization_of_modsym_space(M)
[
(11, 0, 1, Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 9 for G
(11, 0, 3, Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 9 for G
(33, 0, 1, Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 9 for G
]
sage: sage.modular.abvar.abvar.simple_factorization_of_modsym_space(M, simple=False)
[
(11, 0, None, Modular Symbols subspace of dimension 4 of Modular Symbols space of dimension 9 fo
```

```
(33, 0, None, Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 9 fc
]
```

sqrt_poly(*f*)

Return the square root of the polynomial f.

Note: At some point something like this should be a member of the polynomial class. For now this is just used internally by some charpoly functions above.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: f = (x-1)*(x+2)*(x^2 + 1/3*x + 5)
sage: f
x^4 + 4/3*x^3 + 10/3*x^2 + 13/3*x - 10
sage: sage.modular.abvar.abvar.sqrt_poly(f^2)
x^4 + 4/3*x^3 + 10/3*x^2 + 13/3*x - 10
sage: sage.modular.abvar.abvar.sqrt_poly(f)
...
ValueError: f must be a perfect square
sage: sage.modular.abvar.abvar.sqrt_poly(2*f^2)
...
ValueError: f must be monic
```

45.3 Ambient Jacobian Abelian Variety

TESTS:

```
sage: loads(dumps(J0(37))) == J0(37)
True
sage: loads(dumps(J1(13))) == J1(13)
True
```

ModAbVar_ambient_jacobian(*group*)

Return the ambient Jacobian attached to a given congruence subgroup.

The result is cached using a weakref. This function is called internally by modular abelian variety constructors.

INPUT:

- `group` - a congruence subgroup.

OUTPUT: a modular abelian variety attached

EXAMPLES:

```
sage: import sage.modular.abvar.abvar_ambient_jacobian as abvar_ambient_jacobian
sage: A = abvar_ambient_jacobian.ModAbVar_ambient_jacobian(Gamma0(11))
sage: A
Abelian variety J0(11) of dimension 1
sage: B = abvar_ambient_jacobian.ModAbVar_ambient_jacobian(Gamma0(11))
sage: A is B
True
```

You can get access to and/or clear the cache as follows:

```
sage: abvar_ambient_jacobian._cache = {}
sage: B = abvar_ambient_jacobian.ModAbVar_ambient_jacobian(Gamma0(11))
sage: A is B
False
```

class **ModAbVar_ambient_jacobian_class**(*group*)

An ambient Jacobian modular abelian variety attached to a congruence subgroup.

ambient_variety()

Return the ambient modular abelian variety that contains self. Since self is a Jacobian modular abelian variety, this is just self.

OUTPUT: abelian variety

EXAMPLES:

```
sage: A = J0(17)
sage: A.ambient_variety()
Abelian variety J0(17) of dimension 1
sage: A is A.ambient_variety()
True
```

decomposition(*simple=True, bound=None*)

Decompose this ambient Jacobian as a product of abelian subvarieties, up to isogeny.

EXAMPLES:

```
sage: J0(33).decomposition(simple=False)
[
Abelian subvariety of dimension 2 of J0(33),
Abelian subvariety of dimension 1 of J0(33)
]
sage: J0(33).decomposition(simple=False)[1].is_simple()
True
sage: J0(33).decomposition(simple=False)[0].is_simple()
False
sage: J0(33).decomposition(simple=False)
[
Abelian subvariety of dimension 2 of J0(33),
Simple abelian subvariety 33a(None,33) of dimension 1 of J0(33)
]
sage: J0(33).decomposition(simple=True)
[
Simple abelian subvariety 11a(1,33) of dimension 1 of J0(33),
Simple abelian subvariety 11a(3,33) of dimension 1 of J0(33),
Simple abelian subvariety 33a(1,33) of dimension 1 of J0(33)
]
```

degeneracy_map(*level, t=1, check=True*)

Return the t-th degeneracy map from self to J(level). Here t must be a divisor of either level/self.level() or self.level()/level.

INPUT:

- `level` - integer (multiple or divisor of level of self)
- `t` - divisor of quotient of level of self and level
- `check` - bool (default: True); if True do some checks on the input

OUTPUT: a morphism

EXAMPLES:

```
sage: J0(11).degeneracy_map(33)
Degeneracy map from Abelian variety J0(11) of dimension 1 to Abelian variety J0(33) of dimen
sage: J0(11).degeneracy_map(33).matrix()
[ 0 -3  2  1 -2  0]
[ 1 -2  0  1  0 -1]
sage: J0(11).degeneracy_map(33,3).matrix()
[-1  0  0  0  1 -2]
[-1 -1  1 -1  1  0]
sage: J0(33).degeneracy_map(11,1).matrix()
[ 0  1]
[ 0 -1]
[ 1 -1]
[ 0  1]
[-1  1]
[ 0  0]
sage: J0(11).degeneracy_map(33,1).matrix() * J0(33).degeneracy_map(11,1).matrix()
[4 0]
[0 4]
```

dimension()

Return the dimension of this modular abelian variety.

EXAMPLES:

```
sage: J0(2007).dimension()
221
sage: J1(13).dimension()
2
sage: J1(997).dimension()
40920
sage: J0(389).dimension()
32
sage: JH(389,[4]).dimension()
64
sage: J1(389).dimension()
6112
```

group()

Return the group that this Jacobian modular abelian variety is attached to.

EXAMPLES:

```
sage: J1(37).group()
Congruence Subgroup Gamma1(37)
sage: J0(5077).group()
Congruence Subgroup Gamma0(5077)
sage: J = GammaH(11,[3]).modular_abelian_variety(); J
Abelian variety JH(11,[3]) of dimension 1
sage: J.group()
Congruence Subgroup Gamma_H(11) with H generated by [3]
```

groups()

Return the tuple of congruence subgroups attached to this ambient Jacobian. This is always a tuple of length 1.

OUTPUT: tuple

EXAMPLES:

```
sage: J0(37).groups()
(Congruence Subgroup Gamma0(37),)
```

45.4 Finite subgroups of modular abelian varieties

Sage can compute with fairly general finite subgroups of modular abelian varieties. Elements of finite order are represented by equivalence classes of elements in $H_1(A, \mathbf{Q})$ modulo $H_1(A, \mathbf{Z})$. A finite subgroup can be defined by giving generators and via various other constructions. Given a finite subgroup, one can compute generators, as well as the structure as an abstract group. Arithmetic on subgroups is also supported, including adding two subgroups together, checking inclusion, etc.

TODO: Intersection, action of Hecke operators.

AUTHORS:

- William Stein (2007-03)

EXAMPLES:

```
sage: J = J0(33)
sage: C = J.cuspidal_subgroup()
sage: C
Finite subgroup with invariants [10, 10] over QQ of Abelian variety J0(33) of dimension 3
sage: C.order()
100
sage: C.gens()
[[(1/10, 0, 1/10, 1/10, 1/10, 3/10)], [(0, 1/5, 1/10, 0, 1/10, 9/10)], [(0, 0, 1/2, 0, 1/2, 1/2)]]
sage: C.0 + C.1
[(1/10, 1/5, 1/5, 1/10, 1/5, 6/5)]
sage: 10*(C.0 + C.1)
[(0, 0, 0, 0, 0, 0)]
sage: G = C.subgroup([C.0 + C.1]); G
Finite subgroup with invariants [10] over QQbar of Abelian variety J0(33) of dimension 3
sage: G.gens()
[[(1/10, 1/5, 1/5, 1/10, 1/5, 1/5)]]
sage: G.order()
10
sage: G <= C
True
sage: G >= C
False
```

We make a table of the order of the cuspidal subgroup for the first few levels:

```
sage: for N in range(11,40): print N, J0(N).cuspidal_subgroup().order()
...
11 5
12 1
13 1
14 6
15 8
16 1
17 4
18 1
19 3
20 6
21 8
22 25
23 11
24 8
```

```
25 1
26 21
27 9
28 36
29 7
30 192
31 5
32 8
33 100
34 48
35 48
36 12
37 3
38 135
39 56
```

TESTS:

```
sage: G = J0(11).finite_subgroup([[1/3,0], [0,1/5]]); G
Finite subgroup with invariants [15] over QQbar of Abelian variety J0(11) of dimension 1
sage: loads(dumps(G)) == G
True
sage: loads(dumps(G.0)) == G.0
True
```

class FiniteSubgroup(*abvar, field_of_definition=Rational Field*)

abelian_variety()

Return the abelian variety that this is a finite subgroup of.

EXAMPLES:

```
sage: J = J0(42)
sage: G = J.rational_torsion_subgroup(); G
Torsion subgroup of Abelian variety J0(42) of dimension 5
sage: G.abelian_variety()
Abelian variety J0(42) of dimension 5
```

exponent()

Return the exponent of this finite abelian group.

OUTPUT: Integer

EXAMPLES:

```
sage: t = J0(33).hecke_operator(7)
sage: G = t.kernel()[0]; G
Finite subgroup with invariants [2, 2, 2, 2, 4, 4] over QQ of Abelian variety J0(33) of dime
sage: G.exponent()
4
```

field_of_definition()

Return the field over which this finite modular abelian variety subgroup is defined. This is a field over which this subgroup is defined.

EXAMPLES:

```
sage: J = J0(42)
sage: G = J.rational_torsion_subgroup(); G
Torsion subgroup of Abelian variety J0(42) of dimension 5
```

```
sage: G.field_of_definition()
Rational Field
```

gen(*n*)

Return n^{th} generator of self.

EXAMPLES:

```
sage: J = J0(23)
sage: C = J.torsion_subgroup(3)
sage: C.gens()
[[(1/3, 0, 0, 0)], [(0, 1/3, 0, 0)], [(0, 0, 1/3, 0)], [(0, 0, 0, 1/3)]]
sage: C.gen(0)
[(1/3, 0, 0, 0)]
sage: C.gen(3)
[(0, 0, 0, 1/3)]
sage: C.gen(4)
...
IndexError: list index out of range
```

Negative indices wrap around:

```
sage: C.gen(-1)
[(0, 0, 0, 1/3)]
```

gens()

Return generators for this finite subgroup.

EXAMPLES: We list generators for several cuspidal subgroups:

```
sage: J0(11).cuspidal_subgroup().gens()
[[(0, 1/5)]]
sage: J0(37).cuspidal_subgroup().gens()
[[(0, 0, 0, 1/3)]]
sage: J0(43).cuspidal_subgroup().gens()
[[(0, 1/7, 0, 6/7, 0, 5/7)]]
sage: J1(13).cuspidal_subgroup().gens()
[[(1/19, 0, 0, 9/19)], [(0, 1/19, 1/19, 18/19)]]
sage: J0(22).torsion_subgroup(6).gens()
[[(1/6, 0, 0, 0)], [(0, 1/6, 0, 0)], [(0, 0, 1/6, 0)], [(0, 0, 0, 1/6)]]
```

intersection(*other*)

Return the intersection of the finite subgroups self and other.

INPUT:

- `other` - a finite group

OUTPUT: a finite group

EXAMPLES:

```
sage: E11a0, E11a1, B = J0(33)
sage: G = E11a0.torsion_subgroup(6); H = E11a0.torsion_subgroup(9)
sage: G.intersection(H)
Finite subgroup with invariants [3, 3] over QQ of Simple abelian subvariety 11a(1,33) of dim
sage: W = E11a1.torsion_subgroup(15)
sage: G.intersection(W)
Finite subgroup with invariants [] over QQ of Simple abelian subvariety 11a(1,33) of dimensi
sage: E11a0.intersection(E11a1)[0]
Finite subgroup with invariants [5] over QQ of Simple abelian subvariety 11a(1,33) of dimens
```

We intersect subgroups of different abelian varieties.

```
sage: E11a0, E11a1, B = J0(33)
sage: G = E11a0.torsion_subgroup(5); H = E11a1.torsion_subgroup(5)
sage: G.intersection(H)
Finite subgroup with invariants [5] over QQ of Simple abelian subvariety 11a(1,33) of dimens
sage: E11a0.intersection(E11a1)[0]
Finite subgroup with invariants [5] over QQ of Simple abelian subvariety 11a(1,33) of dimens
```

We intersect abelian varieties with subgroups:

```
sage: t = J0(33).hecke_operator(7)
sage: G = t.kernel()[0]; G
Finite subgroup with invariants [2, 2, 2, 2, 4, 4] over QQ of Abelian variety J0(33) of dime
sage: A = J0(33).old_subvariety()
sage: A.intersection(G)
Finite subgroup with invariants [2, 2, 2, 2] over QQ of Abelian subvariety of dimension 2 of
sage: A.hecke_operator(7).kernel()[0]
Finite subgroup with invariants [2, 2, 2, 2] over QQ of Abelian subvariety of dimension 2 of
sage: B = J0(33).new_subvariety()
sage: B.intersection(G)
Finite subgroup with invariants [4, 4] over QQ of Abelian subvariety of dimension 1 of J0(33
sage: B.hecke_operator(7).kernel()[0]
Finite subgroup with invariants [4, 4] over QQ of Abelian subvariety of dimension 1 of J0(33
sage: A.intersection(B)[0]
Finite subgroup with invariants [3, 3] over QQ of Abelian subvariety of dimension 2 of J0(33
```

invariants()

Return elementary invariants of this abelian group, by which we mean a nondecreasing (immutable) sequence of integers n_i, $1 \leq i \leq k$, with n_i dividing n_{i+1}, and such that this group is abstractly isomorphic to $\mathbf{Z}/n_1\mathbf{Z} \times \cdots \times \mathbf{Z}/n_k\mathbf{Z}$.

EXAMPLES:

```
sage: J = J0(38)
sage: C = J.cuspidal_subgroup(); C
Finite subgroup with invariants [3, 45] over QQ of Abelian variety J0(38) of dimension 4
sage: v = C.invariants(); v
[3, 45]
sage: v[0] = 5
...
ValueError: object is immutable; please change a copy instead.
sage: type(v[0])
<type 'sage.rings.integer.Integer'>

sage: C * 3
Finite subgroup with invariants [15] over QQ of Abelian variety J0(38) of dimension 4
```

An example involving another cuspidal subgroup:

```
sage: C = J0(22).cuspidal_subgroup(); C
Finite subgroup with invariants [5, 5] over QQ of Abelian variety J0(22) of dimension 2
sage: C.lattice()
Free module of degree 4 and rank 4 over Integer Ring
Echelon basis matrix:
[1/5 1/5 4/5   0]
[  0   1   0   0]
[  0   0   1   0]
[  0   0   0 1/5]
sage: C.invariants()
[5, 5]
```

is_subgroup(*other*)

Return True exactly if self is a subgroup of other, and both are defined as subgroups of the same ambient abelian variety.

EXAMPLES:

```
sage: C = J0(22).cuspidal_subgroup()
sage: H = C.subgroup([C.0])
sage: K = C.subgroup([C.1])
sage: H.is_subgroup(K)
False
sage: K.is_subgroup(H)
False
sage: K.is_subgroup(C)
True
sage: H.is_subgroup(C)
True
```

lattice()

Return the lattice corresponding to this subgroup in the rational homology of the modular Jacobian product. The elements of the subgroup are represented by vecotors in the ambient vector space (the rational homology), and this returns the lattice they span. EXAMPLES:

```
sage: J = J0(33); C = J[0].cuspidal_subgroup(); C
Finite subgroup with invariants [5] over QQ of Simple abelian subvariety 11a(1,33) of dimens
sage: C.lattice()
Free module of degree 6 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1/5 13/5   -2 -4/5    2 -1/5]
[   0    3   -2   -1    2    0]
```

order()

Return the order (number of elements) of this finite subgroup.

EXAMPLES:

```
sage: J = J0(42)
sage: C = J.cuspidal_subgroup()
sage: C.order()
2304
```

subgroup(*gens*)

Return the subgroup of self spanned by the given generators, which all must be elements of self.

EXAMPLES:

```
sage: J = J0(23)
sage: G = J.torsion_subgroup(11); G
Finite subgroup with invariants [11, 11, 11, 11] over QQ of Abelian variety J0(23) of dimens
```

We create the subgroup of the 11-torsion subgroup of $J_0(23)$ generated by the first 11-torsion point:

```
sage: H = G.subgroup([G.0]); H
Finite subgroup with invariants [11] over QQbar of Abelian variety J0(23) of dimension 2
sage: H.invariants()
[11]
```

We can also create a subgroup from a list of objects that coerce into the ambient rational homology.

```
sage: H == G.subgroup([[1/11,0,0,0]])
True
```

class FiniteSubgroup_lattice(*abvar, lattice, field_of_definition=Algebraic Field, check=True*)

lattice()
Return lattice that defines this finite subgroup.
EXAMPLES:

```
sage: J = J0(11)
sage: G = J.finite_subgroup([[1/3,0], [0,1/5]]); G
Finite subgroup with invariants [15] over QQbar of Abelian variety J0(11) of dimension 1
sage: G.lattice()
Free module of degree 2 and rank 2 over Integer Ring
Echelon basis matrix:
[1/3   0]
[  0 1/5]
```

class TorsionPoint (*parent, element, check=True*)

additive_order()
Return the additive order of this element.
EXAMPLES:

```
sage: J = J0(11); G = J.finite_subgroup([[1/3,0], [0,1/5]])
sage: G.0.additive_order()
3
sage: G.1.additive_order()
5
sage: (G.0 + G.1).additive_order()
15
sage: (3*G.0).additive_order()
1
```

element()
Return an underlying QQ-vector space element that defines this element of a modular abelian variety. This is a vector in the ambient Jacobian variety's rational homology.
EXAMPLES: We create some elements of $J_0(11)$:

```
sage: J = J0(11)
sage: G = J.finite_subgroup([[1/3,0], [0,1/5]]); G
Finite subgroup with invariants [15] over QQbar of Abelian variety J0(11) of dimension 1
sage: G.0.element()
(1/3, 0)
```

The underlying element is a vector over the rational numbers:

```
sage: v = (G.0-G.1).element(); v
(1/3, -1/5)
sage: type(v)
<type 'sage.modules.vector_rational_dense.Vector_rational_dense'>
```

45.5 Torsion subgroups of modular abelian varieties.

Sage can compute information about the structure of the torsion subgroup of a modular abelian variety. Sage computes a multiple of the order by computing the greatest common divisor of the orders of the torsion subgroup of the reduction of the abelian variety modulo p for various primes p. Sage computes a divisor of the order by computing the rational cuspidal subgroup. When these two bounds agree (which is often the case), we determine the exact structure of the torsion subgroup.

AUTHORS:

- William Stein (2007-03)

EXAMPLES: First we consider $J_0(50)$ where everything works out nicely:

```
sage: J = J0(50)
sage: T = J.rational_torsion_subgroup(); T
Torsion subgroup of Abelian variety J0(50) of dimension 2
sage: T.multiple_of_order()
15
sage: T.divisor_of_order()
15
sage: T.gens()
[[(1/15, 3/5, 2/5, 14/15)]]
sage: T.invariants()
[15]
sage: d = J.decomposition(); d
[
Simple abelian subvariety 50a(1,50) of dimension 1 of J0(50),
Simple abelian subvariety 50b(1,50) of dimension 1 of J0(50)
]
sage: d[0].rational_torsion_subgroup().order()
3
sage: d[1].rational_torsion_subgroup().order()
5
```

Next we make a table of the upper and lower bounds for each new factor.

```
sage: for N in range(1,38):
...     for A in J0(N).new_subvariety().decomposition():
...         T = A.rational_torsion_subgroup()
...         print '%-5s%-5s%-5s%-5s'%(N, A.dimension(), T.divisor_of_order(), T.multiple_of_order())
11   1    5    5
14   1    6    6
15   1    8    8
17   1    4    4
19   1    3    3
20   1    6    6
21   1    8    8
23   2    11   11
24   1    8    8
26   1    3    3
26   1    7    7
27   1    3    3
29   2    7    7
30   1    6    12
31   2    5    5
32   1    4    4
33   1    4    4
34   1    6    6
35   1    3    3
35   2    16   16
36   1    6    6
37   1    1    1
37   1    3    3
```

TESTS:

```
sage: T = J0(54).rational_torsion_subgroup()
sage: loads(dumps(T)) == T
True
```

class QQbarTorsionSubgroup(*abvar*)

abelian_variety()

Return the abelian variety that this is the set of all torsion points on.

OUTPUT: abelian variety

EXAMPLES:

```
sage: J0(23).qbar_torsion_subgroup().abelian_variety()
Abelian variety J0(23) of dimension 2
```

field_of_definition()

Return the field of definition of this subgroup. Since this is the group of all torsion it is defined over the base field of this abelian variety.

OUTPUT: a field

EXAMPLES:

```
sage: J0(23).qbar_torsion_subgroup().field_of_definition()
Rational Field
```

class RationalTorsionSubgroup(*abvar*)

The torsion subgroup of a modular abelian variety.

divisor_of_order()

Return a divisor of the order of this torsion subgroup of a modular abelian variety.

EXAMPLES:

```
sage: t = J0(37)[1].rational_torsion_subgroup()
sage: t.divisor_of_order()
3
```

lattice()

Return lattice that defines this torsion subgroup, if possible.

Warning: There is no known algorithm in general to compute the rational torsion subgroup. Use rational_cusp_group to obtain a subgroup of the rational torsion subgroup in general.

EXAMPLES:

```
sage: J0(11).rational_torsion_subgroup().lattice()
Free module of degree 2 and rank 2 over Integer Ring
Echelon basis matrix:
[  1   0]
[  0 1/5]
```

The following fails because in fact I know of no (reasonable) algorithm to provably compute the torsion subgroup in general.

```
sage: T = J0(33).rational_torsion_subgroup()
sage: T.lattice()
...
NotImplementedError: unable to compute the rational torsion subgroup in this case (there is
```

The problem is that the multiple of the order obtained by counting points over finite fields is twice the divisor of the order got from the rational cuspidal subgroup.

```
sage: T.multiple_of_order(30)
200
sage: J0(33).rational_cusp_subgroup().order()
100
```

multiple_of_order(*maxp=None*)

Return a multiple of the order of this torsion group.

The multiple is computed using characteristic polynomials of Hecke operators of odd index not dividing the level.

INPUT:

- `maxp` - (default: None) If maxp is None (the default), return gcd of best bound computed so far with bound obtained by computing gcd's of orders modulo p until this gcd stabilizes for 3 successive primes. If maxp is given, just use all primes up to and including maxp.

EXAMPLES:

```
sage: J = J0(11)
sage: G = J.rational_torsion_subgroup()
sage: G.multiple_of_order(11)
5
sage: J = J0(389)
sage: G = J.rational_torsion_subgroup(); G
Torsion subgroup of Abelian variety J0(389) of dimension 32
sage: G.multiple_of_order()
97
sage: [G.multiple_of_order(p) for p in prime_range(3,11)]
[92645296242160800, 7275, 291]
sage: [G.multiple_of_order(p) for p in prime_range(3,13)]
[92645296242160800, 7275, 291, 97]
sage: [G.multiple_of_order(p) for p in prime_range(3,19)]
[92645296242160800, 7275, 291, 97, 97, 97]

sage: J = J0(33) * J0(11) ; J.rational_torsion_subgroup().order()
...
NotImplementedError: torsion multiple only implemented for Gamma0
```

The next example illustrates calling this function with a larger input and how the result may be cached when maxp is None:

```
sage: T = J0(43)[1].rational_torsion_subgroup()
sage: T.multiple_of_order()
14
sage: T.multiple_of_order(50)
7
sage: T.multiple_of_order()
7
```

order()

Return the order of the torsion subgroup of this modular abelian variety.

This may fail if the multiple obtained by counting points modulo p exceeds the divisor obtained from the rational cuspidal subgroup.

EXAMPLES:

```
sage: a = J0(11)
sage: a.rational_torsion_subgroup().order()
5
sage: a = J0(23)
sage: a.rational_torsion_subgroup().order()
```

```
11
sage: t = J0(37)[1].rational_torsion_subgroup()
sage: t.order()
3
```

possible_orders()

Return the possible orders of this torsion subgroup, computed from a known divisor and multiple of the order.

EXAMPLES:

```
sage: J0(11).rational_torsion_subgroup().possible_orders()
[5]
sage: J0(33).rational_torsion_subgroup().possible_orders()
[100, 200]
```

Note that this function has not been implemented for $J_1(N)$, though it should be reasonably easy to do so soon (see Conrad, Edixhoven, Stein):

```
sage: J1(13).rational_torsion_subgroup().possible_orders()
...
NotImplementedError: torsion multiple only implemented for Gamma0
```

45.6 Cuspidal subgroups of modular abelian varieties

AUTHORS:

- William Stein (2007-03, 2008-02)

EXAMPLES: We compute the cuspidal subgroup of $J_1(13)$:

```
sage: A = J1(13)
sage: C = A.cuspidal_subgroup(); C
Finite subgroup with invariants [19, 19] over QQ of Abelian variety J1(13) of dimension 2
sage: C.gens()
[[(1/19, 0, 0, 9/19)], [(0, 1/19, 1/19, 18/19)]]
sage: C.order()
361
sage: C.invariants()
[19, 19]
```

We compute the cuspidal subgroup of $J_0(54)$:

```
sage: A = J0(54)
sage: C = A.cuspidal_subgroup(); C
Finite subgroup with invariants [3, 3, 3, 3, 3, 9] over QQ of Abelian variety J0(54) of dimension 4
sage: C.gens()
[[(1/3, 0, 0, 0, 0, 1/3, 0, 2/3)], [(0, 1/3, 0, 0, 0, 2/3, 0, 1/3)], [(0, 0, 1/9, 1/9, 1/9, 1/9, 1/9,
sage: C.order()
2187
sage: C.invariants()
[3, 3, 3, 3, 3, 9]
```

We compute the subgroup of the cuspidal subgroup generated by rational cusps.

```
sage: C = J0(54).rational_cusp_subgroup(); C
Finite subgroup with invariants [3, 3, 9] over QQ of Abelian variety J0(54) of dimension 4
sage: C.gens()
[[(1/3, 0, 0, 1/3, 2/3, 1/3, 0, 1/3)], [(0, 0, 1/9, 1/9, 7/9, 7/9, 1/9, 8/9)], [(0, 0, 0, 0, 0, 0, 1/
sage: C.order()
81
sage: C.invariants()
[3, 3, 9]
```

This might not give us the exact rational torsion subgroup, since it might be bigger than order 81:

```
sage: J0(54).rational_torsion_subgroup().multiple_of_order()
243
```

TESTS:

```
sage: C = J0(54).cuspidal_subgroup()
sage: loads(dumps(C)) == C
True
sage: D = J0(54).rational_cusp_subgroup()
sage: loads(dumps(D)) == D
True
```

class **CuspidalSubgroup**(*abvar, field_of_definition=Rational Field*)

EXAMPLES:

```
sage: a = J0(65)[2]
sage: t = a.cuspidal_subgroup()
sage: t.order()
6
```

lattice()

Returned cached tuple of vectors that define elements of the rational homology that generate this finite subgroup.

OUTPUT:

- `tuple` - cached

EXAMPLES:

```
sage: J = J0(27)
sage: G = J.cuspidal_subgroup()
sage: G.lattice()
Free module of degree 2 and rank 2 over Integer Ring
Echelon basis matrix:
[1/3   0]
[  0 1/3]
```

Test that the result is cached:

```
sage: G.lattice() is G.lattice()
True
```

class **CuspidalSubgroup_generic**(*abvar, field_of_definition=Rational Field*)

class **RationalCuspidalSubgroup**(*abvar, field_of_definition=Rational Field*)

EXAMPLES:

```
sage: a = J0(65)[2]
sage: t = a.rational_cusp_subgroup()
sage: t.order()
6
```

lattice()

Return lattice that defines this group.

OUTPUT: lattice

EXAMPLES:

```
sage: G = J0(27).rational_cusp_subgroup()
sage: G.lattice()
Free module of degree 2 and rank 2 over Integer Ring
Echelon basis matrix:
[1/3   0]
[  0   1]
```

Test that the result is cached.

```
sage: G.lattice() is G.lattice()
True
```

is_rational_cusp_gamma0(*c, N, data*)

Return True if the rational number c is a rational cusp of level N. This uses remarks in Glenn Steven's Ph.D. thesis.

INPUT:

- `c` - a cusp
- `N` - a positive integer
- `data` - the list [n for n in range(2,N) if gcd(n,N) == 1], which is passed in as a parameter purely for efficiency reasons.

EXAMPLES:

```
sage: from sage.modular.abvar.cuspidal_subgroup import is_rational_cusp_gamma0
sage: N = 27
sage: data = [n for n in range(2,N) if gcd(n,N) == 1]
sage: is_rational_cusp_gamma0(Cusp(1/3), N, data)
False
sage: is_rational_cusp_gamma0(Cusp(1), N, data)
True
sage: is_rational_cusp_gamma0(Cusp(oo), N, data)
True
sage: is_rational_cusp_gamma0(Cusp(2/9), N, data)
False
```

45.7 Homology of modular abelian varieties.

Sage can compute with homology groups associated to modular abelian varieties with coefficients in any commutative ring. Supported operations include computing matrices and characteristic polynomials of Hecke operators, rank, and rational decomposition as a direct sum of factors (obtained by cutting out kernels of Hecke operators).

AUTHORS:

- William Stein (2007-03)

EXAMPLES:

```
sage: J = J0(43)
sage: H = J.integral_homology()
sage: H
Integral Homology of Abelian variety J0(43) of dimension 3
sage: H.hecke_matrix(19)
[ 0  0 -2  0  2  0]
[ 2 -4 -2  0  2  0]
[ 0  0 -2 -2  0  0]
[ 2  0 -2 -4  2 -2]
[ 0  2  0 -2 -2  0]
[ 0  2  0 -2  0  0]
sage: H.base_ring()
Integer Ring
sage: d = H.decomposition(); d
[
Submodule of rank 2 of Integral Homology of Abelian variety J0(43) of dimension 3,
Submodule of rank 4 of Integral Homology of Abelian variety J0(43) of dimension 3
]
sage: a = d[0]
sage: a.hecke_matrix(5)
[-4  0]
[ 0 -4]
sage: a.T(7)
Hecke operator T_7 on Submodule of rank 2 of Integral Homology of Abelian variety J0(43) of dimensio
```

class Homology(*base_ring, level, weight*)

A homology group of an abelian variety, equipped with a Hecke action.

hecke_polynomial(*n, var='x'*)

Return the n-th Hecke polynomial in the given variable.

INPUT:

- `n` - positive integer
- `var` - string (default: 'x') the variable name

OUTPUT: a polynomial over ZZ in the given variable

EXAMPLES:

```
sage: H = J0(43).integral_homology(); H
Integral Homology of Abelian variety J0(43) of dimension 3
sage: f = H.hecke_polynomial(3); f
x^6 + 4*x^5 - 16*x^3 - 12*x^2 + 16*x + 16
sage: parent(f)
Univariate Polynomial Ring in x over Integer Ring
sage: H.hecke_polynomial(3,'w')
w^6 + 4*w^5 - 16*w^3 - 12*w^2 + 16*w + 16
```

class Homology_abvar(*abvar, base*)

The homology of a modular abelian variety.

abelian_variety()

Return the abelian variety that this is the homology of.

EXAMPLES:

```
sage: H = J0(48).homology()
sage: H.abelian_variety()
Abelian variety J0(48) of dimension 3
```

ambient_hecke_module()

Return the ambient Hecke module that this homology is contained in.

EXAMPLES:

```
sage: H = J0(48).homology(); H
Integral Homology of Abelian variety J0(48) of dimension 3
sage: H.ambient_hecke_module()
Integral Homology of Abelian variety J0(48) of dimension 3
```

free_module()

Return the underlying free module of this homology group.

EXAMPLES:

```
sage: H = J0(48).homology()
sage: H.free_module()
Ambient free module of rank 6 over the principal ideal domain Integer Ring
```

gen(n)

Return n^{th} generator of self.

This is not yet implemented!

EXAMPLES:

```
sage: H = J0(37).homology()
sage: H.gen(0)     # this will change
...
NotImplementedError: homology classes not yet implemented
```

gens()

Return generators of self.

This is not yet implemented!

EXAMPLES:

```
sage: H = J0(37).homology()
sage: H.gens()     # this will change
...
NotImplementedError: homology classes not yet implemented
```

hecke_bound()

Return bound on the number of Hecke operators needed to generate the Hecke algebra as a $\mathbf{Z}$-module acting on this space.

EXAMPLES:

```
sage: J0(48).homology().hecke_bound()
16
sage: J1(15).homology().hecke_bound()
32
```

hecke_matrix(n)

Return the matrix of the n-th Hecke operator acting on this homology group.

INPUT:

- n - a positive integer

OUTPUT: a matrix over the coefficient ring of this homology group

EXAMPLES:

```
sage: H = J0(23).integral_homology()
sage: H.hecke_matrix(3)
[-1 -2  2  0]
[ 0 -3  2 -2]
```

```
[ 2 -4  3 -2]
[ 2 -2  0  1]
```

The matrix is over the coefficient ring:

```
sage: J = J0(23)
sage: J.homology(QQ[I]).hecke_matrix(3).parent()
Full MatrixSpace of 4 by 4 dense matrices over Number Field in I with defining polynomial x^
```

rank()

Return the rank as a module or vector space of this homology group.

EXAMPLES:

```
sage: H = J0(5077).homology(); H
Integral Homology of Abelian variety J0(5077) of dimension 422
sage: H.rank()
844
```

submodule(*U, check=True*)

Return the submodule of this homology group given by U, which should be a submodule of the free module associated to this homology group.

INPUT:

- `U` - submodule of ambient free module (or something that defines one)
- `check` - currently ignored.

Note: We do *not* check that U is invariant under all Hecke operators.

EXAMPLES:

```
sage: H = J0(23).homology(); H
Integral Homology of Abelian variety J0(23) of dimension 2
sage: F = H.free_module()
sage: U = F.span([[1,2,3,4]])
sage: M = H.submodule(U); M
Submodule of rank 1 of Integral Homology of Abelian variety J0(23) of dimension 2
```

Note that the submodule command doesn't actually check that the object defined is a homology group or is invariant under the Hecke operators. For example, the fairly random M that we just defined is not invariant under the Hecke operators, so it is not a Hecke submodule - it is only a $\mathbf{Z}$-submodule.

```
sage: M.hecke_matrix(3)
...
ArithmeticError: subspace is not invariant under matrix
```

class **Homology_over_base**(*abvar, base_ring*)

The homology over a modular abelian variety over an arbitrary base commutative ring (not $\mathbf{Z}$ or $\mathbf{Q}$).

hecke_matrix(*n*)

Return the matrix of the n-th Hecke operator acting on this homology group.

EXAMPLES:

```
sage: t = J1(13).homology(GF(3)).hecke_matrix(3); t
[0 0 2 1]
[1 1 0 2]
[1 1 0 0]
[0 1 2 1]
sage: t.base_ring()
Finite Field of size 3
```

class **Homology_submodule**(*ambient, submodule*)

A submodule of the homology of a modular abelian variety.

ambient_hecke_module()

Return the ambient Hecke module that this homology is contained in.

EXAMPLES:

```
sage: H = J0(48).homology(); H
Integral Homology of Abelian variety J0(48) of dimension 3
sage: d = H.decomposition(); d
[
Submodule of rank 2 of Integral Homology of Abelian variety J0(48) of dimension 3,
Submodule of rank 4 of Integral Homology of Abelian variety J0(48) of dimension 3
]
sage: d[0].ambient_hecke_module()
Integral Homology of Abelian variety J0(48) of dimension 3
```

free_module()

Return the underlying free module of the homology group.

EXAMPLES:

```
sage: H = J0(48).homology()
sage: K = H.decomposition()[1]; K
Submodule of rank 4 of Integral Homology of Abelian variety J0(48) of dimension 3
sage: K.free_module()
Free module of degree 6 and rank 4 over Integer Ring
Echelon basis matrix:
[ 1  0  0  0  0  0]
[ 0  1  0  0  1 -1]
[ 0  0  1  0 -1  1]
[ 0  0  0  1  0 -1]
```

hecke_bound()

Return a bound on the number of Hecke operators needed to generate the Hecke algebra acting on this homology group.

EXAMPLES:

```
sage: d = J0(43).homology().decomposition(2); d
[
Submodule of rank 2 of Integral Homology of Abelian variety J0(43) of dimension 3,
Submodule of rank 4 of Integral Homology of Abelian variety J0(43) of dimension 3
]
```

Because the first factor has dimension 2 it corresponds to an elliptic curve, so we have a Hecke bound of 1.

```
sage: d[0].hecke_bound()
1
sage: d[1].hecke_bound()
8
```

hecke_matrix(*n*)

Return the matrix of the n-th Hecke operator acting on this homology group.

EXAMPLES:

```
sage: d = J0(125).homology(GF(17)).decomposition(2); d
[
Submodule of rank 4 of Homology with coefficients in Finite Field of size 17 of Abelian vari
Submodule of rank 4 of Homology with coefficients in Finite Field of size 17 of Abelian vari
Submodule of rank 8 of Homology with coefficients in Finite Field of size 17 of Abelian vari
]
sage: t = d[0].hecke_matrix(17); t
[16 15 15  0]
```

```
[ 0  5  0  2]
[ 2  0  5 15]
[ 0 15  0 16]
sage: t.base_ring()
Finite Field of size 17
sage: t.fcp()
(x^2 + 13*x + 16)^2
```

rank()

Return the rank of this homology group.

EXAMPLES:

```
sage: d = J0(43).homology().decomposition(2)
sage: [H.rank() for H in d]
[2, 4]
```

class **IntegralHomology**(*abvar*)

The integral homology $H_1(A, \mathbf{Z})$ of a modular abelian variety.

hecke_matrix(*n*)

Return the matrix of the n-th Hecke operator acting on this homology group.

EXAMPLES:

```
sage: J0(48).integral_homology().hecke_bound()
16
sage: t = J1(13).integral_homology().hecke_matrix(3); t
[ 0  0  2 -2]
[-2 -2  0  2]
[-2 -2  0  0]
[ 0 -2  2 -2]
sage: t.base_ring()
Integer Ring
```

hecke_polynomial(*n, var='x'*)

Return the n-th Hecke polynomial on this integral homology group.

EXAMPLES:

```
sage: f = J0(43).integral_homology().hecke_polynomial(2)
sage: f.base_ring()
Integer Ring
sage: factor(f)
(x + 2)^2 * (x^2 - 2)^2
```

class **RationalHomology**(*abvar*)

The rational homology $H_1(A, \mathbf{Q})$ of a modular abelian variety.

hecke_matrix(*n*)

Return the matrix of the n-th Hecke operator acting on this homology group.

EXAMPLES:

```
sage: t = J1(13).homology(QQ).hecke_matrix(3); t
[ 0  0  2 -2]
[-2 -2  0  2]
[-2 -2  0  0]
[ 0 -2  2 -2]
sage: t.base_ring()
Rational Field
sage: t = J1(13).homology(GF(3)).hecke_matrix(3); t
[0 0 2 1]
```

```
[1 1 0 2]
[1 1 0 0]
[0 1 2 1]
sage: t.base_ring()
Finite Field of size 3
```

hecke_polynomial(*n, var='x'*)

Return the n-th Hecke polynomial on this rational homology group.

EXAMPLES:

```
sage: f = J0(43).rational_homology().hecke_polynomial(2)
sage: f.base_ring()
Rational Field
sage: factor(f)
(x + 2) * (x^2 - 2)
```

45.8 Spaces of homomorphisms between modular abelian varieties.

EXAMPLES:

First, we consider J0(37). This jacobian has two simple factors, corresponding to distinct newforms. These two intersect nontrivially in J0(37).

```
sage: J = J0(37)
sage: D = J.decomposition() ; D
[
Simple abelian subvariety 37a(1,37) of dimension 1 of J0(37),
Simple abelian subvariety 37b(1,37) of dimension 1 of J0(37)
]
sage: D[0].intersection(D[1])
(Finite subgroup with invariants [2, 2] over QQ of Simple abelian subvariety 37a(1,37) of dimension 1
 Simple abelian subvariety of dimension 0 of J0(37))
```

As an abstract product, since these newforms are distinct, the corresponding simple abelian varieties are not isogenous, and so there are no maps between them. The endomorphism ring of the corresponding product is thus isomorphic to the direct sum of the endomorphism rings for each factor. Since the factors correspond to abelian varieties of dimension 1, these endomorphism rings are each isomorphic to ZZ.

```
sage: Hom(D[0],D[1]).gens()
()
sage: A = D[0] * D[1] ; A
Abelian subvariety of dimension 2 of J0(37) x J0(37)
sage: A.endomorphism_ring().gens()
(Abelian variety endomorphism of Abelian subvariety of dimension 2 of J0(37) x J0(37),
 Abelian variety endomorphism of Abelian subvariety of dimension 2 of J0(37) x J0(37))
sage: [ x.matrix() for x in A.endomorphism_ring().gens() ]
[[1 0 0 0]
[0 1 0 0]
[0 0 0 0]
[0 0 0 0],
 [0 0 0 0]
[0 0 0 0]
[0 0 1 0]
[0 0 0 1]]
```

However, these two newforms have a congruence between them modulo 2, which gives rise to interesting endomorphisms of J0(37).

```
sage: E = J.endomorphism_ring()
sage: E.gens()
(Abelian variety endomorphism of Abelian variety J0(37) of dimension 2,
 Abelian variety endomorphism of Abelian variety J0(37) of dimension 2)
sage: [ x.matrix() for x in E.gens() ]
[[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1],
 [ 0  1  1 -1]
[ 1  0  1  0]
[ 0  0 -1  1]
[ 0  0  0  1]]
sage: (-1*E.gens()[0] + E.gens()[1]).matrix()
[-1  1  1 -1]
[ 1 -1  1  0]
[ 0  0 -2  1]
[ 0  0  0  0]
```

Of course, these endomorphisms will be reflected in the Hecke algebra, which is in fact the full endomorphism ring of J0(37) in this case:

```
sage: J.hecke_operator(2).matrix()
[-1  1  1 -1]
[ 1 -1  1  0]
[ 0  0 -2  1]
[ 0  0  0  0]
sage: T = E.image_of_hecke_algebra()
sage: T.gens()
(Abelian variety endomorphism of Abelian variety J0(37) of dimension 2,
 Abelian variety endomorphism of Abelian variety J0(37) of dimension 2)
sage: [ x.matrix() for x in T.gens() ]
[[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1],
 [ 0  1  1 -1]
[ 1  0  1  0]
[ 0  0 -1  1]
[ 0  0  0  1]]
sage: T.index_in(E)
1
```

Next, we consider J0(33). In this case, we have both oldforms and newforms. There are two copies of J0(11), one for each degeneracy map from J0(11) to J0(33). There is also one newform at level 33. The images of the two degeneracy maps are, of course, isogenous.

```
sage: J = J0(33)
sage: D = J.decomposition()
sage: D
[
Simple abelian subvariety 11a(1,33) of dimension 1 of J0(33),
Simple abelian subvariety 11a(3,33) of dimension 1 of J0(33),
Simple abelian subvariety 33a(1,33) of dimension 1 of J0(33)
```

```
]
sage: Hom(D[0],D[1]).gens()
(Abelian variety morphism:
  From: Simple abelian subvariety 11a(1,33) of dimension 1 of J0(33)
  To:   Simple abelian subvariety 11a(3,33) of dimension 1 of J0(33),)
sage: Hom(D[0],D[1]).gens()[0].matrix()
[ 0  1]
[-1  0]
```

Then this gives that the component corresponding to the sum of the oldforms will have a rank 4 endomorphism ring. We also have a rank one endomorphism ring for the newform 33a (since it is again 1-dimensional), which gives a rank 5 endomorphism ring for J0(33).

```
sage: DD = J.decomposition(simple=False) ; DD
[
Abelian subvariety of dimension 2 of J0(33),
Abelian subvariety of dimension 1 of J0(33)
]
sage: A, B = DD
sage: A == D[0] + D[1]
True
sage: A.endomorphism_ring().gens()
(Abelian variety endomorphism of Abelian subvariety of dimension 2 of J0(33),
 Abelian variety endomorphism of Abelian subvariety of dimension 2 of J0(33),
 Abelian variety endomorphism of Abelian subvariety of dimension 2 of J0(33),
 Abelian variety endomorphism of Abelian subvariety of dimension 2 of J0(33))
sage: B.endomorphism_ring().gens()
(Abelian variety endomorphism of Abelian subvariety of dimension 1 of J0(33),)
sage: E = J.endomorphism_ring() ; E.gens()
(Abelian variety endomorphism of Abelian variety J0(33) of dimension 3,
 Abelian variety endomorphism of Abelian variety J0(33) of dimension 3,
 Abelian variety endomorphism of Abelian variety J0(33) of dimension 3,
 Abelian variety endomorphism of Abelian variety J0(33) of dimension 3,
 Abelian variety endomorphism of Abelian variety J0(33) of dimension 3)
```

In this case, the image of the Hecke algebra will only have rank 3, so that it is of infinite index in the full endomorphism ring. However, if we call this image T, we can still ask about the index of T in its saturation, which is 1 in this case.

```
sage: T = E.image_of_hecke_algebra()
sage: T.gens()
(Abelian variety endomorphism of Abelian variety J0(33) of dimension 3,
 Abelian variety endomorphism of Abelian variety J0(33) of dimension 3,
 Abelian variety endomorphism of Abelian variety J0(33) of dimension 3)
sage: T.index_in(E)
+Infinity
sage: T.index_in_saturation()
1
```

AUTHORS:

- William Stein (2007-03)
- Craig Citro, Robert Bradshaw (2008-03): Rewrote with modabvar overhaul

class EndomorphismSubring(*A, gens=None*)

abelian_variety()

Return the abelian variety that this endomorphism ring is attached to.

EXAMPLES:

```
sage: J0(11).endomorphism_ring().abelian_variety()
Abelian variety J0(11) of dimension 1
```

discriminant()

Return the discriminant of this ring, which is the discriminant of the trace pairing.

Note: One knows that for modular abelian varieties, the endomorphism ring should be isomorphic to an order in a number field. However, the discriminant returned by this function will be 2^n (n = self.dimension()) times the discriminant of that order, since the elements are represented as 2d x 2d matrices. Notice, for example, that the case of a one dimensional abelian variety, whose endomorphism ring must be ZZ, has discriminant 2, as in the example below.

EXAMPLES:

```
sage: J0(33).endomorphism_ring().discriminant()
-64800
sage: J0(46).endomorphism_ring().discriminant()
24200000000
sage: J0(11).endomorphism_ring().discriminant()
2
```

image_of_hecke_algebra(*check_every=1*)

Compute the image of the Hecke algebra inside this endomorphism subring.

We simply calculate Hecke operators up to the Sturm bound, and look at the submodule spanned by them. While computing, we can check to see if the submodule spanned so far is saturated and of maximal dimension, in which case we may be done. The optional argument check_every determines how many Hecke operators we add in before checking to see if this condition is met.

EXAMPLES:

```
sage: E = J0(33).endomorphism_ring()
sage: E.image_of_hecke_algebra()
Subring of endomorphism ring of Abelian variety J0(33) of dimension 3
sage: E.image_of_hecke_algebra().gens()
(Abelian variety endomorphism of Abelian variety J0(33) of dimension 3,
 Abelian variety endomorphism of Abelian variety J0(33) of dimension 3,
 Abelian variety endomorphism of Abelian variety J0(33) of dimension 3)
sage: [ x.matrix() for x in E.image_of_hecke_algebra().gens() ]
[[1 0 0 0 0 0]
[0 1 0 0 0 0]
[0 0 1 0 0 0]
[0 0 0 1 0 0]
[0 0 0 0 1 0]
[0 0 0 0 0 1],
 [ 0  2  0 -1  1 -1]
[-1 -2  2 -1  2 -1]
[ 0  0  1 -1  3 -1]
[-2  2  0  1  1 -1]
[-1  1  0  2  0 -3]
[-1  1 -1  1  1 -2],
 [ 0  0  1 -1  1 -1]
[ 0 -1  1  0  1 -1]
[ 0  0  1  0  2 -2]
[-2  0  1  1  1 -1]
[-1  0  1  1  0 -1]
[-1  0  0  1  0 -1]]
sage: J0(33).hecke_operator(2).matrix()
```

```
[-1  0  1 -1  1 -1]
[ 0 -2  1  0  1 -1]
[ 0  0  0  0  2 -2]
[-2  0  1  0  1 -1]
[-1  0  1  1 -1 -1]
[-1  0  0  1  0 -2]
```

index_in(*other, check=True*)

Return the index of self in other.

INPUT:

- `other` - another endomorphism subgring of the same abelian variety
- `check` - bool (default: True); whether to do some type and other consistency checks

EXAMPLES:

```
sage: R = J0(33).endomorphism_ring()
sage: R.index_in(R)
1
sage: J = J0(37) ; E = J.endomorphism_ring() ; T = E.image_of_hecke_algebra()
sage: T.index_in(E)
1
sage: J = J0(22) ; E = J.endomorphism_ring() ; T = E.image_of_hecke_algebra()
sage: T.index_in(E)
+Infinity
```

index_in_saturation()

Given a Hecke algebra T, compute its index in its saturation.

EXAMPLES:

```
sage: End(J0(23)).image_of_hecke_algebra().index_in_saturation()
1
sage: End(J0(44)).image_of_hecke_algebra().index_in_saturation()
2
```

class Homspace(*domain, codomain, cat*)

A space of homomorphisms between two modular abelian varieties.

calculate_generators()

If generators haven't already been computed, calculate generators for this homspace. If they have been computed, do nothing.

EXAMPLES:

```
sage: E = End(J0(11))
sage: E.calculate_generators()
```

free_module()

Return this endomorphism ring as a free submodule of a big $\mathbf{Z}^{4nm}$, where n is the dimension of the domain abelian variety and m the dimension of the codomain.

OUTPUT: free module

EXAMPLES:

```
sage: E = Hom(J0(11), J0(22))
sage: E.free_module()
Free module of degree 8 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1  0 -3  1  1  1 -1 -1]
[ 0  1 -3  1  1  1 -1  0]
```

gen(*i=0*)

Return i-th generator of self.

INPUT:

- `i` - an integer

OUTPUT: a morphism

EXAMPLES:

```
sage: E = End(J0(22))
sage: E.gen(0).matrix()
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

gens()

Return tuple of generators for this endomorphism ring.

EXAMPLES:

```
sage: E = End(J0(22))
sage: E.gens()
(Abelian variety endomorphism of Abelian variety J0(22) of dimension 2,
 Abelian variety endomorphism of Abelian variety J0(22) of dimension 2,
 Abelian variety endomorphism of Abelian variety J0(22) of dimension 2,
 Abelian variety endomorphism of Abelian variety J0(22) of dimension 2)
```

matrix_space()

Return the underlying matrix space that we view this endomorphism ring as being embedded into.

EXAMPLES:

```
sage: E = End(J0(22))
sage: E.matrix_space()
Full MatrixSpace of 4 by 4 dense matrices over Integer Ring
```

ngens()

Return number of generators of self.

OUTPUT: integer

EXAMPLES:

```
sage: E = End(J0(22))
sage: E.ngens()
4
```

45.9 Morphisms between modular abelian varieties, including Hecke operators acting on modular abelian varieties.

Sage can compute with Hecke operators on modular abelian varieties. A Hecke operator is defined by given a modular abelian variety and an index. Given a Hecke operator, Sage can compute the characteristic polynomial, and the action of the Hecke operator on various homology groups.

AUTHORS:

- William Stein (2007-03)
- Craig Citro (2008-03)

EXAMPLES:

```
sage: A = J0(54)
sage: t5 = A.hecke_operator(5); t5
Hecke operator T_5 on Abelian variety J0(54) of dimension 4
sage: t5.charpoly().factor()
(x - 3) * (x + 3) * x^2
sage: B = A.new_subvariety(); B
Abelian subvariety of dimension 2 of J0(54)
sage: t5 = B.hecke_operator(5); t5
Hecke operator T_5 on Abelian subvariety of dimension 2 of J0(54)
sage: t5.charpoly().factor()
(x - 3) * (x + 3)
sage: t5.action_on_homology().matrix()
[ 0  3  3 -3]
[-3  3  3  0]
[ 3  3  0 -3]
[-3  6  3 -3]
```

class DegeneracyMap (*parent, A, t*)

t()

Return the list of indices defining self.

EXAMPLES:

```
sage: J0(22).degeneracy_map(44).t()
[1]
sage: J = J0(22) * J0(11)
sage: J.degeneracy_map([44,44], [2,1])
Degeneracy map from Abelian variety J0(22) x J0(11) of dimension 3 to Abelian variety J0(44)
sage: J.degeneracy_map([44,44], [2,1]).t()
[2, 1]
```

class HeckeOperator (*abvar, n*)

A Hecke operator acting on a modular abelian variety.

action_on_homology (*R=Integer Ring*)

Return the action of this Hecke operator on the homology $H_1(A; R)$ of this abelian variety with coefficients in R.

EXAMPLES:

```
sage: A = J0(43)
sage: t2 = A.hecke_operator(2); t2
Hecke operator T_2 on Abelian variety J0(43) of dimension 3
sage: h2 = t2.action_on_homology(); h2
Hecke operator T_2 on Integral Homology of Abelian variety J0(43) of dimension 3
sage: h2.matrix()
[-2  1  0  0  0  0]
[-1  1  1  0 -1  0]
[-1  0 -1  2 -1  1]
[-1  0  1  1 -1  1]
[ 0 -2  0  2 -2  1]
[ 0 -1  0  1  0 -1]
sage: h2 = t2.action_on_homology(GF(2)); h2
Hecke operator T_2 on Homology with coefficients in Finite Field of size 2 of Abelian variet
sage: h2.matrix()
[0 1 0 0 0 0]
[1 1 1 0 1 0]
```

```
[1 0 1 0 1 1]
[1 0 1 1 1 1]
[0 0 0 0 0 1]
[0 1 0 1 0 1]
```

characteristic_polynomial(*var='x'*)

Return the characteristic polynomial of this Hecke operator in the given variable.

INPUT:

- `var` - a string (default: 'x')

OUTPUT: a polynomial in var over the rational numbers.

EXAMPLES:

```
sage: A = J0(43)[1]; A
Simple abelian subvariety 43b(1,43) of dimension 2 of J0(43)
sage: t2 = A.hecke_operator(2); t2
Hecke operator T_2 on Simple abelian subvariety 43b(1,43) of dimension 2 of J0(43)
sage: f = t2.characteristic_polynomial(); f
x^2 - 2
sage: f.parent()
Univariate Polynomial Ring in x over Integer Ring
sage: f.factor()
x^2 - 2
sage: t2.characteristic_polynomial('y')
y^2 - 2
```

charpoly(*var='x'*)

Synonym for `self.characteristic_polynomial(var)`.

INPUT:

- `var` - string (default: 'x')

EXAMPLES:

```
sage: A = J1(13)
sage: t2 = A.hecke_operator(2); t2
Hecke operator T_2 on Abelian variety J1(13) of dimension 2
sage: f = t2.charpoly(); f
x^2 + 3*x + 3
sage: f.factor()
x^2 + 3*x + 3
sage: t2.charpoly('y')
y^2 + 3*y + 3
```

index()

Return the index of this Hecke operator. (For example, if this is the operator T_n, then the index is the integer n.)

OUTPUT:

- `n` - a (Sage) Integer

EXAMPLES:

```
sage: J = J0(15)
sage: t = J.hecke_operator(53)
sage: t
Hecke operator T_53 on Abelian variety J0(15) of dimension 1
sage: t.index()
53
sage: t = J.hecke_operator(54)
sage: t
```

```
Hecke operator T_54 on Abelian variety J0(15) of dimension 1
sage: t.index()
54

sage: J = J1(12345)
sage: t = J.hecke_operator(997) ; t
Hecke operator T_997 on Abelian variety J1(12345) of dimension 5405473
sage: t.index()
997
sage: type(t.index())
<type 'sage.rings.integer.Integer'>
```

matrix()

Return the matrix of self acting on the homology $H_1(A, ZZ)$ of this abelian variety with coefficients in **Z**.

EXAMPLES:

```
sage: J0(47).hecke_operator(3).matrix()
[ 0  0  1 -2  1  0 -1  0]
[ 0  0  1  0 -1  0  0  0]
[-1  2  0  0  2 -2  1 -1]
[-2  1  1 -1  3 -1 -1  0]
[-1 -1  1  0  1  0 -1  1]
[-1  0  0 -1  2  0 -1  0]
[-1 -1  2 -2  2  0 -1  0]
[ 0 -1  0  0  1  0 -1  1]

sage: J0(11).hecke_operator(7).matrix()
[-2  0]
[ 0 -2]
sage: (J0(11) * J0(33)).hecke_operator(7).matrix()
[-2  0  0  0  0  0  0  0]
[ 0 -2  0  0  0  0  0  0]
[ 0  0  0  0  2 -2  2 -2]
[ 0  0  0 -2  2  0  2 -2]
[ 0  0  0  0  2  0  4 -4]
[ 0  0 -4  0  2  2  2 -2]
[ 0  0 -2  0  2  2  0 -2]
[ 0  0 -2  0  0  2  0 -2]

sage: J0(23).hecke_operator(2).matrix()
[ 0  1 -1  0]
[ 0  1 -1  1]
[-1  2 -2  1]
[-1  1  0 -1]
```

n()

Alias for `self.index()`.

EXAMPLES:

```
sage: J = J0(17)
sage: J.hecke_operator(5).n()
5
```

class Morphism(*parent, A*)

restrict_domain(*sub*)

Restrict self to the subvariety sub of self.domain().

EXAMPLES:

```
sage: J = J0(37) ; A, B = J.decomposition()
sage: A.lattice().matrix()
[ 1 -1  1  0]
[ 0  0  2 -1]
sage: B.lattice().matrix()
[1 1 1 0]
[0 0 0 1]
sage: T = J.hecke_operator(2) ; T.matrix()
[-1  1  1 -1]
[ 1 -1  1  0]
[ 0  0 -2  1]
[ 0  0  0  0]
sage: T.restrict_domain(A)
Abelian variety morphism:
  From: Simple abelian subvariety 37a(1,37) of dimension 1 of J0(37)
  To:   Abelian variety J0(37) of dimension 2
sage: T.restrict_domain(A).matrix()
[-2  2 -2  0]
[ 0  0 -4  2]
sage: T.restrict_domain(B)
Abelian variety morphism:
  From: Simple abelian subvariety 37b(1,37) of dimension 1 of J0(37)
  To:   Abelian variety J0(37) of dimension 2
sage: T.restrict_domain(B).matrix()
[0 0 0 0]
[0 0 0 0]
```

class **Morphism_abstract** (*parent*)

A morphism between modular abelian varieties. EXAMPLES:

```
sage: t = J0(11).hecke_operator(2)
sage: from sage.modular.abvar.morphism import Morphism
sage: isinstance(t, Morphism)
True
```

cokernel ()

Return the cokernel of self.

OUTPUT:

- A - an abelian variety (the cokernel)
- phi - a quotient map from self.codomain() to the cokernel of self

EXAMPLES:

```
sage: t = J0(33).hecke_operator(2)
sage: (t-1).cokernel()
(Abelian subvariety of dimension 1 of J0(33),
 Abelian variety morphism:
  From: Abelian variety J0(33) of dimension 3
  To:   Abelian subvariety of dimension 1 of J0(33))
```

Projection will always have cokernel zero.

```
sage: J0(37).projection(J0(37)[0]).cokernel()
(Simple abelian subvariety of dimension 0 of J0(37),
 Abelian variety morphism:
  From: Simple abelian subvariety 37a(1,37) of dimension 1 of J0(37)
  To:   Simple abelian subvariety of dimension 0 of J0(37))
```

Here we have a nontrivial cokernel of a Hecke operator, as the T_2-eigenvalue for the newform 37b is 0.

```
sage: J0(37).hecke_operator(2).cokernel()
(Abelian subvariety of dimension 1 of J0(37),
 Abelian variety morphism:
  From: Abelian variety J0(37) of dimension 2
  To:   Abelian subvariety of dimension 1 of J0(37))
sage: AbelianVariety('37b').newform().q_expansion(5)
q + q^3 - 2*q^4 + O(q^5)
```

complementary_isogeny()

Returns the complementary isogeny of self.

EXAMPLES:

```
sage: J = J0(43)
sage: A = J[1]
sage: T5 = A.hecke_operator(5)
sage: T5.is_isogeny()
True
sage: T5.complementary_isogeny()
Abelian variety endomorphism of Simple abelian subvariety 43b(1,43) of dimension 2 of J0(43)
sage: (T5.complementary_isogeny() * T5).matrix()
[2 0 0 0]
[0 2 0 0]
[0 0 2 0]
[0 0 0 2]
```

factor_out_component_group()

View self as a morphism $f : A \to B$. Then $\ker(f)$ is an extension of an abelian variety C by a finite component group G. This function constructs a morphism g with domain A and codomain Q isogenous to C such that $\ker(g)$ is equal to C.

OUTPUT: a morphism

EXAMPLES:

```
sage: A,B,C = J0(33)
sage: pi = J0(33).projection(A)
sage: pi.kernel()
(Finite subgroup with invariants [5] over QQbar of Abelian variety J0(33) of dimension 3,
 Abelian subvariety of dimension 2 of J0(33))
sage: psi = pi.factor_out_component_group()
sage: psi.kernel()
(Finite subgroup with invariants [] over QQbar of Abelian variety J0(33) of dimension 3,
 Abelian subvariety of dimension 2 of J0(33))
```

ALGORITHM: We compute a subgroup G of B so that the composition $h : A \to B \to B/G$ has kernel that contains $A[n]$ and component group isomorphic to $(\mathbf{Z}/n\mathbf{Z})^{2d}$, where d is the dimension of A. Then h factors through multiplication by n, so there is a morphism $g : A \to B/G$ such that $g \circ [n] = h$. Then g is the desired morphism. We give more details below about how to transform this into linear algebra.

image()

Return the image of this morphism.

OUTPUT: an abelian variety

EXAMPLES: We compute the image of projection onto a factor of $J_0(33)$:

```
sage: A,B,C = J0(33)
sage: A
Simple abelian subvariety 11a(1,33) of dimension 1 of J0(33)
sage: f = J0(33).projection(A)
sage: f.image()
Abelian subvariety of dimension 1 of J0(33)
```

```
sage: f.image() == A
True
```

We compute the image of a Hecke operator:

```
sage: t2 = J0(33).hecke_operator(2); t2.fcp()
(x - 1) * (x + 2)^2
sage: phi = t2 + 2
sage: phi.image()
Abelian subvariety of dimension 1 of J0(33)
```

The sum of the image and the kernel is the whole space:

```
sage: phi.kernel()[1] + phi.image() == J0(33)
True
```

is_isogeny()

Return True if this morphism is an isogeny of abelian varieties.

EXAMPLES:

```
sage: J = J0(39)
sage: Id = J.hecke_operator(1)
sage: Id.is_isogeny()
True
sage: J.hecke_operator(19).is_isogeny()
False
```

kernel()

Return the kernel of this morphism.

OUTPUT:

- G - a finite group
- A - an abelian variety (identity component of the kernel)

EXAMPLES: We compute the kernel of a projection map. Notice that the kernel has a nontrivial abelian variety part.

```
sage: A, B, C = J0(33)
sage: pi = J0(33).projection(B)
sage: pi.kernel()
(Finite subgroup with invariants [20] over QQbar of Abelian variety J0(33) of dimension 3,
 Abelian subvariety of dimension 2 of J0(33))
```

We compute the kernels of some Hecke operators:

```
sage: t2 = J0(33).hecke_operator(2)
sage: t2
Hecke operator T_2 on Abelian variety J0(33) of dimension 3
sage: t2.kernel()
(Finite subgroup with invariants [2, 2, 2, 2] over QQ of Abelian variety J0(33) of dimensior
 Abelian subvariety of dimension 0 of J0(33))
sage: t3 = J0(33).hecke_operator(3)
sage: t3.kernel()
(Finite subgroup with invariants [3, 3] over QQ of Abelian variety J0(33) of dimension 3,
 Abelian subvariety of dimension 0 of J0(33))
```

45.10 Abelian varieties attached to newforms

TESTS:

```
sage: A = AbelianVariety('23a')
sage: loads(dumps(A)) == A
True
```

class ModularAbelianVariety_newform(*f, internal_name=False*)

A modular abelian variety attached to a specific newform.

endomorphism_ring()

Return the endomorphism ring of this newform abelian variety.

EXAMPLES:

```
sage: A = AbelianVariety('23a')
sage: E = A.endomorphism_ring(); E
Endomorphism ring of Newform abelian subvariety 23a of dimension 2 of J0(23)
```

We display the matrices of these two basis matrices:

```
sage: E.0.matrix()
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: E.1.matrix()
[ 0  1 -1  0]
[ 0  1 -1  1]
[-1  2 -2  1]
[-1  1  0 -1]
```

The result is cached:

```
sage: E is A.endomorphism_ring()
True
```

factor_number()

Return factor number.

OUTPUT: int

EXAMPLES:

```
sage: A = AbelianVariety('43b')
sage: A.factor_number()
1
```

label()

Return canonical label that defines this newform modular abelian variety.

OUTPUT: string

EXAMPLES:

```
sage: A = AbelianVariety('43b')
sage: A.label()
'43b'
```

newform(*names=None*)

Return the newform that this modular abelian variety is attached to.

EXAMPLES:

```
sage: f = Newform('37a')
sage: A = f.abelian_variety()
sage: A.newform()
q - 2*q^2 - 3*q^3 + 2*q^4 - 2*q^5 + O(q^6)
```

```
sage: A.newform() is f
True
```

If the a variable name has not ben specified, we must specify one:

```
sage: A = AbelianVariety('67b')
sage: A.newform()
...
TypeError: You must specify the name of the generator.
sage: A.newform('alpha')
q + alpha*q^2 + (-alpha - 3)*q^3 + (-3*alpha - 3)*q^4 - 3*q^5 + O(q^6)
```

If the eigenform is actually over $\mathbf{Q}$ then we don't have to specify the name:

```
sage: A = AbelianVariety('67a')
sage: A.newform()
q + 2*q^2 - 2*q^3 + 2*q^4 + 2*q^5 + O(q^6)
```

45.11 L-series of modular abelian varieties

At the moment very little functionality is implemented – this is mostly a placeholder for future planned work.

AUTHOR:

- William Stein (2007-03)

TESTS:

```
sage: L = J0(37)[0].padic_lseries(5)
sage: loads(dumps(L)) == L
True
sage: L = J0(37)[0].lseries()
sage: loads(dumps(L)) == L
True
```

class **Lseries**(*abvar*)

Base class for L-series attached to modular abelian varieties.

abelian_variety()

Return the abelian variety that this L-series is attached to.

OUTPUT: a modular abelian variety

EXAMPLES:

```
sage: J0(11).padic_lseries(7).abelian_variety()
Abelian variety J0(11) of dimension 1
```

class **Lseries_complex**(*abvar*)

A complex L-series attached to a modular abelian variety.

EXAMPLES:

```
sage: A = J0(37)
sage: A.lseries()
Complex L-series attached to Abelian variety J0(37) of dimension 2
```

rational_part()

Return the rational part of this L-function at the central critical value 1.

NOTE: This is not yet implemented.

EXAMPLES:

```
sage: J0(37).lseries().rational_part()
...
NotImplementedError
```

class **Lseries_padic**(*abvar, p*)

A p-adic L-series attached to a modular abelian variety.

power_series(*n=2, prec=5*)

Return the n-th approximation to this p-adic L-series as a power series in T. Each coefficient is a p-adic number whose precision is provably correct.

NOTE: This is not yet implemented.

EXAMPLES:

```
sage: L = J0(37)[0].padic_lseries(5)
sage: L.power_series()
...
NotImplementedError
sage: L.power_series(3,7)
...
NotImplementedError
```

prime()

Return the prime p of this p-adic L-series.

EXAMPLES:

```
sage: J0(11).padic_lseries(7).prime()
7
```

CHAPTER

FORTYSIX

MISCELLANEOUS MODULAR-FORM-RELATED MODULES

46.1 Dirichlet characters

A `DirichletCharacter` is the extension of a homomorphism

$$(\mathbf{Z}/N\mathbf{Z})^* \to R^*,$$

for some ring R, to the map $\mathbf{Z}/N\mathbf{Z} \to R$ obtained by sending those $x \in \mathbf{Z}/N\mathbf{Z}$ with $\gcd(N, x) > 1$ to 0.

EXAMPLES:

```
sage: G = DirichletGroup(35)
sage: x = G.gens()
sage: e = x[0]*x[1]^2; e
[zeta12^3, zeta12^2 - 1]
sage: e.order()
12
```

This illustrates a canonical coercion.

```
sage: e = DirichletGroup(5, QQ).0
sage: f = DirichletGroup(5,CyclotomicField(4)).0
sage: e*f
[-zeta4]
```

AUTHORS:

- William Stein (2005-09-02): Fixed bug in comparison of Dirichlet characters. It was checking that their values were the same, but not checking that they had the same level!
- William Stein (2006-01-07): added more examples
- William Stein (2006-05-21): added examples of everything; fix a *lot* of tiny bugs and design problem that became clear when creating examples.
- Craig Citro (2008-02-16): speed up __call__ method for Dirichlet characters, miscellaneous fixes

class `DirichletCharacter` (*parent, x, check=True*)
A Dirichlet character

bar()
Return the complex conjugate of this Dirichlet character.
EXAMPLES:

```
sage: e = DirichletGroup(5).0
sage: e
[zeta4]
sage: e.bar()
[-zeta4]
```

base_ring()
Returns the base ring of this Dirichlet character.
EXAMPLES:

```
sage: G = DirichletGroup(11)
sage: G.gen(0).base_ring()
Cyclotomic Field of order 10 and degree 4
sage: G = DirichletGroup(11, RationalField())
sage: G.gen(0).base_ring()
Rational Field
```

bernoulli(*k, algorithm='recurrence', cache=True, **opts*)
Returns the generalized Bernoulli number $B_{k,eps}$.
INPUT:

- `k` - an integer
- `algorithm` - string (default: 'recurrence'); either 'recurrence' or 'definition'. The 'recurrence' algorithm expresses generalized Bernoulli numbers in terms of classical Bernoulli numbers using a recurrence formula and is usually optimal. In this case `**opts` is passed onto the bernoulli function.
- `cache` - if True, cache answers

Let eps be this character (not necessarily primitive), and let $k \geq 0$ be an integer weight. This function computes the (generalized) Bernoulli number $B_{k,eps}$, e.g., as defined on page 44 of Diamond-Im:

$$\sum_{a=1}^{N} \varepsilon(a) t * e^{at}/(e^{Nt} - 1) = sum_{k=0}^{\infty} B_{k,eps}/k! t^k.$$

where N is the modulus of ε.
The default algorithm is the recurrence on page 656 of Cohen's GTM 'Number Theory and Diophantine Equations', section 9.
EXAMPLES:

```
sage: G = DirichletGroup(13)
sage: e = G.0
sage: e.bernoulli(5)
7430/13*zeta12^3 - 34750/13*zeta12^2 - 11380/13*zeta12 + 9110/13
sage: eps = DirichletGroup(9).0
sage: eps.bernoulli(3)
10*zeta6 + 4
sage: eps.bernoulli(3, algorithm="definition")
10*zeta6 + 4
```

change_ring(*R*)
Returns the base extension of self to the ring R.
EXAMPLE:

```
sage: e = DirichletGroup(7, QQ).0
sage: f = e.change_ring(QuadraticField(3, 'a'))
sage: f.parent()
Group of Dirichlet characters of modulus 7 over Number Field in a with defining polynomial x
```

```
sage: e = DirichletGroup(13).0
sage: e.change_ring(QQ)
...
ValueError: cannot coerce element of order 12 into self
```

conductor()

Computes and returns the conductor of this character.

EXAMPLES:

```
sage: G.<a,b> = DirichletGroup(20)
sage: a.conductor()
4
sage: b.conductor()
5
sage: (a*b).conductor()
20
```

decomposition()

Return the decomposition of self as a product of Dirichlet characters of prime power modulus, where the prime powers exactly divide the modulus of this character.

EXAMPLES:

```
sage: G.<a,b> = DirichletGroup(20)
sage: c = a*b
sage: d = c.decomposition(); d
[[-1], [zeta4]]
sage: d[0].parent()
Group of Dirichlet characters of modulus 4 over Cyclotomic Field of order 4 and degree 2
sage: d[1].parent()
Group of Dirichlet characters of modulus 5 over Cyclotomic Field of order 4 and degree 2
```

We can't multiply directly, since coercion of one element into the other parent fails in both cases:

```
sage: d[0]*d[1] == c
...
TypeError: unsupported operand parent(s) for '*': 'Group of Dirichlet characters of modulus
```

We can multiply if we're explicit about where we want the multiplication to take place.

```
sage: G(d[0])*G(d[1]) == c
True
```

Conductors that are divisible by various powers of 2 present some problems as the multiplicative group modulo 2^k is trivial for $k = 1$ and non-cyclic for $k \geq 3$:

```
sage: (DirichletGroup(18).0).decomposition()
[[], [zeta6]]
sage: (DirichletGroup(36).0).decomposition()
[[-1], [1]]
sage: (DirichletGroup(72).0).decomposition()
[[-1, 1], [1]]
```

element()

Return the underlying $\mathbf{Z}/n\mathbf{Z}$-module vector of exponents.

Warning: Please do not change the entries of the returned vector; this vector is mutable *only* because immutable vectors are implemented yet.

EXAMPLE:

```
sage: G.<a,b> = DirichletGroup(20)
sage: a.element()
(2, 0)
sage: b.element()
(0, 1)
```

extend(*M*)

Returns the extension of this character to a Dirichlet character modulo the multiple M of the modulus.

EXAMPLES:

```
sage: G.<a,b> = DirichletGroup(20)
sage: H.<c> = DirichletGroup(4)
sage: c.extend(20)
[-1, 1]
sage: a
[-1, 1]
sage: c.extend(20) == a
True
```

galois_orbit(*sort=True*)

Return the orbit of this character under the action of the absolute Galois group of the prime subfield of the base ring.

EXAMPLES:

```
sage: G = DirichletGroup(30); e = G.1
sage: e.galois_orbit()
[[1, zeta4], [1, -zeta4]]
```

Another example:

```
sage: G = DirichletGroup(13)
sage: G.galois_orbits()
[
[[1]],
[[zeta12], [zeta12^3 - zeta12], [-zeta12], [-zeta12^3 + zeta12]],
[[zeta12^2], [-zeta12^2 + 1]],
[[zeta12^3], [-zeta12^3]],
[[zeta12^2 - 1], [-zeta12^2]],
[[-1]]
]
sage: e = G.0
sage: e
[zeta12]
sage: e.galois_orbit()
[[zeta12], [zeta12^3 - zeta12], [-zeta12], [-zeta12^3 + zeta12]]
sage: e = G.0^2; e
[zeta12^2]
sage: e.galois_orbit()
[[zeta12^2], [-zeta12^2 + 1]]
```

A non-example:

```
sage: chi = DirichletGroup(7, Integers(9), zeta = Integers(9)(2)).0
sage: chi.galois_orbit()
...
TypeError: Galois orbits only defined if base ring is an integral domain
```

gauss_sum(*a=1*)

Return a Gauss sum associated to this Dirichlet character.

The Gauss sum associated to χ is

$$g_a(\chi) = \sum_{r \in \mathbf{Z}/m\mathbf{Z}} \chi(r)\,\zeta^{ar},$$

where m is the modulus of χ and ζ is a primitive m^{th} root of unity, i.e., ζ is `self.parent().zeta()`.
FACTS: If the modulus is a prime p and the character is nontrivial, then the Gauss sum has absolute value $\sqrt{p}$.
CACHING: Computed Gauss sums are *not* cached with this character.
EXAMPLES:

```
sage: G = DirichletGroup(3)
sage: e = G([-1])
sage: e.gauss_sum(1)
2*zeta6 - 1
sage: e.gauss_sum(2)
-2*zeta6 + 1
sage: norm(e.gauss_sum())
3

sage: G = DirichletGroup(13)
sage: e = G.0
sage: e.gauss_sum()
-zeta156^46 + zeta156^45 + zeta156^42 + zeta156^41 + 2*zeta156^40 + zeta156^37 - zeta156^36
sage: factor(norm(e.gauss_sum()))
13^24
```

gauss_sum_numerical(*prec=53, a=1*)

Return a Gauss sum associated to this Dirichlet character as an approximate complex number with prec bits of precision.
INPUT:

- `prec` - integer (deafault: 53), *bits* of precision
- `a` - integer, as for gauss_sum.

The Gauss sum associated to χ is

$$g_a(\chi) = \sum_{r \in \mathbf{Z}/m\mathbf{Z}} \chi(r)\,\zeta^{ar},$$

where m is the modulus of χ and ζ is a primitive m^{th} root of unity, i.e., ζ is `self.parent().zeta()`.
EXAMPLES:

```
sage: G = DirichletGroup(3)
sage: e = G.0
sage: abs(e.gauss_sum_numerical())
1.7320508075...
sage: sqrt(3.0)
1.73205080756888
sage: e.gauss_sum_numerical(a=2)
-...e-15 - 1.7320508075...*I
sage: e.gauss_sum_numerical(a=2, prec=100)
4.7331654313260708324703713917e-30 - 1.7320508075688772935274463415*I
sage: G = DirichletGroup(13)
sage: e = G.0
sage: e.gauss_sum_numerical()
-3.07497205... + 1.8826966926...*I
sage: abs(e.gauss_sum_numerical())
3.60555127546...
```

```
sage: sqrt(13.0)
3.60555127546399
```

is_even()

Return `True` if and only if $\varepsilon(-1) = 1$.

EXAMPLES:

```
sage: G = DirichletGroup(13)
sage: e = G.0
sage: e.is_even()
False
sage: e(-1)
-1
sage: [e.is_even() for e in G]
[True, False, True, False, True, False, True, False, True, False, True, False]
```

Note that `is_even` need not be the negation of is_odd, e.g., in characteristic 2:

```
sage: G.<e> = DirichletGroup(13, GF(4,'a'))
sage: e.is_even()
True
sage: e.is_odd()
True
```

is_odd()

Return `True` if and only if $\varepsilon(-1) = -1$.

EXAMPLES:

```
sage: G = DirichletGroup(13)
sage: e = G.0
sage: e.is_odd()
True
sage: [e.is_odd() for e in G]
[False, True, False, True, False, True, False, True, False, True, False, True]
```

Note that `is_even` need not be the negation of is_odd, e.g., in characteristic 2:

```
sage: G.<e> = DirichletGroup(13, GF(4,'a'))
sage: e.is_even()
True
sage: e.is_odd()
True
```

is_primitive()

Return `True` if and only if this character is primitive, i.e., its conductor equals its modulus.

EXAMPLES:

```
sage: G.<a,b> = DirichletGroup(20)
sage: a.is_primitive()
False
sage: b.is_primitive()
False
sage: (a*b).is_primitive()
True
```

is_trivial()

Returns `True` if this is the trivial character, i.e., has order 1.

EXAMPLES:

```
sage: G.<a,b> = DirichletGroup(20)
sage: a.is_trivial()
False
sage: (a^2).is_trivial()
True
```

jacobi_sum(*char, check=True*)

Return the Jacobi sum associated to these Dirichlet characters (i.e., J(self,char)).

EXAMPLES:

```
sage: D = DirichletGroup(13)
sage: e = D.0
sage: f = D[-2]
sage: e.jacobi_sum(f)
3*zeta156^26 + 2*zeta156^13 - 3
sage: f.jacobi_sum(e)
3*zeta156^26 + 2*zeta156^13 - 3
sage: p = 7
sage: DP = DirichletGroup(p)
sage: f = DP.0
sage: e.jacobi_sum(f)
...
NotImplementedError: Characters must be from the same Dirichlet Group.
sage: all_jacobi_sums = [(DP[i],DP[j],DP[i].jacobi_sum(DP[j]))              ...
...
sage: for s in all_jacobi_sums:
...       print s
([1], [1], 5)
([1], [zeta6], 0)
([1], [zeta6 - 1], 0)
([1], [-1], 0)
([1], [-zeta6], 0)
([1], [-zeta6 + 1], 0)
([zeta6], [zeta6], -zeta42^7 + 3)
([zeta6], [zeta6 - 1], 2*zeta42^7 + 1)
([zeta6], [-1], -2*zeta42^7 - 1)
([zeta6], [-zeta6], zeta42^7 - 3)
([zeta6], [-zeta6 + 1], 1)
([zeta6 - 1], [zeta6 - 1], -3*zeta42^7 + 2)
([zeta6 - 1], [-1], 2*zeta42^7 + 1)
([zeta6 - 1], [-zeta6], -1)
([zeta6 - 1], [-zeta6 + 1], -zeta42^7 - 2)
([-1], [-1], 1)
([-1], [-zeta6], -2*zeta42^7 + 3)
([-1], [-zeta6 + 1], 2*zeta42^7 - 3)
([-zeta6], [-zeta6], 3*zeta42^7 - 1)
([-zeta6], [-zeta6 + 1], -2*zeta42^7 + 3)
([-zeta6 + 1], [-zeta6 + 1], zeta42^7 + 2)
```

Let's check that trivial sums are being calculated correctly:

```
sage: N = 13
sage: D = DirichletGroup(N)
sage: g = D(1)
sage: g.jacobi_sum(g)
11
sage: sum([g(x)*g(1-x) for x in IntegerModRing(N)])
11
```

Now let's take a look at a non-prime modulus. One reason we don't like non-prime moduli is that certain

identities that are used in the code are not valid for non-prime moduli:

```
sage: N = 9
sage: D = DirichletGroup(N)
sage: g = D(1)
sage: g.jacobi_sum(g)
...
ValueError: Characters must have prime moduli at this time -- use check=False to allow non-p
sage: g.jacobi_sum(g, check=False)
5
sage: sum([g(x)*g(1-x) for x in IntegerModRing(N)])
3
```

TODO: Implement Jacobi sums for characters with output in finite fields GF(q) for q non-prime.

kernel()

Return the kernel of this character.

OUTPUT: Currently the kernel is returned as a list. This may change.

EXAMPLES:

```
sage: G.<a,b> = DirichletGroup(20)
sage: a.kernel()
[1, 9, 13, 17]
sage: b.kernel()
[1, 11]
```

kloosterman_sum(*a=1, b=0*)

Return the "twisted" Kloosterman sum associated to this Dirichlet character. This includes Gauss sums, classical Kloosterman sums, Salie sums, etc.

The Kloosterman sum associated to chi and the integers a,b is $$ K(a,b,chi) = sum_{r in (Z/mZ)^times} chi(r),zeta^{ar+br^{-1}}, $$ where m is the modulus of chi and $zeta$ is a primitive mth root of unity, i.e., $zeta$ is code{self.parent().zeta()}. This reduces to to the Gauss sum if b=0.

CACHING: Computed Kloosterman sums are emph{not} cached with this character.

EXAMPLES:

```
sage: G = DirichletGroup(3)
sage: e = G([-1])
sage: e.kloosterman_sum(3,5)
-2*zeta6 + 1
sage: G = DirichletGroup(20)
sage: e = G([1 for  u in G.unit_gens()])
sage: e.kloosterman_sum(7,17)
-2*zeta20^6 + 2*zeta20^4 + 4
```

kloosterman_sum_numerical(*prec=53, a=1, b=0*)

Return the Kloosterman sum associated to this Dirichlet character as an approximate complex number with prec bits of precision.

INPUT: - prec – integer (deafault: 53), *bits* of precision - a – integer, as for kloosterman_sum - b – integer, as for kloosterman_sum.

EXAMPLES:

```
sage: G = DirichletGroup(3)
sage: e = G.0
```

The real component of the numerical value of e is near zero:

```
sage: v=e.kloosterman_sum_numerical()
sage: v.real() < 1.0e15
True
sage: v.imag()
```

```
1.73205080757
sage: G = DirichletGroup(20)
sage: e = G.1
sage: e.kloosterman_sum_numerical(53,3,11)
3.80422606518 - 3.80422606518*I
```

level()

Synonym for modulus.

EXAMPLE:

```
sage: e = DirichletGroup(100, QQ).0
sage: e.level()
100
```

maximize_base_ring()

Let

$$\varepsilon : (\mathbf{Z}/N\mathbf{Z})^* \to \mathbf{Q}(\zeta_n)$$

be a Dirichlet character. This function returns an equal Dirichlet character

$$\chi : (\mathbf{Z}/N\mathbf{Z})^* \to \mathbf{Q}(\zeta_m)$$

where m is the least common multiple of n and the exponent of $(\mathbf{Z}/N\mathbf{Z})^*$.

EXAMPLES:

```
sage: G.<a,b> = DirichletGroup(20,QQ)
sage: b.maximize_base_ring()
[1, -1]
sage: b.maximize_base_ring().base_ring()
Cyclotomic Field of order 4 and degree 2
sage: DirichletGroup(20).base_ring()
Cyclotomic Field of order 4 and degree 2
```

minimize_base_ring()

Return a Dirichlet character that equals this one, but over as small a subfield (or subring) of the base ring as possible.

Note: This function is currently only implemented when the base ring is a number field. It's the identity function in characteristic p.

EXAMPLES:

```
sage: G = DirichletGroup(13)
sage: e = DirichletGroup(13).0
sage: e.base_ring()
Cyclotomic Field of order 12 and degree 4
sage: e.minimize_base_ring().base_ring()
Cyclotomic Field of order 12 and degree 4
sage: (e^2).minimize_base_ring().base_ring()
Cyclotomic Field of order 6 and degree 2
sage: (e^3).minimize_base_ring().base_ring()
Cyclotomic Field of order 4 and degree 2
sage: (e^12).minimize_base_ring().base_ring()
Rational Field
```

modulus()

The modulus of this character.

EXAMPLES:

```
sage: e = DirichletGroup(100, QQ).0
sage: e.modulus()
100
sage: e.conductor()
4
```

multiplicative_order()

The order of this character.

EXAMPLES:

```
sage: e = DirichletGroup(100).1
sage: e.order()    # same as multiplicative_order, since group is multiplicative
20
sage: e.multiplicative_order()
20
sage: e = DirichletGroup(100).0
sage: e.multiplicative_order()
2
```

primitive_character()

Returns the primitive character associated to self.

EXAMPLES:

```
sage: e = DirichletGroup(100).0; e
[-1, 1]
sage: e.conductor()
4
sage: f = e.primitive_character(); f
[-1]
sage: f.modulus()
4
```

restrict(*M*)

Returns the restriction of this character to a Dirichlet character modulo the divisor M of the modulus, which must also be a multiple of the conductor of this character.

EXAMPLES:

```
sage: e = DirichletGroup(100).0
sage: e.modulus()
100
sage: e.conductor()
4
sage: e.restrict(20)
[-1, 1]
sage: e.restrict(4)
[-1]
sage: e.restrict(50)
...
ValueError: conductor(=4) must divide M(=50)
```

values()

Returns a list of the values of this character on each integer between 0 and the modulus.

EXAMPLES:

```
sage: e = DirichletGroup(20)(1)
sage: e.values()
[0, 1, 0, 1, 0, 0, 0, 1, 0, 1, 0, 1, 0, 1, 0, 0, 0, 1, 0, 1]
sage: e = DirichletGroup(20).gen(0)
sage: print e.values()
```

```
[0, 1, 0, -1, 0, 0, 0, -1, 0, 1, 0, -1, 0, 1, 0, 0, 0, 1, 0, -1]
sage: e = DirichletGroup(20).gen(1)
sage: e.values()
[0, 1, 0, -zeta4, 0, 0, 0, zeta4, 0, -1, 0, 1, 0, -zeta4, 0, 0, 0, zeta4, 0, -1]
sage: e = DirichletGroup(21).gen(0) ; e.values()
[0, 1, -1, 0, 1, -1, 0, 0, -1, 0, 1, -1, 0, 1, 0, 0, 1, -1, 0, 1, -1]
sage: e = DirichletGroup(21, base_ring=GF(37)).gen(0) ; e.values()
[0, 1, 36, 0, 1, 36, 0, 0, 36, 0, 1, 36, 0, 1, 0, 0, 1, 36, 0, 1, 36]
sage: e = DirichletGroup(21, base_ring=GF(3)).gen(0) ; e.values()
[0, 1, 2, 0, 1, 2, 0, 0, 2, 0, 1, 2, 0, 1, 0, 0, 1, 2, 0, 1, 2]

sage: chi = DirichletGroup(100151, CyclotomicField(10)).0
sage: ls = chi.values() ; ls[0:10]
[0,
1,
-zeta10^3,
-zeta10,
-zeta10,
1,
zeta10^3 - zeta10^2 + zeta10 - 1,
zeta10,
zeta10^3 - zeta10^2 + zeta10 - 1,
zeta10^2]
```

values_on_gens()

Returns a tuple of the values of this character on each of the minimal generators of $(\mathbf{Z}/N\mathbf{Z})^*$, where N is the modulus.

EXAMPLES:

```
sage: e = DirichletGroup(16)([-1, 1])
sage: e.values_on_gens ()
(-1, 1)
```

DirichletGroup(*modulus, base_ring=None, zeta=None, zeta_order=None, names=None, integral=False*)

The group of Dirichlet characters modulo N with values in the subgroup $\langle \zeta_n \rangle$ of the multiplicative group of the `base_ring`. If the base_ring is omitted then we use $\mathbf{Q}(\zeta_n)$, where n is the exponent of $(\mathbf{Z}/N\mathbf{Z})^*$. If ζ is omitted then we compute and use a maximal-order zeta in base_ring, if possible.

INPUT:

- `modulus` - int
- `base_ring` - Ring (optional), where characters take their values (should be an integral domain).
- `zeta` - Element (optional), element of base_ring; zeta is a root of unity
- `zeta_order` - int (optional), the order of zeta
- `names` - ignored (needed so G.... = DirichletGroup(...) notation works)
- `integral` - boolean (default: `False`). If `True`, return the group with base_ring the ring of integers in the smallest choice of CyclotomicField. Ignored if base_ring is not `None`.

OUTPUT:

- `DirichletGroup` - a group of Dirichlet characters.

EXAMPLES:

The default base ring is a cyclotomic field of order the exponent of $(\mathbf{Z}/N\mathbf{Z})^*$.

```
sage: DirichletGroup(20)
Group of Dirichlet characters of modulus 20 over Cyclotomic Field of order 4 and degree 2
```

We create the group of Dirichlet character mod 20 with values in the rational numbers:

```
sage: G = DirichletGroup(20, QQ); G
Group of Dirichlet characters of modulus 20 over Rational Field
sage: G.order()
4
sage: G.base_ring()
Rational Field
```

The elements of G print as lists giving the values of the character on the generators of $(Z/NZ)^*$:

```
sage: list(G)
[[1, 1], [-1, 1], [1, -1], [-1, -1]]
```

Next we construct the group of Dirichlet character mod 20, but with values in Q(zeta_n):

```
sage: G = DirichletGroup(20)
sage: G.list()
[[1, 1], [-1, 1], [1, zeta4], [-1, zeta4], [1, -1], [-1, -1], [1, -zeta4], [-1, -zeta4]]
```

We next compute several invariants of G:

```
sage: G.gens()
([-1, 1], [1, zeta4])
sage: G.unit_gens()
[11, 17]
sage: G.zeta()
zeta4
sage: G.zeta_order()
4
```

In this example we create a Dirichlet character with values in a number field. We have to give zeta, but not its order.

```
sage: R.<x> = PolynomialRing(QQ)
sage: K.<a> = NumberField(x^4 + 1)
sage: G = DirichletGroup(5, K, a); G
Group of Dirichlet characters of modulus 5 over Number Field in a with defining polynomial x^4 +
sage: G.list()
[[1], [a^2], [-1], [-a^2]]

sage: G.<e> = DirichletGroup(13)
sage: loads(G.dumps()) == G
True

sage: G = DirichletGroup(19, GF(5))
sage: loads(G.dumps()) == G
True
```

We compute a Dirichlet group over a large prime field.

```
sage: p = next_prime(10^40)
sage: g = DirichletGroup(19, GF(p)); g
Group of Dirichlet characters of modulus 19 over Finite Field of size 10000000000000000000000000
```

Note that the root of unity has small order, i.e., it is not the largest order root of unity in the field.

```
sage: g.zeta_order()
2

sage: r4 = CyclotomicField(4).ring_of_integers()
sage: G = DirichletGroup(60, r4)
sage: G.gens()
([-1, 1, 1], [1, -1, 1], [1, 1, zeta4])
sage: val = G.gens()[2].values_on_gens()[2] ; val
zeta4
sage: parent(val)
Maximal Order in Cyclotomic Field of order 4 and degree 2
sage: r4.residue_field(r4.ideal(29).factor()[0][0])(val)
17
sage: r4.residue_field(r4.ideal(29).factor()[0][0])(val) * GF(29)(3)
22
sage: r4.residue_field(r4.ideal(29).factor()[0][0])(G.gens()[2].values_on_gens()[2]) * 3
22
sage: parent(r4.residue_field(r4.ideal(29).factor()[0][0])(G.gens()[2].values_on_gens()[2]) * 3)
Residue field of Fractional ideal (-2*zeta4 + 5)

sage: DirichletGroup(60, integral=True)
Group of Dirichlet characters of modulus 60 over Maximal Order in Cyclotomic Field of order 4 an
sage: parent(DirichletGroup(60, integral=True).gens()[2].values_on_gens()[2])
Maximal Order in Cyclotomic Field of order 4 and degree 2
```

class **DirichletGroup_class**(*modulus, zeta, zeta_order*)

Group of Dirichlet characters modulo N over a given base ring R.

base_extend(*R*)

Returns the Dirichlet group over R obtained by extending scalars, with the same modulus and root of unity as self.

EXAMPLES:

```
sage: G = DirichletGroup(7,QQ); G
Group of Dirichlet characters of modulus 7 over Rational Field
sage: H = G.base_extend(CyclotomicField(6)); H
Group of Dirichlet characters of modulus 7 over Cyclotomic Field of order 6 and degree 2
sage: H.zeta()
-1
sage: G.base_extend(ZZ)
...
TypeError: No coercion map from 'Rational Field' to 'Integer Ring' is defined.
```

change_ring(*R, zeta=None, zeta_order=None*)

Returns the Dirichlet group over R with the same modulus as self.

EXAMPLES:

```
sage: G = DirichletGroup(7,QQ); G
Group of Dirichlet characters of modulus 7 over Rational Field
sage: G.change_ring(CyclotomicField(6))
Group of Dirichlet characters of modulus 7 over Cyclotomic Field of order 6 and degree 2
```

decomposition()

Returns the Dirichlet groups of prime power modulus corresponding to primes dividing modulus.

(Note that if the modulus is 2 mod 4, there will be a "factor" of $(\mathbf{Z}/2\mathbf{Z})^*$, which is the trivial group.)

EXAMPLES:

```
sage: DirichletGroup(20).decomposition()
[
Group of Dirichlet characters of modulus 4 over Cyclotomic Field of order 4 and degree 2,
Group of Dirichlet characters of modulus 5 over Cyclotomic Field of order 4 and degree 2
]
sage: DirichletGroup(20,GF(5)).decomposition()
[
Group of Dirichlet characters of modulus 4 over Finite Field of size 5,
Group of Dirichlet characters of modulus 5 over Finite Field of size 5
]
```

exponent()

Return the exponent of this group.

EXAMPLES:

```
sage: DirichletGroup(20).exponent()
4
sage: DirichletGroup(20,GF(3)).exponent()
2
sage: DirichletGroup(20,GF(2)).exponent()
1
sage: DirichletGroup(37).exponent()
36
```

galois_orbits(*v=None, reps_only=False, sort=True, check=True*)

Return a list of the Galois orbits of Dirichlet characters in self, or in v if v is not None.

INPUT:

- `v` - (optional) list of elements of self
- `reps_only` - (optional: default False) if True only returns representatives for the orbits.
- `sort` - (optional: default True) whether to sort the list of orbits and the orbits themselves (slightly faster if False).
- `check` - (optional, default: True) whether or not to explicitly coerce each element of v into self.

The Galois group is the absolute Galois group of the prime subfield of Frac(R). If R is not a domain, an error will be raised.

EXAMPLES:

```
sage: DirichletGroup(20).galois_orbits()
[
[[1, 1]],
[[1, zeta4], [1, -zeta4]],
[[1, -1]],
[[-1, 1]],
[[-1, zeta4], [-1, -zeta4]],
[[-1, -1]]
]
sage: DirichletGroup(17, Integers(6), zeta=Integers(6)(5)).galois_orbits()
...
TypeError: Galois orbits only defined if base ring is an integral domain
sage: DirichletGroup(17, Integers(9), zeta=Integers(9)(2)).galois_orbits()
...
TypeError: Galois orbits only defined if base ring is an integral domain
```

gen(*n=0*)

Return the n-th generator of self.

EXAMPLES:

```
sage: G = DirichletGroup(20)
sage: G.gen(0)
[-1, 1]
sage: G.gen(1)
[1, zeta4]
sage: G.gen(2)
...
IndexError: n(=2) must be between 0 and 1

sage: G.gen(-1)
...
IndexError: n(=-1) must be between 0 and 1
```

gens()

Returns generators of self.

EXAMPLES:

```
sage: G = DirichletGroup(20)
sage: G.gens()
([-1, 1], [1, zeta4])
```

integers_mod()

Returns the group of integers $\mathbf{Z}/N\mathbf{Z}$ where N is the modulus of self.

EXAMPLES:

```
sage: G = DirichletGroup(20)
sage: G.integers_mod()
Ring of integers modulo 20
```

modulus()

Returns the modulus of self.

EXAMPLES:

```
sage: G = DirichletGroup(20)
sage: G.modulus()
20
```

ngens()

Returns the number of generators of self.

EXAMPLES:

```
sage: G = DirichletGroup(20)
sage: G.ngens()
2
```

order()

Return the number of elements of self. This is the same as len(self).

EXAMPLES:

```
sage: DirichletGroup(20).order()
8
sage: DirichletGroup(37).order()
36
```

random_element()

Return a random element of self.

The element is computed by multiplying a random power of each generator together, where the power is between 0 and the order of the generator minus 1, inclusive.

EXAMPLES:

```
sage: DirichletGroup(37).random_element()
[zeta36^4]
sage: DirichletGroup(20).random_element()
[-1, 1]
sage: DirichletGroup(60).random_element()
[1, -1, 1]
```

unit_gens()

Returns the minimal generators for the units of $(\mathbf{Z}/N\mathbf{Z})^*$, where N is the modulus of self.

EXAMPLES:

```
sage: DirichletGroup(37).unit_gens()
[2]
sage: DirichletGroup(20).unit_gens()
[11, 17]
sage: DirichletGroup(60).unit_gens()
[31, 41, 37]
sage: DirichletGroup(20,QQ).unit_gens()
[11, 17]
```

zeta()

Returns the chosen root zeta of unity in the base ring R.

EXAMPLES:

```
sage: DirichletGroup(37).zeta()
zeta36
sage: DirichletGroup(20).zeta()
zeta4
sage: DirichletGroup(60).zeta()
zeta4
sage: DirichletGroup(60,QQ).zeta()
-1
sage: DirichletGroup(60, GF(25,'a')).zeta()
2
```

zeta_order()

Returns the order of the chosen root zeta of unity in the base ring R.

EXAMPLES:

```
sage: DirichletGroup(20).zeta_order()
4
sage: DirichletGroup(60).zeta_order()
4
sage: DirichletGroup(60, GF(25,'a')).zeta_order()
4
sage: DirichletGroup(19).zeta_order()
18
```

TrivialCharacter(*N, base_ring=Rational Field*)

Return the trivial character of the given modulus, with values in the given base ring.

EXAMPLE:

```
sage: t = trivial_character(7)
sage: [t(x) for x in [0..20]]
[0, 1, 1, 1, 1, 1, 1, 0, 1, 1, 1, 1, 1, 1, 0, 1, 1, 1, 1, 1, 1]
sage: t(1).parent()
Rational Field
sage: trivial_character(7, Integers(3))(1).parent()
Ring of integers modulo 3
```

is_DirichletCharacter(*x*)
Return True if x is of type DirichletCharacter.

EXAMPLES:

```
sage: from sage.modular.dirichlet import is_DirichletCharacter
sage: is_DirichletCharacter(trivial_character(3))
True
sage: is_DirichletCharacter([1])
False
```

is_DirichletGroup(*x*)
Returns True if x is a Dirichlet group.

EXAMPLES:

```
sage: from sage.modular.dirichlet import is_DirichletGroup
sage: is_DirichletGroup(DirichletGroup(11))
True
sage: is_DirichletGroup(11)
False
sage: is_DirichletGroup(DirichletGroup(11).0)
False
```

kronecker_character(*d*)
Returns the quadratic Dirichlet character (d/.) of minimal conductor.

EXAMPLES:

```
sage: kronecker_character(97*389*997^2)
[-1, -1]
```

```
sage: a = kronecker_character(1)
sage: b = DirichletGroup(2401,QQ)(a)     # NOTE -- over QQ!
sage: b.modulus()
2401
```

AUTHORS:

- Jon Hanke (2006-08-06)

kronecker_character_upside_down(*d*)
Returns the quadratic Dirichlet character (./d) of conductor d, for d0.

EXAMPLES:

```
sage: kronecker_character_upside_down(97*389*997^2)
[-1, -1, 1]
```

AUTHORS:

- Jon Hanke (2006-08-06)

trivial_character(*N, base_ring=Rational Field*)
Return the trivial character of the given modulus, with values in the given base ring.

EXAMPLE:

```
sage: t = trivial_character(7)
sage: [t(x) for x in [0..20]]
[0, 1, 1, 1, 1, 1, 1, 0, 1, 1, 1, 1, 1, 1, 0, 1, 1, 1, 1, 1, 1]
sage: t(1).parent()
Rational Field
sage: trivial_character(7, Integers(3))(1).parent()
Ring of integers modulo 3
```

46.2 The set $\mathbb{P}^1(\mathbb{Q})$ of cusps

EXAMPLES:

```
sage: Cusps
Set P^1(QQ) of all cusps

sage: Cusp(oo)
Infinity
```

class Cusp(*a, b=None, parent=None, check=True*)

A cusp.

A cusp is either a rational number or infinity, i.e., an element of the projective line over Q. A Cusp is stored as a pair (a,b), where gcd(a,b)=1 and a,b are of type Integer.

EXAMPLES:

```
sage: a = Cusp(2/3); b = Cusp(oo)
sage: a.parent()
Set P^1(QQ) of all cusps
sage: a.parent() is b.parent()
True
```

apply(*g*)

Return g(self), where g=[a,b,c,d] is a list of length 4, which we view as a linear fractional transformation.

EXAMPLES: Apply the identity matrix:

```
sage: Cusp(0).apply([1,0,0,1])
0
sage: Cusp(0).apply([0,-1,1,0])
Infinity
sage: Cusp(0).apply([1,-3,0,1])
-3
```

denominator()

Return the denominator of the cusp a/b.

EXAMPLES:

```
sage: x=Cusp(6,9); x
2/3
sage: x.denominator()
3
sage: Cusp(oo).denominator()
0
sage: Cusp(-5/10).denominator()
2
```

galois_action(*t, N*)

Suppose this cusp is α, G is a congruence subgroup of level N, and σ is the automorphism in the Galois group of $\mathbf{Q}(\zeta_N)/\mathbf{Q}$ that sends ζ_N to ζ_N^t. Then this function computes a cusp β such that $\sigma([\alpha]) = [\beta]$, where $[\alpha]$ is the equivalence class of α modulo G.

INPUT:

- t – integer that is coprime to N
- N – positive integer (level)

OUTPUT:

- a cusp

EXAMPLES:

```
sage: Cusp(1/10).galois_action(3, 50)
1/170
sage: Cusp(oo).galois_action(3, 50)
Infinity
sage: Cusp(0).galois_action(3, 50)
0
```

Here we compute explicitly the permutations of the action for t=3 on cusps for Gamma0(50):

```
sage: N = 50; t=3; G = Gamma0(N); C = G.cusps()
sage: cl = lambda z: exists(C, lambda y:y.is_gamma0_equiv(z, N))[1]
sage: for i in range(5): print i, t^i, [cl(alpha.galois_action(t^i,N)) for alpha in C]
0 1 [0, 1/25, 1/10, 1/5, 3/10, 2/5, 1/2, 3/5, 7/10, 4/5, 9/10, Infinity]
1 3 [0, 1/25, 7/10, 2/5, 1/10, 4/5, 1/2, 1/5, 9/10, 3/5, 3/10, Infinity]
2 9 [0, 1/25, 9/10, 4/5, 7/10, 3/5, 1/2, 2/5, 3/10, 1/5, 1/10, Infinity]
3 27 [0, 1/25, 3/10, 3/5, 9/10, 1/5, 1/2, 4/5, 1/10, 2/5, 7/10, Infinity]
4 81 [0, 1/25, 1/10, 1/5, 3/10, 2/5, 1/2, 3/5, 7/10, 4/5, 9/10, Infinity]
```

REFERENCES:

- Section 1.3 of Glenn Stevens, "Arithmetic on Modular Curves"
- There is a long comment about our algorithm in the source code for this function.

WARNING: In some cases N must fit in a long long, i.e., there are cases where this algorithm isn't fully implemented.

AUTHORS:

- William Stein, 2009-04-18

is_gamma0_equiv(*other, N, transformation=False*)

Return whether self and other are equivalent modulo the action of $\Gamma_0(N)$ via linear fractional transformations.

INPUT:

- `other` - Cusp
- `N` - an integer (specifies the group Gamma_0(N))
- `transformation` - bool (default: False), if True, also return upper left entry of a matrix in Gamma_0(N) that sends self to other.

OUTPUT:

- `bool` - True if self and other are equivalent
- `integer` - returned only if transformation is True

EXAMPLES:

```
sage: x = Cusp(2,3)
sage: y = Cusp(4,5)
sage: x.is_gamma0_equiv(y, 2)
```

```
True
sage: x.is_gamma0_equiv(y, 2, True)
(True, 1)
sage: x.is_gamma0_equiv(y, 3)
False
sage: x.is_gamma0_equiv(y, 3, True)
(False, None)
sage: Cusp(1,0)
Infinity
sage: z = Cusp(1,0)
sage: x.is_gamma0_equiv(z, 3, True)
(True, 2)
```

ALGORITHM: See Proposition 2.2.3 of Cremona's book "Algorithms for Modular Elliptic Curves", or Prop 2.27 of Stein's Ph.D. thesis.

is_gamma1_equiv(*other, N*)

Return whether self and other are equivalent modulo the action of Gamma_1(N) via linear fractional transformations.

INPUT:

- `other` - Cusp
- `N` - an integer (specifies the group Gamma_1(N))

OUTPUT:

- `bool` - True if self and other are equivalent
- `int` - 0, 1 or -1, gives further information about the equivalence: If the two cusps are u1/v1 and u2/v2, then they are equivalent if and only if v1 = v2 (mod N) and u1 = u2 (mod gcd(v1,N)) or v1 = -v2 (mod N) and u1 = -u2 (mod gcd(v1,N)) The sign is +1 for the first and -1 for the second. If the two cusps are not equivalent then 0 is returned.

EXAMPLES:

```
sage: x = Cusp(2,3)
sage: y = Cusp(4,5)
sage: x.is_gamma1_equiv(y,2)
(True, 1)
sage: x.is_gamma1_equiv(y,3)
(False, 0)
sage: z = Cusp(QQ(x) + 10)
sage: x.is_gamma1_equiv(z,10)
(True, 1)
sage: z = Cusp(1,0)
sage: x.is_gamma1_equiv(z, 3)
(True, -1)
sage: Cusp(0).is_gamma1_equiv(oo, 1)
(True, 1)
sage: Cusp(0).is_gamma1_equiv(oo, 3)
(False, 0)
```

is_gamma_h_equiv(*other, G*)

Return a pair (b, t), where b is True or False as self and other are equivalent under the action of G, and t is 1 or -1, as described below.

Two cusps $u1/v1$ and $u2/v2$ are equivalent modulo Gamma_H(N) if and only if $v1 = h*v2 (\mathrm{mod} N)$ and $u1 = h^{(-1)}*u2 (\mathrm{mod} gcd(v1,N))$ or $v1 = -h*v2 (mod N)$ and $u1 = -h^{(-1)}*u2 (\mathrm{mod} gcd(v1,N))$ for some $h \in H$. Then t is 1 or -1 as c and c' fall into the first or second case, respectively.

INPUT:

- `other` - Cusp

- G - a congruence subgroup Gamma_H(N)

OUTPUT:

- bool - True if self and other are equivalent
- int - -1, 0, 1; extra info

EXAMPLES:

```
sage: x = Cusp(2,3)
sage: y = Cusp(4,5)
sage: x.is_gamma_h_equiv(y,GammaH(13,[2]))
(True, 1)
sage: x.is_gamma_h_equiv(y,GammaH(13,[5]))
(False, 0)
sage: x.is_gamma_h_equiv(y,GammaH(5,[]))
(False, 0)
sage: x.is_gamma_h_equiv(y,GammaH(23,[4]))
(True, -1)
```

Enumerating the cusps for a space of modular symbols uses this function.

```
sage: G = GammaH(25,[6]) ; M = G.modular_symbols() ; M
Modular Symbols space of dimension 11 for Congruence Subgroup Gamma_H(25) with H generated b
sage: M.cusps()
[37/75, 1/2, 31/125, 1/4, -2/5, 2/5, -1/5, 1/10, -3/10, 1/15, 7/15, 9/20]
sage: len(M.cusps())
12
```

This is always one more than the associated space of weight 2 Eisenstein series.

```
sage: G.dimension_eis(2)
11
sage: M.cuspidal_subspace()
Modular Symbols subspace of dimension 0 of Modular Symbols space of dimension 11 for Congrue
sage: G.dimension_cusp_forms(2)
0
```

is_infinity()

Returns True if this is the cusp infinity.

EXAMPLES:

```
sage: Cusp(3/5).is_infinity()
False
sage: Cusp(1,0).is_infinity()
True
sage: Cusp(0,1).is_infinity()
False
```

numerator()

Return the numerator of the cusp a/b.

EXAMPLES:

```
sage: x=Cusp(6,9); x
2/3
sage: x.numerator()
2
sage: Cusp(oo).numerator()
1
sage: Cusp(-5/10).numerator()
-1
```

class Cusps_class()
The set of cusps.

EXAMPLES:

```
sage: C = Cusps; C
Set P^1(QQ) of all cusps
sage: loads(C.dumps()) == C
True
```

46.3 Dimensions of spaces of modular forms

AUTHORS:

- William Stein
- Jordi Quer

ACKNOWLEDGEMENT: The dimension formulas and implementations in this module grew out of a program that Bruce Kaskel wrote (around 1996) in PARI, which Kevin Buzzard subsequently extended. I (William Stein) then implemented it in C++ for Hecke. I also implemented it in Magma. Also, the functions for dimensions of spaces with nontrivial character are based on a paper (that has no proofs) by Cohen and Oesterle (Springer Lecture notes in math, volume 627, pages 69-78). The formulas for $\Gamma_H(N)$ were found and implemented by Jordi Quer.

The formulas here are more complete than in Hecke or Magma.

Currently the input to each function below is an integer and either a Dirichlet character ε or a finite index subgroup of $\mathrm{SL}_2(\mathbf{Z})$. If the input is a Dirichlet character ε, the dimensions are for subspaces of $M_k(\Gamma_1(N), \varepsilon)$, where N is the modulus of ε.

These functions mostly call the methods dimension_cusp_forms, dimension_modular_forms and so on of the corresponding congruence subgroup classes.

CO_delta(*r, p, N, eps*)
This is used as an intermediate value in computations related to the paper of Cohen-Oesterle.

INPUT:

- `r` - positive integer
- `p` - a prime
- `N` - positive integer
- `eps` - character

OUTPUT: element of the base ring of the character

EXAMPLES:

```
sage: G.<eps> = DirichletGroup(7)
sage: sage.modular.dims.CO_delta(1,5,7,eps^3)
2
```

CO_nu(*r, p, N, eps*)
This is used as an intermediate value in computations related to the paper of Cohen-Oesterle.

INPUT:

- `r` - positive integer
- `p` - a prime

- N - positive integer
- eps - character

OUTPUT: element of the base ring of the character

EXAMPLES:

```
sage: G.<eps> = DirichletGroup(7)
sage: G.<eps> = DirichletGroup(7)
sage: sage.modular.dims.CO_nu(1,7,7,eps)
-1
```

CohenOesterle(*eps, k*)

Compute the Cohen-Oesterle function associate to eps, k. This is a summand in the formula for the dimension of the space of cusp forms of weight 2 with character ε.

INPUT:

- eps - Dirichlet character
- k - integer

OUTPUT: element of the base ring of eps.

EXAMPLES:

```
sage: G.<eps> = DirichletGroup(7)
sage: sage.modular.dims.CohenOesterle(eps, 2)
-2/3
sage: sage.modular.dims.CohenOesterle(eps, 4)
-1
```

dimension_cusp_forms(*X, k=2*)

The dimension of the space of cusp forms for the given congruence subgroup or Dirichlet character.

INPUT:

- X - congruence subgroup or Dirichlet character or integer
- k - weight (integer)

EXAMPLES:

```
sage: dimension_cusp_forms(5,4)
1

sage: dimension_cusp_forms(Gamma0(11),2)
1
sage: dimension_cusp_forms(Gamma1(13),2)
2

sage: dimension_cusp_forms(DirichletGroup(13).0^2,2)
1
sage: dimension_cusp_forms(DirichletGroup(13).0,3)
1

sage: dimension_cusp_forms(Gamma0(11),2)
1
sage: dimension_cusp_forms(Gamma0(11),0)
0
sage: dimension_cusp_forms(Gamma0(1),12)
```

```
1
sage: dimension_cusp_forms(Gamma0(1),2)
0
sage: dimension_cusp_forms(Gamma0(1),4)
0

sage: dimension_cusp_forms(Gamma0(389),2)
32
sage: dimension_cusp_forms(Gamma0(389),4)
97
sage: dimension_cusp_forms(Gamma0(2005),2)
199
sage: dimension_cusp_forms(Gamma0(11),1)
0

sage: dimension_cusp_forms(Gamma1(11),2)
1
sage: dimension_cusp_forms(Gamma1(1),12)
1
sage: dimension_cusp_forms(Gamma1(1),2)
0
sage: dimension_cusp_forms(Gamma1(1),4)
0

sage: dimension_cusp_forms(Gamma1(389),2)
6112
sage: dimension_cusp_forms(Gamma1(389),4)
18721
sage: dimension_cusp_forms(Gamma1(2005),2)
159201

sage: dimension_cusp_forms(Gamma1(11),1)
0

sage: e = DirichletGroup(13).0
sage: e.order()
12
sage: dimension_cusp_forms(e,2)
0
sage: dimension_cusp_forms(e^2,2)
1
```

dimension_eis(*X*, *k=2*)

The dimension of the space of eisenstein series for the given congruence subgroup.

INPUT:

- X - congruence subgroup or Dirichlet character or integer
- k - weight (integer)

EXAMPLES:

```
sage: dimension_eis(5,4)
2
```

```
sage: dimension_eis(Gamma0(11),2)
1
sage: dimension_eis(Gamma1(13),2)
11
sage: dimension_eis(Gamma1(2006),2)
3711

sage: e = DirichletGroup(13).0
sage: e.order()
12
sage: dimension_eis(e,2)
0
sage: dimension_eis(e^2,2)
2

sage: e = DirichletGroup(13).0
sage: e.order()
12
sage: dimension_eis(e,2)
0
sage: dimension_eis(e^2,2)
2
sage: dimension_eis(e,13)
2

sage: G = DirichletGroup(20)
sage: dimension_eis(G.0,3)
4
sage: dimension_eis(G.1,3)
6
sage: dimension_eis(G.1^2,2)
6

sage: G = DirichletGroup(200)
sage: e = prod(G.gens(), G(1))
sage: e.conductor()
200
sage: dimension_eis(e,2)
4

sage: dimension_modular_forms(Gamma1(4), 11)
6
```

dimension_modular_forms(*X*, *k=2*)

The dimension of the space of cusp forms for the given congruence subgroup (either $\Gamma_0(N)$, $\Gamma_1(N)$, or $\Gamma_H(N)$) or Dirichlet character.

INPUT:

- X - congruence subgroup or Dirichlet character
- k - weight (integer)

EXAMPLES:

```
sage: dimension_modular_forms(Gamma0(11),2)
2
sage: dimension_modular_forms(Gamma0(11),0)
1
sage: dimension_modular_forms(Gamma1(13),2)
13
sage: dimension_modular_forms(GammaH(11, [10]), 2)
10
sage: dimension_modular_forms(GammaH(11, [10]))
10
sage: dimension_modular_forms(GammaH(11, [10]), 4)
20
sage: e = DirichletGroup(20).1
sage: dimension_modular_forms(e,3)
9
sage: dimension_cusp_forms(e,3)
3
sage: dimension_eis(e,3)
6
sage: dimension_modular_forms(11,2)
2
```

dimension_new_cusp_forms (*X, k=2, p=0*)

Return the dimension of the new (or p-new) subspace of cusp forms for the character or group X.

INPUT:

- X - integer, congruence subgroup or Dirichlet character
- k - weight (integer)
- p - 0 or a prime

EXAMPLES:

```
sage: dimension_new_cusp_forms(100,2)
1

12
sage: dimension_new_cusp_forms(Gamma1(30),3)
12
```

eisen(*p*)

Return the Eisenstein number n which is the numerator of $(p-1)/12$.

INPUT:

- p - a prime

OUTPUT: Integer

EXAMPLES:

```
sage: [(p,sage.modular.dims.eisen(p)) for p in prime_range(24)]
[(2, 1), (3, 1), (5, 1), (7, 1), (11, 5), (13, 1), (17, 4), (19, 3), (23, 11)]
```

sturm_bound(*level, weight=2*)

Returns the Sturm bound for modular forms with given level and weight. For more details, see the documentation for the sturm_bound method of sage.modular.arithgroup.CongruenceSubgroup objects.

INPUT:

- level - an integer (interpreted as a level for Gamma0) or a congruence subgroup
- weight - an integer ≥ 2 (default: 2)

EXAMPLES:

```
sage: sturm_bound(11,2)
2
sage: sturm_bound(389,2)
65
sage: sturm_bound(1,12)
1
sage: sturm_bound(100,2)

```

46.4 Conjectural Slopes of Hecke Polynomial

Interface to Kevin Buzzard's PARI program for computing conjectural slopes of characteristic polynomials of Hecke operators.

AUTHORS:

- William Stein (2006-03-05): Sage interface
- Kevin Buzzard: PARI program that implements underlying functionality

buzzard_tpslopes(*p, N, kmax*)

Returns a vector of length kmax, whose k'th entry ($0 \leq k \leq k_{max}$) is the conjectural sequence of valuations of eigenvalues of T_p on forms of level N, weight k, and trivial character.

This conjecture is due to Kevin Buzzard, and is only made assuming that p does not divide N and if p is $\Gamma_0(N)$-regular.

EXAMPLES:

```
sage: c = buzzard_tpslopes(2,1,50)
sage: c[50]
[4, 8, 13]
```

Hence Buzzard would conjecture that the 2-adic valuations of the eigenvalues of T_2 on cusp forms of level 1 and weight 50 are $[4, 8, 13]$, which indeed they are, as one can verify by an explicit computation using, e.g., modular symbols:

```
sage: M = ModularSymbols(1,50, sign=1).cuspidal_submodule()
sage: T = M.hecke_operator(2)
sage: f = T.charpoly('x')
sage: f.newton_slopes(2)
[13, 8, 4]
```

AUTHORS:

- Kevin Buzzard: several GP/PARI scripts
- William Stein (2006-03-17): small Sage wrapper of Buzzard's scripts

gp()

Return a copy of the GP interpreter with the appropriate files loaded.

EXAMPLE:

```
sage: sage.modular.buzzard.gp()
GP/PARI interpreter
```

46.5 Eta-products on modular curves $X_0(N)$.

This package provides a class for representing eta-products, which are meromorphic functions on modular curves of the form

$$\prod_{d|N} \eta(q^d)^{r_d}$$

where $\eta(q)$ is Dirichlet's eta function $q^{1/24}\prod_{n=1}^{\infty}(1-q^n)$. These are useful for obtaining explicit models of modular curves.

See trac ticket #3934 for background.

AUTHOR:

- David Loeffler (2008-08-22): initial version

AllCusps(N)

Return a list of CuspFamily objects corresponding to the cusps of $X_0(N)$.

INPUT:

- N - (integer): the level

EXAMPLES:

```
sage: AllCusps(18)
[(Inf), (c_{2}), (c_{3,1}), (c_{3,2}), (c_{6,1}), (c_{6,2}), (c_{9}), (0)]
```

class CuspFamily(*N, width, label=None*)

A family of elliptic curves parametrising a region of $X_0(N)$.

level()

The level of this cusp.

EXAMPLES:

```
sage: e = CuspFamily(10, 1)
sage: e.level()
10
```

sage_cusp()

Return the corresponding element of $\mathbb{P}^1(\mathbf{Q})$.

EXAMPLE:

```
sage: CuspFamily(10, 1).sage_cusp() # not implemented
Infinity
```

width()

The width of this cusp.

EXAMPLES:

```
sage: e = CuspFamily(10, 1)
sage: e.width()
1
```

EtaGroup(*level*)

Create the group of eta products of the given level.

EXAMPLES:

```
sage: EtaGroup(12)
Group of eta products on X_0(12)
sage: EtaGroup(1/2)
...
TypeError: Level (=1/2) must be a positive integer
sage: EtaGroup(0)
...
ValueError: Level (=0) must be a positive integer
```

class EtaGroupElement(*parent, rdict*)

degree()

Return the degree of self as a map $X_0(N) \to \mathbb{P}^1$, which is equal to the sum of all the positive coefficients in the divisor of self.

EXAMPLES:

```
sage: e = EtaProduct(12, {1:-336, 2:576, 3:696, 4:-216, 6:-576, 12:-144})
sage: e.degree()
230
```

divisor()

Return the divisor of self, as a formal sum of CuspFamily objects.

EXAMPLES:

```
sage: e = EtaProduct(12, {1:-336, 2:576, 3:696, 4:-216, 6:-576, 12:-144})
sage: e.divisor() # FormalSum seems to print things in a random order?
-131*(Inf) - 50*(c_{2}) + 11*(0) + 50*(c_{6}) + 169*(c_{4}) - 49*(c_{3})
sage: e = EtaProduct(2^8, {8:1,32:-1})
```

```
sage: e.divisor() # random
-(c_{2}) - (Inf) - (c_{8,2}) - (c_{8,3}) - (c_{8,4}) - (c_{4,2}) - (c_{8,1}) - (c_{4,1}) + (
```

level()

Return the level of this eta product.

EXAMPLES:

```
sage: e = EtaProduct(3, {3:12, 1:-12})
sage: e.level()
3
sage: EtaProduct(12, {6:6, 2:-6}).level() # not the lcm of the d's
12
sage: EtaProduct(36, {6:6, 2:-6}).level() # not minimal
36
```

order_at_cusp(*cusp*)

Return the order of vanishing of self at the given cusp.

INPUT:

- cusp - a CuspFamily object

OUTPUT:

- an integer

EXAMPLES:

```
sage: e = EtaProduct(2, {2:24, 1:-24})
sage: e.order_at_cusp(CuspFamily(2, 1)) # cusp at infinity
1
sage: e.order_at_cusp(CuspFamily(2, 2)) # cusp 0
-1
```

qexp(*n*)

The q-expansion of self at the cusp at infinity.

INPUT:

- n (integer): number of terms to calculate

OUTPUT:

- a power series over $\mathbf{Z}$ in the variable q, with a *relative* precision of $1 + O(q^n)$.

ALGORITHM: Calculates eta to (n/m) terms, where m is the smallest integer dividing self.level() such that self.r(m) != 0. Then multiplies.

EXAMPLES:

```
sage: EtaProduct(36, {6:6, 2:-6}).qexp(10)
q + 6*q^3 + 27*q^5 + 92*q^7 + 279*q^9 + O(q^11)
sage: R.<q> = ZZ[[]]
sage: EtaProduct(2,{2:24,1:-24}).qexp(100) == delta_qexp(101)(q^2)/delta_qexp(101)(q)
True
```

r(*d*)

Return the exponent r_d of $\eta(q^d)$ in self.

EXAMPLES:

```
sage: e = EtaProduct(12, {2:24, 3:-24})
sage: e.r(3)
-24
sage: e.r(4)
0
```

class EtaGroup_class(*level*)

The group of eta products of a given level under multiplication.

basis(*reduce=True*)

Produce a basis for the free abelian group of eta-products of level N (under multiplication), attempting to find basis vectors of the smallest possible degree.

INPUT:

- `reduce` - a boolean (default True) indicating whether or not to apply LLL-reduction to the calculated basis

EXAMPLE:

```
sage: EtaGroup(5).basis()
[Eta product of level 5 : (eta_1)^6 (eta_5)^-6]
sage: EtaGroup(12).basis()
[Eta product of level 12 : (eta_1)^2 (eta_2)^1 (eta_3)^2 (eta_4)^-1 (eta_6)^-7 (eta_12)^3,
Eta product of level 12 : (eta_1)^-2 (eta_2)^3 (eta_3)^6 (eta_4)^-1 (eta_6)^-9 (eta_12)^3,
Eta product of level 12 : (eta_1)^-3 (eta_2)^2 (eta_3)^1 (eta_4)^-1 (eta_6)^-2 (eta_12)^3,
Eta product of level 12 : (eta_1)^1 (eta_2)^-1 (eta_3)^-3 (eta_4)^-2 (eta_6)^7 (eta_12)^-2,
Eta product of level 12 : (eta_1)^-6 (eta_2)^9 (eta_3)^2 (eta_4)^-3 (eta_6)^-3 (eta_12)^1]
sage: EtaGroup(12).basis(reduce=False) # much bigger coefficients
[Eta product of level 12 : (eta_2)^24 (eta_12)^-24,
Eta product of level 12 : (eta_1)^-336 (eta_2)^576 (eta_3)^696 (eta_4)^-216 (eta_6)^-576 (et
Eta product of level 12 : (eta_1)^-8 (eta_2)^-2 (eta_6)^2 (eta_12)^8,
Eta product of level 12 : (eta_1)^1 (eta_2)^9 (eta_3)^13 (eta_4)^-4 (eta_6)^-15 (eta_12)^-4,
Eta product of level 12 : (eta_1)^15 (eta_2)^-24 (eta_3)^-29 (eta_4)^9 (eta_6)^24 (eta_12)^5
```

ALGORITHM: An eta product of level N is uniquely determined by the integers r_d for $d|N$ with $d < N$, since $\sum_{d|N} r_d = 0$. The valid r_d are those that satisfy two congruences modulo 24, and one congruence modulo 2 for every prime divisor of N. We beef up the congruences modulo 2 to congruences modulo 24 by multiplying by 12. To calculate the kernel of the ensuing map $\mathbf{Z}^m \to (\mathbf{Z}/24\mathbf{Z})^n$ we lift it arbitrarily to an integer matrix and calculate its Smith normal form. This gives a basis for the lattice.

This lattice typically contains "large" elements, so by default we pass it to the reduce_basis() function which performs LLL-reduction to give a more manageable basis.

level()

Return the level of self. EXAMPLES:

```
sage: EtaGroup(10).level()
10
```

reduce_basis(*long_etas*)

Produce a more manageable basis via LLL-reduction.

INPUT:

- `long_etas` - a list of EtaGroupElement objects (which should all be of the same level)

OUTPUT:

- a new list of EtaGroupElement objects having hopefully smaller norm

ALGORITHM: We define the norm of an eta-product to be the L^2 norm of its divisor (as an element of the free $\mathbf{Z}$-module with the cusps as basis and the standard inner product). Applying LLL-reduction to this gives a basis of hopefully more tractable elements. Of course we'd like to use the L^1 norm as this is just twice the degree, which is a much more natural invariant, but L^2 norm is easier to work with!

EXAMPLES:

```
sage: EtaGroup(4).reduce_basis([ EtaProduct(4, {1:8,2:24,4:-32}), EtaProduct(4, {1:8, 4:-8})
[Eta product of level 4 : (eta_1)^8 (eta_4)^-8,
Eta product of level 4 : (eta_1)^-8 (eta_2)^24 (eta_4)^-16]
```

EtaProduct (*level, dict*)

Create an EtaGroupElement object representing the function $\prod_{d|N} \eta(q^d)^{r_d}$. Checks the critera of Ligozat to ensure that this product really is the q-expansion of a meromorphic function on X_0(N).

INPUT:

- `level` - (integer): the N such that this eta product is a function on X_0(N).
- `dict` - (dictionary): a dictionary indexed by divisors of N such that the coefficient of $\eta(q^d)$ is r[d]. Only nonzero coefficients need be specified. If Ligozat's criteria are not satisfied, a ValueError will be raised.

OUTPUT:

- an EtaGroupElement object, whose parent is the EtaGroup of level N and whose coefficients are the given dictionary.

Note: The dictionary dict does not uniquely specify N. It is possible for two EtaGroupElements with different N's to be created with the same dictionary, and these represent different objects (although they will have the same q-expansion at the cusp ∞).

EXAMPLES:

```
sage: EtaProduct(3, {3:12, 1:-12})
Eta product of level 3 : (eta_1)^-12 (eta_3)^12
sage: EtaProduct(3, {3:6, 1:-6})
...
ValueError: sum d r_d (=12) is not 0 mod 24
sage: EtaProduct(3, {4:6, 1:-6})
...
ValueError: 4 does not divide 3
```

eta_poly_relations (*eta_elements, degree, labels=, ['x1', 'x2'], verbose=False*)

Find polynomial relations between eta products.

INPUTS:

- `eta_elements` - (list): a list of EtaGroupElement objects. Not implemented unless this list has precisely two elements. degree
- `degree` - (integer): the maximal degree of polynomial to look for.
- `labels` - (list of strings): labels to use for the polynomial returned.
- `verbose` ` - (boolean, default False): if True, prints information as it goes.

OUTPUTS: a list of polynomials which is a Groebner basis for the part of the ideal of relations between eta_elements which is generated by elements up to the given degree; or None, if no relations were found.

ALGORITHM: An expression of the form $\sum_{0 \le i,j \le d} a_{ij} x^i y^j$ is zero if and only if it vanishes at the cusp infinity to degree at least $v = d(deg(x) + deg(y))$. For all terms up to q^v in the q-expansion of this expression to be zero is a system of $v + k$ linear equations in d^2 coefficients, where k is the number of nonzero negative coefficients that can appear.

Solving these equations and calculating a basis for the solution space gives us a set of polynomial relations, but this is generally far from a minimal generating set for the ideal, so we calculate a Groebner basis.

As a test, we calculate five extra terms of q-expansion and check that this doesn't change the answer.

EXAMPLES:

```
sage: t = EtaProduct(26, {2:2,13:2,26:-2,1:-2})
sage: u = EtaProduct(26, {2:4,13:2,26:-4,1:-2})
sage: eta_poly_relations([t, u], 3)
sage: eta_poly_relations([t, u], 4)
[x1^3*x2 - 13*x1^3 - 4*x1^2*x2 - 4*x1*x2 - x2^2 + x2]
```

Use verbose=True to see the details of the computation:

```
sage: eta_poly_relations([t, u], 3, verbose=True)
Trying to find a relation of degree 3
Lowest order of a term at infinity = -12
Highest possible degree of a term = 15
Trying all coefficients from q^-12 to q^15 inclusive
No polynomial relation of order 3 valid for 28 terms
Check: Trying all coefficients from q^-12 to q^20 inclusive
No polynomial relation of order 3 valid for 33 terms

sage: eta_poly_relations([t, u], 4, verbose=True)
Trying to find a relation of degree 4
Lowest order of a term at infinity = -16
Highest possible degree of a term = 20
Trying all coefficients from q^-16 to q^20 inclusive
Check: Trying all coefficients from q^-16 to q^25 inclusive
[x1^3*x2 - 13*x1^3 - 4*x1^2*x2 - 4*x1*x2 - x2^2 + x2]
```

num_cusps_of_width(*N, d*)

Return the number of cusps on $X_0(N)$ of width d.

INPUT:

- N - (integer): the level
- d - (integer): an integer dividing N, the cusp width

EXAMPLES:

```
sage: [num_cusps_of_width(18,d) for d in divisors(18)]
[1, 1, 2, 2, 1, 1]
```

qexp_eta(*ps_ring, n*)

Return the q-expansion of $\eta(q)/q^{1/24}$, where $\eta(q)$ is Dedekind's function

$$\eta(q) = q^{1/24}\prod_{i=1}^{\infty}(1-q^i)$$

as an element of ps_ring, to precision n. Completely naive algorithm.

INPUT:

- ps_ring - (PowerSeriesRing): a power series ring - we pass this as an argument as we frequently need to create multiple series in the same ring.
- n - (integer): the number of terms to compute.

OUTPUT: An element of ps_ring which is the q-expansion of $\eta(q)/q^{1/24}$ truncated to n terms.

ALGORITHM: Multiply out the product $\prod_{i=1}^{n}(1-q^i)$. Could perhaps be speeded up by using the identity

$$\eta(q) = q^{1/24}(1+\sum_{i\geq 1}(-1)^n(q^{n(3n+1)/2}+q^{n(3n-1)/2}),$$

but I'm lazy.

EXAMPLES:

```
sage: qexp_eta(ZZ[['q']], 100)
1 - q - q^2 + q^5 + q^7 - q^12 - q^15 + q^22 + q^26 - q^35 - q^40 + q^51 + q^57 - q^70 - q^77 +
```

46.6 The space of p-adic weights

A p-adic weight is a continuous character $\mathbf{Z}_p^\times \to \mathbf{C}_p^\times$. These are the $\mathbf{C}_p$-points of a rigid space over $\mathbf{Q}_p$, which is isomorphic to a disjoint union of copies (indexed by $(\mathbf{Z}/p\mathbf{Z})^\times$) of the open unit p-adic disc.

Sage supports both "classical points", which are determined by the data of a Dirichlet character modulo p^m for some m and an integer k (corresponding to the character $z \mapsto z^k\chi(z)$) and "non-classical points" which are determined by the data of an element of $(\mathbf{Z}/p\mathbf{Z})^\times$ and an element $w \in \mathbf{C}_p$ with $|w-1| < 1$.

EXAMPLES:

```
sage: W = pAdicWeightSpace(17)
sage: W
Space of 17-adic weight-characters defined over '17-adic Field with capped relative precision 20'
sage: L = Qp(17).extension(x^2 - 17, names='a'); L.rename('L')
sage: W.base_extend(L)
Space of 17-adic weight-characters defined over 'L'
```

We create a simple element of $\mathcal{W}$: the algebraic character, $x \mapsto x^6$:

```
sage: kappa = W(6)
sage: kappa(5)
15625
sage: kappa(5) == 5^6
True
```

A locally algebraic character, $x \mapsto x^6\chi(x)$ for χ a Dirichlet character mod p:

```
sage: kappa2 = W(6, DirichletGroup(17, Qp(17)).0^8)
sage: kappa2(5) == -5^6
True
sage: kappa2(13) == 13^6
True
```

A non-locally-algebraic character, sending the generator 18 of $1 + 17\mathbf{Z}_{17}$ to 35 and acting as $\mu \mapsto \mu^4$ on the group of 16th roots of unity:

```
sage: kappa3 = W(35 + O(17^20), 4, algebraic=False)
sage: kappa3(2)
16 + 8*17 + ... + O(17^20)
```

AUTHORS:

- David Loeffler (2008-9)

class **AlgebraicWeight** (*parent, k, chi=None*)

A point in weight space corresponding to a locally algebraic character, of the form $x \mapsto \chi(x)x^k$ where k is an integer and χ is a Dirichlet character modulo p^n for some n.

TESTS:

```
sage: w = pAdicWeightSpace(23)(12, DirichletGroup(23, QQ).0) # exact
sage: w == loads(dumps(w))
True
sage: w = pAdicWeightSpace(23)(12, DirichletGroup(23, Qp(23)).0) # inexact
sage: w == loads(dumps(w))
```

```
True
sage: w is loads(dumps(w)) # elements are not globally unique
False
```

Lvalue()

Return the value of the p-adic L-function of $\mathbf{Q}$ evaluated at this weight-character. If the character is $x \mapsto x^k\chi(x)$ where $k > 0$ and χ has conductor a power of p, this is an element of the number field generated by the values of χ, equal to the value of the complex L-function $L(1-k,\chi)$. If χ is trivial, it is equal to $(1-p^{k-1})\zeta(1-k)$.

At present this is not implemented in any other cases, except the trivial character (for which the value is ∞).

TODO: Implement this more generally using the Amice transform machinery in sage/schemes/elliptic_curves/padic_lseries.py, which should clearly be factored out into a separate class.

EXAMPLES:

```
sage: pAdicWeightSpace(7)(4).Lvalue() == (1 - 7^3)*zeta__exact(-3)
True
sage: pAdicWeightSpace(7)(5, DirichletGroup(7, Qp(7)).0^4).Lvalue()
0
sage: pAdicWeightSpace(7)(6, DirichletGroup(7, Qp(7)).0^4).Lvalue()
1 + 2*7 + 7^2 + 3*7^3 + 3*7^5 + 4*7^6 + 2*7^7 + 5*7^8 + 2*7^9 + 3*7^10 + 6*7^11 + 2*7^12 + 3
```

chi()

If this character is $x \mapsto x^k\chi(x)$ for an integer k and a Dirichlet character χ, return χ.

EXAMPLE:

```
sage: kappa = pAdicWeightSpace(29)(13, DirichletGroup(29, Qp(29)).0^14)
sage: kappa.chi()
[28 + 28*29 + 28*29^2 + ... + O(29^20)]
```

k()

If this character is $x \mapsto x^k\chi(x)$ for an integer k and a Dirichlet character χ, return k.

EXAMPLE:

```
sage: kappa = pAdicWeightSpace(29)(13, DirichletGroup(29, Qp(29)).0^14)
sage: kappa.k()
13
```

teichmuller_type()

Return the Teichmuller type of this weight-character κ, which is the unique $t \in \mathbf{Z}/(p-1)\mathbf{Z}$ such that $\kappa(\mu) = \mu^t$ for mu a $(p-1)$-st root of 1.

For $p = 2$ this doesn't make sense, but we still want the Teichmuller type to correspond to the index of the component of weight space in which κ lies, so we return 1 if κ is odd and 0 otherwise.

EXAMPLE:

```
sage: pAdicWeightSpace(11)(2, DirichletGroup(11,QQ).0).teichmuller_type()
7
sage: pAdicWeightSpace(29)(13, DirichletGroup(29, Qp(29)).0).teichmuller_type()
14
sage: pAdicWeightSpace(2)(3, DirichletGroup(4,QQ).0).teichmuller_type()
0
```

class **ArbitraryWeight**(*parent, w, t*)

teichmuller_type()

Return the Teichmuller type of this weight-character κ, which is the unique $t \in \mathbf{Z}/(p-1)\mathbf{Z}$ such that $\kappa(\mu) = \mu^t$ for mu a $(p-1)$-st root of 1.

For $p = 2$ this doesn't make sense, but we still want the Teichmuller type to correspond to the index of the component of weight space in which κ lies, so we return 1 if κ is odd and 0 otherwise.

EXAMPLES:

```
sage: pAdicWeightSpace(17)(1 + 3*17 + 2*17^2 + O(17^3), 8, False).teichmuller_type()
8
sage: pAdicWeightSpace(2)(1 + 2 + O(2^2), 1, False).teichmuller_type()
1
```

class **WeightCharacter**(*parent*)

Abstract base class representing an element of the p-adic weight space $Hom(\mathbf{Z}_p^\times, \mathbf{C}_p^\times)$.

Lvalue()

Return the value of the p-adic L-function of $\mathbf{Q}$, which can be regarded as a rigid-analytic function on weight space, evaluated at this character.

EXAMPLES:

```
sage: W = pAdicWeightSpace(11)
sage: sage.modular.overconvergent.weightspace.WeightCharacter(W).Lvalue()
...
NotImplementedError
```

base_extend(*R*)

Extend scalars to the base ring R (which must have a canonical map from the current base ring)

EXAMPLE:

```
sage: w = pAdicWeightSpace(17, QQ)(3)
sage: w.base_extend(Qp(17))
3
```

is_even()

Return True if this weight-character sends -1 to +1.

EXAMPLE:

```
sage: pAdicWeightSpace(17)(0).is_even()
True
sage: pAdicWeightSpace(17)(11).is_even()
False
sage: pAdicWeightSpace(17)(1 + 17 + O(17^20), 3, False).is_even()
False
sage: pAdicWeightSpace(17)(1 + 17 + O(17^20), 4, False).is_even()
True
```

is_trivial()

Return True if and only if this is the trivial character.

EXAMPLES:

```
sage: pAdicWeightSpace(11)(2).is_trivial()
False
sage: pAdicWeightSpace(11)(2, DirichletGroup(11, QQ).0).is_trivial()
False
sage: pAdicWeightSpace(11)(0).is_trivial()
True
```

one_over_Lvalue()

Return the reciprocal of the p-adic L-function evaluated at this weight-character. If the weight-character is odd, then the L-function is zero, so an error will be raised.

EXAMPLES:

```
sage: pAdicWeightSpace(11)(4).one_over_Lvalue()
-12/133
sage: pAdicWeightSpace(11)(3, DirichletGroup(11, QQ).0).one_over_Lvalue()
-1/6
sage: pAdicWeightSpace(11)(3).one_over_Lvalue()
...
ZeroDivisionError: Rational division by zero
sage: pAdicWeightSpace(11)(0).one_over_Lvalue()
0
sage: type(_)
<type 'sage.rings.integer.Integer'>
```

pAdicEisensteinSeries(*ring, prec=20*)

Calculate the q-expansion of the p-adic Eisenstein series of given weight-character, normalised so the constant term is 1.

EXAMPLE:

```
sage: kappa = pAdicWeightSpace(3)(3, DirichletGroup(3,QQ).0)
sage: kappa.pAdicEisensteinSeries(QQ[['q']], 20)
1 - 9*q + 27*q^2 - 9*q^3 - 117*q^4 + 216*q^5 + 27*q^6 - 450*q^7 + 459*q^8 - 9*q^9 - 648*q^10
```

values_on_gens()

If κ is this character, calculate the values $(\kappa(r), t)$ where r is $1 + p$ (or 5 if $p = 2$) and t is the unique element of $\mathbf{Z}/(p-1)\mathbf{Z}$ such that $\kappa(\mu) = \mu^t$ for μ a (p-1)st root of unity. (If $p = 2$, we take t to be 0 or 1 according to whether κ is odd or even.) These two values uniquely determine the character κ.

EXAMPLES:

```
sage: W=pAdicWeightSpace(11); W(2).values_on_gens()
(1 + 2*11 + 11^2 + O(11^20), 2)
sage: W(2, DirichletGroup(11, QQ).0).values_on_gens()
(1 + 2*11 + 11^2 + O(11^20), 7)
sage: W(1 + 2*11 + O(11^5), 4, algebraic = False).values_on_gens()
(1 + 2*11 + O(11^5), 4)
```

class **WeightSpace_class**(*p, base_ring*)

The space of p-adic weight-characters $\mathcal{W} = \mathrm{Hom}(\mathbf{Z}_p^\times, \mathbf{C}_p^\times)$. This isomorphic to a disjoint union of $(p-1)$ open discs of radius 1 (or 2 such discs if $p = 2$), with the parameter on the open disc corresponding to the image of $1 + p$ (or 5 if $p = 2$)

TESTS:

```
sage: W = pAdicWeightSpace(3)
sage: W is loads(dumps(W))
True
```

base_extend(*R*)

Extend scalars to the ring R. There must be a canonical coercion map from the present base ring to R.

EXAMPLE:

```
sage: W = pAdicWeightSpace(3, QQ)
sage: W.base_extend(Qp(3))
Space of 3-adic weight-characters defined over '3-adic Field with capped relative precision
sage: W.base_extend(IntegerModRing(12))
...
TypeError: No coercion map from 'Rational Field' to 'Ring of integers modulo 12' is defined
```

prime()

Return the prime p such that this is a p-adic weight space.

EXAMPLE:

```
sage: pAdicWeightSpace(17).prime()
17
```

WeightSpace_constructor(*p, base_ring=None*)

Construct the p-adic weight space for the given prime p. A p-adic weight is a continuous character $\mathbf{Z}_p^\times \to \mathbf{C}_p^\times$. These are the $\mathbf{C}_p$-points of a rigid space over $\mathbf{Q}_p$, which is isomorphic to a disjoint union of copies (indexed by $(\mathbf{Z}/p\mathbf{Z})^\times$) of the open unit p-adic disc.

Note that the "base ring" of a p-adic weight is the smallest ring containing the image of $\mathbf{Z}$; in particular, although the default base ring is $\mathbf{Q}_p$, base ring $\mathbf{Q}$ will also work.

EXAMPLES:

```
sage: pAdicWeightSpace(3) # indirect doctest
Space of 3-adic weight-characters defined over '3-adic Field with capped relative precision 20'
sage: pAdicWeightSpace(3, QQ)
Space of 3-adic weight-characters defined over 'Rational Field'
sage: pAdicWeightSpace(10)
...
ValueError: p must be prime
```

46.7 Overconvergent p-adic modular forms for small primes

This module implements computations of the U_p-operator on overconvergent modular forms of level $\Gamma_0(p)$, where p is one of the primes $\{2, 3, 5, 7, 13\}$, using the algorithms described in:

David Loeffler, "Spectral expansions of overconvergent modular functions", Int. Math. Res. Not 2007(050).

AUTHORS:

- David Loeffler (August 2008): initial version

class OverconvergentModularFormElement(*parent, gexp=None, qexp=None*)

A class representing an element of a space of overconvergent modular forms.

EXAMPLE:

```
sage: K.<w> = Qp(5).extension(x^7 - 5); s = OverconvergentModularForms(5, 6, 1/21, base_ring=K).
sage: s == loads(dumps(s))
True
```

additive_order()

Return the additive order of this element (required attribute for all elements deriving from sage.modules.ModuleElement)

EXAMPLES:

```
sage: M = OverconvergentModularForms(13, 10, 1/2, base_ring = Qp(13).extension(x^2 - 13,name
sage: M.gen(0).additive_order()
+Infinity
sage: M(0).additive_order()
1
```

base_extend(*R*)

Return a copy of self but with coefficients in the given ring.

EXAMPLES:

```
sage: M = OverconvergentModularForms(7, 10, 1/2, prec=5)
sage: f = M.1
sage: f.base_extend(Qp(7, 4))
7-adic overconvergent modular form of weight-character 10 with q-expansion (7 + O(7^5))*q +
```

eigenvalue()

Return the U_p-eigenvalue of this eigenform. Raises an error unless this element was explicitly flagged as an eigenform, using the _notify_eigen function.

EXAMPLE:

```
sage: M = OverconvergentModularForms(3, 0, 1/2)
sage: f = M.eigenfunctions(3)[1]
sage: f.eigenvalue()
3^2 + 3^4 + 2*3^6 + 3^7 + 3^8 + 2*3^9 + 2*3^10 + 3^12 + 3^16 + 2*3^17 + 3^18 + 3^20 + 2*3^21
sage: M.gen(4).eigenvalue()
...
TypeError: eigenvalue only defined for eigenfunctions
```

gexp()

Return the formal power series in g corresponding to this overconvergent modular form (so the result is F where this modular form is $E_k^* \times F(g)$, where g is the appropriately normalised parameter of $X_0(p)$).

EXAMPLE:

```
sage: M = OverconvergentModularForms(3, 0, 1/2)
sage: f = M.eigenfunctions(3)[1]
sage: f.gexp()
(3^-3 + O(3^91))*g + (3^-1 + 1 + 2*3 + 3^2 + 2*3^3 + 3^5 + 3^7 + 3^10 + 3^11 + 3^14 + 3^15 +
```

governing_term(*r*)

The degree of the series term with largest norm on the r-overconvergent region.

EXAMPLES:

```
sage: o=OverconvergentModularForms(3, 0, 1/2)
sage: f=o.eigenfunctions(10)[1]
sage: f.governing_term(1/2)
1
```

is_eigenform()

Return True if this is an eigenform. At present this returns False unless this element was explicitly flagged as an eigenform, using the _notify_eigen function.

EXAMPLE:

```
sage: M = OverconvergentModularForms(3, 0, 1/2)
sage: f = M.eigenfunctions(3)[1]
sage: f.is_eigenform()
True
sage: M.gen(4).is_eigenform()
False
```

is_integral()

Test whether or not this element has q-expansion coefficients that are p-adically integral. This should always be the case with eigenfunctions, but sometimes if n is very large this breaks down for unknown reasons!

EXAMPLE:

```
sage: M = OverconvergentModularForms(2, 0, 1/3)
sage: q = QQ[['q']].gen()
sage: M(q - 17*q^2 + O(q^3)).is_integral()
```

```
True
sage: M(q - q^2/2 + 6*q^7  + O(q^9)).is_integral()
False
```

prec()

Return the series expansion precision of this overconvergent modular form. (This is not the same as the p-adic precision of the coefficients.)

EXAMPLE:

```
sage: OverconvergentModularForms(5, 6, 1/3,prec=15).gen(1).prec()
15
```

prime()

If this is a p-adic modular form, return p.

EXAMPLE:

```
sage: OverconvergentModularForms(2, 0, 1/2).an_element().prime()
2
```

qexp()

Return the q-expansion of self, to as high precision as it is known.

EXAMPLE:

```
sage: OverconvergentModularForms(3, 4, 1/2).gen(0).qexp()
1 - 120/13*q - 1080/13*q^2 - 120/13*q^3 - 8760/13*q^4 - 15120/13*q^5 - 1080/13*q^6 - 41280/1
```

r_ord(*r*)

The p-adic valuation of self on the r-overconvergent region.

EXAMPLES:

```
sage: o=OverconvergentModularForms(3, 0, 1/2)
sage: t = o([1, 1, 1/3])
sage: t.r_ord(1/2)
1
sage: t.r_ord(2/3)
3
```

slope()

Return the slope of this eigenform, i.e. the valuation of its U_p-eigenvalue. Raises an error unless this element was explicitly flagged as an eigenform, using the _notify_eigen function.

EXAMPLE:

```
sage: M = OverconvergentModularForms(3, 0, 1/2)
sage: f = M.eigenfunctions(3)[1]
sage: f.slope()
2
sage: M.gen(4).slope()
...
TypeError: slope only defined for eigenfunctions
```

valuation_plot()

Draw a graph depicting the growth of the norm of this overconvergent modular form as it approaches the boundary of the overconvergent region.

EXAMPLE:

```
sage: o=OverconvergentModularForms(3, 0, 1/2)
sage: f=o.eigenfunctions(4)[1]
sage: f.valuation_plot()
```

weight()

Return the weight of this overconvergent modular form.

EXAMPLES:

```
sage: M = OverconvergentModularForms(13, 10, 1/2, base_ring = Qp(13).extension(x^2 - 13,name
sage: M.gen(0).weight()
10
```

OverconvergentModularForms(*prime, weight, radius, base_ring=Rational Field, prec=20, char=None*)

Create a space of overconvergent p-adic modular forms of level $\Gamma_0(p)$, over the given base ring. The base ring need not be a p-adic ring (the spaces we compute with typically have bases over $\mathbf{Q}$).

INPUT:

- `prime` - a prime number p, which must be one of the primes $\{2, 3, 5, 7, 13\}$, or the congruence subgroup Gamma0(p) where p is one of these primes.
- `weight` - an integer (which at present must be 0 or ≥ 2), the weight.
- `radius` - a rational number in the interval $\left(0, \frac{p}{p+1}\right)$, the radius of overconvergence.
- `base_ring` (default: $\mathbf{Q}$), a ring over which to compute. This need not be a p-adic ring.
- `prec` - an integer (default: 20), the number of q-expansion terms to compute.
- `char` - a Dirichlet character modulo p or `None` (the default). Here `None` is interpreted as the trivial character modulo p.

The character χ and weight k must satisfy $(-1)^k = \chi(-1)$, and the base ring must contain an element v such that $\mathrm{ord}_p(v) = \frac{12r}{p-1}$ where r is the radius of overconvergence (and ord_p is normalised so $\mathrm{ord}_p(p) = 1$).

EXAMPLES:

```
sage: OverconvergentModularForms(3, 0, 1/2)
Space of 3-adic 1/2-overconvergent modular forms of weight-character 0 over Rational Field
sage: OverconvergentModularForms(3, 16, 1/2)
Space of 3-adic 1/2-overconvergent modular forms of weight-character 16 over Rational Field
sage: OverconvergentModularForms(3, 3, 1/2, char = DirichletGroup(3,QQ).0)
Space of 3-adic 1/2-overconvergent modular forms of weight-character (3, 3, [-1]) over Rational
```

class OverconvergentModularFormsSpace(*prime, weight, radius, base_ring, prec, char*)

A space of overconvergent modular forms of level $\Gamma_0(p)$, where p is a prime such that $X_0(p)$ has genus 0.

Elements are represented as power series, with a formal power series F corresponding to the modular form $E_k^* \times F(g)$ where E_k^* is the p-deprived Eisenstein series of weight-character k, and g is a uniformiser of $X_0(p)$ normalised so that the r-overconvergent region $X_0(p)_{\geq r}$ corresponds to $|g| \leq 1$.

TESTS:

```
sage: K.<w> = Qp(13).extension(x^2-13); M = OverconvergentModularForms(13, 20, radius=1/2, base_
sage: M is loads(dumps(M))
True
```

base_extend(*ring*)

Return the base extension of self to the given base ring. There must be a canonical map to this ring from the current base ring, otherwise a TypeError will be raised.

EXAMPLES:

```
sage: M = OverconvergentModularForms(2, 0, 1/2, base_ring = Qp(2))
sage: M.base_extend(Qp(2).extension(x^2 - 2, names="w"))
Space of 2-adic 1/2-overconvergent modular forms of weight-character 0 over Eisenstein Exter
sage: M.base_extend(QQ)
...
TypeError: Base extension of self (over '2-adic Field with capped relative precision 20') to
```

change_ring(*ring*)

Return the space corresponding to self but over the given base ring.

EXAMPLES:

```
sage: M = OverconvergentModularForms(2, 0, 1/2)
sage: M.change_ring(Qp(2))
Space of 2-adic 1/2-overconvergent modular forms of weight-character 0 over 2-adic Field wit
```

character()

Return the character of self. For overconvergent forms, the weight and the character are unified into the concept of a weight-character, so this returns exactly the same thing as self.weight().

EXAMPLE:

```
sage: OverconvergentModularForms(3, 0, 1/2).character()
0
sage: type(OverconvergentModularForms(3, 0, 1/2).character())
<class '...weightspace.AlgebraicWeight'>
sage: OverconvergentModularForms(3, 3, 1/2, char=DirichletGroup(3,QQ).0).character()
(3, 3, [-1])
```

coordinate_vector(*x*)

Write x as a vector with respect to the basis given by self.basis(). Here x must be an element of this space or something that can be converted into one. If x has precision less than the default precision of self, then the returned vector will be shorter.

EXAMPLES:

```
sage: M = OverconvergentModularForms(Gamma0(3), 0, 1/3, prec=4)
sage: M.coordinate_vector(M.gen(2))
(0, 0, 1, 0)
sage: q = QQ[['q']].gen(); M.coordinate_vector(q - q^2 + O(q^4))
(0, 1/9, -13/81, 74/243)
sage: M.coordinate_vector(q - q^2 + O(q^3))
(0, 1/9, -13/81)
```

cps_u(*n, use_recurrence=False*)

Compute the characteristic power series of U_p acting on self, using an n x n matrix.

EXAMPLES:

```
sage: OverconvergentModularForms(3, 16, 1/2, base_ring=Qp(3)).cps_u(4)
1 + O(3^20) + (2 + 2*3 + 2*3^2 + 2*3^4 + 3^5 + 3^6 + 3^7 + 3^11 + 3^12 + 2*3^14 + 3^16 + 3^1
sage: OverconvergentModularForms(3, 16, 1/2, base_ring=Qp(3), prec=30).cps_u(10)
1 + O(3^20) + (2 + 2*3 + 2*3^2 + 2*3^4 + 3^5 + 3^6 + 3^7 + 2*3^15 + O(3^16))*T + (2*3^3 + 3^
```

eigenfunctions(*n, F=None, exact_arith=True*)

Calculate approximations to eigenfunctions of self. These are the eigenfunctions of self.hecke_matrix(p, n), which are approximations to the true eigenfunctions. Returns a list of OverconvergentModularFormElement objects, in increasing order of slope.

INPUT:

- `n` - integer. The size of the matrix to use.
- `F` - None, or a field over which to calculate eigenvalues. If the field is None, the current base ring is used. If the base ring is not a p-adic ring, an error will be raised.
- `exact_arith` - True or False (default True). If True, use exact rational arithmetic to calculate the matrix of the U operator and its characteristic power series, even when the base ring is an inexact p-adic ring. This is typically slower, but more numerically stable.

NOTE: Try using `set_verbose(1, 'sage/modular/overconvergent')` to get more feedback on what is going on in this algorithm. For even more feedback, use 2 instead of 1.

EXAMPLES:

```
sage: X = OverconvergentModularForms(2, 2, 1/6).eigenfunctions(8, Qp(2, 100))
sage: X[1]
2-adic overconvergent modular form of weight-character 2 with q-expansion (1 + O(2^36))*q +
sage: [x.slope() for x in X]
[0, 4, 8, 14, 16, 18, 26, 30]
```

gen(*i*)

Return the ith module generator of self.

EXAMPLE:

```
sage: M = OverconvergentModularForms(3, 2, 1/2, prec=4)
sage: M.gen(0)
3-adic overconvergent modular form of weight-character 2 with q-expansion 1 + 12*q + 36*q^2
sage: M.gen(1)
3-adic overconvergent modular form of weight-character 2 with q-expansion 27*q + 648*q^2 + 7
sage: M.gen(30)
3-adic overconvergent modular form of weight-character 2 with q-expansion O(q^4)
```

gens()

Return a generator object that iterates over the (infinite) set of basis vectors of self.

EXAMPLES:

```
sage: o = OverconvergentModularForms(3, 12, 1/2)
sage: t = o.gens()
sage: t.next()
3-adic overconvergent modular form of weight-character 12 with q-expansion 1 - 32760/6120394
sage: t.next()
3-adic overconvergent modular form of weight-character 12 with q-expansion 27*q + 1982919301
```

gens_dict()

Return a dictionary mapping the names of generators of this space to their values. (Required by parent class definition.) As this does not make any sense here, this raises a TypeError.

EXAMPLES:

```
sage: M = OverconvergentModularForms(2, 4, 1/6)
sage: M.gens_dict()
...
TypeError: gens_dict does not make sense as number of generators is infinite
```

hecke_matrix(*m, n, use_recurrence=False, exact_arith=False*)

Calculate the matrix of the T_m operator in the basis of this space, truncated to an $n \times n$ matrix. Conventions are that operators act on the left on column vectors (this is the opposite of the conventions of the sage.modules.matrix_morphism class!) Uses naive q-expansion arguments if use_recurrence=False and uses the Kolberg style recurrences if use_recurrence=True.

The argument "exact_arith" causes the computation to be done with rational arithmetic, even if the base ring is an inexact p-adic ring. This is useful as there can be precision loss issues (particularly with use_recurrence=False).

EXAMPLES:

```
sage: OverconvergentModularForms(2, 0, 1/2).hecke_matrix(2, 4)
[    1     0     0     0]
[    0    24    64     0]
[    0    32  1152  4608]
[    0     0  3072 61440]
sage: OverconvergentModularForms(2, 12, 1/2, base_ring=pAdicField(2)).hecke_matrix(2, 3) * (
[        1 + O(2^2)                   0                   0]
[                 0       2^3 + O(2^5)       2^6 + O(2^8)]
[                 0       2^4 + O(2^6) 2^7 + 2^8 + O(2^9)]
```

```
sage: OverconvergentModularForms(2, 12, 1/2, base_ring=pAdicField(2)).hecke_matrix(2, 3, exa
[                              1                               0
[                              0                33881928/1414477                              6
[                              0 -192898739923312/2000745183529             1626332544/141447
```

hecke_operator(*f*, *m*)

Given an element f and an integer m, calculates the Hecke operator T_m acting on f.

The input may be either a "bare" power series, or an OverconvergentModularFormElement object; the return value will be of the same type.

EXAMPLE:

```
sage: M = OverconvergentModularForms(3, 0, 1/2)
sage: f = M.1
sage: M.hecke_operator(f, 3)
3-adic overconvergent modular form of weight-character 0 with q-expansion 2430*q + 265356*q^
sage: M.hecke_operator(f.qexp(), 3)
2430*q + 265356*q^2 + 10670373*q^3 + 249948828*q^4 + 4113612864*q^5 + 52494114852*q^6 + O(q^
```

is_exact()

True if elements of this space are represented exactly, i.e., there is no precision loss when doing arithmetic. As this is never true for overconvergent modular forms spaces, this returns False.

EXAMPLES:

```
sage: OverconvergentModularForms(13, 12, 0).is_exact()
False
```

ngens()

The number of generators of self (as a module over its base ring), i.e. infinity.

EXAMPLES:

```
sage: M = OverconvergentModularForms(2, 4, 1/6)
sage: M.ngens()
+Infinity
```

normalising_factor()

The normalising factor c such that $g = cf$ is a parameter for the r-overconvergent disc in $X_0(p)$, where f is the standard uniformiser.

EXAMPLE:

```
sage: L.<w> = Qp(7).extension(x^2 - 7)
sage: OverconvergentModularForms(7, 0, 1/4, base_ring=L).normalising_factor()
w + O(w^41)
```

prec()

Return the series precision of self. Note that this is different from the p-adic precision of the base ring.

EXAMPLE:

```
sage: OverconvergentModularForms(3, 0, 1/2).prec()
20
sage: OverconvergentModularForms(3, 0, 1/2,prec=40).prec()
40
```

prime()

Return the residue characteristic of self, i.e. the prime p such that this is a p-adic space.

EXAMPLES:

```
sage: OverconvergentModularForms(5, 12, 1/3).prime()
5
```

radius()

The radius of overconvergence of this space.

EXAMPLE:

```
sage: OverconvergentModularForms(3, 0, 1/3).radius()
1/3
```

recurrence_matrix(*use_smithline=True*)

Return the recurrence matrix satisfied by the coefficients of U, that is a matrix $R = (r_{rs})_{r,s=1...p}$ such that $u_{ij} = \sum_{r,s=1}^{p} r_{rs} u_{i-r,j-s}$. Uses an elegant construction which I believe is due to Smithline. See my paper in IMRN (full citation in reference manual).

EXAMPLES:

```
sage: OverconvergentModularForms(2, 0, 0).recurrence_matrix()
[  48    1]
[4096    0]
sage: OverconvergentModularForms(2, 0, 1/2).recurrence_matrix()
[48 64]
[64  0]
sage: OverconvergentModularForms(3, 0, 0).recurrence_matrix()
[   270     36      1]
[ 26244    729      0]
[531441      0      0]
sage: OverconvergentModularForms(5, 0, 0).recurrence_matrix()
[     1575      1300       315        30         1]
[   162500     39375      3750       125         0]
[  4921875    468750     15625         0         0]
[ 58593750   1953125         0         0         0]
[244140625         0         0         0         0]
sage: OverconvergentModularForms(7, 0, 0).recurrence_matrix()
[       4018        8624        5915        1904         322          28           1]
[     422576      289835       93296       15778        1372          49           0]
[   14201915     4571504      773122       67228        2401           0           0]
[  224003696    37882978     3294172      117649           0           0           0]
[ 1856265922   161414428     5764801           0           0           0           0]
[ 7909306972   282475249           0           0           0           0           0]
[13841287201           0           0           0           0           0           0]
sage: OverconvergentModularForms(13, 0, 0).recurrence_matrix()
[         15145         124852         354536 ...
```

slopes(*n, use_recurrence=False*)

Compute the slopes of the U_p operator acting on self, using an n x n matrix.

EXAMPLES:: sage: OverconvergentModularForms(5,2,1/3,base_ring=Qp(5),prec=100).slopes(5) [0, 2, 5, 6, 9] sage: OverconvergentModularForms(2,1,1/3,char=DirichletGroup(4,QQ).0).slopes(5) [0, 2, 4, 6, 8]

weight()

Return the character of self. For overconvergent forms, the weight and the character are unified into the concept of a weight-character, so this returns exactly the same thing as self.character().

EXAMPLE:

```
sage: OverconvergentModularForms(3, 0, 1/2).weight()
0
sage: type(OverconvergentModularForms(3, 0, 1/2).weight())
<class '...weightspace.AlgebraicWeight'>
sage: OverconvergentModularForms(3, 3, 1/2, char=DirichletGroup(3,QQ).0).weight()
(3, 3, [-1])
```

46.8 Module of Supersingular Points

The module of divisors on the modular curve $X_0(N)$ over F_p supported at supersingular points.

AUTHORS:

- William Stein
- David Kohel
- Iftikhar Burhanuddin

EXAMPLES:

```
sage: x = SupersingularModule(389)
sage: m = x.T(2).matrix()
sage: a = m.change_ring(GF(97))
sage: D = a.decomposition()
sage: D[:3]
[
(Vector space of degree 33 and dimension 1 over Finite Field of size 97
Basis matrix:
[ 0  0  0  1 96 96  1 96 96  0  2 96 96  0  1  0  1  2 95  0  1  1  0  1  0 95  0 96 95  1 96  0  2],
(Vector space of degree 33 and dimension 1 over Finite Field of size 97
Basis matrix:
[ 0  1 96 75 16 81 22 17 17  0  0 80 80  1 16 40 74  0  0 96 81 23 57 74  0  0  0 24  0 23 73  0  0],
(Vector space of degree 33 and dimension 1 over Finite Field of size 97
Basis matrix:
[ 0  1 96 90 90  7  7  6 91  0  0 91  6 13  7  0 91  0  0 84 90  6  0  6  0  0  0 90  0 91  7  0  0],
]
sage: len(D)
9
```

We compute a Hecke operator on a space of huge dimension!:

```
sage: X = SupersingularModule(next_prime(100000))
sage: t = X.T(2).matrix()            # long time (but still less than a minute!)
sage: t.nrows()                      # long time
8334
```

TESTS:

```
sage: X = SupersingularModule(389)
sage: T = X.T(2).matrix().change_ring(QQ)
sage: d = T.decomposition()
sage: len(d)
6
sage: [a[0].dimension() for a in d]
[1, 1, 2, 3, 6, 20]
sage: loads(dumps(X)) == X
True
sage: loads(dumps(d)) == d
True
```

Phi2_quad(*J3, ssJ1, ssJ2*)

This function returns a certain quadratic polynomial over a finite field in indeterminate J3.

The roots of the polynomial along with ssJ1 are the neighboring/2-isogenous supersingular j-invariants of ssJ2.

INPUT:

- J3 – indeterminate of a univariate polynomial ring defined over a finite field with p^2 elements where p is a prime number
- ssJ2, ssJ2 – supersingular j-invariants over the finite field

OUTPUT:

- polynomial – defined over the finite field

EXAMPLES: The following code snippet produces a factor of the modular polynomial $\Phi_2(x, j_{in})$, where j_{in} is a supersingular j-invariant defined over the finite field with 37^2 elements:

```
sage: F = GF(37^2, 'a')
sage: X = PolynomialRing(F, 'x').gen()
sage: j_in = supersingular_j(F)
sage: poly = sage.modular.ssmod.ssmod.Phi_polys(2,X,j_in)
sage: poly.roots()
[(8, 1), (27*a + 23, 1), (10*a + 20, 1)]
sage: sage.modular.ssmod.ssmod.Phi2_quad(X, F(8), j_in)
x^2 + 31*x + 31
```

Note: Given a root (j1,j2) to the polynomial $Phi_2(J1, J2)$, the pairs (j2,j3) not equal to (j2,j1) which solve $Phi_2(j2, j3)$ are roots of the quadratic equation:

J3^2 + (-j2^2 + 1488*j2 + (j1 - 162000))*J3 + (-j1 + 1488)*j2^2 + (1488*j1 + 40773375)*j2 + j1^2 - 162000*j1 + 8748000000

This will be of use to extend the 2-isogeny graph, once the initial three roots are determined for $Phi_2(J1, J2)$.

AUTHORS:

- David Kohel – kohel@maths.usyd.edu.au
- Iftikhar Burhanuddin – burhanud@usc.edu

Phi_polys(*L, x, j*)

This function returns a certain polynomial of degree $L + 1$ in the indeterminate x over a finite field.

The roots of the **modular** polynomial $\Phi(L, x, j)$ are the L-isogenous supersingular j-invariants of j.

INPUT:

- L – integer, either 2,3,5,7 or 11
- x – indeterminate of a univariate polynomial ring defined over a finite field with p^2 elements, where p is a prime number
- j – supersingular j-invariant over the finite field

OUTPUT:

- polynomial – defined over the finite field

EXAMPLES: The following code snippet produces the modular polynomial $\Phi_L(x, j_{in})$, where j_{in} is a supersingular j-invariant defined over the finite field with 7^2 elements:

```
sage: F = GF(7^2, 'a')
sage: X = PolynomialRing(F, 'x').gen()
sage: j_in = supersingular_j(F)
sage: sage.modular.ssmod.ssmod.Phi_polys(2,X,j_in)
x^3 + 3*x^2 + 3*x + 1
sage: sage.modular.ssmod.ssmod.Phi_polys(3,X,j_in)
x^4 + 4*x^3 + 6*x^2 + 4*x + 1
```

```
sage: sage.modular.ssmod.ssmod.Phi_polys(5,X,j_in)
x^6 + 6*x^5 + x^4 + 6*x^3 + x^2 + 6*x + 1
sage: sage.modular.ssmod.ssmod.Phi_polys(7,X,j_in)
x^8 + x^7 + x + 1
sage: sage.modular.ssmod.ssmod.Phi_polys(11,X,j_in)
x^12 + 5*x^11 + 3*x^10 + 3*x^9 + 5*x^8 + x^7 + x^5 + 5*x^4 + 3*x^3 + 3*x^2 + 5*x + 1
```

AUTHORS:

- William Stein – wstein@gmail.com
- David Kohel – kohel@maths.usyd.edu.au
- Iftikhar Burhanuddin – burhanud@usc.edu

class SupersingularModule(*prime=2, level=1, base_ring=Integer Ring*)

The module of supersingular points in a given characteristic, with given level structure.

The characteristic must not divide the level.

NOTE: Currently, only level 1 is implemented.

EXAMPLES:

```
sage: S = SupersingularModule(17)
sage: S
Module of supersingular points on X_0(1)/F_17 over Integer Ring
sage: S = SupersingularModule(16)
...
ValueError: the argument prime must be a prime number
sage: S = SupersingularModule(prime=17, level=34)
...
ValueError: the argument level must be coprime to the argument prime
sage: S = SupersingularModule(prime=17, level=5)
...
NotImplementedError: supersingular modules of level > 1 not yet implemented
```

dimension()

Return the dimension of the space of modular forms of weight 2 and level equal to the level associated to self.

INPUT:

- `self` – SupersingularModule object

OUTPUT: integer – dimension, nonnegative

EXAMPLES:

```
sage: S = SupersingularModule(7)
sage: S.dimension()
1

sage: S = SupersingularModule(15073)
sage: S.dimension()
1256

sage: S = SupersingularModule(83401)
sage: S.dimension()
6950
```

NOTES: The case of level > 1 has not yet been implemented.

AUTHORS:

•David Kohel – kohel@maths.usyd.edu.au

•Iftikhar Burhanuddin – burhanud@usc.edu

hecke_matrix(*L*)

This function returns the L^{th} Hecke matrix.

INPUT:

•`self` – SupersingularModule object

•`L` – integer, positive

OUTPUT: matrix – sparse integer matrix

EXAMPLES: This example computes the action of the Hecke operator T_2 on the module of supersingular points on $X_0(1)/F_{37}$:

```
sage: S = SupersingularModule(37)
sage: M = S.hecke_matrix(2)
sage: M
[1 1 1]
[1 0 2]
[1 2 0]
```

This example computes the action of the Hecke operator T_3 on the module of supersingular points on $X_0(1)/F_{67}$:

```
sage: S = SupersingularModule(67)
sage: M = S.hecke_matrix(3)
sage: M
[0 0 0 0 2 2]
[0 0 1 1 1 1]
[0 1 0 2 0 1]
[0 1 2 0 1 0]
[1 1 0 1 0 1]
[1 1 1 0 1 0]
```

Note: The first list — list_j — returned by the supersingular_points function are the rows *and* column indexes of the above hecke matrices and its ordering should be kept in mind when interpreting these matrices.

AUTHORS:

•David Kohel – kohel@maths.usyd.edu.au

•Iftikhar Burhanuddin – burhanud@usc.edu

level()

This function returns the level associated to self.

INPUT:

•`self` – SupersingularModule object

OUTPUT: integer – the level, positive

EXAMPLES:

```
sage: S = SupersingularModule(15073)
sage: S.level()
1
```

AUTHORS:

•David Kohel – kohel@maths.usyd.edu.au

•Iftikhar Burhanuddin – burhanud@usc.edu

prime()

This function returns the characteristic of the finite field associated to self.

INPUT:

•self – SupersingularModule object

OUTPUT:

•integer – charateristic, positive

EXAMPLES:

```
sage: S = SupersingularModule(19)
sage: S.prime()
19
```

AUTHORS:

•David Kohel – kohel@maths.usyd.edu.au

•Iftikhar Burhanuddin – burhanud@usc.edu

rank()

Return the dimension of the space of modular forms of weight 2 and level equal to the level associated to self.

INPUT:

•self – SupersingularModule object

OUTPUT: integer – dimension, nonnegative

EXAMPLES:

```
sage: S = SupersingularModule(7)
sage: S.dimension()
1

sage: S = SupersingularModule(15073)
sage: S.dimension()
1256

sage: S = SupersingularModule(83401)
sage: S.dimension()
6950
```

NOTES: The case of level > 1 has not yet been implemented.

AUTHORS:

•David Kohel – kohel@maths.usyd.edu.au

•Iftikhar Burhanuddin – burhanud@usc.edu

supersingular_points()

This function computes the supersingular j-invariants over the finite field associated to self.

INPUT:

•self – SupersingularModule object

OUTPUT: list_j, dict_j – list_j is the list of supersingular j-invariants, dict_j is a dictionary with these j-invariants as keys and their indexes as values. The latter is used to speed up j-invariant look-up. The indexes are based on the order of their *discovery*.

EXAMPLES:

The following examples calculate supersingular j-invariants over finite fields with characteristic 7, 11 and 37:

```
sage: S = SupersingularModule(7)
sage: S.supersingular_points()
([6], {6: 0})

sage: S = SupersingularModule(11)
```

```
sage: S.supersingular_points()
([1, 0], {0: 1, 1: 0})

sage: S = SupersingularModule(37)
sage: S.supersingular_points()
([8, 27*a + 23, 10*a + 20], {8: 0, 10*a + 20: 2, 27*a + 23: 1})
```

AUTHORS:

- David Kohel – kohel@maths.usyd.edu.au
- Iftikhar Burhanuddin – burhanud@usc.edu

upper_bound_on_elliptic_factors(*p=None, ellmax=2*)

Return an upper bound (provably correct) on the number of elliptic curves of conductor equal to the level of this supersingular module.

INPUT:

- p - (default: 997) prime to work modulo

ALGORITHM: Currently we only use T_2. Function will be extended to use more Hecke operators later.

The prime p is replaced by the smallest prime that doesn't divide the level.

EXAMPLE:

```
sage: SupersingularModule(37).upper_bound_on_elliptic_factors()
2
```

(There are 4 elliptic curves of conductor 37, but only 2 isogeny classes.)

weight()

This function returns the weight associated to self.

INPUT:

- self – SupersingularModule object

OUTPUT: integer – weight, positive

EXAMPLES:

```
sage: S = SupersingularModule(19)
sage: S.weight()
2
```

AUTHORS:

- David Kohel – kohel@maths.usyd.edu.au
- Iftikhar Burhanuddin – burhanud@usc.edu

dimension_supersingular_module(*prime, level=1*)

This function returns the dimension of the Supersingular module, which is equal to the dimension of the space of modular forms of weight 2 and conductor equal to prime times level.

INPUT:

- prime – integer, prime
- level – integer, positive

OUTPUT: dimension – integer, nonnegative

EXAMPLES: The code below computes the dimensions of Supersingular modules with level=1 and prime = 7, 15073 and 83401:

```
sage: dimension_supersingular_module(7)
1

sage: dimension_supersingular_module(15073)
1256

sage: dimension_supersingular_module(83401)
6950
```

NOTES: The case of level > 1 has not been implemented yet.

AUTHORS:

- David Kohel – kohel@maths.usyd.edu.au
- Iftikhar Burhanuddin - burhanud@usc.edu

supersingular_D(*prime*)

This function returns a fundamental discriminant D of an imaginary quadratic field, where the given prime does not split (see Silverman's Advanced Topics in the Arithmetic of Elliptic Curves, page 184, exercie 2.30(d).)

INPUT:

- prime – integer, prime

OUTPUT: D – integer, negative

EXAMPLES:

These examples return *supersingular discriminants* for 7, 15073 and 83401:

```
sage: supersingular_D(7)
-4

sage: supersingular_D(15073)
-15

sage: supersingular_D(83401)
-7
```

AUTHORS:

- David Kohel - kohel@maths.usyd.edu.au
- Iftikhar Burhanuddin - burhanud@usc.edu

supersingular_j(*FF*)

This function returns a supersingular j-invariant over the finite field FF.

INPUT:

- `FF` – finite field with p^2 elements, where p is a prime number

OUTPUT: finite field element – a supersingular j-invariant defined over the finite field FF

EXAMPLES:

The following examples calculate supersingular j-invariants for a few finite fields:

```
sage: supersingular_j(GF(7^2, 'a'))
6
```

Observe that in this example the j-invariant is not defined over the prime field:

```
sage: supersingular_j(GF(15073^2,'a'))  # optional -- requires database
10630*a + 6033

sage: supersingular_j(GF(83401^2, 'a'))
67977
```

46.9 Brandt Modules

AUTHORS:

- Jon Bober
- Alia Hamieh
- Victoria de Quehen
- William Stein
- Gonzalo Tornaria

46.9.1 Introduction

This tutorial outlines the construction of Brandt modules in SAGE. The importance of this construction is that it provides us with a method to compute modular forms on $\Gamma_0(N)$ as outlined in Pizer's paper [Pi]. In fact there exists a non-canonical Hecke algebra isomorphism between the Brandt modules and a certain subspace of $S_2(\Gamma_0(pM))$ which contains all the newforms.

The Brandt module is the free abelian group on right ideal classes of a quaternion order together with a natural Hecke action determined by Brandt matrices.

Quaternion Algebras

A quaternion algebra over $\mathbf{Q}$ is a central simple algebra of dimension 4 over $\mathbf{Q}$. Such an algebra A is said to be ramified at a place v of $\mathbf{Q}$ if and only if $A_v = A \otimes \mathbf{Q}_v$ is a division algebra. Otherwise A is said to be split at v.

`A = QuaternionAlgebra(p)` returns the quaternion algebra A over $\mathbf{Q}$ ramified precisely at the places p and ∞.

`A = QuaternionAlgebra(k,a,b)` returns a quaternion algebra with basis $\{1, i, j, j\}$ over $\mathbb{K}$ such that $i^2 = a$, $j^2 = b$ and $ij = k$.

An order R in a quaternion algebra is a 4-dimensional lattice on A which is also a subring containing the identity.

`R = A.maximal_order()` returns a maximal order R in the quaternion algebra A.

An Eichler order $\mathcal{O}$ in a quaternion algebra is the intersection of two maximal orders. The level of $\mathcal{O}$ is its index in any maximal order containing it.

`O = A.order_of_level_N` returns an Eichler order $\mathcal{O}$ in A of level N where p does not divide N.

A right $\mathcal{O}$-ideal I is a lattice on A such that $I_p = a_p\mathcal{O}$ (for some $a_p \in A_p^*$) for all $p < \infty$. Two right $\mathcal{O}$-ideals I and J are said to belong to the same class if $I = aJ$ for some $a \in A^*$. (Left $\mathcal{O}$-ideals are defined in a similar fashion.)

The right order of I is defined to be the set of elements in A which fix I under right multiplication.

right_order (R, basis) returns the right ideal of I in R given a basis for the right ideal I contained in the maximal order R.

ideal_classes(self) returns a tuple of all right ideal classes in self which, for the purpose of constructing the Brandt module B(p,M), is taken to be an Eichler order of level M.

The implementation of this method is especially interesting. It depends on the construction of a Hecke module defined as a free abelian group on right ideal classes of a quaternion algebra with the following action

where $(n, pM) = 1$ and the sum is over cyclic $\mathcal{O}$-module homomorphisms $\phi : I \to J `of degree` n$ up to isomorphism of J. Equivalently one can sum over the inclusions of the submodules $J \to n^{-1}I$. The rough idea is to start with the trivial ideal class containing the order $\mathcal{O}$ itself. Using the method cyclic_submodules(self, I, p) one computes $T_p([\mathcal{O}])$ for some prime integer \$p\$ not dividing the level of the order $\mathcal{O}$. Apply this method repeatedly and test for equivalence among resulting ideals. A theorem of Serre asserts that one gets a complete set of ideal class representatives after a finite number of repetitions.

One can prove that two ideals I and J are equivalent if and only if there exists an element $\alpha \in I\overline{J}$ such $N(\alpha) = N(I)N(J)$.

is_equivalent(I,J) returns true if I and J are equivalent. This method first compares the theta series of I and J. If they are the same, it computes the theta series of the lattice $I\overline{(J)}$. It returns true if the n^{th} coefficient of this series is nonzero where $n = N(J)N(I)$.

The theta series of a lattice L over the quaternion algebra A is defined as

L.theta_series(T,q) returns a power series representing $\theta_L(q)$ up to a precision of $\mathcal{O}(q^{T+1})$.

Hecke Structure

The Hecke structure defined on the Brandt module is given by the Brandt matrices which can be computed using the definition of the Hecke operators given earlier.

hecke_matrix_from_defn (self,n) returns the matrix of the nth Hecke operator $B_0(n)$ acting on self, computed directly from the definition.

However, one can efficiently compute Brandt matrices using theta series. In fact, let $\{I_1, ..., I_h\}$ be a set of right $\mathcal{O}$-ideal class representatives. The (i,j) entry in the Brandt matrix $B_0(n)$ is the product of the n^{th} coefficient in the theta series of the lattice $I_i\overline{I_j}$ and the first coefficient in the theta series of the lattice $I_i\overline{I_i}$.

compute_hecke_matrix_brandt(self,n) returns the nth Hecke matrix, computed using theta series.

Example

```
sage: B = BrandtModule(23)

sage: B.maximal_order()
Order of Quaternion Algebra (-1, -23) with base ring Rational Field with basis (1/2 + 1/2*j, 1/2*i +

sage: B.right_ideals()
(Fractional ideal (2 + 2*j, 2*i + 2*k, 4*j, 4*k), Fractional ideal (2 + 2*j, 2*i + 6*k, 8*j, 8*k), Fr

sage: B.hecke_matrix(2)
[1 2 0]
[1 1 1]
[0 3 0]

sage: B.brandt_series(3)
```

```
[1/4 + q + q^2 + O(q^3)      1/4 + q^2 + O(q^3)            1/4 + O(q^3)]
[  1/2 + 2*q^2 + O(q^3) 1/2 + q + q^2 + O(q^3)   1/2 + 3*q^2 + O(q^3)]
[           1/6 + O(q^3)      1/6 + q^2 + O(q^3)        1/6 + q + O(q^3)]
```

Further Examples

We decompose a Brandt module over both **Z** and **Q**.:

```
sage: B = BrandtModule(43, base_ring=ZZ); B
Brandt module of dimension 4 of level 43 of weight 2 over Integer Ring
sage: D = B.decomposition()
sage: D
[
Subspace of dimension 1 of Brandt module of dimension 4 of level 43 of weight 2 over Integer Ring,
Subspace of dimension 1 of Brandt module of dimension 4 of level 43 of weight 2 over Integer Ring,
Subspace of dimension 2 of Brandt module of dimension 4 of level 43 of weight 2 over Integer Ring
]
sage: D[0].basis()
((0, 0, 1, -1),)
sage: D[1].basis()
((1, 2, 2, 2),)
sage: D[2].basis()
((1, 1, -1, -1), (0, 2, -1, -1))
sage: B = BrandtModule(43, base_ring=QQ); B
Brandt module of dimension 4 of level 43 of weight 2 over Rational Field
sage: B.decomposition()[2].basis()
((1, 0, -1/2, -1/2), (0, 1, -1/2, -1/2))
```

BrandtModule(*N, M=1, weight=2, base_ring=Rational Field, use_cache=True*)

Return the Brandt module of given weight associated to the prime power p^r and integer M, where p and M are coprime.

INPUT:
- N – a product of primes with odd exponents
- M – an integer coprime to q (default: 1)
- weight – an integer that is at least 2 (default: 2)
- base_ring – the base ring (default: QQ)
- use_cache – whether to use the cache (default: True)

OUTPUT:
- a Brandt module

EXAMPLES:

```
sage: BrandtModule(17)
Brandt module of dimension 2 of level 17 of weight 2 over Rational Field
sage: BrandtModule(17,15)
Brandt module of dimension 32 of level 17*15 of weight 2 over Rational Field
sage: BrandtModule(3,7)
Brandt module of dimension 2 of level 3*7 of weight 2 over Rational Field
sage: BrandtModule(3,weight=2)
```

```
Brandt module of dimension 1 of level 3 of weight 2 over Rational Field
sage: BrandtModule(11, base_ring=ZZ)
Brandt module of dimension 2 of level 11 of weight 2 over Integer Ring
sage: BrandtModule(11, base_ring=QQbar)
Brandt module of dimension 2 of level 11 of weight 2 over Algebraic Field
```

The use_cache option determines whether the Brandt module returned by this function is cached.:

```
sage: BrandtModule(37) is BrandtModule(37)
True
sage: BrandtModule(37,use_cache=False) is BrandtModule(37,use_cache=False)
False
```

TESTS:

Note that N and M must be coprime:

```
sage: BrandtModule(3,15)
...
ValueError: M must be coprime to N
```

Only weight 2 is currently implemented:

```
sage: BrandtModule(3,weight=4)
...
NotImplementedError: weight != 2 not yet implemented
```

Brandt modules are cached:

```
sage: B = BrandtModule(3,5,2,ZZ)
sage: B is BrandtModule(3,5,2,ZZ)
True
```

class **BrandtModuleElement** (*parent, x*)

monodromy_pairing (*x*)

Return the monodromy pairing of self and x.

EXAMPLES:

```
sage: B = BrandtModule(5,13)
sage: B.monodromy_weights()
(1, 3, 1, 1, 1, 3)
sage: (B.0 + B.1).monodromy_pairing(B.0 + B.1)
4
```

class **BrandtModule_class** (*N, M, weight, base_ring*)

A Brandt module.

EXAMPLES:

```
sage: BrandtModule(3, 10)
Brandt module of dimension 4 of level 3*10 of weight 2 over Rational Field
```

M ()

Return the auxiliary level (prime to p part) of the quaternion order used to compute this Brandt module.

EXAMPLES:

```
sage: BrandtModule(7,5,2,ZZ).M()
5
```

N()

Return ramification level N.

EXAMPLES:

```
sage: BrandtModule(7,5,2,ZZ).N()
7
```

brandt_series(*prec, var='q'*)

Return matrix of power series $\sum T_n q^n$ to the given precision. Note that the Hecke operators in this series are always over $\mathbf{Q}$, even if the base ring of this Brandt module is not $\mathbf{Q}$.

INPUT:
- prec – positive intege
- var – string (default: q)

OUTPUT: matrix of power series with coefficients in $\mathbf{Q}$

EXAMPLES:

```
sage: B = BrandtModule(11)
sage: B.brandt_series(2)
[1/4 + q + O(q^2)     1/4 + O(q^2)]
[    1/6 + O(q^2) 1/6 + q + O(q^2)]
sage: B.brandt_series(5)
[1/4 + q + q^2 + 2*q^3 + 5*q^4 + O(q^5)   1/4 + 3*q^2 + 3*q^3 + 3*q^4 + O(q^5)]
[  1/6 + 2*q^2 + 2*q^3 + 2*q^4 + O(q^5)         1/6 + q + q^3 + 4*q^4 + O(q^5)]
```

Asking for a smaller precision works.:

```
sage: B.brandt_series(3)
[1/4 + q + q^2 + O(q^3)   1/4 + 3*q^2 + O(q^3)]
[  1/6 + 2*q^2 + O(q^3)       1/6 + q + O(q^3)]
sage: B.brandt_series(3,var='t')
[1/4 + t + t^2 + O(t^3)   1/4 + 3*t^2 + O(t^3)]
[  1/6 + 2*t^2 + O(t^3)       1/6 + t + O(t^3)]
```

cyclic_supermodules(*I, p*)

Return a list of rescaled versions of the fractional right ideals J such that J contains I and the quotient has group structure the product of two cyclic groups of order p.

We emphasize again that J is rescaled to be integral.

INPUT: I – ideal I in R = self.order_of_level_N() p – prime p coprime to self.level()

OUTPUT: list of the p+1 fractional right R-ideals that contain I such that J/I is GF(p) x GF(p).

EXAMPLES:

```
sage: B = BrandtModule(11)
sage: I = B.order_of_level_N().unit_ideal()
sage: B.cyclic_supermodules(I, 2)
[Fractional ideal (1/2 + 3/2*j + k, 1/2*i + j + 1/2*k, 2*j, 2*k),
 Fractional ideal (1/2 + 1/2*i + 1/2*j + 1/2*k, i + k, j + k, 2*k),
 Fractional ideal (1/2 + 1/2*j + k, 1/2*i + j + 3/2*k, 2*j, 2*k)]
sage: B.cyclic_supermodules(I, 3)
[Fractional ideal (1/2 + 1/2*j, 1/2*i + 5/2*k, 3*j, 3*k),
 Fractional ideal (1/2 + 3/2*j + 2*k, 1/2*i + 2*j + 3/2*k, 3*j, 3*k),
 Fractional ideal (1/2 + 3/2*j + k, 1/2*i + j + 3/2*k, 3*j, 3*k),
 Fractional ideal (1/2 + 5/2*j, 1/2*i + 1/2*k, 3*j, 3*k)]
sage: B.cyclic_supermodules(I, 11)
...
ValueError: p must be coprime to the level
```

eisenstein_subspace()

Return the 1-dimensional subspace of self on which the Hecke operators T_p act as $p+1$ for p coprime to the level.

NOTE: This function assumes that the base field has characteristic 0.

EXAMPLES:

```
sage: B = BrandtModule(11); B.eisenstein_subspace()
Subspace of dimension 1 of Brandt module of dimension 2 of level 11 of weight 2 over Rationa
sage: B.eisenstein_subspace() is B.eisenstein_subspace()
True
sage: BrandtModule(3,11).eisenstein_subspace().basis()
((1, 1),)
sage: BrandtModule(7,10).eisenstein_subspace().basis()
((1, 1, 1, 1/2, 1, 1, 1/2, 1, 1, 1),)
sage: BrandtModule(7,10,base_ring=ZZ).eisenstein_subspace().basis()
((2, 2, 2, 1, 2, 2, 1, 2, 2, 2),)
```

free_module()

Return the underlying free module of the Brandt module.

EXAMPLES:

```
sage: B = BrandtModule(10007,389)
sage: B.free_module()
Vector space of dimension 325196 over Rational Field
```

maximal_order()

Return a maximal order in the quaternion algebra associated to this Brandt module.

EXAMPLES:

```
sage: BrandtModule(17).maximal_order()
Order of Quaternion Algebra (-17, -3) with base ring Rational Field with basis (1/2 + 1/2*j,
sage: BrandtModule(17).maximal_order() is BrandtModule(17).maximal_order()
True
```

monodromy_weights()

Return the weights for the monodromy pairing on this Brandt module. The weights are associated to each ideal class in our fixed choice of basis. The weight of an ideal class $[I]$ is half the number of units of the right order I.

NOTE: The base ring must be $\mathbf{Q}$ or $\mathbf{Z}$.

EXAMPLES:

```
sage: BrandtModule(11).monodromy_weights()
(2, 3)
sage: BrandtModule(37).monodromy_weights()
(1, 1, 1)
sage: BrandtModule(43).monodromy_weights()
(2, 1, 1, 1)
sage: BrandtModule(7,10).monodromy_weights()
(1, 1, 1, 2, 1, 1, 2, 1, 1, 1)
sage: BrandtModule(5,13).monodromy_weights()
(1, 3, 1, 1, 1, 3)
```

order_of_level_N()

Return Eichler order of level N = p^(2*r+1)*M in the quaternion algebra.

EXAMPLES:

```
sage: BrandtModule(7).order_of_level_N()
Order of Quaternion Algebra (-1, -7) with base ring Rational Field with basis (1/2 + 1/2*j,
sage: BrandtModule(7,13).order_of_level_N()
Order of Quaternion Algebra (-1, -7) with base ring Rational Field with basis (1/2 + 1/2*j +
sage: BrandtModule(7,3*17).order_of_level_N()
Order of Quaternion Algebra (-1, -7) with base ring Rational Field with basis (1/2 + 1/2*j +
```

quaternion_algebra()

Return the quaternion algebra A over QQ ramified precisely at p and infinity used to compute this Brandt module.

EXAMPLES:

```
sage: BrandtModule(997).quaternion_algebra()
Quaternion Algebra (-2, -997) with base ring Rational Field
sage: BrandtModule(2).quaternion_algebra()
Quaternion Algebra (-1, -1) with base ring Rational Field
sage: BrandtModule(3).quaternion_algebra()
Quaternion Algebra (-1, -3) with base ring Rational Field
sage: BrandtModule(5).quaternion_algebra()
Quaternion Algebra (-2, -5) with base ring Rational Field
sage: BrandtModule(17).quaternion_algebra()
Quaternion Algebra (-17, -3) with base ring Rational Field
```

right_ideals(*B=None*)

Return sorted tuple of representatives for the equivalence classes of right ideals in self.

OUTPUT: • sorted tuple of fractional ideals

EXAMPLES:

```
sage: B = BrandtModule(23)
sage: B.right_ideals()
(Fractional ideal (2 + 2*j, 2*i + 2*k, 4*j, 4*k),
 Fractional ideal (2 + 2*j, 2*i + 6*k, 8*j, 8*k),
 Fractional ideal (2 + 10*j + 8*k, 2*i + 8*j + 6*k, 16*j, 16*k))
```

TEST:

```
sage: B = BrandtModule(1009)
sage: Is = B.right_ideals()
sage: n = len(Is)
sage: prod(not Is[i].is_equivalent(Is[j]) for i in range(n) for j in range(i))
1
```

class **BrandtSubmodule**(*ambient, submodule, dual_free_module=None, check=True*)

basis_for_left_ideal(*R, gens*)

Return a basis for the left ideal of R with given generators.

INPUT: • R – quaternion order
• gens – list of elements of R

OUTPUT: • list of four elements of R

EXAMPLES:

```
sage: B = BrandtModule(17); A = B.quaternion_algebra(); i,j,k = A.gens()
sage: sage.modular.quatalg.brandt.basis_for_left_ideal(B.maximal_order(), [i+j,i-j,2*k,A(3)])
[1/2 + 1/6*j + 2/3*k, 1/2*i + 1/2*k, 1/3*j + 1/3*k, k]
sage: sage.modular.quatalg.brandt.basis_for_left_ideal(B.maximal_order(), [3*(i+j),3*(i-j),6*k,A
[3/2 + 1/2*j + 2*k, 3/2*i + 3/2*k, j + k, 3*k]
```

benchmark_magma(*levels, silent=False*)

INPUT: • levels – list of pairs (p,M) where p is a prime not dividing M
• silent – bool, default False; if True surpress printing during computation

OUTPUT: • list of 4-tuples ('magma', p, M, tm), where tm is the CPU time in seconds to compute T2 using Magma

EXAMPLES:

```
sage: a = sage.modular.quatalg.brandt.benchmark_magma([(11,1), (37,1), (43,1), (97,1)])  # optic
('magma', 11, 1, ...)
('magma', 37, 1, ...)
('magma', 43, 1, ...)
('magma', 97, 1, ...)
sage: a = sage.modular.quatalg.brandt.benchmark_magma([(11,2), (37,2), (43,2), (97,2)])  # optic
('magma', 11, 2, ...)
('magma', 37, 2, ...)
('magma', 43, 2, ...)
('magma', 97, 2, ...)
```

benchmark_sage(*levels, silent=False*)

INPUT: • levels – list of pairs (p,M) where p is a prime not dividing M
• silent – bool, default False; if True surpress printing during computation

OUTPUT: • list of 4-tuples ('sage', p, M, tm), where tm is the CPU time in seconds to compute T2 using Sage

EXAMPLES:

```
sage: a = sage.modular.quatalg.brandt.benchmark_sage([(11,1), (37,1), (43,1), (97,1)])
('sage', 11, 1, ...)
('sage', 37, 1, ...)
('sage', 43, 1, ...)
('sage', 97, 1, ...)
sage: a = sage.modular.quatalg.brandt.benchmark_sage([(11,2), (37,2), (43,2), (97,2)])
('sage', 11, 2, ...)
('sage', 37, 2, ...)
('sage', 43, 2, ...)
('sage', 97, 2, ...)
```

class_number(*p, r, M*)

Return the class number of an order of level N = p^r*M in the quaternion algebra over QQ ramified precisely at p and infinity.

This is an implementation of Theorem 1.12 of [Pizer, 1980].

INPUT: • p – a prime
• r – an odd positive integer (default: 1)
• M – an integer coprime to q (default: 1)

OUTPUT: Integer

EXAMPLES:

```
sage: sage.modular.quatalg.brandt.class_number(389,1,1)
33
sage: sage.modular.quatalg.brandt.class_number(389,1,2)  # TODO -- right?
97
sage: sage.modular.quatalg.brandt.class_number(389,3,1)  # TODO -- right?
4892713
```

maximal_order(*A*)

Return a maximal order in the quaternion algebra ramified at p and infinity.

This is an implementation of Proposition 5.2 of [Pizer, 1980].

INPUT: • A – quaternion algebra ramified precisely at p and infinity

OUTPUT: • a maximal order in A

EXAMPLES:

```
sage: A = BrandtModule(17).quaternion_algebra()
sage: sage.modular.quatalg.brandt.maximal_order(A)
Order of Quaternion Algebra (-17, -3) with base ring Rational Field with basis (1/2 + 1/2*j, 1/2
```

quaternion_order_with_given_level (*A, level*)

Return an order in the quaternion algebra A with given level. (Implemented only when the base field is the rational numbers.)

INPUT: **level – The level of the order to be returned. Currently this is only implemented** when the level is divisible by at most one power of a prime that ramifies in this quaternion algebra.

EXAMPLES:

```
sage: from sage.modular.quatalg.brandt import quaternion_order_with_given_level, maximal_order
sage: A.<i,j,k> = QuaternionAlgebra(5)
sage: level = 2 * 5 * 17
sage: O = quaternion_order_with_given_level(A, level)
sage: M = maximal_order(A)
sage: L = O.free_module()
sage: N = M.free_module()
sage: print L.index_in(N) == level/5  #check that the order has the right index in the maximal o
True
```

right_order (*R, basis*)

Given a basis for a left ideal I, return the right order in the quaternion order R of elements such that I*x is contained in I.

INPUT: • R – order in quaternion algebra

• basis – basis for an ideal I

OUTPUT: • order in quaternion algebra

EXAMPLES:

We do a consistency check with the ideal equal to a maximal order.:

```
sage: B = BrandtModule(17); basis = sage.modular.quatalg.brandt.basis_for_left_ideal(B.maximal_o
sage: sage.modular.quatalg.brandt.right_order(B.maximal_order(), basis)
Order of Quaternion Algebra (-17, -3) with base ring Rational Field with basis (1/2 + 1/6*j + 2/
sage: basis
[1/2 + 1/6*j + 2/3*k, 1/2*i + 1/2*k, 1/3*j + 1/3*k, k]

sage: B = BrandtModule(17); A = B.quaternion_algebra(); i,j,k = A.gens()
sage: basis = sage.modular.quatalg.brandt.basis_for_left_ideal(B.maximal_order(), [i*j-j])
sage: sage.modular.quatalg.brandt.right_order(B.maximal_order(), basis)
Order of Quaternion Algebra (-17, -3) with base ring Rational Field with basis (1/2 + 1/2*i + 1/
```

CHAPTER

FORTYSEVEN

HISTORY AND LICENSE

Sage was initially created by William Stein in 2004–2005, using Python, IPython, PARI, SWIG, Pyrex, NTL, and GMP. These programs are all open source and released under the GPL or a GPL-compatible license.

All Sage releases are released under the GPL. All documentation is released under the GNU Free Documentation License.

47.1 The GNU General Public License

Version 2, June 1991

```
Copyright (C) 1989, 1991 Free Software Foundation, Inc.
51 Franklin Street, Fifth Floor, Boston, MA  02110-1301, USA

Everyone is permitted to copy and distribute verbatim copies
of this license document, but changing it is not allowed.
```

47.1.1 Preamble

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public License is intended to guarantee your freedom to share and change free software–to make sure the software is free for all its users. This General Public License applies to most of the Free Software Foundation's software and to any other program whose authors commit to using it. (Some other Free Software Foundation software is covered by the GNU Library General Public License instead.) You can apply it to your programs, too.

When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.

We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors' reputations.

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

The precise terms and conditions for copying, distribution and modification follow.

47.1.2 Terms and Conditions For Copying, Distribution and Modification

1. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The "Program", below, refers to any such program or work, and a "work based on the Program" means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or translated into another language. (Hereinafter, translation is included without limitation in the term "modification".) Each licensee is addressed as "you".

   Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

2. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.

   You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

   You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:

   (a) You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.

   (b) You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.

   (c) If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this License. (Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

3. These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program.

In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

4. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:

   (a) Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

   (b) Accompany it with a written offer, valid for at least three years, to give any third party, for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

   (c) Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

   The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

   If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

5. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

6. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Program or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Program (or any work based on the Program), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Program or works based on it.

7. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties to this License.

8. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Program at all. For example, if a patent license would not permit royalty-free redistribution of the Program by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Program.

If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system, which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot impose that choice.

This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

9. If the distribution and/or use of the Program is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.

10. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

    Each version is given a distinguishing version number. If the Program specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.

11. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

NO WARRANTY

1. Because the program is licensed free of charge, there is no warranty for the program, to the extent permitted by applicable law. Except when otherwise stated in writing the copyright holders and/or other parties provide the program "as is" without warranty of any kind, either expressed or implied, including, but not limited to, the implied warranties of merchantability and fitness for a particular purpose. The entire risk as to the quality and performance of the program is with you. Should the program prove defective, you assume the cost of all necessary servicing, repair or correction.

2. In no event unless required by applicable law or agreed to in writing will any copyright holder, or any other party who may modify and/or redistribute the program as permitted above, be liable to you for damages, including any general, special, incidental or consequential damages arising out of the use or inability to use the program (including but not limited to loss of data or data being rendered inaccurate or losses sustained by you or third parties or a failure of the program to operate with any other programs), even if such holder or other party has been advised of the possibility of such damages.

End of Terms and Conditions

47.1.3 Appendix: How to Apply These Terms to Your New Programs

If you develop a new program, and you want it to be of the greatest possible use to the public, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each source file to most effectively convey the exclusion of warranty; and each file should have at least the "copyright" line and a pointer to where the full notice is found.

```
one line to give the program's name and a brief idea of what it
does.
Copyright (C) yyyy name of author

This program is free software; you can redistribute it and/or
modify it under the terms of the GNU General Public License as
published by the Free Software Foundation; either version 2 of the
License, or (at your option) any later version.

This program is distributed in the hope that it will be useful, but
WITHOUT ANY WARRANTY; without even the implied warranty of
MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU
General Public License for more details.

You should have received a copy of the GNU General Public License
along with this program; if not, write to the Free Software

```

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this when it starts in an interactive mode:

```
Gnomovision version 69, Copyright (C) yyyy name of author
Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type
'show w'.
This is free software, and you are welcome to redistribute it under
certain conditions; type 'show c' for details.
```

The hypothetical commands show w and show c should show the appropriate parts of the General Public License. Of course, the commands you use may be called something other than show w and show c; they could even be mouse-clicks or menu items–whatever suits your program.

You should also get your employer (if you work as a programmer) or your school, if any, to sign a "copyright disclaimer" for the program, if necessary. Here is a sample; alter the names:

```
Yoyodyne, Inc., hereby disclaims all copyright interest in the
program
'Gnomovision' (which makes passes at compilers) written by James
Hacker.

signature of Ty Coon, 1 April 1989
Ty Coon, President of Vice
```

This General Public License does not permit incorporating your program into proprietary programs. If your program is a subroutine library, you may consider it more useful to permit linking proprietary applications with the library. If this is what you want to do, use the GNU Library General Public License instead of this License.
