sage: H3.t_action_on_basis(Permutation([1,3,2]), 2)
T[1, 2, 3]
```

SymmetricGroupAlgebra(*R*, *n*)

Returns the symmetric group algebra of order n over R.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3); QS3
Symmetric group algebra of order 3 over Rational Field
sage: QS3(1)
[1, 2, 3]
sage: QS3(2)
2*[1, 2, 3]
sage: basis = [QS3(p) for p in Permutations(3)]
sage: a = sum(basis); a
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: a^2
6*[1, 2, 3] + 6*[1, 3, 2] + 6*[2, 1, 3] + 6*[2, 3, 1] + 6*[3, 1, 2] + 6*[3, 2, 1]
sage: a^2 == 6*a
True
sage: b = QS3([3, 1, 2])
sage: b
[3, 1, 2]
sage: b*a
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: b*a == a
True
```

class **SymmetricGroupAlgebraElement_n**(*A*, *x*)

class **SymmetricGroupAlgebra_n**(*R*, *n*)

cpi(*p*)

Returns the centrally primitive idempotent for the symmetric group of order n for the irreducible corresponding indexed by the partition p.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ,3)
sage: QS3.cpi([2,1])
2/3*[1, 2, 3] - 1/3*[2, 3, 1] - 1/3*[3, 1, 2]
```

```
sage: QS3.cpi([3])
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] + 1/6*[3, 2, 1
sage: QS3.cpi([1,1,1])
1/6*[1, 2, 3] - 1/6*[1, 3, 2] - 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] - 1/6*[3, 2, 1
```

cpis()

Returns a list of the centrally primitive idempotents.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ,3)
sage: a = QS3.cpis()
sage: a[0]  # [3]
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] + 1/6*[3, 2, 1
sage: a[1]  # [2, 1]
2/3*[1, 2, 3] - 1/3*[2, 3, 1] - 1/3*[3, 1, 2]
```

dft(*form='seminormal'*)

Returns the discrete Fourier transform for self.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.dft()
[   1    1    1    1    1    1]
[   1  1/2   -1 -1/2 -1/2  1/2]
[   0  3/4    0  3/4 -3/4 -3/4]
[   0    1    0   -1    1   -1]
[   1 -1/2    1 -1/2 -1/2 -1/2]
[   1   -1   -1    1    1   -1]
```

epsilon_ik(*itab, ktab, star=0*)

Returns the seminormal basis element of self corresponding to the pair of tableaux itab and ktab.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: a = QS3.epsilon_ik([[1,2,3]], [[1,2,3]]); a
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] + 1/6*[3, 2, 1
sage: QS3.dft()*vector(a)
(1, 0, 0, 0, 0, 0)
sage: a = QS3.epsilon_ik([[1,2],[3]], [[1,2],[3]]); a
1/3*[1, 2, 3] - 1/6*[1, 3, 2] + 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2] - 1/6*[3, 2, 1
sage: QS3.dft()*vector(a)
(0, 0, 0, 0, 1, 0)
```

jucys_murphy(*k*)

Returns the Jucys-Murphy element J_k for the symmetric group algebra.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.jucys_murphy(2)
[2, 1, 3]
sage: QS3.jucys_murphy(3)
[1, 3, 2] + [3, 2, 1]
sage: QS5 = SymmetricGroupAlgebra(QQ, 5)
sage: QS5.jucys_murphy(4)
[1, 2, 4, 3, 5] + [1, 4, 3, 2, 5] + [4, 2, 3, 1, 5]
```

seminormal_basis()

Returns a list of the seminormal basis elements of self.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ,3)
sage: QS3.seminormal_basis()
[1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] + 1/6*[3, 2,
1/3*[1, 2, 3] + 1/6*[1, 3, 2] - 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2] + 1/6*[3, 2, 1
1/3*[1, 3, 2] + 1/3*[2, 3, 1] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1],
1/4*[1, 3, 2] - 1/4*[2, 3, 1] + 1/4*[3, 1, 2] - 1/4*[3, 2, 1],
1/3*[1, 2, 3] - 1/6*[1, 3, 2] + 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2] - 1/6*[3, 2, 1
1/6*[1, 2, 3] - 1/6*[1, 3, 2] - 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] - 1/6*[3, 2, 1
```

e (*tableau, star=0*)

The unnormalized Young projection operator.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import e
sage: e([[1,2]])
[1, 2] + [2, 1]
sage: e([[1],[2]])
[1, 2] - [2, 1]
```

There are differing conventions for the order of the symmetrizers and antisymmetrizers. This example illustrates our conventions:

```
sage: e([[1,2],[3]])
[1, 2, 3] + [2, 1, 3] - [3, 1, 2] - [3, 2, 1]
```

e_hat (*tab, star=0*)

The Young projection operator, an idempotent in the rational group algebra.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import e_hat
sage: e_hat([[1,2,3]])
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] + 1/6*[3, 2, 1]
sage: e_hat([[1],[2]])
1/2*[1, 2] - 1/2*[2, 1]
```

There are differing conventions for the order of the symmetrizers and antisymmetrizers. This example illustrates our conventions:

```
sage: e_hat([[1,2],[3]])
1/3*[1, 2, 3] + 1/3*[2, 1, 3] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1]
```

e_ik (*itab, ktab, star=0*)

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import e_ik
sage: e_ik([[1,2,3]], [[1,2,3]])
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: e_ik([[1,2,3]], [[1,2,3]], star=1)
[1, 2] + [2, 1]
```

epsilon (*tab, star=0*)

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import epsilon
sage: epsilon([[1,2]])
1/2*[1, 2] + 1/2*[2, 1]
```

```
sage: epsilon([[1],[2]])
1/2*[1, 2] - 1/2*[2, 1]
```

epsilon_ik(*itab, ktab, star=0*)

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import epsilon_ik
sage: epsilon_ik([[1,2],[3]], [[1,3],[2]])
1/4*[1, 3, 2] - 1/4*[2, 3, 1] + 1/4*[3, 1, 2] - 1/4*[3, 2, 1]
sage: epsilon_ik([[1,2],[3]], [[1,3],[2]], star=1)
...
ValueError: the two tableaux must be of the same shape
```

kappa(*alpha*)

Returns κ_α which is n! divided by the number of standard tableaux of shape α.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import kappa
sage: kappa(Partition([2,1]))
3
sage: kappa([2,1])
3
```

pi_ik(*itab, ktab*)

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import pi_ik
sage: pi_ik([[1,3],[2]], [[1,2],[3]])
[1, 3, 2]
```

seminormal_test(*n*)

Runs a variety of tests to verify that the construction of the seminormal basis works as desired. The numbers appearing are Theorems in James and Kerber's 'Representation Theory of the Symmetric Group'.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import seminormal_test
sage: seminormal_test(3)
True
```

17.31.4 Schubert Polynomials

SchubertPolynomialRing(*R*)

Returns the Schubert polynomial ring over R on the X basis.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ); X
Schubert polynomial ring with X basis over Integer Ring
sage: X(1)
X[1]
sage: X([1,2,3])*X([2,1,3])
X[2, 1]
sage: X([2,1,3])*X([2,1,3])
X[3, 1, 2]
sage: X([2,1,3])+X([3,1,2,4])
```

```
X[2, 1] + X[3, 1, 2]
sage: a = X([2,1,3])+X([3,1,2,4])
sage: a^2
X[3, 1, 2] + 2*X[4, 1, 2, 3] + X[5, 1, 2, 3, 4]
```

class SchubertPolynomialRing_xbasis(R)

class SchubertPolynomial_class(A, x)

divided_difference(i)

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,1])
sage: a.divided_difference(1)
X[2, 3, 1]
sage: a.divided_difference([3,2,1])
X[1]
```

expand()

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: X([2,1,3]).expand()
x0
sage: map(lambda x: x.expand(), [X(p) for p in Permutations(3)])
[1, x0 + x1, x0, x0*x1, x0^2, x0^2*x1]
```

TESTS: Calling .expand() should always return an element of an MPolynomialRing

```
sage: X = SchubertPolynomialRing(ZZ)
sage: f = X([1]); f
X[1]
sage: type(f.expand())
<type 'sage.rings.polynomial.multi_polynomial_libsingular.MPolynomial_libsingular'>
sage: f.expand()
1
sage: f = X([1,2])
sage: type(f.expand())
<type 'sage.rings.polynomial.multi_polynomial_libsingular.MPolynomial_libsingular'>
sage: f = X([1,3,2,4])
sage: type(f.expand())
<type 'sage.rings.polynomial.multi_polynomial_libsingular.MPolynomial_libsingular'>
```

multiply_variable(i)

Returns the Schubert polynomial obtained by multiplying self by the variable x_i.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,4,1])
sage: a.multiply_variable(0)
X[4, 2, 3, 1]
sage: a.multiply_variable(1)
X[3, 4, 2, 1]
sage: a.multiply_variable(2)
X[3, 2, 5, 1, 4] - X[3, 4, 2, 1] - X[4, 2, 3, 1]
sage: a.multiply_variable(3)
X[3, 2, 4, 5, 1]
```

scalar_product(x)

Returns the standard scalar product of self and x.
EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,4,1])
sage: a.scalar_product(a)
0
sage: b = X([4,3,2,1])
sage: b.scalar_product(a)
X[1, 3, 4, 6, 2, 5]
sage: Permutation([1, 3, 4, 6, 2, 5, 7]).to_lehmer_code()
[0, 1, 1, 2, 0, 0, 0]
sage: s = SFASchur(ZZ)
sage: c = s([2,1,1])
sage: b.scalar_product(a).expand()
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3 + x0^2*x2*x3 + 3*x0*x1*x2*x3
sage: c.expand(4)
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3 + x0^2*x2*x3 + 3*x0*x1*x2*x3
```

is_SchubertPolynomial(*x*)

Returns True if x is a Schubert polynomial and False otherwise.

EXAMPLES:

```
sage: from sage.combinat.schubert_polynomial import is_SchubertPolynomial
sage: X = SchubertPolynomialRing(ZZ)
sage: a = 1
sage: is_SchubertPolynomial(a)
False
sage: b = X(1)
sage: is_SchubertPolynomial(b)
True
sage: c = X([2,1,3])
sage: is_SchubertPolynomial(c)
True
```

17.31.5 Partition/Diagram Algebras

class PartitionAlgebraElement_ak(*A*, *x*)

class PartitionAlgebraElement_bk(*A*, *x*)

class PartitionAlgebraElement_generic(*A*, *x*)

class PartitionAlgebraElement_pk(*A*, *x*)

class PartitionAlgebraElement_prk(*A*, *x*)

class PartitionAlgebraElement_rk(*A*, *x*)

class PartitionAlgebraElement_sk(*A*, *x*)

class PartitionAlgebraElement_tk(*A*, *x*)

class PartitionAlgebra_ak(*R*, *k*, *n*, *name=None*)

class PartitionAlgebra_bk(*R*, *k*, *n*, *name=None*)

class PartitionAlgebra_generic(*R*, *cclass*, *n*, *k*, *name=None*, *prefix=None*)

class PartitionAlgebra_pk(*R*, *k*, *n*, *name=None*)

class PartitionAlgebra_prk(*R*, *k*, *n*, *name=None*)

class **PartitionAlgebra_rk**(*R, k, n, name=None*)

class **PartitionAlgebra_sk**(*R, k, n, name=None*)

class **PartitionAlgebra_tk**(*R, k, n, name=None*)

class **SetPartitionsAk_k**(*k*)

class **SetPartitionsAkhalf_k**(*k*)

cardinality()

TESTS:

```
sage: SetPartitionsAk(1.5).cardinality()
5
sage: SetPartitionsAk(2.5).cardinality()
52
sage: SetPartitionsAk(3.5).cardinality()
877
```

class **SetPartitionsBk_k**(*k*)

cardinality()

Returns the number of set partitions in B_k where k is an integer. This is given by (2k)!! = (2k-1)*(2k-3)*...*5*3*1.

EXAMPLES:

```
sage: SetPartitionsBk(3).cardinality()
15
sage: SetPartitionsBk(2).cardinality()
3
sage: SetPartitionsBk(1).cardinality()
1
sage: SetPartitionsBk(4).cardinality()
105
sage: SetPartitionsBk(5).cardinality()
945
```

class **SetPartitionsBkhalf_k**(*k*)

cardinality()

TESTS:

```
sage: B3p5 = SetPartitionsBk(3.5)
sage: B3p5.cardinality()
15
```

class **SetPartitionsIk_k**(*k*)

cardinality()

TESTS:

```
sage: SetPartitionsIk(2).cardinality()
13
```

class **SetPartitionsIkhalf_k**(*k*)

cardinality()

TESTS:

```
sage: SetPartitionsIk(1.5).cardinality()
4
sage: SetPartitionsIk(2.5).cardinality()
50
sage: SetPartitionsIk(3.5).cardinality()
871
```

class SetPartitionsPRk_k(k)

cardinality()
TESTS:

```
sage: SetPartitionsPRk(2).cardinality()
6
sage: SetPartitionsPRk(3).cardinality()
20
sage: SetPartitionsPRk(4).cardinality()
70
sage: SetPartitionsPRk(5).cardinality()
252
```

class SetPartitionsPRkhalf_k(k)

cardinality()
TESTS:

```
sage: SetPartitionsPRk(2.5).cardinality()
6
sage: SetPartitionsPRk(3.5).cardinality()
20
sage: SetPartitionsPRk(4.5).cardinality()
70
```

class SetPartitionsPk_k(k)

cardinality()
TESTS:

```
sage: SetPartitionsPk(2).cardinality()
14
sage: SetPartitionsPk(3).cardinality()
132
sage: SetPartitionsPk(4).cardinality()
1430
```

class SetPartitionsPkhalf_k(k)

cardinality()
TESTS:

```
sage: SetPartitionsPk(2.5).cardinality()
42
sage: SetPartitionsPk(1.5).cardinality()
5
```

class SetPartitionsRk_k(k)

cardinality()
TESTS:

```
sage: SetPartitionsRk(2).cardinality()
7
sage: SetPartitionsRk(3).cardinality()
34
sage: SetPartitionsRk(4).cardinality()
209
sage: SetPartitionsRk(5).cardinality()
1546
```

class **SetPartitionsRkhalf_k**(k)

cardinality()
TESTS:

```
sage: SetPartitionsRk(2.5).cardinality()
7
sage: SetPartitionsRk(3.5).cardinality()
34
sage: SetPartitionsRk(4.5).cardinality()
209
```

class **SetPartitionsSk_k**(k)

cardinality()
Returns k!.
TESTS:

```
sage: SetPartitionsSk(2).cardinality()
2
sage: SetPartitionsSk(3).cardinality()
6
sage: SetPartitionsSk(4).cardinality()
24
sage: SetPartitionsSk(5).cardinality()
120
```

class **SetPartitionsSkhalf_k**(k)

cardinality()
TESTS:

```
sage: SetPartitionsSk(2.5).cardinality()
2
sage: SetPartitionsSk(3.5).cardinality()
6
sage: SetPartitionsSk(4.5).cardinality()
24

sage: ks = [2.5, 3.5, 4.5, 5.5]
sage: sks = [SetPartitionsSk(k) for k in ks]
sage: all([ sk.cardinality() == len(sk.list()) for sk in sks])
True
```

class **SetPartitionsTk_k**(k)

cardinality()
TESTS:

```
sage: SetPartitionsTk(2).cardinality()
2
sage: SetPartitionsTk(3).cardinality()
5
sage: SetPartitionsTk(4).cardinality()
14
sage: SetPartitionsTk(5).cardinality()
42
```

class **SetPartitionsTkhalf_k**(*k*)

cardinality()
TESTS:

```
sage: SetPartitionsTk(2.5).cardinality()
2
sage: SetPartitionsTk(3.5).cardinality()
5
sage: SetPartitionsTk(4.5).cardinality()
14
```

create_set_partition_function(*letter, k*)
EXAMPLES:

```
sage: from sage.combinat.partition_algebra import create_set_partition_function
sage: create_set_partition_function('A', 3)
Set partitions of {1, ..., 3, -1, ..., -3}
```

identity(*k*)
Returns the identity set partition 1, -1, ..., k, -k

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: pa.identity(2)
{{2, -2}, {1, -1}}
```

is_planar(*sp*)
Returns True if the diagram corresponding to the set partition is planar; otherwise, it returns False.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: pa.is_planar( pa.to_set_partition([[1,-2],[2,-1]]))
False
sage: pa.is_planar( pa.to_set_partition([[1,-1],[2,-2]]))
True
```

pair_to_graph(*sp1, sp2*)
Returns a graph consisting of the graphs of set partitions sp1 and sp2 along with edges joining the bottom row (negative numbers) of sp1 to the top row (positive numbers) of sp2.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = pa.to_set_partition([[1,-2],[2,-1]])
```

```
sage: g = pa.pair_to_graph( sp1, sp2 ); g
Graph on 8 vertices

sage: g.vertices() #random
[(1, 2), (-1, 1), (-2, 2), (-1, 2), (-2, 1), (2, 1), (2, 2), (1, 1)]
sage: g.edges() #random
[((1, 2), (-1, 1), None),
 ((1, 2), (-2, 2), None),
 ((-1, 1), (2, 1), None),
 ((-1, 2), (2, 2), None),
 ((-2, 1), (1, 1), None),
 ((-2, 1), (2, 2), None)]
```

propagating_number(*sp*)

Returns the propagating number of the set partition sp. The propagating number is the number of blocks with both a positive and negative number.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = pa.to_set_partition([[1,2],[-2,-1]])
sage: pa.propagating_number(sp1)
2
sage: pa.propagating_number(sp2)
0
```

set_partition_composition(*sp1, sp2*)

Returns a tuple consisting of the composition of the set partitions sp1 and sp2 and the number of components removed from the middle rows of the graph.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = pa.to_set_partition([[1,-2],[2,-1]])
sage: pa.set_partition_composition(sp1, sp2) == (pa.identity(2), 0)
True
```

to_graph(*sp*)

Returns a graph representing the set partition sp.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: g = pa.to_graph( pa.to_set_partition([[1,-2],[2,-1]])); g
Graph on 4 vertices

sage: g.vertices() #random
[1, 2, -2, -1]
sage: g.edges() #random
[(1, -2, None), (2, -1, None)]
```

to_set_partition(*l, k=None*)

Coverts a list of a list of numbers to a set partitions. Each list of numbers in the outer list specifies the numbers contained in one of the blocks in the set partition.

If k is specified, then the set partition will be a set partition of 1, ..., k, -1, ..., -k. Otherwise, k will default to the minimum number needed to contain all of the specified numbers.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: pa.to_set_partition([[1,-1],[2,-2]]) == pa.identity(2)
True
```

17.32 Tableaux and Tableaux-like Objects

17.32.1 Tableaux

SemistandardTableaux(*p=None, mu=None*)

Returns the combinatorial class of semistandard tableaux.

If p is specified and is a partition, then it returns the class of semistandard tableaux of shape p (and max entry sum(p))

If p is specified and is an integer, it returns the class of semistandard tableaux of size p.

If mu is also specified, then it returns the class of semistandard tableaux with evaluation/content mu.

EXAMPLES:

```
sage: SST = SemistandardTableaux([2,1]); SST
Semistandard tableaux of shape [2, 1]
sage: SST.list()
[[[1, 1], [2]],
 [[1, 1], [3]],
 [[1, 2], [2]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[1, 3], [3]],
 [[2, 2], [3]],
 [[2, 3], [3]]]
```

```
sage: SST = SemistandardTableaux(3); SST
Semistandard tableaux of size 3
sage: SST.list()
[[[1, 1, 1]],
 [[1, 1, 2]],
 [[1, 1, 3]],
 [[1, 2, 2]],
 [[1, 2, 3]],

class **SemistandardTableaux_all**()

list()
TESTS:

```
sage: SemistandardTableaux().list()
...
NotImplementedError
```

class **SemistandardTableaux_n**(*n*)

cardinality()
EXAMPLES:

```
sage: SemistandardTableaux(3).cardinality()
19
sage: SemistandardTableaux(4).cardinality()
116
sage: ns = range(1, 6)
sage: ssts = [ SemistandardTableaux(n) for n in ns ]
sage: all([sst.cardinality() == len(sst.list()) for sst in ssts])
True
```

object_class()

class **SemistandardTableaux_nmu**(*n*, *mu*)

cardinality()
EXAMPLES:

```
sage: SemistandardTableaux(3, [2,1]).cardinality()
2
sage: SemistandardTableaux(4, [2,2]).cardinality()
3
```

class **SemistandardTableaux_p**(*p*)

cardinality()
EXAMPLES:

```
sage: SemistandardTableaux([2,1]).cardinality()
8
sage: SemistandardTableaux([2,2,1]).cardinality()
75
sage: s = SFASchur(QQ)
sage: s([2,2,1]).expand(5)(1,1,1,1,1)
75
sage: SemistandardTableaux([5]).cardinality()
126
sage: SemistandardTableaux([3,2,1]).cardinality()
896
```

object_class()

class **SemistandardTableaux_pmu**(*p*, *mu*)

cardinality()

EXAMPLES:

```
sage: SemistandardTableaux([2,2], [2, 1, 1]).cardinality()
1
sage: SemistandardTableaux([2,2,2], [2, 2, 1,1]).cardinality()
1
sage: SemistandardTableaux([2,2,2], [2, 2, 2]).cardinality()
1
sage: SemistandardTableaux([3,2,1], [2, 2, 2]).cardinality()
2
```

list()

EXAMPLES:

```
sage: SemistandardTableaux([2,2], [2, 1, 1]).list()
[[[1, 1], [2, 3]]]
sage: SemistandardTableaux([2,2,2], [2, 2, 1,1]).list()
[[[1, 1], [2, 2], [3, 4]]]
sage: SemistandardTableaux([2,2,2], [2, 2, 2]).list()
[[[1, 1], [2, 2], [3, 3]]]
sage: SemistandardTableaux([3,2,1], [2, 2, 2]).list()
[[[1, 1, 2], [2, 3], [3]], [[1, 1, 3], [2, 2], [3]]]
```

object_class()

StandardTableau(t)

Returns the standard tableau object corresponding to t.

Note that Sage uses the English convention for partitions and tableaux.

EXAMPLES:

```
sage: t = StandardTableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.shape()
[3, 2]
sage: t.is_standard()
True

sage: t = StandardTableau([[1,2,3],[4,4]])
...
ValueError: not a standard tableau
```

class **StandardTableau_class**(t)

content(k)

Returns the content of k in a standard tableau. That is, if k appears in row r and column c of the tableau then we return $c - r$.

EXAMPLES:

```
sage: StandardTableau([[1,2],[3,4]]).content(3)
-1

sage: StandardTableau([[1,2],[3,4]]).content(6)
...
ValueError: 6 does not appear in tableau
```

StandardTableaux(*n=None*)

Returns the combinatorial class of standard tableaux. If n is specified and is an integer, then it returns the combinatorial class of all standard tableaux of size n. If n is a partition, then it returns the class of all standard tableaux of shape n.

EXAMPLES:

```
sage: ST = StandardTableaux(3); ST
Standard tableaux of size 3
sage: ST.first()
[[1, 2, 3]]
sage: ST.last()
[[1], [2], [3]]
sage: ST.cardinality()
4
sage: ST.list()
[[[1, 2, 3]], [[1, 3], [2]], [[1, 2], [3]], [[1], [2], [3]]]

sage: ST = StandardTableaux([2,2]); ST
Standard tableaux of shape [2, 2]
sage: ST.first()
[[1, 3], [2, 4]]
sage: ST.last()
[[1, 2], [3, 4]]
sage: ST.cardinality()
2
sage: ST.list()
[[[1, 3], [2, 4]], [[1, 2], [3, 4]]]
```

class **StandardTableaux_all**()

class **StandardTableaux_n**(*n*)

cardinality()

EXAMPLES:

```
sage: StandardTableaux(3).cardinality()
4
sage: ns = [1,2,3,4,5,6]
sage: sts = [StandardTableaux(n) for n in ns]
sage: all([st.cardinality() == len(st.list()) for st in sts])
True
```

object_class()

class **StandardTableaux_partition**(*p*)

cardinality()

Returns the number of standard Young tableaux associated with a partition pi

A formula for the number of Young tableaux associated with a given partition. In each box, write the sum of one plus the number of boxes horizontally to the right and vertically below the box (the hook length). The number of tableaux is then n! divided by the product of all hook lengths.

For example, consider the partition [3,2,1] of 6 with Ferrers Diagram:

```
# # #
# #
#
```

When we fill in the boxes with the hook lengths, we obtain:

```
5 3 1
3 1
1
```

The hook length formula returns 6!/(5*3*1*3*1*1) = 16.

EXAMPLES:

```
sage: StandardTableaux([3,2,1]).cardinality()
16
sage: StandardTableaux([2,2]).cardinality()
2
sage: StandardTableaux([5]).cardinality()
1
sage: StandardTableaux([6,5,5,3]).cardinality()
6651216
```

REFERENCES:

- http://mathworld.wolfram.com/HookLengthFormula.html

list()

Returns a list of the standard Young tableau associated with a partition p.

EXAMPLES:

```
sage: StandardTableaux([2,2]).list()
[[[1, 3], [2, 4]], [[1, 2], [3, 4]]]
sage: StandardTableaux([5]).list()
[[[1, 2, 3, 4, 5]]]
sage: StandardTableaux([3,2,1]).list()
[[[1, 4, 6], [2, 5], [3]],
 [[1, 3, 6], [2, 5], [4]],
 [[1, 2, 6], [3, 5], [4]],
 [[1, 3, 6], [2, 4], [5]],
 [[1, 2, 6], [3, 4], [5]],
 [[1, 4, 5], [2, 6], [3]],
 [[1, 3, 5], [2, 6], [4]],
 [[1, 2, 5], [3, 6], [4]],
 [[1, 3, 4], [2, 6], [5]],
 [[1, 2, 4], [3, 6], [5]],
 [[1, 2, 3], [4, 6], [5]],
 [[1, 3, 5], [2, 4], [6]],
 [[1, 2, 5], [3, 4], [6]],
 [[1, 3, 4], [2, 5], [6]],
 [[1, 2, 4], [3, 5], [6]],
 [[1, 2, 3], [4, 5], [6]]]
```

random_element()

Returns a random standard tableau of shape p using the Green-Nijenhuis-Wilf Algorithm.

EXAMPLES:

```
sage: StandardTableaux([2,2]).random_element()
[[1, 2], [3, 4]]
```

Tableau(*t*)

Returns the tableau object corresponding to t.

Note that Sage uses the English convention for partitions and tableaux.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.shape()
[3, 2]
sage: t.is_standard()
True
```

class Tableau_class(*t*)

anti_restrict(*n*)

Returns the skew tableau formed by removing all of the boxes from self that are filled with a number less than

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.anti_restrict(1)
[[None, 2, 3], [4, 5]]
sage: t.anti_restrict(2)
[[None, None, 3], [4, 5]]
sage: t.anti_restrict(3)
[[None, None, None], [4, 5]]
sage: t.anti_restrict(4)
[[None, None, None], [None, 5]]
```

atom()

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).atom()
[2, 2]
sage: Tableau([[1,2,3],[4,5],[6]]).atom()
[3, 2, 1]
```

attacking_pairs()

Returns a list of the attacking pairs of self. An pair of boxes (c, d) is said to be attacking if one of the following conditions hold:

1.c and d lie in the same row with c to the west of d

2.c is in the row immediately to the south of d and c lies strictly east of d.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[2,5]])
sage: t.attacking_pairs()
[((0, 0), (0, 1)),
 ((0, 0), (0, 2)),
 ((0, 1), (0, 2)),
 ((1, 0), (1, 1)),
 ((1, 1), (0, 0))]
```

boxes()

Returns a list of the coordinates of the boxes of self.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).boxes()
[(0, 0), (0, 1), (1, 0), (1, 1)]
```

bump(*x*)

Schensted's row-bumping (or row-insertion) algorithm.

EXAMPLES:

```
sage: t = Tableau([[1,2],[3]])
sage: t.bump(1)
[[1, 1], [2], [3]]
sage: t
[[1, 2], [3]]
sage: t.bump(2)
[[1, 2, 2], [3]]
sage: t.bump(3)
[[1, 2, 3], [3]]
sage: t
[[1, 2], [3]]
sage: t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t.bump(2)
[[1, 2, 2, 2], [2, 3, 3, 5], [4, 4, 5], [5, 6, 6]]
```

bump_multiply(*left, right*)

Multiply two tableaux using Schensted's bump.

This product makes the set of tableaux into an associative monoid. The empty tableaux is the unit in this monoid.

Fulton, William. 'Young Tableaux' p11-12

EXAMPLES:

```
sage: t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t2 = Tableau([[1,2],[3]])
sage: t.bump_multiply(t2)
[[1, 1, 2, 2, 3], [2, 2, 3, 5], [3, 4, 5], [4, 6, 6], [5]]
```

charge()

EXAPMLES:

```
sage: Tableau([[1,1],[2,2],[3]]).charge()
0
sage: Tableau([[1,1,3],[2,2]]).charge()
1
sage: Tableau([[1,1,2],[2],[3]]).charge()
1
sage: Tableau([[1,1,2],[2,3]]).charge()
2
sage: Tableau([[1,1,2,3],[2]]).charge()
2
sage: Tableau([[1,1,2,2],[3]]).charge()
3
sage: Tableau([[1,1,2,2,3]]).charge()
4
```

cocharge()

EXAPMLES:

```
sage: Tableau([[1,1],[2,2],[3]]).cocharge()
4
sage: Tableau([[1,1,3],[2,2]]).cocharge()
3
sage: Tableau([[1,1,2],[2],[3]]).cocharge()
2
sage: Tableau([[1,1,2],[2,3]]).cocharge()
2
sage: Tableau([[1,1,2,3],[2]]).cocharge()
1
sage: Tableau([[1,1,2,2],[3]]).cocharge()
```

```
1
sage: Tableau([[1,1,2,2,3]]).cocharge()
0
```

column_stabilizer()
Return the PermutationGroup corresponding to the column stabilizer of self.
EXAMPLES:

```
sage: cs = Tableau([[1,2,3],[4,5]]).column_stabilizer()
sage: cs.order() == factorial(2)*factorial(2)
True
sage: PermutationGroupElement([(1,3,2),(4,5)]) in cs
False
sage: PermutationGroupElement([(1,4)]) in cs
True
```

conjugate()
Returns the conjugate of the tableau t.
EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).conjugate()
[[1, 3], [2, 4]]
```

corners()
Returns the corners of the tableau t.
EXAMPLES:

```
sage: Tableau([[1, 4, 6], [2, 5], [3]]).corners()
[[0, 2], [1, 1], [2, 0]]
sage: Tableau([[1, 3], [2, 4]]).corners()
[[1, 1]]
```

descents()
Returns a list of the boxes (i,j) such that self[i][j] > self[i-1][j].
EXAMPLES:

```
sage: Tableau( [[1,4],[2,3]] ).descents()
[(1, 0)]
sage: Tableau( [[1,2],[3,4]] ).descents()
[(1, 0), (1, 1)]
```

down()
An iterator for all the tableaux that can be obtained from self by removing a box. Note that this iterates just over a single tableaux. EXAMPLES:

```
sage: t = Tableau([[1,2],[3]])
sage: [x for x in t.down()]
[[[1, 2]]]
```

down_list()
Returns a list of all the tableaux that can be obtained from self by removing a box. Note that this is just a single tableaux.
EXAMPLES:

```
sage: t = Tableau([[1,2],[3]])
sage: t.down_list()
[[[1, 2]]]
```

entry(*box*)
Returns the entry of box in self. Box is a tuple (i,j) of coordinates.

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,4]])
sage: t.entry( (0,0) )
1
sage: t.entry( (1,1) )
4
```

evaluation()

Returns the evaluation of the word from tableau t.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).evaluation()
[1, 1, 1, 1]
```

height()

Returns the height of the tableau.

EXAMPLES:

```
sage: Tableau([[1,2,3],[4,5]]).height()
2
sage: Tableau([[1,2,3]]).height()
1
sage: Tableau([]).height()
0
```

insert_word(*w, left=False*)

EXAMPLES:

```
sage: t0 = Tableau([])
sage: w = [1,1,2,3,3,3,3]
sage: t0.insert_word(w)
[[1, 1, 2, 3, 3, 3, 3]]
sage: t0.insert_word(w,left=True)
[[1, 1, 2, 3, 3, 3, 3]]
sage: w.reverse()
sage: t0.insert_word(w)
[[1, 1, 3, 3], [2, 3], [3]]
sage: t0.insert_word(w,left=True)
[[1, 1, 3, 3], [2, 3], [3]]
```

inversion_number()

Returns the inversion number of self.

The inversion number is defined to be the number of inversion of self minus the sum of the arm lengths of the descents of self.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[2,5]])
sage: t.inversion_number()
0
```

inversions()

Returns a list of the inversions of self. An inversion is an attacking pair (c,d) such that the entry of c in self is greater than the entry of d.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[2,5]])
sage: t.inversions()
[((1, 1), (0, 0))]
```

is_rectangular()
Returns True if the tableau t is rectangular and False otherwise.
EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).is_rectangular()
True
sage: Tableau([[1,2,3],[4,5],[6]]).is_rectangular()
False
```

is_standard()
Returns True if t is a standard tableau and False otherwise.
EXAMPLES:

```
sage: Tableau([[1, 3], [2, 4]]).is_standard()
True
sage: Tableau([[1, 2], [2, 4]]).is_standard()
False
sage: Tableau([[2, 3], [2, 4]]).is_standard()
False
sage: Tableau([[5, 3], [2, 4]]).is_standard()
False
```

k_weight(*k*)
Returns the k-weight of self.
EXAMPLES:

```
sage: Tableau([[1,2],[2,3]]).k_weight(1)
[1, 1, 1]
sage: Tableau([[1,2],[2,3]]).k_weight(2)
[1, 2, 1]
sage: t = Tableau([[1,1,1,2,5],[2,3,6],[3],[4]])
sage: t.k_weight(1)
[2, 1, 1, 1, 1, 1]
sage: t.k_weight(2)
[3, 2, 2, 1, 1, 1]
sage: t.k_weight(3)
[3, 1, 2, 1, 1, 1]
sage: t.k_weight(4)
[3, 2, 2, 1, 1, 1]
sage: t.k_weight(5)
[3, 2, 2, 1, 1, 1]
```

katabolism()
EXAMPLES:

```
sage: Tableau([]).katabolism()
[]
sage: Tableau([[1,2,3,4,5]]).katabolism()
[[1, 2, 3, 4, 5]]
sage: Tableau([[1,1,3,3],[2,3],[3]]).katabolism()
[[1, 1, 2, 3, 3, 3], [3]]
sage: Tableau([[1, 1, 2, 3, 3, 3], [3]]).katabolism()
[[1, 1, 2, 3, 3, 3, 3]]
```

katabolism_projector(*parts*)
EXAMPLES:

```
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.katabolism_projector([[4,2,1]])
[[1, 1, 3, 3], [2, 3], [3]]
```

```
sage: t.katabolism_projector([[1]])
[]
sage: t.katabolism_projector([[2,1],[1]])
[]
sage: t.katabolism_projector([[1,1],[4,1]])
[[1, 1, 3, 3], [2, 3], [3]]
```

katabolism_sequence()

EXAMPLES:

```
sage: t = Tableau([[1,2,3,4,5,6,8],[7,9]])
sage: t.katabolism_sequence()
[[[1, 2, 3, 4, 5, 6, 8], [7, 9]],
 [[1, 2, 3, 4, 5, 6, 7, 9], [8]],
 [[1, 2, 3, 4, 5, 6, 7, 8], [9]],
 [[1, 2, 3, 4, 5, 6, 7, 8, 9]]]
```

lambda_katabolism(*part*)

EXAMPLES:

```
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.lambda_katabolism([])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.lambda_katabolism([1])
[[1, 2, 3, 3, 3], [3]]
sage: t.lambda_katabolism([1,1])
[[1, 3, 3, 3], [3]]
sage: t.lambda_katabolism([2,1])
[[3, 3, 3, 3]]
sage: t.lambda_katabolism([4,2,1])
[]
sage: t.lambda_katabolism([5,1])
[[3, 3]]
sage: t.lambda_katabolism([4,1])
[[3, 3]]
```

last_letter_lequal(*tab2*)

Returns True if self is less than or equal to tab2 in the last letter ordering.

EXAMPLES:

```
sage: st = StandardTableaux([3,2])
sage: f = lambda b: 1 if b else 0
sage: matrix( [ [ f(t1.last_letter_lequal(t2)) for t2 in st] for t1 in st] )
[1 1 1 1 1]
[0 1 1 1 1]
[0 0 1 1 1]
[0 0 0 1 1]
[0 0 0 0 1]
```

major_index()

Returns the major index of self. The major index is defined to be the sum of the number of descents of self and the sum of their legs.

EXAMPLES

```
sage: Tableau( [[1,4],[2,3]] ).major_index()
1
sage: Tableau( [[1,2],[3,4]] ).major_index()
2
```

pp()

Returns a pretty print string of the tableau.

EXAMPLES:

```
sage: Tableau([[1,2,3],[3,4],[5]]).pp()
  1  2  3
  3  4
  5
```

promotion(*n*)

Promotion operator defined on rectangular tableaux using jeu de taquin

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,3]])
sage: t.promotion(2)
[[1, 1], [2, 3]]
sage: t = Tableau([[1,1,1],[2,2,3],[3,4,4]])
sage: t.promotion(3)
[[1, 1, 2], [2, 2, 3], [3, 4, 4]]
sage: t = Tableau([[1,2],[2]])
sage: t.promotion(3)
...
ValueError: Tableau is not rectangular
```

promotion_inverse(*n*)

Inverse promotion operator defined on rectangular tableaux using jeu de taquin

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,3]])
sage: t.promotion_inverse(2)
[[1, 2], [2, 3]]
sage: t = Tableau([[1,2],[2,3]])
sage: t.promotion_inverse(2)
[[1, 1], [2, 3]]
```

promotion_operator(*i*)

EXAMPLES:

```
sage: t = Tableau([[1,2],[3]])
sage: t.promotion_operator(1)
[[[1, 2], [3], [4]], [[1, 2], [3, 4]], [[1, 2, 4], [3]]]
sage: t.promotion_operator(2)
[[[1, 1], [2, 3], [4]],
 [[1, 1, 2], [3], [4]],
 [[1, 1, 4], [2, 3]],
 [[1, 1, 2, 4], [3]]]
sage: Tableau([[1]]).promotion_operator(2)
[[[1, 1], [2]], [[1, 1, 2]]]
sage: Tableau([[1,1],[2]]).promotion_operator(3)
[[[1, 1, 1], [2, 2], [3]],
 [[1, 1, 1, 2], [2], [3]],
 [[1, 1, 1, 3], [2, 2]],
 [[1, 1, 1, 2, 3], [2]]]
```

TESTS:

```
sage: Tableau([]).promotion_operator(2)
[[[1, 1]]]
sage: Tableau([]).promotion_operator(1)
[[[1]]]
```

raise_action_from_words(*f*, **args*)

EXAMPLES:

```
sage: from sage.combinat.tableau import symmetric_group_action_on_values
sage: import functools
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: f = functools.partial(t.raise_action_from_words, symmetric_group_action_on_values)
sage: f([1,2,3])
[[1, 1, 3, 3], [2, 3], [3]]
sage: f([3,2,1])
[[1, 1, 1, 1], [2, 3], [3]]
sage: f([1,3,2])
[[1, 1, 2, 2], [2, 2], [3]]
```

reduced_lambda_katabolism(*part*)

EXAMPLES:

```
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.reduced_lambda_katabolism([])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.reduced_lambda_katabolism([1])
[[1, 2, 3, 3, 3], [3]]
sage: t.reduced_lambda_katabolism([1,1])
[[1, 3, 3, 3], [3]]
sage: t.reduced_lambda_katabolism([2,1])
[[3, 3, 3, 3]]
sage: t.reduced_lambda_katabolism([4,2,1])
[]
sage: t.reduced_lambda_katabolism([5,1])
0
sage: t.reduced_lambda_katabolism([4,1])
0
```

restrict(*n*)

Returns the restriction of the standard tableau to n.

EXAMPLES:

```
sage: Tableau([[1,2],[3],[4]]).restrict(3)
[[1, 2], [3]]
sage: Tableau([[1,2],[3],[4]]).restrict(2)
[[1, 2]]
sage: Tableau([[1,1],[2]]).restrict(1)
[[1, 1]]
```

rotate_180()

Returns the tableau obtained by rotating t by 180 degrees.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).rotate_180()
[[4, 3], [2, 1]]
```

row_stabilizer()

Return the PermutationGroup corresponding to the row stabilizer of self.

EXAMPLES:

```
sage: rs = Tableau([[1,2,3],[4,5]]).row_stabilizer()
sage: rs.order() == factorial(3)*factorial(2)
True
sage: PermutationGroupElement([(1,3,2),(4,5)]) in rs
True
```

```
sage: PermutationGroupElement([(1,4)]) in rs
False
sage: rs = Tableau([[1],[2],[3]]).row_stabilizer()
sage: rs.order()
1
```

schensted_insert(*i, left=False*)

EXAMPLES:

```
sage: t = Tableau([[3,5],[7]])
sage: t.schensted_insert(8)
[[3, 5, 8], [7]]
sage: t.schensted_insert(8, left=True)
[[3, 5], [7], [8]]
```

shape()

Returns the shape of a tableau t.

EXAMPLES:

```
sage: Tableau([[1,2,3],[4,5],[6]]).shape()
[3, 2, 1]
```

size()

Returns the size of the shape of the tableau t.

EXAMPLES:

```
sage: Tableau([[1, 4, 6], [2, 5], [3]]).size()
6
sage: Tableau([[1, 3], [2, 4]]).size()
4
```

slide_multiply(*left, right*)

Multiply two tableaux using jeu de taquin.

This product makes the set of tableaux into an associative monoid. The empty tableaux is the unit in this monoid.

Fulton, William. 'Young Tableaux' p15

EXAMPLES:

```
sage: t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t2 = Tableau([[1,2],[3]])
sage: t.slide_multiply(t2)
[[1, 1, 2, 2, 3], [2, 2, 3, 5], [3, 4, 5], [4, 6, 6], [5]]
```

socle()

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).socle()
2
sage: Tableau([[1,2,3,4]]).socle()
4
```

symmetric_group_action_on_values(*perm*)

EXAMPLES:

```
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.symmetric_group_action_on_values([1,2,3])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.symmetric_group_action_on_values([3,2,1])
[[1, 1, 1, 1], [2, 3], [3]]
```

```
sage: t.symmetric_group_action_on_values([1,3,2])
[[1, 1, 2, 2], [2, 2], [3]]
```

to_chain()

Returns the chain of partitions corresponding to the (semi)standard tableau.

EXAMPLES:

```
sage: Tableau([[1,2],[3],[4]]).to_chain()
[[], [1], [2], [2, 1], [2, 1, 1]]
sage: Tableau([[1,1],[2]]).to_chain()
[[], [2], [2, 1]]
sage: Tableau([[1,1],[3]]).to_chain()
[[], [2], [2], [2, 1]]
sage: Tableau([]).to_chain()
[[]]
```

to_list()

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,4]])
sage: l = t.to_list(); l
[[1, 2], [3, 4]]
sage: l[0][0] = 2
sage: t
[[1, 2], [3, 4]]
```

to_permutation()

Returns a permutation with the entries of self obtained by reading self in the reading order.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).to_permutation()
[3, 4, 1, 2]
```

to_word()

An alias for to_word_by_row.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).to_word()
word: 3412
sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word()
word: 325146
```

to_word_by_column()

Returns the word obtained from a column reading of the tableau t.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).to_word_by_column()
word: 3142
sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word_by_column()
word: 321546
```

to_word_by_row()

Returns a word obtained from a row reading of the tableau t.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).to_word_by_row()
word: 3412
sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word_by_row()
word: 325146
```

up()
An iterator for all the tableaux that can be obtained from self by adding a box. EXAMPLES:

```
sage: t = Tableau([[1,2]])
sage: [x for x in t.up()]
[[[1, 2, 3]], [[1, 2], [3]]]
```

up_list()
Returns a list of all the tableaux that can be obtained from self by adding a box.
EXAMPLES:

```
sage: t = Tableau([[1,2]])
sage: t.up_list()
[[[1, 2, 3]], [[1, 2], [3]]]
```

vertical_flip()
Returns the tableau obtained by vertically flipping the tableau t. This only works for rectangular tableau.
EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).vertical_flip()
[[3, 4], [1, 2]]
```

weight()
Returns the evaluation of the word from tableau t.
EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).evaluation()
[1, 1, 1, 1]
```

Tableaux(*n=None*)
Returns the combinatorial class of tableaux. If n is specified, then it returns the combinatorial class of all tableaux of size n.
EXAMPLES:

```
sage: T = Tableaux(); T
Tableaux
sage: [[1,2],[3,4]] in T
True
sage: [[1,2],[3]] in T
True
sage: [1,2,3] in T
False

sage: T = Tableaux(4); T
Tableaux of size 4
sage: [[1,2],[3,4]] in T
True
sage: [[1,2],[3]] in T
False
sage: [1,2,3] in T
False
```

class **Tableaux_all**()

list()
TESTS:

```
sage: Tableaux().list()
...
NotImplementedError
```

class Tableaux_n(*n*)

list()

TESTS:

```
sage: Tableaux(3).list()
...
NotImplementedError
```

from_chain(*chain*)

Returns a semistandard tableau from a chain of partitions.

EXAMPLES:

```
sage: from sage.combinat.tableau import from_chain
sage: from_chain([[], [2], [2, 1], [3, 2, 1]])
[[1, 1, 3], [2, 3], [3]]
```

from_shape_and_word(*shape, w*)

Returns a tableau from a shape and word.

EXAMPLES:

```
sage: from sage.combinat.tableau import from_shape_and_word
sage: t = Tableau([[1, 3], [2], [4]])
sage: shape = t.shape(); shape
[2, 1, 1]
sage: word  = t.to_word(); word
word: 4213
sage: from_shape_and_word(shape, word)
[[1, 3], [2], [4]]
```

symmetric_group_action_on_values(*word, perm*)

EXAMPLES:

```
sage: from sage.combinat.tableau import symmetric_group_action_on_values
sage: symmetric_group_action_on_values([1,1,1],[1,3,2])
[1, 1, 1]
sage: symmetric_group_action_on_values([1,1,1],[2,1,3])
[2, 2, 2]
sage: symmetric_group_action_on_values([1,2,1],[2,1,3])
[2, 2, 1]
sage: symmetric_group_action_on_values([2,2,2],[2,1,3])
[1, 1, 1]
sage: symmetric_group_action_on_values([2,1,2],[2,1,3])
[2, 1, 1]
sage: symmetric_group_action_on_values([2,2,3,1,1,2,2,3],[1,3,2])
[2, 3, 3, 1, 1, 2, 3, 3]
sage: symmetric_group_action_on_values([2,1,1],[2,1])
[2, 1, 2]
sage: symmetric_group_action_on_values([2,2,1],[2,1])
[1, 2, 1]
sage: symmetric_group_action_on_values([1,2,1],[2,1])
[2, 2, 1]
```

unmatched_places(*w, open, close*)

EXAMPLES:

```
sage: from sage.combinat.tableau import unmatched_places
sage: unmatched_places([2,2,2,1,1,1],2,1)
([], [])
sage: unmatched_places([1,1,1,2,2,2],2,1)
([0, 1, 2], [3, 4, 5])
sage: unmatched_places([], 2, 1)
([], [])
sage: unmatched_places([1,2,4,6,2,1,5,3],2,1)
([0], [1])
sage: unmatched_places([2,2,1,2,4,6,2,1,5,3], 2, 1)
([], [0, 3])
sage: unmatched_places([3,1,1,1,2,1,2], 2, 1)
([1, 2, 3], [6])
```

17.32.2 Skew Tableaux

SemistandardSkewTableaux(*p=None, mu=None*)

Returns a combinatorial class of semistandard skew tableaux.

EXAMPLES:

```
sage: SemistandardSkewTableaux()
Semistandard skew tableaux
```

```
sage: SemistandardSkewTableaux(3)
Semistandard skew tableaux of size 3
```

```
sage: SemistandardSkewTableaux([[2,1],[]])
Semistandard skew tableaux of shape [[2, 1], []]
```

```
sage: SemistandardSkewTableaux([[2,1],[]],[2,1])
Semistandard skew tableaux of shape [[2, 1], []] and weight [2, 1]
```

```
sage: SemistandardSkewTableaux(3, [2,1])
Semistandard skew tableaux of size 3 and weight [2, 1]
```

class **SemistandardSkewTableaux_all**()

class **SemistandardSkewTableaux_n**(*n*)

cardinality()

EXAMPLES:

```
sage: SemistandardSkewTableaux(2).cardinality()
8
```

class **SemistandardSkewTableaux_nmu**(*n, mu*)

cardinality()

EXAMPLES:

```
sage: SemistandardSkewTableaux(2,[1,1]).cardinality()
4
```

class SemistandardSkewTableaux_p(*p*)

cardinality()
EXAMPLES:

```
sage: SemistandardSkewTableaux([[2,1],[]]).cardinality()
8
```

class SemistandardSkewTableaux_pmu(*p, mu*)

list()
EXAMPLES:

```
sage: SemistandardSkewTableaux([[2,1],[]],[2,1]).list()
[[[1, 1], [2]]]
```

SkewTableau(*st=None, expr=None*)
Returns the skew tableau object corresponding to st.

Note that Sage uses the English convention for partitions and tableaux.

EXAMPLES:

```
sage: st = SkewTableau([[None, 1],[2,3]]); st
[[None, 1], [2, 3]]
sage: st.inner_shape()
[1]
sage: st.outer_shape()
[2, 2]
```

The expr form of a skew tableau consists of the inner partition followed by a list of the entries in row from bottom to top.

```
sage: SkewTableau(expr=[[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

class SkewTableau_class(*t*)

boxes()
Returns on the entries in self with content c.
EXAMPLES:

```
sage: s = SkewTableau([[None,1,2],[3],[6]])
sage: s.boxes()
[(0, 1), (0, 2), (1, 0), (2, 0)]
```

boxes_by_content(*c*)
Returns the coordinates of the boxes in self with content c.

```
sage: s = SkewTableau([[None,1,2],[3,4,5],[6]])
sage: s.boxes_by_content(0)
[(1, 1)]
sage: s.boxes_by_content(1)
[(0, 1), (1, 2)]
sage: s.boxes_by_content(2)
```

```
[(0, 2)]
sage: s.boxes_by_content(-1)
[(1, 0)]
sage: s.boxes_by_content(-2)
[(2, 0)]
```

conjugate()
Returns the conjugate of the skew tableau.
EXAMPLES:

```
sage: SkewTableau([[None,1],[2,3]]).conjugate()
[[None, 2], [1, 3]]
```

entries_by_content(*c*)
Returns on the entries in self with content c.
EXAMPLES:

```
sage: s = SkewTableau([[None,1,2],[3,4,5],[6]])
sage: s.entries_by_content(0)
[4]
sage: s.entries_by_content(1)
[1, 5]
sage: s.entries_by_content(2)
[2]
sage: s.entries_by_content(-1)
[3]
sage: s.entries_by_content(-2)
[6]
```

evaluation()
Returns the evaluation of the word from skew tableau.
EXAMPLES:

```
sage: SkewTableau([[1,2],[3,4]]).evaluation()
[1, 1, 1, 1]
```

filling()
Returns a list of the non-empty entries in self.
EXAMPLES:

```
sage: t = SkewTableau([[None,1],[2,3]])
sage: t.filling()
[[1], [2, 3]]
```

inner_shape()
Returns the inner shape of the tableau.
EXAMPLES:

```
sage: SkewTableau([[None,1,2],[None,3],[4]]).inner_shape()
[1, 1]
```

inner_size()
Returns the size of the inner shape of the skew tableau.
EXAMPLES:

```
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).inner_size()
2
sage: SkewTableau([[None, 2], [1, 3]]).inner_size()
1
```

is_ribbon()

Returns True if and only if self is a ribbon, that is if it has no 2x2 boxes.

EXAMPLES:

```
sage: SkewTableau([[None,1],[2,3]]).is_ribbon()
True
sage: SkewTableau([[None,1,2],[3,4,5]]).is_ribbon()
False
```

is_semistandard()

Returns True if self is a semistandard skew tableau and False otherwise.

EXAMPLES:

```
sage: SkewTableau([[None, 2, 2], [1, 3]]).is_semistandard()
True
sage: SkewTableau([[None, 2], [2, 4]]).is_semistandard()
True
sage: SkewTableau([[None, 3], [2, 4]]).is_semistandard()
True
sage: SkewTableau([[None, 2], [1, 2]]).is_semistandard()
False
```

is_standard()

Returns True if self is a standard skew tableau and False otherwise.

EXAMPLES:

```
sage: SkewTableau([[None, 2], [1, 3]]).is_standard()
True
sage: SkewTableau([[None, 2], [2, 4]]).is_standard()
False
sage: SkewTableau([[None, 3], [2, 4]]).is_standard()
False
sage: SkewTableau([[None, 2], [2, 4]]).is_standard()
False
```

outer_shape()

Returns the outer shape of the tableau.

EXAMPLES:

```
sage: SkewTableau([[None,1,2],[None,3],[4]]).outer_shape()
[3, 2, 1]
```

outer_size()

Returns the size of the outer shape of the skew tableau.

EXAMPLES:

```
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).outer_size()
6
sage: SkewTableau([[None, 2], [1, 3]]).outer_size()
4
```

pp()

Returns a pretty print string of the tableau.

EXAMPLES:

```
sage: SkewTableau([[None,2,3],[None,4],[5]]).pp()
  .  2  3
  .  4
  5
```

rectify()

Returns a Tableau formed by applying the jeu de taquin process to self.

Fulton, William. 'Young Tableaux'. p15

EXAMPLES:

```
sage: s = SkewTableau([[None,1],[2,3]])
sage: s.rectify()
[[1, 3], [2]]
```

restrict(*n*)

Returns the restriction of the (semi)standard skew tableau to all the numbers less than or equal to n.

EXAMPLES:

```
sage: SkewTableau([[None,1],[2],[3]]).restrict(2)
[[None, 1], [2]]
sage: SkewTableau([[None,1],[2],[3]]).restrict(1)
[[None, 1]]
sage: SkewTableau([[None,1],[1],[2]]).restrict(1)
[[None, 1], [1]]
```

shape()

Returns the shape of a tableau t.

EXAMPLES:

```
sage: SkewTableau([[None,1,2],[None,3],[4]]).shape()
[[3, 2, 1], [1, 1]]
```

size()

Returns the number of boxes in the skew tableau.

EXAMPLES:

```
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).size()
4
sage: SkewTableau([[None, 2], [1, 3]]).size()
3
```

slide(*corner=None*)

Fulton, William. 'Young Tableaux'. p12-13

EXAMPLES:

```
sage: st = SkewTableau([[None, None, None, None,2],[None, None, None, None,6], [None, 2, 4,
sage: st.slide([2,0])
[[None, None, None, None, 2], [None, None, None, None, 6], [2, 2, 4, 4], [3, 5, 6], [5]]
```

to_chain()

Returns the chain of partitions corresponding to the (semi)standard skew tableau.

EXAMPLES:

```
sage: SkewTableau([[None,1],[2],[3]]).to_chain()
[[1], [2], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain()
[[1], [2, 1], [2, 1, 1]]
```

to_expr()

The first list in a result corresponds to the inner partition of the skew shape. The second list is a list of the rows in the skew tableau read from the bottom up.

Provided for compatibility with MuPAD-Combinat. In MuPAD-Combinat, if t is a skew tableau, then to_expr gives the same result as expr(t) would give in MuPAD-Combinat.

EXAMPLES:

```
sage: SkewTableau([[None,1,1,3],[None,2,2],[1]]).to_expr()
[[1, 1], [[1], [2, 2], [1, 1, 3]]]
sage: SkewTableau([]).to_expr()
[[], []]
```

to_ribbon()

Returns the ribbon version of self.

EXAMPLES:

```
sage: SkewTableau([[None,1],[2,3]]).to_ribbon()
[[1], [2, 3]]
```

to_tableau()

Returns a tableau with the same filling. This only works if the inner shape of the skew tableau has size zero.

EXAMPLES:

```
sage: SkewTableau([[1,2],[3,4]]).to_tableau()
[[1, 2], [3, 4]]
```

to_word()

An alias for SkewTableau.to_word_by_row().

EXAMPLES:

```
sage: SkewTableau([[None,1],[2,3]]).to_word()
word: 231
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).to_word()
word: 1324
```

to_word_by_column()

Returns the word obtained from a column reading of the skew tableau

EXAMPLES:

```
sage: s = SkewTableau([[None,1],[2,3]])
sage: s.pp()
  .  1
  2  3
sage: s.to_word_by_column()
word: 132

sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])
sage: s.pp()
.  2  4
.  3
1
sage: s.to_word_by_column()
word: 4231
```

to_word_by_row()

Returns a word obtained from a row reading of the skew tableau.

EXAMPLES:

```
sage: s = SkewTableau([[None,1],[2,3]])
sage: s.pp()
  .  1
  2  3
sage: s.to_word_by_row()
word: 231
sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])
```

```
sage: s.pp()
  .  2  4
  .  3
  1
sage: s.to_word_by_row()
word: 1324
```

weight()

Returns the evaluation of the word from skew tableau.

EXAMPLES:

```
sage: SkewTableau([[1,2],[3,4]]).evaluation()
[1, 1, 1, 1]
```

StandardSkewTableaux(*skp=None*)

Returns the combinatorial class of standard skew tableaux of shape skp (where skp is a skew partition).

EXAMPLES:

```
sage: StandardSkewTableaux([[3, 2, 1], [1, 1]]).list()
[[[None, 1, 2], [None, 3], [4]],
 [[None, 1, 2], [None, 4], [3]],
 [[None, 1, 3], [None, 2], [4]],
 [[None, 1, 4], [None, 2], [3]],
 [[None, 1, 3], [None, 4], [2]],
 [[None, 1, 4], [None, 3], [2]],
 [[None, 2, 3], [None, 4], [1]],
 [[None, 2, 4], [None, 3], [1]]]
```

class **StandardSkewTableaux_all**()

class **StandardSkewTableaux_n**(*n*)

cardinality()

EXAMPLES:

```
sage: StandardSkewTableaux(1).cardinality()
1
sage: StandardSkewTableaux(2).cardinality()
4
sage: StandardSkewTableaux(3).cardinality()
24
sage: StandardSkewTableaux(4).cardinality()
194
```

class **StandardSkewTableaux_skewpartition**(*skp*)

cardinality()

Returns the number of standard skew tableaux with shape of the skew partition skp.

EXAMPLES:

```
sage: StandardSkewTableaux([[3, 2, 1], [1, 1]]).cardinality()
8
```

list()

Returns a list for all the standard skew tableaux with shape of the skew partition skp. The standard skew tableaux are ordered lexicographically by the word obtained from their row reading.

EXAMPLES:

```
sage: StandardSkewTableaux([[3, 2, 1], [1, 1]]).list()
[[[None, 1, 2], [None, 3], [4]],
 [[None, 1, 2], [None, 4], [3]],
 [[None, 1, 3], [None, 2], [4]],
 [[None, 1, 4], [None, 2], [3]],
 [[None, 1, 3], [None, 4], [2]],
 [[None, 1, 4], [None, 3], [2]],
 [[None, 2, 3], [None, 4], [1]],
 [[None, 2, 4], [None, 3], [1]]]
```

object_class()

from_expr(*expr*)

Returns a SkewTableau from a MuPAD-Combinat expr for a skew tableau. The first list in expr is the inner shape of the skew tableau. The second list are the entries in the rows of the skew tableau from bottom to top.

Provided primarily for compatibility with MuPAD-Combinat.

EXAMPLES:

```
sage: import sage.combinat.skew_tableau as skew_tableau
sage: sage.combinat.skew_tableau.from_expr([[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

from_shape_and_word(*shape, word*)

Returns the skew tableau corresponding to the skew partition shape and the word obtained from the row reading.

EXAMPLES:

```
sage: import sage.combinat.skew_tableau as skew_tableau
sage: t = SkewTableau([[None, 1, 3], [None, 2], [4]])
sage: shape = t.shape()
sage: word  = t.to_word()
sage: skew_tableau.from_shape_and_word(shape, word)
[[None, 1, 3], [None, 2], [4]]
```

17.32.3 Ribbons

Ribbon(*r*)

Returns a ribbon tableau object.

A ribbon is a skew tableau that does not contain a 2x2 box. A ribbon is given by a list of the rows from top to bottom.

EXAMPLES:

```
sage: Ribbon([[2,3],[1,4,5]])
[[2, 3], [1, 4, 5]]
sage: Ribbon([[2,3],[1,4,5]]).to_skew_tableau()
[[None, None, 2, 3], [1, 4, 5]]
```

class **Ribbon_class**(*l*)

evaluation()

Returns the evaluation of the word from ribbon.

EXAMPLES:

```
sage: Ribbon([[1,2],[3,4]]).evaluation()
[1, 1, 1, 1]
```

height()
Returns the height of the ribbon.
EXAMPLES:

```
sage: Ribbon([[2,3],[1,4,5]]).height()
2
```

is_standard()
Returns True is the ribbon is standard and False otherwise. ribbon are standard if they are filled with the numbers 1...size and they are increasing along both rows and columns.
EXAMPLES:

```
sage: Ribbon([[2,3],[1,4,5]]).is_standard()
True
sage: Ribbon([[2,2],[1,4,5]]).is_standard()
False
sage: Ribbon([[4,5],[1,2,3]]).is_standard()
False
```

ribbon_shape()
Returns the ribbon shape. The ribbon shape is given just by the number of boxes in each row.
EXAMPLES:

```
sage: Ribbon([[2,3],[1,4,5]]).ribbon_shape()
[2, 3]
```

shape()
Returns the skew partition corresponding to the shape of the ribbon.
EXAMPLES:

```
sage: Ribbon([[2,3],[1,4,5]]).shape()
[[4, 3], [2]]
```

size()
Returns the size (number of boxes) in the ribbon.
EXAMPLES:

```
sage: Ribbon([[2,3],[1,4,5]]).size()
5
```

spin()
Returns the spin of self.
EXAMPLES:

```
sage: Ribbon([[2,3],[1,4,5]]).spin()
1/2
```

to_permutation()
Returns the permutation corresponding to the ribbon tableau.
EXAMPLES:

```
sage: r = Ribbon([[1], [2,3], [4, 5, 6]])
sage: r.to_permutation()
[4, 5, 6, 2, 3, 1]
```

to_skew_tableau()
Returns the skew tableau corresponding to the ribbon tableau.

EXAMPLES:

```
sage: Ribbon([[2,3],[1,4,5]]).to_skew_tableau()
[[None, None, 2, 3], [1, 4, 5]]
```

to_word()

An alias for Ribbon.to_word_by_row().

EXAMPLES:

```
sage: Ribbon([[1],[2,3]]).to_word_by_row()
word: 231
sage: Ribbon([[2, 4], [3], [1]]).to_word_by_row()
word: 1324
```

to_word_by_column()

Returns the word obtained from a column reading of the ribbon

EXAMPLES:

```
sage: Ribbon([[1],[2,3]]).to_word_by_column()
word: 132
sage: Ribbon([[2, 4], [3], [1]]).to_word_by_column()
word: 4231
```

to_word_by_row()

Returns a word obtained from a row reading of the ribbon.

EXAMPLES:

```
sage: Ribbon([[1],[2,3]]).to_word_by_row()
word: 231
sage: Ribbon([[2, 4], [3], [1]]).to_word_by_row()
word: 1324
```

width()

Returns the width of the ribbon.

EXAMPLES:

```
sage: Ribbon([[2,3],[1,4,5]]).width()
4
```

StandardRibbons(*shape*)

Returns the combinatorial class of standard ribbon tableaux of shape shape.

EXAMPLES:

```
sage: StandardRibbons([2,2])
Standard ribbon tableaux of shape [2, 2]
sage: StandardRibbons([2,2]).first()
[[2, 4], [1, 3]]
sage: StandardRibbons([2,2]).last()
[[1, 2], [3, 4]]
sage: StandardRibbons([2,2]).cardinality()
5
sage: StandardRibbons([2,2]).list()
[[[2, 4], [1, 3]],
 [[2, 3], [1, 4]],
 [[1, 4], [2, 3]],
 [[1, 3], [2, 4]],
 [[1, 2], [3, 4]]]
sage: StandardRibbons([3,2,2]).cardinality()
155
```

class **StandardRibbons_shape**(*shape*)

first()
Returns the first standard ribbon of ribbon shape shape.
EXAMPLES:

```
sage: StandardRibbons([2,2]).first()
[[2, 4], [1, 3]]
```

last()
Returns the first standard ribbon of ribbon shape shape.
EXAMPLES:

```
sage: StandardRibbons([2,2]).last()
[[1, 2], [3, 4]]
```

from_permutation(*p*)
Returns a standard ribbon of size len(p) from a Permutation p. The lengths of each row are given by the distance between the descents of the permutation p.
EXAMPLES:

```
sage: import sage.combinat.ribbon as ribbon
sage: [ribbon.from_permutation(p) for p in Permutations(3)]
[[[1, 2, 3]], [[2], [1, 3]], [[1, 3], [2]], [[1], [2, 3]], [[1, 2], [3]], [[1], [2], [3]]]
```

from_shape_and_word(*shape, word*)
Returns the ribbon corresponding to the given ribbon shape and word.
EXAMPLES:

```
sage: import sage.combinat.ribbon as ribbon
sage: ribbon.from_shape_and_word([2,3],[1,2,3,4,5])
[[1, 2], [3, 4, 5]]
```

17.32.4 Ribbon Tableaux

MultiSkewTableau(*x*)
Returns a multi skew tableau object which is a tuple of skew tableau.
EXAMPLES:

```
sage: s = MultiSkewTableau([ [[None,1],[2,3]], [[1,2],[2]] ])
sage: s.size()
6
sage: s.weight()
[2, 3, 1]
sage: s.shape()
[[[2, 2], [1]], [[2, 1], []]]
```

class **MultiSkewTableau_class**(*l*)

inversion_pairs()
Returns a list of the inversion pairs of self.
EXAMPLES:

```
sage: s = MultiSkewTableau([ [[2,3],[5,5]], [[1,1],[3,3]], [[2],[6]] ])
sage: s.inversion_pairs()
[((0, (0, 0)), (1, (0, 0))),
 ((0, (1, 0)), (1, (0, 1))),
 ((0, (1, 1)), (1, (0, 0))),
 ((0, (1, 1)), (1, (1, 1))),
 ((0, (1, 1)), (2, (0, 0))),
 ((1, (0, 1)), (2, (0, 0))),
 ((1, (1, 1)), (2, (0, 0)))]
```

inversions()

Returns the number of inversion pairs of self.

EXAMPLES:

```
sage: t1 = SkewTableau([[1]])
sage: t2 = SkewTableau([[2]])
sage: MultiSkewTableau([t1,t1]).inversions()
0
sage: MultiSkewTableau([t1,t2]).inversions()
0
sage: MultiSkewTableau([t2,t2]).inversions()
0
sage: MultiSkewTableau([t2,t1]).inversions()
1
sage: s = MultiSkewTableau([ [[2,3],[5,5]], [[1,1],[3,3]], [[2],[6]] ])
sage: s.inversions()
7
```

shape()

Returns the shape of self.

EXAMPLES:

```
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.shape()
[[[2, 2], [1]], [[2, 2], [1]], [[2, 2], [1]]]
```

size()

Returns the size of self, which is the sum of the sizes of the skew tableaux in self.

EXAMPLES:

```
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.size()
9
```

weight()

Returns the weight of self.

EXAMPLES:

```
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.weight()
[5, 3, 1]
```

RibbonTableau(*rt=None, expr=None*)

Returns a ribbon tableau object.

EXAMPLES:

```
sage: rt = RibbonTableau([[None, 1],[2,3]]); rt
[[None, 1], [2, 3]]
sage: rt.inner_shape()
[1]
sage: rt.outer_shape()
[2, 2]

sage: RibbonTableau(expr=[[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

class RibbonTableau_class(*t*)

evaluation()

Returns the evaluation of the ribbon tableau

EXAMPLES:

```
sage: RibbonTableau([[0, 0, 3, 0], [1, 1, 0], [2, 0, 4]]).evaluation()
[2, 1, 1, 1]
```

length()

Returns the length of the ribbons into a ribbon tableau.

EXAMPLES:

```
sage: RibbonTableau([[None, 1],[2,3]]).length()
1
sage: RibbonTableau([[1,0],[2,0]]).length()
2
```

to_word()

Returns a word obtained from a row reading of self.

EXAMPLES:

```
sage: R = RibbonTableau([[0, 0, 3, 0], [1, 1, 0], [2, 0, 4]])
sage: R.to_word()
word: 2041100030
```

RibbonTableaux(*shape, weight, length*)

Returns the combinatorial class of ribbon tableaux of skew shape shape and weight weight tiled by ribbons of length length.

EXAMPLES:

```
sage: RibbonTableaux([[2,1],[]],[1,1,1],1)
Ribbon tableaux of shape [[2, 1], []] and weight [1, 1, 1] with 1-ribbons
```

class RibbonTableaux_shapeweightlength(*shape, weight, length*)

cardinality()

EXAMPLES:

```
sage: RibbonTableaux([[2,1],[]],[1,1,1],1).cardinality()
2
sage: RibbonTableaux([[2,2],[]],[1,1],2).cardinality()
2
sage: RibbonTableaux([[4,3,3],[]],[2,1,1,1],2).cardinality()
5
```

TESTS:

```
sage: RibbonTableaux([6,6,6], [4,2], 3).cardinality()
6
sage: RibbonTableaux([3,3,3,2,1], [3,1], 3).cardinality()
1
sage: RibbonTableaux([3,3,3,2,1], [2,2], 3).cardinality()
2
sage: RibbonTableaux([3,3,3,2,1], [2,1,1], 3).cardinality()
5
sage: RibbonTableaux([3,3,3,2,1], [1,1,1,1], 3).cardinality()
12
sage: RibbonTableaux([5,4,3,2,1],[2,2,1],3).cardinality()
10

sage: RibbonTableaux([8,7,6,5,1,1],[3,2,2,1],3).cardinality()
85
sage: RibbonTableaux([5,4,3,2,1,1,1],[2,2,1],3).cardinality()
10

sage: RibbonTableaux([7,7,7,2,1,1],[3,2,0,1,1],3).cardinality()
25
```

Weights with some zeros in the middle and end

```
sage: RibbonTableaux([3,3,3], [0,1,0,2,0], 3).cardinality()
3
sage: RibbonTableaux([3,3,3],[1,0,1,0,1,0,0,0],3).cardinality()
6
```

list()

EXAMPLES:

```
sage: RibbonTableaux([[2,1],[]],[1,1,1],1).list()
[[[1, 3], [2]], [[1, 2], [3]]]
sage: RibbonTableaux([[2,2],[]],[1,1],2).list()
[[[0, 0], [1, 2]], [[1, 0], [2, 0]]]
```

SemistandardMultiSkewTableaux(*shape, weight*)

Returns the combinatorial class of semistandard multi skew tableaux. A multi skew tableau is a k-tuple of skew tableaux of givens shape with a specified total weight.

EXAMPLES:

```
sage: s = SemistandardMultiSkewTableaux([ [[2,1],[]], [[2,2],[1]] ], [2,2,2]); s
Semistandard multi skew tableaux of shape [[[2, 1], []], [[2, 2], [1]]] and weight [2, 2, 2]
sage: s.list()
[[[[1, 1], [2]], [[None, 2], [3, 3]]],
 [[[1, 2], [2]], [[None, 1], [3, 3]]],
 [[[1, 3], [2]], [[None, 2], [1, 3]]],
 [[[1, 3], [2]], [[None, 1], [2, 3]]],
 [[[1, 1], [3]], [[None, 2], [2, 3]]],
 [[[1, 2], [3]], [[None, 2], [1, 3]]],
 [[[1, 2], [3]], [[None, 1], [2, 3]]],
 [[[2, 2], [3]], [[None, 1], [1, 3]]],
 [[[1, 3], [3]], [[None, 1], [2, 2]]],
 [[[2, 3], [3]], [[None, 1], [1, 2]]]]
```

class **SemistandardMultiSkewTtableaux_shapeweight**(*shape, weight*)

list()

EXAMPLES:

```
sage: sp = SkewPartitions(3).list()
sage: SemistandardMultiSkewTableaux([sp[0], sp[-1]],[2,2,2]).list()
[[[[1], [2], [3]], [[1, 2, 3]]]]

sage: a = SkewPartition([[8,7,6,5,1,1],[2,1,1]])
sage: weight = [3,3,2]
sage: k = 3
sage: s = SemistandardMultiSkewTableaux(a.r_quotient(k),weight)
sage: len(s.list())
34
sage: RibbonTableaux(a,weight,k).cardinality()
34
```

cospin_polynomial (*part, weight, length*)

Returns the cospin polynomial associated to part, weight, and length.

EXAMPLES:

```
sage: from sage.combinat.ribbon_tableau import cospin_polynomial
sage: cospin_polynomial([6,6,6],[4,2],3)
t^4 + t^3 + 2*t^2 + t + 1
sage: cospin_polynomial([3,3,3,2,1], [3,1], 3)
1
sage: cospin_polynomial([3,3,3,2,1], [2,2], 3)
t + 1
sage: cospin_polynomial([3,3,3,2,1], [2,1,1], 3)
t^2 + 2*t + 2
sage: cospin_polynomial([3,3,3,2,1], [1,1,1,1], 3)
t^3 + 3*t^2 + 5*t + 3
sage: cospin_polynomial([5,4,3,2,1,1,1], [2,2,1], 3)
2*t^2 + 6*t + 2
sage: cospin_polynomial([[6]*6, [3,3]], [4,4,2], 3)
3*t^4 + 6*t^3 + 9*t^2 + 5*t + 3
```

count_rec (*nexts, current, part, weight, length*)

INPUT:

- `nexts, current, part` - skew partitions
- `weight` - non-negative integer list
- `length` - integer

TESTS:

```
sage: from sage.combinat.ribbon_tableau import count_rec
sage: count_rec([], [], [[2, 1, 1], []], [2], 2)
[0]
sage: count_rec([[0], [1]], [[[2, 1, 1], [0, 0, 2, 0]], [[4], [2, 0, 0, 0]]], [[4, 1, 1], []], [
[1]
sage: count_rec([], [[[], [2, 2]]], [[2, 2], []], [2], 2)
[1]
sage: count_rec([], [[[], [2, 0, 2, 0]]], [[4], []], [2], 2)
[1]
sage: count_rec([[1], [1]], [[[2, 2], [0, 0, 2, 0]], [[4], [2, 0, 0, 0]]], [[4, 2], []], [2, 1],
[2]
sage: count_rec([[1], [1], [2]], [[[2, 2, 2], [0, 0, 2, 0]], [[4, 1, 1], [0, 2, 0, 0]], [[4, 2],
[4]
```

```
sage: count_rec([[4], [1]], [[[4, 2, 2], [0, 0, 2, 0]], [[4, 3, 1], [0, 2, 0, 0]]], [[4, 3, 3],
[5]
```

from_expr(*l*)

Returns a RibbonTableau from a MuPAD-Combinat expr for a skew tableau. The first list in expr is the inner shape of the skew tableau. The second list are the entries in the rows of the skew tableau from bottom to top.

Provided primarily for compatibility with MuPAD-Combinat.

EXAMPLES:

```
sage: import sage.combinat.ribbon_tableau as ribbon_tableau
sage: sage.combinat.ribbon_tableau.from_expr([[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
sage: type(_)
<class 'sage.combinat.ribbon_tableau.RibbonTableau_class'>
```

graph_implementation_rec(*skp, weight, length, function*)

TESTS:

```
sage: from sage.combinat.ribbon_tableau import graph_implementation_rec, list_rec
sage: graph_implementation_rec(SkewPartition([[1], []]), [1], 1, list_rec)
[[[], [[1]]]]
sage: graph_implementation_rec(SkewPartition([[2, 1], []]), [1, 2], 1, list_rec)
[[[], [[2], [1, 2]]]]
sage: graph_implementation_rec(SkewPartition([[], []]), [0], 1, list_rec)
[[[], []]]
```

insertion_tableau(*skp, perm, evaluation, tableau, length*)

INPUT:

- `skp` - skew partitions
- `perm, evaluation` - non-negative integers
- `tableau` - skew tableau
- `length` - integer

TESTS:

```
sage: from sage.combinat.ribbon_tableau import insertion_tableau
sage: insertion_tableau([[1], []], [1], 1, [[], []], 1)
[[], [[1]]]
sage: insertion_tableau([[2, 1], []], [1, 1], 2, [[], [[1]]], 1)
[[], [[2], [1, 2]]]
sage: insertion_tableau([[2, 1], []], [0, 0], 3, [[], [[2], [1, 2]]], 1)
[[], [[2], [1, 2]]]
sage: insertion_tableau([[1, 1], []], [1], 2, [[], [[1]]], 1)
[[], [[2], [1]]]
sage: insertion_tableau([[2], []], [0, 1], 2, [[], [[1]]], 1)
[[], [[1, 2]]]
sage: insertion_tableau([[2, 1], []], [0, 1], 3, [[], [[2], [1]]], 1)
[[], [[2], [1, 3]]]
sage: insertion_tableau([[1, 1], []], [2], 1, [[], []], 2)
[[], [[1], [0]]]
sage: insertion_tableau([[2], []], [2, 0], 1, [[], []], 2)
[[], [[1, 0]]]
sage: insertion_tableau([[2, 2], []], [0, 2], 2, [[], [[1], [0]]], 2)
[[], [[1, 2], [0, 0]]]
```

```
sage: insertion_tableau([[2, 2], []], [2, 0], 2, [[], [[1, 0]]], 2)
[[], [[2, 0], [1, 0]]]
sage: insertion_tableau([[2, 2], [1]], [3, 0], 1, [[], []], 3)
[[1], [[1, 0], [0]]]
```

list_rec (*nexts, current, part, weight, length*)

INPUT:

- `nexts, current, part` - skew partitions
- `weight` - non-negative integer list
- `length` - integer

TESTS:

```
sage: from sage.combinat.ribbon_tableau import list_rec
sage: list_rec([], [[[], [1]]], [[1], []], [1], 1)
[[[], [[1]]]]
sage: list_rec([[[[], [[1]]]]], [[[1], [1, 1]]], [[2, 1], []], [1, 2], 1)
[[[], [[2], [1, 2]]]]
sage: list_rec([], [[[1], [3, 0]]], [[2, 2], [1]], [1], 3)
[[[1], [[1, 0], [0]]]]
sage: list_rec([[[[], [[2]]]]], [[[1], [1, 1]]], [[2, 1], []], [0, 1, 2], 1)
[[[], [[3], [2, 3]]]]
sage: list_rec([], [[[], [2]]], [[1, 1], []], [1], 2)
[[[], [[1], [0]]]]
sage: list_rec([], [[[], [2, 0]]], [[2], []], [1], 2)
[[[], [[1, 0]]]]
sage: list_rec([[[[], [[1], [0]]]]], [[[], [[1, 0]]]]], [[[1, 1], [0, 2]], [[2], [2, 0]]], [[2, 2
[[[], [[1, 2], [0, 0]]], [[], [[2, 0], [1, 0]]]]
sage: list_rec([], [[[], [2, 2]]], [[2, 2], []], [2], 2)
[[[], [[1, 1], [0, 0]]]]
sage: list_rec([], [[[], [1, 1]]], [[2], []], [2], 1)
[[[], [[1, 1]]]]
sage: list_rec([[[[], [[1, 1]]]]], [[[2], [1, 1]]], [[2, 2], []], [2, 2], 1)
[[[], [[2, 2], [1, 1]]]]
```

spin_polynomial (*part, weight, length*)

Returns the spin polynomial associated to part, weight, and length.

EXAMPLES:

```
sage: from sage.combinat.ribbon_tableau import spin_polynomial
sage: spin_polynomial([6,6,6],[4,2],3)
t^6 + t^5 + 2*t^4 + t^3 + t^2
sage: spin_polynomial([6,6,6],[4,1,1],3)
t^6 + 2*t^5 + 3*t^4 + 2*t^3 + t^2
sage: spin_polynomial([3,3,3,2,1], [2,2], 3)
t^(7/2) + t^(5/2)
sage: spin_polynomial([3,3,3,2,1], [2,1,1], 3)
2*t^(7/2) + 2*t^(5/2) + t^(3/2)
sage: spin_polynomial([3,3,3,2,1], [1,1,1,1], 3)
3*t^(7/2) + 5*t^(5/2) + 3*t^(3/2) + sqrt(t)
sage: spin_polynomial([5,4,3,2,1,1,1], [2,2,1], 3)
2*t^(9/2) + 6*t^(7/2) + 2*t^(5/2)
sage: spin_polynomial([[6]*6, [3,3]], [4,4,2], 3)
3*t^9 + 5*t^8 + 9*t^7 + 6*t^6 + 3*t^5
```

spin_polynomial_square(*part, weight, length*)

Returns the spin polynomial associated with part, weight, and length, with the substitution t -> t^2 made.

EXAMPLES:

```
sage: from sage.combinat.ribbon_tableau import spin_polynomial_square
sage: spin_polynomial_square([6,6,6],[4,2],3)
t^12 + t^10 + 2*t^8 + t^6 + t^4
sage: spin_polynomial_square([6,6,6],[4,1,1],3)
t^12 + 2*t^10 + 3*t^8 + 2*t^6 + t^4
sage: spin_polynomial_square([3,3,3,2,1], [2,2], 3)
t^7 + t^5
sage: spin_polynomial_square([3,3,3,2,1], [2,1,1], 3)
2*t^7 + 2*t^5 + t^3
sage: spin_polynomial_square([3,3,3,2,1], [1,1,1,1], 3)
3*t^7 + 5*t^5 + 3*t^3 + t
sage: spin_polynomial_square([5,4,3,2,1,1,1], [2,2,1], 3)
2*t^9 + 6*t^7 + 2*t^5
sage: spin_polynomial_square([[6]*6, [3,3]], [4,4,2], 3)
3*t^18 + 5*t^16 + 9*t^14 + 6*t^12 + 3*t^10
```

spin_rec(*t, nexts, current, part, weight, length*)

Routine used for constructing the spin polynomial.

INPUT:

- `weight` - list of non-negative integers
- `length` - the length of the ribbons we're tiling with
- `t` - the variable

EXAMPLES:

```
sage: from sage.combinat.ribbon_tableau import spin_rec
sage: sp = SkewPartition
sage: t = ZZ['t'].gen()
sage: spin_rec(t, [], [[[], [3, 3]]], sp([[2, 2, 2], []]), [2], 3)
[t^4]
sage: spin_rec(t, [[0], [t^4]], [[[2, 1, 1, 1, 1], [0, 3]], [[2, 2, 2], [3, 0]]], sp([[2, 2, 2,
[t^5]
sage: spin_rec(t, [], [[[], [3, 3, 0]]], sp([[3, 3], []]), [2], 3)
[t^2]
sage: spin_rec(t, [[t^4], [t^3], [t^2]], [[[2, 2, 2], [0, 0, 3]], [[3, 2, 1], [0, 3, 0]], [[3, 3
[t^6 + t^4 + t^2]
sage: spin_rec(t, [[t^5], [t^4], [t^6 + t^4 + t^2]], [[[2, 2, 2, 2, 1], [0, 0, 3]], [[3, 3, 1, 1
[2*t^7 + 2*t^5 + t^3]
```

17.33 Symmetric Functions

17.33.1 Symmetric Functions

AUTHORS:

- Mike Hansen (2007-06-15)

```
sage: s = SymmetricFunctionAlgebra(QQ, basis='schur')
sage: e = SymmetricFunctionAlgebra(QQ, basis='elementary')
sage: f1 = s([2,1]); f1
s[2, 1]
sage: f2 = e(f1); f2
e[2, 1] - e[3]
sage: f1 == f2
True
sage: f1.expand(3, alphabet=['x','y','z'])
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
sage: f2.expand(3, alphabet=['x','y','z'])
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2

sage: m = SFAMonomial(QQ)

sage: m = SFAMonomial(QQ)
sage: f = sum([m(p) for p in P3])
sage: m.get_print_style()
'lex'
sage: f
m[1, 1, 1] + m[2, 1] + m[3]
sage: m.set_print_style('length')
sage: f
m[3] + m[2, 1] + m[1, 1, 1]
sage: m.set_print_style('maximal_part')
sage: f
m[1, 1, 1] + m[2, 1] + m[3]
sage: m.set_print_style('lex')

sage: s = SFASchur(QQ)
sage: m = SFAMonomial(QQ)
sage: m([3])*s([2,1])
2*m[3, 1, 1, 1] + m[3, 2, 1] + 2*m[4, 1, 1] + m[4, 2] + m[5, 1]
sage: s(m([3])*s([2,1]))
s[2, 1, 1, 1, 1] - s[2, 2, 2] - s[3, 3] + s[5, 1]
sage: s(s([2,1])*m([3]))
s[2, 1, 1, 1, 1] - s[2, 2, 2] - s[3, 3] + s[5, 1]
sage: e = SFAElementary(QQ)
sage: e([4])*e([3])*e([1])
e[4, 3, 1]

sage: s = SFASchur(QQ)
sage: z = s([2,1]) + s([1,1,1])
sage: z.coefficient([2,1])
1
sage: z.length()
2
sage: z.support()
[[1, 1, 1], [2, 1]]
sage: z.degree()
3
```

SFAElementary(*R*)

Returns the symmetric function algebra over R with the elementary symmetric functions as the basis.

EXAMPLES:

```
sage: SFAElementary(QQ)
Symmetric Function Algebra over Rational Field, Elementary symmetric functions as basis
```

SFAHomogeneous(*R*)

Returns the symmetric function algebra over R with the Homogeneous symmetric functions as the basis.

EXAMPLES:

```
sage: SFAHomogeneous(QQ)
Symmetric Function Algebra over Rational Field, Homogeneous symmetric functions as basis
```

SFAMonomial(*R*)

Returns the symmetric function algebra over R with the monomial symmetric functions as the basis.

EXAMPLES:

```
sage: SFAMonomial(QQ)
Symmetric Function Algebra over Rational Field, Monomial symmetric functions as basis
```

SFAPower(*R*)

Returns the symmetric function algebra over R with the power-sum symmetric functions as the basis.

EXAMPLES:

```
sage: SFAPower(QQ)
Symmetric Function Algebra over Rational Field, Power symmetric functions as basis
```

SFASchur(*R*)

Returns the symmetric function algebra over R with the Schur symmetric functions as the basis.

EXAMPLES:

```
sage: SFASchur(QQ)
Symmetric Function Algebra over Rational Field, Schur symmetric functions as basis
```

SymmetricFunctionAlgebra(*R*, *basis='schur'*)

Return the free algebra over the ring R on n generators with given names.

INPUT:

- R - ring with identity basis

OUTPUT: A SymmetricFunctionAlgebra

EXAMPLES:

```
sage: SymmetricFunctionAlgebra(QQ)
Symmetric Function Algebra over Rational Field, Schur symmetric functions as basis
```

```
sage: SymmetricFunctionAlgebra(QQ, basis='m')
Symmetric Function Algebra over Rational Field, Monomial symmetric functions as basis
```

```
sage: SymmetricFunctionAlgebra(QQ, basis='power')
Symmetric Function Algebra over Rational Field, Power symmetric functions as basis
```

class **SymmetricFunctionAlgebraElement_generic**(*A*, *x*)

degree()

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1]) + 3
sage: z.degree()
4
```

derivative_with_respect_to_p1(*n=1*)

Returns the symmetric function obtained by taking the derivative of self with respect to the power-sum symmetric function p([1]) when the expansion of self in the power-sum basis is considered as a polynomial in p([1])'s.

EXAMPLES:

```
sage: p = SFAPower(QQ)
sage: a = p([1,1,1])
sage: a.derivative_with_respect_to_p1()
3*p[1, 1]
sage: a.derivative_with_respect_to_p1(1)
3*p[1, 1]
sage: a.derivative_with_respect_to_p1(2)
6*p[1]
sage: a.derivative_with_respect_to_p1(3)
6*p[]

sage: s = SFASchur(QQ)
sage: s([3]).derivative_with_respect_to_p1()
s[2]
sage: s([2,1]).derivative_with_respect_to_p1()
s[1, 1] + s[2]
sage: s([1,1,1]).derivative_with_respect_to_p1()
s[1, 1]
```

expand(*n, alphabet='x'*)

Expands the symmetric function as a symmetric polynomial in n variables.

EXAMPLES:

```
sage: J =JackPolynomialsJ(QQ, t=2)
sage: J([2,1]).expand(3)
4*x0^2*x1 + 4*x0*x1^2 + 4*x0^2*x2 + 6*x0*x1*x2 + 4*x1^2*x2 + 4*x0*x2^2 + 4*x1*x2^2
```

hl_creation_operator(*nu*)

This is the vertex operator that generalizes Jing's operator It is from: Hall-Littlewood Vertex Operators and Kostka Polynomials, Shimizono-Zabrocki, Proposition 5 It is a linear operator that rases the degree by sum(nu) This creation operator is a t-analogue of multiplication by s(nu)

INPUT:

- nu - a partition

EXAMPLES:

```
sage: s = SFASchur(QQ['t'])
sage: s([2]).hl_creation_operator([3,2])
s[3, 2, 2] + t*s[3, 3, 1] + t*s[4, 2, 1] + t^2*s[4, 3] + t^2*s[5, 2]
sage: HLQp = HallLittlewoodQp(QQ)
sage: HLQp(s([2]).hl_creation_operator([2]).hl_creation_operator([3]))
Qp[3, 2, 2]
sage: s([2,2]).hl_creation_operator([2,1])
t*s[2, 2, 2, 1] + t^2*s[3, 2, 1, 1] + t^2*s[3, 2, 2] + t^3*s[3, 3, 1] + t^3*s[4, 2, 1] + t^4
sage: s(1).hl_creation_operator([2,1,1])
```

```
s[2, 1, 1]
sage: s(0).hl_creation_operator([2,1,1])
0
sage: s([3,2]).hl_creation_operator([2,1,1])
(t^2-t)*s[2, 2, 2, 2, 1] + t^3*s[3, 2, 2, 1, 1] + (t^3-t^2)*s[3, 2, 2, 2] + t^3*s[3, 3, 1, 1
```

inner_plethysm(*x*)

Returns the inner plethysm of self with x.

The result of f.inner_plethysm(g) is linear in f and linear in 'homogeneous pieces' of g. So, to describe this function, we assume without loss that f is some Schur function s(la) and g is a homogeneous symmetric function of degree n. The function g can be thought of as the character of an irreducible representation, rho, of the symmetric group S_n. Let N be the dimension of this representation. If the number of parts of la is greater then N, then f.inner_plethysm(g) = 0 by definition. Otherwise, we can interpret f as the character of an irreducible GL_N representation, call it σ. Now $\sigma \circ \rho$ is an S_n representation and, by definition, the character of this representation is f.inner_plethysm(g).

REFERENCES:

- King, R. 'Branching rules for $GL_m \supset \Sigma_n$ and the evaluation of inner plethysms.' J. Math. Phys. 15, 258 (1974)

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: p = SFAPower(QQ)
sage: h = SFAHomogeneous(QQ)
sage: s([2,1]).inner_plethysm(s([1,1,1]))
0
sage: h([2]).inner_plethysm(s([2,1]))
h[2, 1]
sage: s(_)
s[2, 1] + s[3]

sage: f = s([2,1]) + 2*s([3,1])
sage: f.itensor(f)
s[1, 1, 1] + s[2, 1] + 4*s[2, 1, 1] + 4*s[2, 2] + s[3] + 4*s[3, 1] + 4*s[4]
sage: s( h([1,1]).inner_plethysm(f) )
s[1, 1, 1] + s[2, 1] + 4*s[2, 1, 1] + 4*s[2, 2] + s[3] + 4*s[3, 1] + 4*s[4]

sage: s([]).inner_plethysm(s([1,1]) + 2*s([2,1])+s([3]))
s[2] + s[3]
sage: [s([]).inner_plethysm(s(p)) for p in Partitions(4)]
[s[4], s[4], s[4], s[4], s[4]]
```

inner_tensor(*x*)

Returns the inner tensor product of self and x in the basis of self.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2] + 4*s[3, 1, 1, 1]
```

TESTS:

```
sage: s = SFASchur(QQ)
sage: a = s([8,8])
sage: a.itensor(a) #long
s[4, 4, 4, 4] + s[5, 5, 3, 3] + s[5, 5, 5, 1] + s[6, 4, 4, 2] + s[6, 6, 2, 2] + s[6, 6, 4] +
```

internal_product(*x*)

Returns the inner tensor product of self and x in the basis of self.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2] + 4*s[3, 1, 1, 1]
```

TESTS:

```
sage: s = SFASchur(QQ)
sage: a = s([8,8])
sage: a.itensor(a) #long
s[4, 4, 4, 4] + s[5, 5, 3, 3] + s[5, 5, 5, 1] + s[6, 4, 4, 2] + s[6, 6, 2, 2] + s[6, 6, 4] +
```

is_schur_positive()

Returns True if and only if self is Schur positive. If s is the space of Schur functions over self's base ring, then this is the same as self._is_positive(s).

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: a = s([2,1]) + s([3])
sage: a.is_schur_positive()
True
sage: a = s([2,1]) - s([3])
sage: a.is_schur_positive()
False

sage: QQx = QQ['x']
sage: s = SFASchur(QQx)
sage: x = QQx.gen()
sage: a = (1+x)*s([2,1])
sage: a.is_schur_positive()
True
sage: a = (1-x)*s([2,1])
sage: a.is_schur_positive()
False
```

itensor(*x*)

Returns the inner tensor product of self and x in the basis of self.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
```

```
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2] + 4*s[3, 1, 1, 1]
```

TESTS:

```
sage: s = SFASchur(QQ)
sage: a = s([8,8])
sage: a.itensor(a) #long
s[4, 4, 4, 4] + s[5, 5, 3, 3] + s[5, 5, 5, 1] + s[6, 4, 4, 2] + s[6, 6, 2, 2] + s[6, 6, 4] +
```

kronecker_product(*x*)

Returns the inner tensor product of self and x in the basis of self.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2] + 4*s[3, 1, 1, 1]
```

TESTS:

```
sage: s = SFASchur(QQ)
sage: a = s([8,8])
sage: a.itensor(a) #long
s[4, 4, 4, 4] + s[5, 5, 3, 3] + s[5, 5, 5, 1] + s[6, 4, 4, 2] + s[6, 6, 2, 2] + s[6, 6, 4] +
```

omega()

Returns the image of self under the Frobenius / omega automorphism. The default implementation converts to the Schurs performs the automorphism and changes back.

EXAMPLES:

```
sage: J = JackPolynomialsP(QQ,1)
sage: a = J([2,1]) + J([1,1,1])
sage: a.omega()
JackP[2, 1] + JackP[3]
```

plethysm(*x, include=None, exclude=None*)

Returns the outer plethysm of self with x.

By default, the degree one elements are the generators for the self's base ring.

INPUT:

- `x` - a symmetric function
- `include` - a list of variables to be treated as degree one elements instead of the default degree one elements
- `exclude` - a list of variables to be excluded from the default degree one elements

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: h = SFAHomogeneous(QQ)
sage: s ( h([3])( h([2]) ) )
s[2, 2, 2] + s[4, 2] + s[6]
sage: p = SFAPower(QQ)
sage: p([3])( s([2,1]) )
1/3*p[3, 3, 3] - 1/3*p[9]
sage: e = SFAElementary(QQ)
sage: e([3])( e([2]) )
e[3, 3] + e[4, 1, 1] - 2*e[4, 2] - e[5, 1] + e[6]
```

```
sage: R.<t> = QQ[]
sage: s = SFASchur(R);
sage: a = s([3])
sage: f = t*s([2])
sage: a(f)
t^3*s[2, 2, 2] + t^3*s[4, 2] + t^3*s[6]
sage: f(a)
t*s[4, 2] + t*s[6]
```

restrict_degree(*d, exact=True*)

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_degree(2)
0
sage: z.restrict_degree(1)
s[1]
sage: z.restrict_degree(3)
s[1, 1, 1] + s[2, 1]
sage: z.restrict_degree(3, exact=False)
s[1] + s[1, 1, 1] + s[2, 1]
```

restrict_partition_lengths(*l, exact=True*)

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_partition_lengths(2)
s[2, 1]
sage: z.restrict_partition_lengths(2, exact=False)
s[1] + s[2, 1] + s[4]
```

restrict_parts(*n*)

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_parts(2)
s[1] + s[1, 1, 1] + s[2, 1]
sage: z.restrict_parts(1)
s[1] + s[1, 1, 1]
```

scalar(*x*)

Returns standard scalar product between self and s.

This is the default implementation that converts both self and x into Schur functions and performs the scalar product that basis.

EXAMPLES:

```
sage: e = SFAElementary(QQ)
sage: h = SFAHomogeneous(QQ)
sage: m = SFAMonomial(QQ)
sage: p4 = Partitions(4)
sage: matrix([ [e(a).scalar(h(b)) for a in p4] for b in p4])
[ 0  0  0  0  1]
[ 0  0  0  1  4]
[ 0  0  1  2  6]
[ 0  1  2  5 12]
[ 1  4  6 12 24]
```

```
sage: matrix([ [h(a).scalar(e(b)) for a in p4] for b in p4])
[ 0  0  0  0  1]
[ 0  0  0  1  4]
[ 0  0  1  2  6]
[ 0  1  2  5 12]
[ 1  4  6 12 24]
sage: matrix([ [m(a).scalar(e(b)) for a in p4] for b in p4])
[-1  2  1 -3  1]
[ 0  1  0 -2  1]
[ 0  0  1 -2  1]
[ 0  0  0 -1  1]
[ 0  0  0  0  1]
sage: matrix([ [m(a).scalar(h(b)) for a in p4] for b in p4])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
```

scalar_hl (*x, t=None*)

Returns the standard Hall-Littlewood scalar product of self and x.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: a = s([2,1])
sage: sp = a.scalar_t(a); sp
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
sage: sp.parent()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

scalar_t (*x, t=None*)

Returns the standard Hall-Littlewood scalar product of self and x.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: a = s([2,1])
sage: sp = a.scalar_t(a); sp
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
sage: sp.parent()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

skew_by (*x*)

Returns the element whose result is the dual to multiplication by x applied to self.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: s([3,2]).skew_by(s([2]))
s[2, 1] + s[3]
sage: s([3,2]).skew_by(s([1,1,1]))
0
sage: s([3,2,1]).skew_by(s([2,1]))
s[1, 1, 1] + 2*s[2, 1] + s[3]

sage: p = SFAPower(QQ)
sage: p([4,3,3,2,2,1]).skew_by(p([2,1]))
4*p[4, 3, 3, 2]
sage: zee = sage.combinat.sf.sfa.zee
sage: zee([4,3,3,2,2,1])/zee([4,3,3,2])
4
```

theta(*a*)

Returns the image of self under the theta automorphism which sends $p[k]$ to $a * p[k]$.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: s([2,1]).theta(2)
2*s[1, 1, 1] + 6*s[2, 1] + 2*s[3]
sage: p = SFAPower(QQ)
sage: p([2]).theta(2)
2*p[2]
```

theta_qt(*q, t*)

Returns the image of self under the theta automorphism which sends $p[k]$ to $(1-q^k)/(1-t^k) * p[k]$.

EXAMPLES:

```
sage: QQqt = QQ['q,t'].fraction_field()
sage: q,t = QQqt.gens()
sage: p = SFAPower(QQqt)
sage: p([2]).theta_qt(q,t)
((-q^2+1)/(-t^2+1))*p[2]
sage: p([2,1]).theta_qt(q,t)
((q^3-q^2-q+1)/(t^3-t^2-t+1))*p[2, 1]
```

class **SymmetricFunctionAlgebra_generic**(*R, element_class=None*)

basis_name()

Returns the name of the basis of self.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: s.basis_name()
'schur'
sage: p = SFAPower(QQ)
sage: p.basis_name()
'power'
sage: h = SFAHomogeneous(QQ)
sage: h.basis_name()
'homogeneous'
sage: e = SFAElementary(QQ)
sage: e.basis_name()
'elementary'
sage: m = SFAMonomial(QQ)
sage: m.basis_name()
'monomial'
```

dual_basis(*scalar=None, scalar_name='', prefix=None*)

Returns the dual basis of self with respect to the scalar product scalar. If scalar is None, then the standard (Hall) scalar product is used.

EXAMPLES: The duals of the elementary symmetric functions with respect to the Hall scalar product are the forgotten symmetric functions.

```
sage: e = SFAElementary(QQ)
sage: f = e.dual_basis(prefix='f'); f
Dual basis to Symmetric Function Algebra over Rational Field, Elementary symmetric functions
sage: f([2,1])^2
4*f[2, 2, 1, 1] + 6*f[2, 2, 2] + 2*f[3, 2, 1] + 2*f[3, 3] + 2*f[4, 1, 1] + f[4, 2]
sage: f([2,1]).scalar(e([2,1]))
1
```

```
sage: f([2,1]).scalar(e([1,1,1]))
0
```

Since the power-sum symmetric functions are orthogonal, their duals with respect to the Hall scalar product are scalar multiples of themselves.

```
sage: p = SFAPower(QQ)
sage: q = p.dual_basis(prefix='q'); q
Dual basis to Symmetric Function Algebra over Rational Field, Power symmetric functions as b
sage: q([2,1])^2
4*q[2, 2, 1, 1]
sage: p([2,1]).scalar(q([2,1]))
1
sage: p([2,1]).scalar(q([1,1,1]))
0
```

get_print_style()

Returns the value of the current print style for self.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: s.get_print_style()
'lex'
sage: s.set_print_style('length')
sage: s.get_print_style()
'length'
sage: s.set_print_style('lex')
```

prefix()

Returns the prefix on the elements of self.

EXAMPLES:

```
sage: schur = SFASchur(QQ)
sage: schur([3,2,1])
s[3, 2, 1]
sage: schur.prefix()
's'
```

set_print_style(*ps*)

Set the value of the current print style to ps.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: s.get_print_style()
'lex'
sage: s.set_print_style('length')
sage: s.get_print_style()
'length'
sage: s.set_print_style('lex')
```

transition_matrix(*basis, n*)

Returns the transitions matrix between self and basis for the homogenous component of degree n.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: m = SFAMonomial(QQ)
sage: s.transition_matrix(m,5)
[1 1 1 1 1 1 1]
[0 1 1 2 2 3 4]
```

```
[0 0 1 1 2 3 5]
[0 0 0 1 1 3 6]
[0 0 0 0 1 2 5]
[0 0 0 0 0 1 4]
[0 0 0 0 0 0 1]

sage: p = SFAPower(QQ)
sage: s.transition_matrix(p, 4)
[ 1/4  1/3  1/8  1/4 1/24]
[-1/4    0 -1/8  1/4  1/8]
[   0 -1/3  1/4    0 1/12]
[ 1/4    0 -1/8 -1/4  1/8]
[-1/4  1/3  1/8 -1/4 1/24]
sage: StoP = s.transition_matrix(p,4)
sage: a = s([3,1])+5*s([1,1,1,1])-s([4])
sage: a
5*s[1, 1, 1, 1] + s[3, 1] - s[4]
sage: mon = a.support()
sage: coeffs = a.coefficients()
sage: coeffs
[5, 1, -1]
sage: mon
[[1, 1, 1, 1], [3, 1], [4]]
sage: cm = matrix([[-1,1,0,0,5]])
sage: cm * StoP
[-7/4  4/3  3/8 -5/4 7/24]
sage: p(a)
7/24*p[1, 1, 1, 1] - 5/4*p[2, 1, 1] + 3/8*p[2, 2] + 4/3*p[3, 1] - 7/4*p[4]

sage: h = SFAHomogeneous(QQ)
sage: e = SFAElementary(QQ)
sage: s.transition_matrix(m,7) == h.transition_matrix(s,7).transpose()
True

sage: h.transition_matrix(m, 7) == h.transition_matrix(m, 7).transpose()
True

sage: h.transition_matrix(e, 7) == e.transition_matrix(h, 7)
True

sage: p.transition_matrix(s, 5)
[ 1 -1  0  1  0 -1  1]
[ 1  0 -1  0  1  0 -1]
[ 1 -1  1  0 -1  1 -1]
[ 1  1 -1  0 -1  1  1]
[ 1  0  1 -2  1  0  1]
[ 1  2  1  0 -1 -2 -1]
[ 1  4  5  6  5  4  1]

sage: e.transition_matrix(m,7) == e.transition_matrix(m,7).transpose()
True
```

is_SymmetricFunction(*x*)

Returns True if x is a symmetric function.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import is_SymmetricFunction
sage: s = SFASchur(QQ)
```

```
sage: is_SymmetricFunction(2)
False
sage: is_SymmetricFunction(s(2))
True
sage: is_SymmetricFunction(s([2,1]))
True
```

is_SymmetricFunctionAlgebra(*x*)

Return True if x is a symmetric function algebra; otherwise, return False.

EXAMPLES:

```
sage: sage.combinat.sf.sfa.is_SymmetricFunctionAlgebra(5)
False
sage: sage.combinat.sf.sfa.is_SymmetricFunctionAlgebra(ZZ)
False
sage: sage.combinat.sf.sfa.is_SymmetricFunctionAlgebra(SymmetricFunctionAlgebra(ZZ,'schur'))
True
```

zee(*part*)

Returns the size of the centralizer of permutations of cycle type part. Note that this is the inner product between p(part) and itself where p is the power-sum symmetric functions.

INPUT:

- `part` - an integer partition (for example, [2,1,1])

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import zee
sage: zee([2,1,1])
4
```

17.33.2 Classical symmetric functions.

class SymmetricFunctionAlgebraElement_classical(*A, x*)

A symmetric function.

class SymmetricFunctionAlgebra_classical(*R, basis, element_class, prefix*)

is_commutative()

Return True if this symmetric function algebra is commutative.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: s.is_commutative()
True
```

is_field()

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: s.is_field()
False
```

init()

Set up the conversion functions between the classical bases.

EXAMPLES:

```
sage: from sage.combinat.sf.classical import init
sage: sage.combinat.sf.classical.conversion_functions = {}
sage: init()
sage: sage.combinat.sf.classical.conversion_functions[('schur', 'power')]
<built-in function t_SCHUR_POWSYM_symmetrica>
```

17.33.3 Schur symmetric functions

class SymmetricFunctionAlgebraElement_schur(*A*, *x*)

expand(*n*, *alphabet='x'*)

Expands the symmetric function as a symmetric polynomial in n variables.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: a = s([2,1])
sage: a.expand(2)
x0^2*x1 + x0*x1^2
sage: a.expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
sage: a.expand(4)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2 + x0^2*x3 + 2*x0*x1*x
sage: a.expand(2, alphabet='y')
y0^2*y1 + y0*y1^2
sage: a.expand(2, alphabet=['a','b'])
a^2*b + a*b^2
sage: s([1,1,1,1]).expand(3)
0
```

omega()

Returns the image of self under the Frobenius / omega automorphism.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: s([2,1]).omega()
s[2, 1]
sage: s([2,1,1]).omega()
s[3, 1]
```

scalar(*x*)

Returns the standard scalar product between self and x.

Note that the Schur functions are self-dual with respect to this scalar product. They are also lower-triangularly related to the monomial symmetric functions with respect to this scalar product.

EXAMPLES:

```
sage: s = SFASchur(ZZ)
sage: a = s([2,1])
sage: b = s([1,1,1])
sage: c = 2*s([1,1,1])
sage: d = a + b
sage: a.scalar(a)
1
sage: b.scalar(b)
1
sage: b.scalar(a)
```

```
0
sage: b.scalar(c)
2
sage: c.scalar(c)
4
sage: d.scalar(a)
1
sage: d.scalar(b)
1
sage: d.scalar(c)
2

sage: m = SFAMonomial(ZZ)
sage: p4 = Partitions(4)
sage: l = [ [s(p).scalar(m(q)) for q in p4] for p in p4]
sage: matrix(l)
[ 1  0  0  0  0]
[-1  1  0  0  0]
[ 0 -1  1  0  0]
[ 1 -1 -1  1  0]
[-1  2  1 -3  1]
```

class **SymmetricFunctionAlgebra_schur**(*R*)

dual_basis(*scalar=None, scalar_name='', prefix=None*)

The dual basis to the Schur basis with respect to the standard scalar product is the Schur basis since it is self-dual.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: ds = s.dual_basis()
sage: s is ds
True
```

is_schur_basis()

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: s.is_schur_basis()
True
```

17.33.4 Monomial symmetric functions

class **SymmetricFunctionAlgebraElement_monomial**(*A, x*)

expand(*n, alphabet='x'*)

Expands the symmetric function as a symmetric polynomial in n variables.

EXAMPLES:

```
sage: m = SFAMonomial(QQ)
sage: m([2,1]).expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
sage: m([1,1,1]).expand(2)
0
sage: m([2,1]).expand(3,alphabet='z')
z0^2*z1 + z0*z1^2 + z0^2*z2 + z1^2*z2 + z0*z2^2 + z1*z2^2
```

```
sage: m([2,1]).expand(3,alphabet='x,y,z')
x^2*y + x*y^2 + x^2*z + y^2*z + x*z^2 + y*z^2
```

class SymmetricFunctionAlgebra_monomial(*R*)

dual_basis(*scalar=None, scalar_name='', prefix=None*)

The dual basis of the monomial basis with respect to the standard scalar product is the homogeneous basis.

EXAMPLES:

```
sage: m = SFAMonomial(QQ)
sage: h = SFAHomogeneous(QQ)
sage: m.dual_basis() == h
True
```

17.33.5 Multiplicative symmetric functions

class SymmetricFunctionAlgebra_multiplicative(*R, basis, element_class, prefix*)

17.33.6 Elementary symmetric functions

class SymmetricFunctionAlgebraElement_elementary(*A, x*)

expand(*n, alphabet='x'*)

Expands the symmetric function as a symmetric polynomial in n variables.

EXAMPLES:

```
sage: e = SFAElementary(QQ)
sage: e([2,1]).expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 3*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
sage: e([1,1,1]).expand(2)
x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + x1^3
sage: e([3]).expand(2)
0
sage: e([2]).expand(3)
x0*x1 + x0*x2 + x1*x2
sage: e([3]).expand(4,alphabet='x,y,z,t')
x*y*z + x*y*t + x*z*t + y*z*t
sage: e([3]).expand(4,alphabet='y')
y0*y1*y2 + y0*y1*y3 + y0*y2*y3 + y1*y2*y3
```

omega()

Returns the image of self under the Frobenius / omega automorphism.

EXAMPLES:

```
sage: e = SFAElementary(QQ)
sage: a = e([2,1]); a
e[2, 1]
sage: a.omega()
e[1, 1, 1] - e[2, 1]

sage: h = SFAHomogeneous(QQ)
sage: h(e([2,1]).omega())
h[2, 1]
```

class SymmetricFunctionAlgebra_elementary(*R*)

17.33.7 Homogenous symmetric functions

class SymmetricFunctionAlgebraElement_homogeneous(*A*, *x*)

expand(*n*, *alphabet='x'*)

Expands the symmetric function as a symmetric polynomial in n variables.

EXAMPLES:

```
sage: h = SFAHomogeneous(QQ)
sage: h([3]).expand(2)
x0^3 + x0^2*x1 + x0*x1^2 + x1^3
sage: h([1,1,1]).expand(2)
x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + x1^3
sage: h([2,1]).expand(3)
x0^3 + 2*x0^2*x1 + 2*x0*x1^2 + x1^3 + 2*x0^2*x2 + 3*x0*x1*x2 + 2*x1^2*x2 + 2*x0*x2^2 + 2*x1*
sage: h([3]).expand(2,alphabet='y')
y0^3 + y0^2*y1 + y0*y1^2 + y1^3
sage: h([3]).expand(2,alphabet='x,y')
x^3 + x^2*y + x*y^2 + y^3
sage: h([3]).expand(3,alphabet='x,y,z')
x^3 + x^2*y + x*y^2 + y^3 + x^2*z + x*y*z + y^2*z + x*z^2 + y*z^2 + z^3
```

omega()

Returns the image of self under the Frobenius / omega automorphism.

EXAMPLES:

```
sage: h = SFAHomogeneous(QQ)
sage: a = h([2,1]); a
h[2, 1]
sage: a.omega()
h[1, 1, 1] - h[2, 1]
sage: e = SFAElementary(QQ)
sage: e(h([2,1]).omega())
e[2, 1]
```

class SymmetricFunctionAlgebra_homogeneous(*R*)

dual_basis(*scalar=None*, *prefix=None*)

The dual basis of the homogeneous basis with respect to the standard scalar product is the monomial basis.

EXAMPLES:

```
sage: m = SFAMonomial(QQ)
sage: h = SFAHomogeneous(QQ)
sage: h.dual_basis() == m
True
```

17.33.8 Power-sum symmetric functions

class SymmetricFunctionAlgebraElement_power(*A*, *x*)

expand(*n*, *alphabet='x'*)

Expands the symmetric function as a symmetric polynomial in n variables.

EXAMPLES:

```
sage: p = SFAPower(QQ)
sage: a = p([2])
sage: a.expand(2)
x0^2 + x1^2
sage: a.expand(3, alphabet=['a','b','c'])
a^2 + b^2 + c^2
sage: p([2,1,1]).expand(2)
x0^4 + 2*x0^3*x1 + 2*x0^2*x1^2 + 2*x0*x1^3 + x1^4
sage: p([7]).expand(4)
x0^7 + x1^7 + x2^7 + x3^7
sage: p([7]).expand(4,alphabet='t')
t0^7 + t1^7 + t2^7 + t3^7
sage: p([7]).expand(4,alphabet='x,y,z,t')
x^7 + y^7 + z^7 + t^7
```

omega()

Returns the image of self under the Frobenius / omega automorphism.

EXAMPLES:

```
sage: p = SFAPower(QQ)
sage: a = p([2,1]); a
p[2, 1]
sage: a.omega()
-p[2, 1]
```

scalar(x)

Returns the standard scalar product of self and x.

Note that the power-sum symmetric functions are orthogonal under this scalar product. The value of $\langle p_\lambda, p_\lambda \rangle$ is given by the size of the centralizer in S_n of a permutation of cycle type λ.

EXAMPLES:

```
sage: p = SFAPower(QQ)
sage: p4 = Partitions(4)
sage: matrix([ [p(a).scalar(p(b)) for a in p4] for b in p4])
[ 4  0  0  0  0]
[ 0  3  0  0  0]
[ 0  0  8  0  0]
[ 0  0  0  4  0]
[ 0  0  0  0 24]
```

class **SymmetricFunctionAlgebra_power**(R)

17.33.9 Generic dual bases symmetric functions

class **SymmetricFunctionAlgebraElement_dual**(A, *dictionary=None*, *dual=None*)

dual()

Returns self in the dual basis.

EXAMPLES:

```
sage: m = SFAMonomial(QQ)
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2,1])
sage: a.dual()
3*m[1, 1, 1] + 2*m[2, 1] + m[3]
```

expand(*n, alphabet='x'*)

EXAMPLES:

```
sage: m = SFAMonomial(QQ)
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(zee)
sage: a = h([2,1])+h([3])
sage: a.expand(2)
2*x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + 2*x1^3
sage: a.dual().expand(2)
2*x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + 2*x1^3
sage: a.expand(2,alphabet='y')
2*y0^3 + 3*y0^2*y1 + 3*y0*y1^2 + 2*y1^3
sage: a.expand(2,alphabet='x,y')
2*x^3 + 3*x^2*y + 3*x*y^2 + 2*y^3
```

omega()

Returns the image of self under the Frobenius / omega automorphism.

EXAMPLES:

```
sage: m = SFAMonomial(QQ)
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(zee)
sage: hh = SFAHomogeneous(QQ)
sage: hh([2,1]).omega()
h[1, 1, 1] - h[2, 1]
sage: h([2,1]).omega()
d_m[1, 1, 1] - d_m[2, 1]
```

scalar(*x*)

Returns the standard scalar product of self and x.

EXAMPLES:

```
sage: m = SFAMonomial(QQ)
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2,1])
sage: a.scalar(a)
2
```

scalar_hl(*x*)

Returns the Hall-Littlewood scalar product of self and x.

EXAMPLES:

```
sage: m = SFAMonomial(QQ)
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2,1])
sage: a.scalar_hl(a)
(t + 2)/(-t^4 + 2*t^3 - 2*t + 1)
```

class SymmetricFunctionAlgebra_dual(*dual_basis, scalar, scalar_name='', prefix=None*)

dual_basis(*scalar=None, scalar_name='', prefix=None*)

Return the dual basis to self. If a the scalar option is not passed, then it returns the dual basis with respect to the scalar product used to define self.

EXAMPLES:

```
sage: m = SFAMonomial(QQ)
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: h.dual_basis()
Symmetric Function Algebra over Rational Field, Monomial symmetric functions as basis
sage: m2 = h.dual_basis(zee, prefix='m2')
sage: m([2])^2
2*m[2, 2] + m[4]
sage: m2([2])^2
2*m2[2, 2] + m2[4]
```

transition_matrix(*basis, n*)

Returns the transition matrix between the n^{th} homogeneous component of self and basis.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: e = SFAElementary(QQ)
sage: f = e.dual_basis()
sage: f.transition_matrix(s, 5)
[ 1 -1  0  1  0 -1  1]
[-2  1  1 -1 -1  1  0]
[-2  2 -1 -1  1  0  0]
[ 3 -1 -1  1  0  0  0]
[ 3 -2  1  0  0  0  0]
[-4  1  0  0  0  0  0]
[ 1  0  0  0  0  0  0]
sage: e.transition_matrix(s, 5).inverse().transpose()
[ 1 -1  0  1  0 -1  1]
[-2  1  1 -1 -1  1  0]
[-2  2 -1 -1  1  0  0]
[ 3 -1 -1  1  0  0  0]
[ 3 -2  1  0  0  0  0]
[-4  1  0  0  0  0  0]
[ 1  0  0  0  0  0  0]
```

17.33.10 Symmetric functions defined by orthogonality and triangularity.

One characterization of Schur functions is that they are upper triangularly related to the monomial symmetric functions and orthogonal with respect to the Hall scalar product. We can use the class SymmetricFunctionAlgebra_orthotriang to obtain the Schur functions from this definition.

```
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
sage: m = SFAMonomial(QQ)
sage: s =  SymmetricFunctionAlgebra_orthotriang(QQ, m, zee, 's', 'Schur functions')
sage: s([2,1])^2
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1] + s[4, 2]

sage: s2 = SFASchur(QQ)
sage: s2([2,1])^2
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1] + s[4, 2]
```

class SymmetricFunctionAlgebraElement_orthotriang(*A, x*)

class SymmetricFunctionAlgebra_orthotriang(*R, base, scalar, prefix, name, leading_coeff=None*)

17.33.11 Kostka-Foulkes Polynomials

Based on the algorithms in John Stembridge's SF package for Maple which can be found at http://www.math.lsa.umich.edu/~jrs/maple.html .

KostkaFoulkesPolynomial(*mu, nu, t=None*)

Returns the Kostka-Foulkes polynomial $K_{\mu,\nu}(t)$.

EXAMPLES:

```
sage: KostkaFoulkesPolynomial([2,2],[2,2])
1
sage: KostkaFoulkesPolynomial([2,2],[4])
0
sage: KostkaFoulkesPolynomial([2,2],[1,1,1,1])
t^4 + t^2
sage: KostkaFoulkesPolynomial([2,2],[2,1,1])
t
sage: q = PolynomialRing(QQ,'q').gen()
sage: KostkaFoulkesPolynomial([2,2],[2,1,1],q)
q
```

compat(*n, mu, nu*)

Generate all possible partitions of n that can precede μ, ν in a rigging sequence.

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import *
sage: compat(4, [1], [2,1])
[[1, 1, 1, 1], [2, 1, 1], [2, 2], [3, 1], [4]]
sage: compat(3, [1], [2,1])
[[1, 1, 1], [2, 1], [3]]
sage: compat(2, [1], [])
[[2]]
sage: compat(3, [1], [])
[[2, 1], [3]]
sage: compat(3, [2], [1])
[[3]]
sage: compat(4, [1,1], [])
[[2, 2], [3, 1], [4]]
sage: compat(4, [2], [])
[[4]]
```

dom(*mu, snu*)

Returns True if `sum(mu[:i+1]) >= snu[i]` for all 0 <= i < len(snu); otherwise, it returns False.

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import *
sage: dom([3,2,1],[2,4,5])
True
sage: dom([3,2,1],[2,4,7])
False
sage: dom([3,2,1],[2,6,5])
False
sage: dom([3,2,1],[4,4,4])
False
```

kfpoly(*mu, nu, t=None*)

Returns the Kostka-Foulkes polynomial $K_{\mu,\nu}(t)$ by generating all rigging sequences for the shape μ, and then selecting those of content ν.

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import kfpoly
sage: kfpoly([2,2], [2,1,1])
t
sage: kfpoly([4], [2,1,1])
t^3
sage: kfpoly([4], [2,2])
t^2
sage: kfpoly([1,1,1,1], [2,2])
0
```

q_bin(*a, b, t=None*)

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import *
sage: t = PolynomialRing(ZZ, 't').gen()
sage: q_bin(4,2, t)
t^8 + t^7 + 2*t^6 + 2*t^5 + 3*t^4 + 2*t^3 + 2*t^2 + t + 1
sage: q_bin(4,3, t)
t^12 + t^11 + 2*t^10 + 3*t^9 + 4*t^8 + 4*t^7 + 5*t^6 + 4*t^5 + 4*t^4 + 3*t^3 + 2*t^2 + t + 1
```

riggings(*part*)

Generate all possible rigging sequences for a fixed sage.combinat.partition.

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import *
sage: riggings([3])
[[[1, 1, 1]], [[2, 1]], [[3]]]
sage: riggings([2,1])
[[[2, 1], [1]], [[3], [1]]]
sage: riggings([1,1,1])
[[[3], [2], [1]]]
sage: riggings([2,2])
[[[2, 2], [1, 1]], [[3, 1], [1, 1]], [[4], [1, 1]], [[4], [2]]]
sage: riggings([2,2,2])
[[[3, 3], [2, 2], [1, 1]],
 [[4, 2], [2, 2], [1, 1]],
 [[5, 1], [2, 2], [1, 1]],
 [[6], [2, 2], [1, 1]],
 [[5, 1], [3, 1], [1, 1]],
 [[6], [3, 1], [1, 1]],
 [[6], [4], [2]]]
```

schur_to_hl(*mu, t=None*)

Returns a dictionary corresponding to s_μ in Hall-Littlewood P basis.

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import *
sage: schur_to_hl([1,1,1])
{[1, 1, 1]: 1}
sage: a = schur_to_hl([2,1])
sage: for m,c in sorted(a.iteritems()): print m, c
[1, 1, 1] t^2 + t
```

```
[2, 1] 1
sage: a = schur_to_hl([3])
sage: for m,c in sorted(a.iteritems()): print m, c
[1, 1, 1] t^3
[2, 1] t
[3] 1
sage: a = schur_to_hl([4])
sage: for m,c in sorted(a.iteritems()): print m, c
[1, 1, 1, 1] t^6
[2, 1, 1] t^3
[2, 2] t^2
[3, 1] t
[4] 1
sage: a = schur_to_hl([3,1])
sage: for m,c in sorted(a.iteritems()): print m, c
[1, 1, 1, 1] t^5 + t^4 + t^3
[2, 1, 1] t^2 + t
[2, 2] t
[3, 1] 1
sage: a = schur_to_hl([2,2])
sage: for m,c in sorted(a.iteritems()): print m, c
[1, 1, 1, 1] t^4 + t^2
[2, 1, 1] t
[2, 2] 1
sage: a = schur_to_hl([2,1,1])
sage: for m,c in sorted(a.iteritems()): print m, c
[1, 1, 1, 1] t^3 + t^2 + t
[2, 1, 1] 1
sage: a = schur_to_hl([1,1,1,1])
sage: for m,c in sorted(a.iteritems()): print m, c
[1, 1, 1, 1] 1
sage: a = schur_to_hl([2,2,2])
sage: for m,c in sorted(a.iteritems()): print m, c
[1, 1, 1, 1, 1, 1] t^9 + t^7 + t^6 + t^5 + t^3
[2, 1, 1, 1, 1] t^4 + t^2
[2, 2, 1, 1] t
[2, 2, 2] 1
```

weight(*rg*, *t=None*)

Returns the weight of a rigging.

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import *
sage: t = PolynomialRing(ZZ, 't').gen()
sage: weight([[2,1], [1]], t)
1
sage: weight([[3],[1]], t)
t^2 + t
sage: weight([[2,1],[3]], t)
t^4
sage: weight([[2, 2], [1, 1]],t)
1
sage: weight([[3, 1], [1, 1]],t)
t
sage: weight([[4], [1, 1]],t)
t^4
sage: weight([[4], [2]],t)
```

```
t^2
```

17.33.12 Hall-Littlewood Polynomials

class HallLittlewoodElement_generic(*A*, *x*)

expand(*n*, *alphabet='x'*)

Expands the symmetric function as a symmetric polynomial in n variables.

EXAMPLES:

```
sage: HLP  = HallLittlewoodP(QQ)
sage: HLQ  = HallLittlewoodQ(QQ)
sage: HLQp = HallLittlewoodQp(QQ)
sage: HLP([2]).expand(2)
x0^2 + (-t + 1)*x0*x1 + x1^2
sage: HLQ([2]).expand(2)
(-t + 1)*x0^2 + (t^2 - 2*t + 1)*x0*x1 + (-t + 1)*x1^2
sage: HLQp([2]).expand(2)
x0^2 + x0*x1 + x1^2
```

scalar(*x*)

Returns standard scalar product between self and s.

This is the default implementation that converts both self and x into Schur functions and performs the scalar product that basis.

EXAMPLES:

```
sage: HLP  = HallLittlewoodP(QQ)
sage: HLQ  = HallLittlewoodQ(QQ)
sage: HLQp = HallLittlewoodQp(QQ)
sage: HLP([2]).scalar(HLQp([2]))
1
sage: HLP([2]).scalar(HLQp([1,1]))
0
```

scalar_hl(*x*, *t=None*)

Returns the standard Hall-Littlewood scalar product of self and x.

EXAMPLES:

```
sage: HLP  = HallLittlewoodP(QQ)
sage: HLQ  = HallLittlewoodQ(QQ)
sage: HLQp = HallLittlewoodQp(QQ)
sage: HLP([2]).scalar_hl(HLQ([2]))
1
sage: HLP([2]).scalar_hl(HLQ([1,1]))
0
```

class HallLittlewoodElement_p(*A*, *x*)

class HallLittlewoodElement_q(*A*, *x*)

class HallLittlewoodElement_qp(*A*, *x*)

HallLittlewoodP(*R*, *t=None*)

Returns the algebra of symmetric functions in Hall-Littlewood P basis. This is the same as the HL basis in John Stembridge's SF examples file.

If t is not specified, then the base ring will be obtained by making the univariate polynomial ring over R with the variable t and taking its fraction field.

EXAMPLES:

```
sage: HallLittlewoodP(QQ)
Hall-Littlewood polynomials in the P basis over Fraction Field of Univariate Polynomial Ring in
sage: HallLittlewoodP(QQ, t=-1)
Hall-Littlewood polynomials in the P basis with t=-1 over Rational Field
sage: HLP = HallLittlewoodP(QQ)
sage: s = SFASchur(HLP.base_ring())
sage: s(HLP([2,1]))
(-t^2-t)*s[1, 1, 1] + s[2, 1]
```

The Hall-Littlewood polynomials in the P basis at $t = 0$ are the Schur functions.

```
sage: HLP = HallLittlewoodP(QQ,t=0)
sage: s = SFASchur(HLP.base_ring())
sage: s(HLP([2,1])) == s([2,1])
True
```

The Hall-Littlewood polynomials in the P basis at $t = 1$ are the monomial symmetric functions.

```
sage: HLP = HallLittlewoodP(QQ,t=1)
sage: m = SFAMonomial(HLP.base_ring())
sage: m(HLP([2,2,1])) == m([2,2,1])
True
```

HallLittlewoodQ(*R, t=None*)

Returns the algebra of symmetric functions in Hall-Littlewood Q basis. This is the same as the Q basis in John Stembridge's SF examples file.

If t is not specified, then the base ring will be obtained by making the univariate polynomial ring over R with the variable t and taking its fraction field.

EXAMPLES:

```
sage: HallLittlewoodQ(QQ)
Hall-Littlewood polynomials in the Q basis over Fraction Field of Univariate Polynomial Ring in
sage: HallLittlewoodQ(QQ, t=-1)
Hall-Littlewood polynomials in the Q basis with t=-1 over Rational Field
```

HallLittlewoodQp(*R, t=None*)

Returns the algebra of symmetric functions in Hall-Littlewood Q' (Qp) basis. This is dual to the Hall-Littlewood P basis with respect to the standard scalar product.

If t is not specified, then the base ring will be obtained by making the univariate polynomial ring over R with the variable t and taking its fraction field.

EXAMPLES:

```
sage: HallLittlewoodQp(QQ)
Hall-Littlewood polynomials in the Qp basis over Fraction Field of Univariate Polynomial Ring in
sage: HallLittlewoodQp(QQ, t=-1)
Hall-Littlewood polynomials in the Qp basis with t=-1 over Rational Field
```

class **HallLittlewood_generic**(*R, t=None*)

transition_matrix(*basis, n*)

Returns the transitions matrix between self and basis for the homogenous component of degree n.

EXAMPLES:

```
sage: HLP = HallLittlewoodP(QQ)
sage: s   = SFASchur(HLP.base_ring())
sage: HLP.transition_matrix(s, 4)
[             1             -t              0            t^2           -t^3]
[             0              1             -t             -t      t^3 + t^2]
[             0              0              1             -t             t^3]
[             0              0              0              1 -t^3 - t^2 - t]
[             0              0              0              0              1]
sage: HLQ = HallLittlewoodQ(QQ)
sage: HLQ.transition_matrix(s,3)
[                         -t + 1                       t^2 - t                      -t^3 + t^
[                              0             t^2 - 2*t + 1           -t^4 + t^3 + t^2 -
[                              0                        0 -t^6 + t^5 + t^4 - t^2 - t +
sage: HLQp = HallLittlewoodQp(QQ)
sage: HLQp.transition_matrix(s,3)
[      1       0       0]
[      t       1       0]
[    t^3 t^2 + t       1]
```

class HallLittlewood_p(*R*, *t=None*)

class HallLittlewood_q(*R*, *t=None*)

class HallLittlewood_qp(*R*, *t=None*)

17.33.13 Jack Polynomials

class JackPolynomial_generic(*A*, *x*)

scalar_jack(*x*)
EXAMPLES:

```
sage: P = JackPolynomialsP(QQ)
sage: Q = JackPolynomialsQ(QQ)
sage: p = Partitions(3).list()
sage: matrix([[P(a).scalar_jack(Q(b)) for a in p] for b in p])
[1 0 0]
[0 1 0]
[0 0 1]
```

class JackPolynomial_j(*A*, *x*)

class JackPolynomial_p(*A*, *x*)

scalar_jack(*x*)
EXAMPLES:

```
sage: P = JackPolynomialsP(QQ)
sage: l = [P(p) for p in Partitions(3)]
sage: matrix([[a.scalar_jack(b) for a in l] for b in l])
[  6*t^3/(2*t^2 + 3*t + 1)                          0                          0]
[                       0     (2*t^3 + t^2)/(t + 2)                          0]
[                       0                          0 1/6*t^3 + 1/2*t^2 + 1/3*t]
```

class JackPolynomial_q(*A*, *x*)

JackPolynomialsJ(*R*, *t=None*)
Returns the algebra of Jack polynomials in the J basis.

If t is not specified, then the base ring will be obtained by making the univariate polynomial ring over R with the variable t and taking its fraction field.

EXAMPLES:

```
sage: JackPolynomialsJ(QQ)
Jack polynomials in the J basis over Fraction Field of Univariate Polynomial Ring in t over Rati
sage: JackPolynomialsJ(QQ,t=-1)
Jack polynomials in the J basis with t=-1 over Rational Field
```

At t = 1, the Jack polynomials in the J basis are scalar multiples of the Schur functions with the scalar given by a Partition's hook_product method at 1.

```
sage: J = JackPolynomialsJ(QQ, t=1)
sage: s = SFASchur(J.base_ring())
sage: p = Partition([3,2,1,1])
sage: s(J(p)) == p.hook_product(1)*s(p)
True
```

At t = 2, the Jack polynomials on the J basis are scalar multiples of the zonal polynomials with the scalar given by a Partition's hook_product method at 1.

```
sage: t = 2
sage: J = JackPolynomialsJ(QQ,t=t)
sage: Z = ZonalPolynomials(J.base_ring())
sage: p = Partition([2,2,1])
sage: Z(J(p)) == p.hook_product(t)*Z(p)
True
```

JackPolynomialsP(*R, t=None*)

Returns the algebra of Jack polynomials in the P basis.

If t is not specified, then the base ring will be obtained by making the univariate polynomial ring over R with the variable t and taking its fraction field.

EXAMPLES:

```
sage: JackPolynomialsP(QQ)
Jack polynomials in the P basis over Fraction Field of Univariate Polynomial Ring in t over Rati
sage: JackPolynomialsP(QQ,t=-1)
Jack polynomials in the P basis with t=-1 over Rational Field
```

At t = 1, the Jack polynomials on the P basis are the Schur symmetric functions.

```
sage: P = JackPolynomialsP(QQ,1)
sage: s = SFASchur(QQ)
sage: P([2,1])^2
JackP[2, 2, 1, 1] + JackP[2, 2, 2] + JackP[3, 1, 1, 1] + 2*JackP[3, 2, 1] + JackP[3, 3] + JackP[
sage: s([2,1])^2
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1] + s[4, 2]
```

At t = 2, the Jack polynomials on the P basis are the zonal polynomials.

```
sage: P = JackPolynomialsP(QQ,2)
sage: Z = ZonalPolynomials(QQ)
sage: P([2])^2
64/45*JackP[2, 2] + 16/21*JackP[3, 1] + JackP[4]
sage: Z([2])^2
64/45*Z[2, 2] + 16/21*Z[3, 1] + Z[4]
sage: Z(P([2,1]))
```

```
Z[2, 1]
sage: P(Z([2,1]))
JackP[2, 1]
```

JackPolynomialsQ(*R*, *t=None*)

Returns the algebra of Jack polynomials in the Q basis.

If t is not specified, then the base ring will be obtained by making the univariate polynomial ring over R with the variable t and taking its fraction field.

EXAMPLES:

```
sage: JackPolynomialsQ(QQ)
Jack polynomials in the Q basis over Fraction Field of Univariate Polynomial Ring in t over Rati
sage: JackPolynomialsQ(QQ,t=-1)
Jack polynomials in the Q basis with t=-1 over Rational Field
```

JackPolynomialsQp(*R*, *t=None*)

Returns the algebra of Jack polynomials in the Qp, which is dual to the P basis with respect to the standard scalar product.

If t is not specified, then the base ring will be obtained by making the univariate polynomial ring over R with the variable t and taking its fraction field.

EXAMPLES:

```
sage: Qp = JackPolynomialsQp(QQ)
sage: P = JackPolynomialsP(QQ)
sage: a = Qp([2])
sage: a.scalar(P([2]))
1
sage: a.scalar(P([1,1]))
0
sage: P(Qp([2]))
((t-1)/(t+1))*JackP[1, 1] + JackP[2]
```

class JackPolynomials_generic(*R*, *t=None*)

class JackPolynomials_j(*R*, *t=None*)

class JackPolynomials_p(*R*, *t=None*)

class JackPolynomials_q(*R*, *t=None*)

ZonalPolynomials(*R*)

Returns the algebra of zonal polynomials.

EXAMPLES:

```
sage: Z = ZonalPolynomials(QQ)
sage: a = Z([2])
sage: Z([2])^2
64/45*Z[2, 2] + 16/21*Z[3, 1] + Z[4]
```

c1(*part*, *t*)

EXAMPLES:

```
sage: from sage.combinat.sf.jack import c1
sage: t = QQ['t'].gen()
sage: [c1(p,t) for p in Partitions(3)]
[2*t^2 + 3*t + 1, t + 2, 6]
```

c2 (*part, t*)

EXAMPLES:

```
sage: from sage.combinat.sf.jack import c2
sage: t = QQ['t'].gen()
sage: [c2(p,t) for p in Partitions(3)]
[6*t^3, 2*t^3 + t^2, t^3 + 3*t^2 + 2*t]
```

scalar_jack (*part1, part2, t*)

Returns the Jack scalar product between p(part1) and p(part2) where p is the power-sum basis.

EXAMPLES:

```
sage: Q.<t> = QQ[]
sage: from sage.combinat.sf.jack import scalar_jack
sage: matrix([[scalar_jack(p1,p2,t) for p1 in Partitions(4)] for p2 in Partitions(4)])
[   4*t       0       0       0       0]
[     0  3*t^2       0       0       0]
[     0       0  8*t^2       0       0]
[     0       0       0  4*t^3       0]
[     0       0       0       0 24*t^4]
```

17.33.14 k-Schur Functions

class kSchurFunction_generic (*A, x*)

class kSchurFunction_t (*A, x*)

kSchurFunctions (*R, k, t=None*)

Returns the k-Schur functions. See the examples below for caveats on their use.

EXAMPLES:

```
sage: ks3 = kSchurFunctions(QQ, 3); ks3
k-Schur Functions at level 3 over Univariate Polynomial Ring in t over Rational Field
sage: s = SFASchur(ks3.base_ring()) # Allow 't' coefficients for the Schurs.
sage: t = ks3.t # Allow 't' as input
sage: s(ks3([3,2,1]))
s[3, 2, 1] + t*s[4, 1, 1] + t*s[4, 2] + t^2*s[5, 1]

sage: ks3(s([3, 2, 1]) + t*s([4, 1, 1]) + t*s([4, 2]) + t^2*s([5, 1]))
ks3[3, 2, 1]

sage: ks3([4,3,2,1])  # k-Schurs are indexed by partitions with first part \le k.
0
```

Attempting to convert a function that is not in the linear span of the k-Schur's raises an error.

```
sage: ks3(s([4]))
...
ValueError: s[4] is not in the space spanned by k-Schur Functions at level 3 over Univariate Pol
```

Note that the product of k-Schurs is not guaranteed to be in the space spanned by the k-Schurs. In general, we only have that a k-Schur times a j-Schur is a (k+j)-Schur. This fact is not currently incorporated into the Sage design, so the multiplication of k-Schur functions may return an error. This example shows how to get around this 'manually'.

```
sage: ks2 = kSchurFunctions(QQ, 2)
sage: ks2([2,1])^2
...
ValueError: s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + (2*t+2)*s[3, 2, 1] + (t^2+1)*s[3,
3] + (2*t+1)*s[4, 1, 1] + (t^2+2*t+1)*s[4, 2] + (t^2+2*t)*s[5, 1] + t^2*s[6] is not in the
space spanned by k-Schur Functions at level 2 over Univariate Polynomial Ring in t over
Rational Field.
```

```
sage: f = s(ks2([2,1]))^2; f # Convert to Schur functions first and multiply there.
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + (2*t+2)*s[3, 2, 1] + (t^2+1)*s[3,
3] + (2*t+1)*s[4, 1, 1] + (t^2+2*t+1)*s[4, 2] + (t^2+2*t)*s[5, 1] + t^2*s[6]
sage: ks4 = kSchurFunctions(QQ, 4)
sage: ks4(f) # The product of two 'ks2's is a 'ks4'.
ks4[2, 2, 1, 1] + ks4[2, 2, 2] + ks4[3, 1, 1, 1] + (t+2)*ks4[3, 2, 1] + (t^2+1)*ks4[3, 3] + (t+1
```

However, at t=1, the product of k-Schurs is in the span of the k-Schurs. Below are some examples at t=1.

```
sage: ks3 = kSchurFunctions(QQ, 3, 1); ks3
k-Schur Functions at level 3 with t=1 over Rational Field
sage: s = SFASchur(ks3.base_ring())
sage: ks3(s([3]))
ks3[3]
sage: s(ks3([3,2,1]))
s[3, 2, 1] + s[4, 1, 1] + s[4, 2] + s[5, 1]
sage: ks3([2,1])^2
ks3[2, 2, 1, 1] + ks3[2, 2, 2] + ks3[3, 1, 1, 1]
```

class kSchurFunctions_generic(*R, element_class=None*)

class kSchurFunctions_t(*R, k, t=None*)

17.33.15 LLT Polynomials

LLT(*R, k, t=None*)

Returns a class for working with LLT polynomials.

EXAMPLES:

```
sage: L3 = LLT(QQ,3); L3
LLT polynomials at level 3 over Fraction Field of Univariate Polynomial Ring in t over Rational
sage: L3.cospin([3,2,1])
(t+1)*m[1, 1] + m[2]
sage: L3.hcospin()
LLT polynomials in the HCosp basis at level 3 with t=t over Fraction Field of Univariate Polynom
```

class LLTElement_cospin(*A, x*)

class LLTElement_generic(*A, x*)

class LLTElement_spin(*A, x*)

LLTHCospin(*R, level, t=None*)

Returns the LLT polynomials in the HCospin basis at level level.

EXAMPLES:

```
sage: HCosp3 = LLTHCospin(QQ,3)
sage: HCosp3([1])^2
1/t*HCosp3[1, 1] + ((t-1)/t)*HCosp3[2]
```

LLTHSpin(*R, level, t=None*)

Returns the LLT polynomials in the HSpin basis at level level.

EXAMPLES:

```
sage: HSp3 = LLTHSpin(QQ,3)
sage: HSp3([1])^2
HSp[1, 1] + (-t+1)*HSp[2]
```

class **LLT_class**(*R, k, t=None*)

base_ring()

Returns the base ring of self.

EXAMPLES:

```
sage: LLT(QQ,3).base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

cospin(*skp*)

EXAMPLES:

```
sage: L3 = LLT(QQ,3)
sage: L3.cospin([2,1])
m[1]
sage: L3.cospin([3,2,1])
(t+1)*m[1, 1] + m[2]
sage: s = SFASchur(L3.base_ring())
sage: s(L3.cospin([[2],[1],[2]]))
t^4*s[2, 2, 1] + t^3*s[3, 1, 1] + (t^3+t^2)*s[3, 2] + (t^2+t)*s[4, 1] + s[5]
```

hcospin()

Returns the HCopsin basis.

EXAMPLES:

```
sage: LLT(QQ,3).hcospin()
LLT polynomials in the HCosp basis at level 3 with t=t over Fraction Field of Univariate Pol
```

hspin()

Returns the HSpin basis.

EXAMPLES:

```
sage: LLT(QQ,3).hspin()
LLT polynomials in the HSp basis at level 3 with t=t over Fraction Field of Univariate Polyn
```

level()

Returns the level of self.

EXAMPLES:

```
sage: LLT(QQ,3).level()
3
```

spin_square(*skp*)

Returns the spin polynomial associated with skp with the substitution $t \to t^2$ made.

EXAMPLES:

```
sage: L3 = LLT(QQ,3)
sage: L3.spin_square([2,1])
t*m[1]
sage: L3.spin_square([3,2,1])
```

```
(t^3+t)*m[1, 1] + t^3*m[2]
sage: L3.spin_square([[1],[1],[1]])
(t^6+2*t^4+2*t^2+1)*m[1, 1, 1] + (t^6+t^4+t^2)*m[2, 1] + t^6*m[3]
```

class **LLT_cospin**(*R*, *level*, *t=None*)

class **LLT_generic**(*R*, *level*, *t=None*)

level()

Returns the level of self.

EXAMPLES:

```
sage: from sage.combinat.sf.llt import *
sage: HSp3 = LLT_spin(QQ, 3)
sage: HSp3.level()
3
```

class **LLT_spin**(*R*, *level*, *t=None*)

17.33.16 Macdonald Polynomials

class **MacdonaldPolynomial_generic**(*A*, *x*)

nabla()

Returns the value of the nabla operator applied to self. The eigenvectors of the nabla operator are the Macdonald polynomials in the Ht basis.

EXAMPLES:

```
sage: from sage.combinat.sf.macdonald import *
sage: P = MacdonaldPolynomialsP(QQ)
sage: P([1,1]).nabla()
((q^2*t+q*t^2-2*t)/(q*t-1))*McdP[1, 1] + McdP[2]
```

omega_qt()

Returns the image of self under the ω_{qt} automorphism.

EXAMPLES:

```
sage: H = MacdonaldPolynomialsH(QQ)
sage: H([1,1]).omega_qt()
((2*q^2-2*q*t-2*q+2*t)/(t^3-t^2-t+1))*McdH[1, 1] + ((q-1)/(t-1))*McdH[2]
```

scalar_qt(*x*)

Returns the qt-Hall scalar product of self and x by converting both to the power-sum basis.

EXAMPLES:

```
sage: H = MacdonaldPolynomialsH(QQ)
sage: H([1]).scalar_qt(H([1]))
(-q + 1)/(-t + 1)
```

class **MacdonaldPolynomial_h**(*A*, *x*)

class **MacdonaldPolynomial_ht**(*A*, *x*)

nabla()

Returns the value of the nabla operator applied to self. The eigenvectors of the nabla operator are the Macdonald polynomials in the Ht basis.

EXAMPLES:

```
sage: Ht = MacdonaldPolynomialsHt(QQ)
sage: t = Ht.t; q = Ht.q;
sage: a = sum(Ht(p) for p in Partitions(3))
sage: a.nabla() == t^3*Ht([1,1,1])+q*t*Ht([2,1]) + q^3*Ht([3])
True
```

class MacdonaldPolynomial_j(*A*, *x*)

scalar_qt(*x*)

Returns the qt-Hall scalar product of self and x. If x is in the Macdonald J basis, then specialized code is used; otherwise, both are converted to the power-sums and the scalar product is carried out there.

EXAMPLES:

```
sage: J = MacdonaldPolynomialsJ(QQ)
sage: J([1,1]).scalar_qt(J([1,1]))
q^2*t^4 - q^2*t^3 - q*t^4 - q^2*t^2 + q^2*t + 2*q*t^2 + t^3 - t^2 - q - t + 1
sage: J([1,1]).scalar_qt(J([2]))
0
sage: J([2]).scalar_qt(J([2]))
q^4*t^2 - q^4*t - q^3*t^2 - q^2*t^2 + q^3 + 2*q^2*t + q*t^2 - q^2 - q - t + 1
```

class MacdonaldPolynomial_p(*A*, *x*)

scalar_qt(*x*)

Returns the qt-Hall scalar product of self and x. If x is in the Macdonald P or Q basis, then specialized code is used; otherwise, both are converted to the power-sums and the scalar product is carried out there.

EXAMPLES:

```
sage: Q = MacdonaldPolynomialsQ(QQ)
sage: P = MacdonaldPolynomialsP(QQ)
sage: a = P([2])
sage: b = Q([2])
sage: a.scalar_qt(a)
(q^3 - q^2 - q + 1)/(q*t^2 - q*t - t + 1)
sage: a.scalar_qt(b)
1
```

class MacdonaldPolynomial_q(*A*, *x*)

scalar_qt(*x*)

Returns the qt-Hall scalar product of self and x. If x is in the Macdonald P basis, then specialized code is used; otherwise, both are converted to the power-sums and the scalar product is carried out there.

EXAMPLES:

```
sage: Q = MacdonaldPolynomialsQ(QQ)
sage: H = MacdonaldPolynomialsH(QQ)
sage: a = Q([2])
sage: a.scalar_qt(a)
(-q*t^2 + q*t + t - 1)/(-q^3 + q^2 + q - 1)
sage: a.scalar_qt(H([1,1]))
t
```

class MacdonaldPolynomial_s(*A*, *x*)

creation(*k*)

EXAMPLES:

```
sage: S = MacdonaldPolynomialsS(QQ)
sage: a = S(1)
sage: a.creation(1)
(-q+1)*McdS[1]
sage: a.creation(2)
(q^2*t-q*t-q+1)*McdS[1, 1] + (q^2-q*t-q+t)*McdS[2]
```

omega_qt()

Returns the image of self under the Frobenius / omega automorphism.

EXAMPLES:

```
sage: S = MacdonaldPolynomialsS(QQ)
sage: S([1,1]).omega_qt()
(t/(t^3-t^2-t+1))*McdS[1, 1] + ((-1)/(-t^3+t^2+t-1))*McdS[2]
```

MacdonaldPolynomialsH(*R, q=None, t=None*)

Returns the Macdonald polynomials on the H basis. When the H basis is expanded on the Schur basis, the coefficients are the qt-Kostka numbers.

EXAMPLES:

```
sage: H = MacdonaldPolynomialsH(QQ)
sage: s = SFASchur(H.base_ring())
sage: s(H([2]))
q*s[1, 1] + s[2]
sage: s(H([1,1]))
s[1, 1] + t*s[2]
```

MacdonaldPolynomialsHt(*R, q=None, t=None*)

Returns the Macdonald polynomials on the Ht basis. The elements of the Ht basis are eigenvectors of the nabla operator. When expanded on the Schur basis, the coefficients are the modified qt-Kostka numbers.

EXAMPLES:

```
sage: Ht = MacdonaldPolynomialsHt(QQ)
sage: [Ht(p).nabla() for p in Partitions(3)]
[q^3*McdHt[3], q*t*McdHt[2, 1], t^3*McdHt[1, 1, 1]]

sage: s = SFASchur(Ht.base_ring())
sage: from sage.combinat.sf.macdonald import qt_kostka
sage: q,t = Ht.base_ring().gens()
sage: s(Ht([2,1]))
q*t*s[1, 1, 1] + (q+t)*s[2, 1] + s[3]
sage: qt_kostka([1,1,1],[2,1]).subs(t=1/t)*t^Partition([2,1]).weighted_size()
q*t
sage: qt_kostka([2,1],[2,1]).subs(t=1/t)*t^Partition([2,1]).weighted_size()
q + t
sage: qt_kostka([3],[2,1]).subs(t=1/t)*t^Partition([2,1]).weighted_size()
1
```

MacdonaldPolynomialsJ(*R, q=None, t=None*)

Returns the Macdonald polynomials on the J basis also known as the integral form of the Macdonald polynomials. These are scalar multiples of both the P and Q bases. When expressed in the P or Q basis, the scaling coefficients are polynomials in q and t rather than rational functions.

EXAMPLES:

```
sage: J = MacdonaldPolynomialsJ(QQ); J
Macdonald polynomials in the J basis over Fraction Field of Multivariate Polynomial Ring in q, t
sage: P = MacdonaldPolynomialsP(QQ)
sage: Q = MacdonaldPolynomialsQ(QQ)
sage: P(J([2]))
(q*t^2-q*t-t+1)*McdP[2]
sage: P(J([1,1]))
(t^3-t^2-t+1)*McdP[1, 1]
sage: Q(J([2]))
(q^3-q^2-q+1)*McdQ[2]
sage: Q(J([1,1]))
(q^2*t-q*t-q+1)*McdQ[1, 1]
```

MacdonaldPolynomialsP(*R, q=None, t=None*)

Returns the Macdonald polynomials on the P basis. These are upper triangularly related to the monomial symmetric functions and are orthogonal with respect to the qt-Hall scalar product.

EXAMPLES:

```
sage: P = MacdonaldPolynomialsP(QQ); P
Macdonald polynomials in the P basis over Fraction Field of Multivariate Polynomial Ring in q, t
sage: m = SFAMonomial(P.base_ring())
sage: P.transition_matrix(m,2)
[                          1 (q*t - q + t - 1)/(q*t - 1)]
[                          0                         1]
sage: P([1,1]).scalar_qt(P([2]))
0
sage: P([2]).scalar_qt(P([2]))
(q^3 - q^2 - q + 1)/(q*t^2 - q*t - t + 1)
sage: P([1,1]).scalar_qt(P([1,1]))
(q^2*t - q*t - q + 1)/(t^3 - t^2 - t + 1)
```

When q = 0, the Macdonald polynomials on the P basis are the same as the Hall-Littlewood polynomials on the P basis.

```
sage: P = MacdonaldPolynomialsP(QQ,q=0)
sage: P([2])^2
(t+1)*McdP[2, 2] + (-t+1)*McdP[3, 1] + McdP[4]
sage: HLP = HallLittlewoodP(QQ)
sage: HLP([2])^2
(t+1)*P[2, 2] + (-t+1)*P[3, 1] + P[4]
```

MacdonaldPolynomialsQ(*R, q=None, t=None*)

Returns the Macdonald polynomials on the Q basis. These are dual to the Macdonald polynomials on the P basis with respect to the qt-Hall scalar product.

EXAMPLES:

```
sage: Q = MacdonaldPolynomialsQ(QQ); Q
Macdonald polynomials in the Q basis over Fraction Field of Multivariate Polynomial Ring in q, t
sage: P = MacdonaldPolynomialsP(QQ)
sage: Q([2]).scalar_qt(P([2]))
1
sage: Q([2]).scalar_qt(P([1,1]))
0
sage: Q([1,1]).scalar_qt(P([2]))
0
sage: Q([1,1]).scalar_qt(P([1,1]))
```

```
1
sage: Q(P([2]))
((q^3-q^2-q+1)/(q*t^2-q*t-t+1))*McdQ[2]
sage: Q(P([1,1]))
((q^2*t-q*t-q+1)/(t^3-t^2-t+1))*McdQ[1, 1]
```

MacdonaldPolynomialsS(*R, q=None, t=None*)

Returns the modified Schur functions defined by the plethystic substitution $S_\mu = s_\mu[X(1-t)]$. When the Macdonald polynomials in the J basis are expressed in terms of the modified Schur functions, the coefficients are qt-Kostka numbers.

EXAMPLES:

```
sage: S = MacdonaldPolynomialsS(QQ)
sage: J = MacdonaldPolynomialsJ(QQ)
sage: S(J([2]))
q*McdS[1, 1] + ((-1)/(-1))*McdS[2]
sage: S(J([1,1]))
McdS[1, 1] + t*McdS[2]
sage: from sage.combinat.sf.macdonald import qt_kostka
sage: qt_kostka([2],[1,1])
t
sage: qt_kostka([1,1],[2])
q
```

class MacdonaldPolynomials_generic(*R, q=None, t=None*)

class MacdonaldPolynomials_h(*R, q=None, t=None*)

class MacdonaldPolynomials_ht(*R, q=None, t=None*)

class MacdonaldPolynomials_j(*R, q=None, t=None*)

class MacdonaldPolynomials_p(*R, q=None, t=None*)

class MacdonaldPolynomials_q(*R, q=None, t=None*)

class MacdonaldPolynomials_s(*R, q=None, t=None*)

c1(*part, q, t*)

This function returns the qt-Hall scalar product between J(part) and P(part).

EXAMPLES:

```
sage: from sage.combinat.sf.macdonald import c1
sage: R.<q,t> = QQ[]
sage: c1(Partition([2,1]),q,t)
-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1
sage: c1(Partition([1,1]),q,t)
q^2*t - q*t - q + 1
```

c2(*part, q, t*)

This function returns the qt-Hall scalar product between J(part) and Q(part).

EXAMPLES:

```
sage: from sage.combinat.sf.macdonald import c2
sage: R.<q,t> = QQ[]
sage: c2(Partition([1,1]),q,t)
t^3 - t^2 - t + 1
sage: c2(Partition([2,1]),q,t)
-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1
```

qt_kostka(*lam, mu*)

Returns the $K_{\lambda\mu}(q,t)$ by computing the change of basis from the Macdonald H basis to the Schurs.

EXAMPLES:

```
sage: from sage.combinat.sf.macdonald import qt_kostka
sage: qt_kostka([2,1,1],[1,1,1,1])
t^3 + t^2 + t
sage: qt_kostka([1,1,1,1],[2,1,1])
q
sage: qt_kostka([1,1,1,1],[3,1])
q^3
sage: qt_kostka([1,1,1,1],[1,1,1,1])
1
sage: qt_kostka([2,1,1],[2,2])
q^2*t + q*t + q
sage: qt_kostka([2,2],[2,2])
q^2*t^2 + 1
sage: qt_kostka([4],[3,1])
t
sage: qt_kostka([2,2],[3,1])
q^2*t + q
sage: qt_kostka([3,1],[2,1,1])
q*t^3 + t^2 + t
sage: qt_kostka([2,1,1],[2,1,1])
q*t^2 + q*t + 1
sage: qt_kostka([2,1],[1,1,1,1])
0
```

17.33.17 Non-symmetric Macdonald Polynomials

class AugmentedLatticeDiagramFilling(*l, pi=None*)

are_attacking(*i, j, ii, jj*)

Returns True if the boxes (i,j) and (ii,jj) in self are attacking.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: all( a.are_attacking(i,j,ii,jj) for (i,j),(ii,jj) in a.attacking_boxes())
True
sage: a.are_attacking(1,1,3,2)
False
```

attacking_boxes()

Returns a list of pairs of boxes in self that are attacking.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.attacking_boxes()[:5]
[((1, 1), (2, 1)),
 ((1, 1), (3, 1)),
 ((1, 1), (6, 1)),
 ((1, 1), (2, 0)),
 ((1, 1), (3, 0))]
```

boxes()

Returns a list of the coordinates of the boxes of self, including the 'basement row'.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.boxes()
[(1, 1),
 (1, 2),
 (2, 1),
 (3, 1),
 (3, 2),
 (3, 3),
 (6, 1),
 (6, 2),
 (1, 0),
 (2, 0),
 (3, 0),
 (4, 0),
 (5, 0),
 (6, 0)]
```

coeff(*q*, *t*)

Returns the coefficient in front of self in the HHL formula for the expansion of the non-symmetric Macdonald polynomial E(self.shape()).

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: q,t = var('q,t')
sage: a.coeff(q,t)
(t - 1)^4/((q*t^2 - 1)^2*(q^2*t^3 - 1)^2)
```

coeff_integral(*q*, *t*)

Returns the coefficient in front of self in the HHL formula for the expansion of the integral non-symmetric Macdonald polynomial E(self.shape())

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: q,t = var('q,t')
sage: a.coeff_integral(q,t)
(t - 1)^4*(q*t^2 - 1)^2*(q^2*t^3 - 1)^2
```

coinv()

Returns self's co-inversion statistic.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.coinv()
2
```

descents()

Returns a list of the descents of self.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.descents()
[(1, 2), (3, 2)]
```

inv()

Returns self's inversion statistic.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.inv()
15
```

inversions()

Returns a list of the inversions of self.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.inversions()[:5]
[((6, 2), (3, 2)),
 ((1, 2), (6, 1)),
 ((1, 2), (3, 1)),
 ((1, 2), (2, 1)),
 ((6, 1), (3, 1))]
sage: len(a.inversions())
25
```

is_non_attacking()

Returns True if self in non-attacking.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.is_non_attacking()
True
sage: a = AugmentedLatticeDiagramFilling([[1, 1, 1], [2, 3], [3]])
sage: a.is_non_attacking()
False
sage: a = AugmentedLatticeDiagramFilling([[2,2],[1]])
sage: a.is_non_attacking()
False
sage: pi = Permutation([2,1]).to_permutation_group_element()
sage: a = AugmentedLatticeDiagramFilling([[2,2],[1]],pi)
sage: a.is_non_attacking()
True
```

maj()

Returns the major index of self.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.maj()
3
```

permuted_filling(*sigma*)

EXAMPLES:

```
sage: pi=Permutation([2,1,4,3]).to_permutation_group_element()
sage: fill=[[2],[1,2,3],[],[3,1]]
sage: AugmentedLatticeDiagramFilling(fill).permuted_filling(pi)
[[2, 1], [1, 2, 1, 4], [4], [3, 4, 2]]
```

reading_order()

Returns a list of coordinates of the boxes in self, starting from the top right, and reading from right to left. Note that this includes the 'basement row' of self.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.reading_order()
```

```
[(3, 3),
 (6, 2),
 (3, 2),
 (1, 2),
 (6, 1),
 (3, 1),
 (2, 1),
 (1, 1),
 (6, 0),
 (5, 0),
 (4, 0),
 (3, 0),
 (2, 0),
 (1, 0)]
```

reading_word()

Return the reading word of self, obtained by reading the boxes entries of self from right to left, starting in the upper right.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.reading_word()
word: 25465321
```

shape()

Returns the shape of self.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.shape()
[2, 1, 3, 0, 0, 2]
```

weight()

Returns the weight of self.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.weight()
[1, 2, 1, 1, 2, 1]
```

E(*mu, q=None, t=None, pi=None*)

Returns the non-symmetric Macdonald polynomial in type A corresponding to a shape mu, with basement permuted according to pi.

Note that if both q and t are specified, then they must have the same parent.

REFERENCE:

- 'A combinatorial formula for non-symmetric Macdonald polynomials'. Haiman, Haglund, and Loehr. http://arxiv.org/abs/math/0601693

EXAMPLES:

```
sage: from sage.combinat.sf.ns_macdonald import E
sage: E([0,0,0])
1
sage: E([1,0,0])
x0
sage: E([0,1,0])
((-t + 1)/(-q*t^2 + 1))*x0 + x1
```

```
sage: E([0,0,1])
((-t + 1)/(-q*t + 1))*x0 + ((-t + 1)/(-q*t + 1))*x1 + x2
sage: E([1,1,0])
x0*x1
sage: E([1,0,1])
((-t + 1)/(-q*t^2 + 1))*x0*x1 + x0*x2
sage: E([0,1,1])
((-t + 1)/(-q*t + 1))*x0*x1 + ((-t + 1)/(-q*t + 1))*x0*x2 + x1*x2
sage: E([2,0,0])
x0^2 + ((-q*t + q)/(-q*t + 1))*x0*x1 + ((-q*t + q)/(-q*t + 1))*x0*x2
sage: E([0,2,0])
((-t + 1)/(-q^2*t^2 + 1))*x0^2 + ((-q^2*t^3 + q^2*t^2 - q*t^2 + 2*q*t - q + t - 1)/(-q^3*t^3 + q
```

E_integral (*mu, q=None, t=None, pi=None*)

Returns the integral form for the non-symmetric Macdonald polynomial in type A corresponding to a shape mu.

Note that if both q and t are specified, then they must have the same parent.

REFERENCE:

- 'A combinatorial formula for non-symmetric Macdonald polynomials'. Haiman, Haglund, and Loehr. http://arxiv.org/abs/math/0601693

EXAMPLES:

```
sage: from sage.combinat.sf.ns_macdonald import E_integral
sage: E_integral([0,0,0])
1
sage: E_integral([1,0,0])
(-t + 1)*x0
sage: E_integral([0,1,0])
(-q*t^2 + 1)*x0 + (-t + 1)*x1
sage: E_integral([0,0,1])
(-q*t + 1)*x0 + (-q*t + 1)*x1 + (-t + 1)*x2
sage: E_integral([1,1,0])
(t^2 - 2*t + 1)*x0*x1
sage: E_integral([1,0,1])
(q*t^3 - q*t^2 - t + 1)*x0*x1 + (t^2 - 2*t + 1)*x0*x2
sage: E_integral([0,1,1])
(q^2*t^3 + q*t^4 - q*t^3 - q*t^2 - q*t - t^2 + t + 1)*x0*x1 + (q*t^2 - q*t - t + 1)*x0*x2 + (t^2
sage: E_integral([2,0,0])
(t^2 - 2*t + 1)*x0^2 + (q^2*t^2 - q^2*t - q*t + q)*x0*x1 + (q^2*t^2 - q^2*t - q*t + q)*x0*x2
sage: E_integral([0,2,0])
(q^2*t^3 - q^2*t^2 - t + 1)*x0^2 + (q^4*t^3 - q^3*t^2 - q^2*t + q*t^2 - q*t + q - t + 1)*x0*x1 +
```

Ht (*mu, q=None, t=None, pi=None*)

Returns the symmetric Macdonald polynomial using the Haiman, Haglund, and Loehr formula.

Note that if both q and t are specified, then they must have the same parent.

REFERENCE:

- 'A combinatorial formula for non-symmetric Macdonald polynomials'. Haiman, Haglund, and Loehr. http://arxiv.org/abs/math/0601693

EXAMPLES:

```
sage: from sage.combinat.sf.ns_macdonald import Ht
sage: HHt = MacdonaldPolynomialsHt(QQ)
sage: Ht([0,0,1])
```

```
x0 + x1 + x2
sage: HHt([1]).expand(3)
x0 + x1 + x2
sage: Ht([0,0,2])
x0^2 + (q + 1)*x0*x1 + x1^2 + (q + 1)*x0*x2 + (q + 1)*x1*x2 + x2^2
sage: HHt([2]).expand(3)
x0^2 + (q + 1)*x0*x1 + x1^2 + (q + 1)*x0*x2 + (q + 1)*x1*x2 + x2^2
```

class LatticeDiagram(*l*)

a(*i, j*)

Returns len(self.arm(i,j)).

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.a(5,2)
3
```

arm(*i, j*)

Returns the arm of the box (i,j) in self.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.arm(5,2)
[(1, 2), (3, 2), (8, 1)]
```

arm_left(*i, j*)

Returns the left arm of the box (i,j) in self.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.arm_left(5,2)
[(1, 2), (3, 2)]
```

arm_right(*i, j*)

Returns the right arm of the box (i,j) in self.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.arm_right(5,2)
[(8, 1)]
```

boxes()

EXAMPLES:

```
sage: a = LatticeDiagram([3,0,2])
sage: a.boxes()
[(1, 1), (1, 2), (1, 3), (3, 1), (3, 2)]
sage: a = LatticeDiagram([2, 1, 3, 0, 0, 2])
sage: a.boxes()
[(1, 1), (1, 2), (2, 1), (3, 1), (3, 2), (3, 3), (6, 1), (6, 2)]
```

boxes_same_and_lower_right(*ii, jj*)

Returns a list of the boxes that are in the same row as self, and in the row below self (including the basement) that are strictly to the right of self.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a = a.shape()
sage: a.boxes_same_and_lower_right(1,1)
[(2, 1), (3, 1), (6, 1), (2, 0), (3, 0), (4, 0), (5, 0), (6, 0)]
sage: a.boxes_same_and_lower_right(1,2)
[(3, 2), (6, 2), (2, 1), (3, 1), (6, 1)]
sage: a.boxes_same_and_lower_right(3,3)
[(6, 2)]
sage: a.boxes_same_and_lower_right(2,3)
[(3, 3), (3, 2), (6, 2)]
```

flip()

Returns the flip of the self where flip is defined as follows. Let r = max(self). Then self.flip()[i] = r - self[i].

EXAMPLES:

```
sage: a = LatticeDiagram([3,0,2])
sage: a.flip()
[0, 3, 1]
```

l(*i, j*)

Returns the self[i] - j.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.l(5,2)
1
```

leg(*i, j*)

Returns the leg of the box (i,j) in self.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.leg(5,2)
[(5, 3)]
```

size()

Returns the number of boxes in self.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.size()
22
```

class **NonattackingBacktracker**(*shape, pi=None*)

get_next_pos(*ii, jj*)

EXAMPLES:

```
sage: from sage.combinat.sf.ns_macdonald import NonattackingBacktracker
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: n = NonattackingBacktracker(a.shape())
sage: n.get_next_pos(1, 1)
(2, 1)
sage: n.get_next_pos(6, 1)
(1, 2)
sage: n = NonattackingBacktracker(LatticeDiagram([2,2,2]))
sage: n.get_next_pos(3, 1)
(1, 2)
```

NonattackingFillings(*shape, pi=None*)

Returning the combinatorial class of nonattacking fillings of a given shape.

EXAMPLES:

```
sage: NonattackingFillings([0,1,2])
Nonattacking fillings of [0, 1, 2]
sage: NonattackingFillings([0,1,2]).list()
[[[1], [2, 1], [3, 2, 1]],
 [[1], [2, 1], [3, 2, 2]],
 [[1], [2, 1], [3, 2, 3]],
 [[1], [2, 1], [3, 3, 1]],
 [[1], [2, 1], [3, 3, 2]],
 [[1], [2, 1], [3, 3, 3]],
 [[1], [2, 2], [3, 1, 1]],
 [[1], [2, 2], [3, 1, 2]],
 [[1], [2, 2], [3, 1, 3]],
 [[1], [2, 2], [3, 3, 1]],
 [[1], [2, 2], [3, 3, 2]],
 [[1], [2, 2], [3, 3, 3]]]
```

class **NonattackingFillings_shape**(*shape, pi=None*)

flip()

Returns the nonattacking fillings of the the flipped shape.

EXAMPLES:

```
sage: NonattackingFillings([0,1,2]).flip()
Nonattacking fillings of [2, 1, 0]
```

17.34 Root Systems

17.34.1 Cartan types

class **CartanTypeFactory**()

samples(*finite=False, affine=False, crystalographic=False*)

Returns a sample of the implemented cartan types

With finite=True resp. affine=True, one can restrict to finite resp. affine only cartan types

EXAMPLES:

```
sage: CartanType.samples(finite=True)
[['A', 1], ['A', 5], ['B', 5], ['C', 5], ['D', 5], ['E', 6], ['E', 7], ['E', 8], ['F', 4], [

sage: CartanType.samples(affine=True)
[['A', 1, 1], ['A', 5, 1], ['B', 5, 1], ['C', 5, 1], ['D', 5, 1], ['E', 6, 1], ['E', 7, 1],

sage: CartanType.samples()
[['A', 1], ['A', 5], ['B', 5], ['C', 5], ['D', 5], ['E', 6], ['E', 7], ['E', 8], ['F', 4], [
sage: CartanType.samples(crystalographic=True)
[['A', 1], ['A', 5], ['B', 5], ['C', 5], ['D', 5], ['E', 6], ['E', 7], ['E', 8], ['F', 4], [
```

class **CartanType_abstract**()

Abstract class for cartan types

Subclasses should implement:

- type()
- type_string()
- dynkin_diagram()
- cartan_matrix()
- is_finite()
- is_affine()
- is_irreducible()

dual()
Returns the dual cartan type, possibly just as a formal dual.
EXAMPLES:

```
sage: CartanType(['F',4]).dual()
['F', 4]^*
```

index_set()
Returns the index set for self.
EXAMPLES:

```
sage: CartanType(['A', 3, 1]).index_set()
[0, 1, 2, 3]
sage: CartanType(['D', 4]).index_set()
[1, 2, 3, 4]
```

is_affine()
Returns whether self is affine.
EXAMPLES:

```
sage: CartanType(['A', 3]).is_affine()
False
sage: CartanType(['A', 3, 1]).is_affine()
True
```

is_crystalographic()
Returns whether this Cartan type is simple laced
EXAMPLES:

```
sage: [ [t, t.is_crystalographic() ] for t in CartanType.samples(finite=True) ]
[[['A', 1], True], [['A', 5], True],
[['B', 5], True], [['C', 5], True], [['D', 5], True],
[['E', 6], True], [['E', 7], True], [['E', 8], True],
[['F', 4], True], [['G', 2], True],
[['I', 5], False], [['H', 3], False], [['H', 4], False]]
```

TESTS:

```
sage: all(t.is_crystalographic() for t in CartanType.samples(affine=True))
True
```

is_finite()
Returns whether this Cartan type is finite. This should be overridden in any subclass.
EXAMPLES:

```
sage: from sage.combinat.root_system.cartan_type import CartanType_abstract
sage: C = CartanType_abstract()
sage: C.is_irreducible()
...
NotImplementedError
```

```
sage: CartanType(['A',4]).is_finite()
True
sage: CartanType(['A',4, 1]).is_finite()
False
```

is_irreducible()

Report whether this Cartan type is irreducible (i.e. simple). This should be overridden in any subclass.

EXAMPLES:

```
sage: from sage.combinat.root_system.cartan_type import CartanType_abstract
sage: C = CartanType_abstract()
sage: C.is_irreducible()
...
NotImplementedError
```

is_reducible()

Report whether the root system is reducible (i.e. not simple), that is whether it can be factored as a product of root systems.

EXAMPLES:

```
sage: CartanType("A2xB3").is_reducible()
True
sage: CartanType(['A',2]).is_reducible()
False
```

is_simple_laced()

Returns whether this Cartan type is simple laced

EXAMPLES:

```
sage: [ [t, t.is_simply_laced() ] for t in CartanType.samples() ]
[[['A', 1], True], [['A', 5], True],
[['B', 5], False], [['C', 5], False], [['D', 5], True],
[['E', 6], True], [['E', 7], True], [['E', 8], True],
[['F', 4], False], [['G', 2], False], [['I', 5], False], [['H', 3], False], [['H', 4], False
[['A', 1, 1], False], [['A', 5, 1], True],
[['B', 5, 1], False], [['C', 5, 1], False], [['D', 5, 1], True],
[['E', 6, 1], True], [['E', 7, 1], True], [['E', 8, 1], True],
[['F', 4, 1], False], [['G', 2, 1], False],
[['A', 2, 2], False], [['A', 10, 2], False], [['A', 9, 2], False], [['D', 5, 2], False], [['
```

rank()

Returns the rank of self.

EXAMPLES:

```
sage: CartanType(['A', 4]).rank()
4
sage: CartanType(['A', 7, 2]).rank()
4
sage: CartanType(['I', 8]).rank()
2
```

root_system()

Returns the root system associated to self.

EXAMPLES:

```
sage: CartanType(['A',4]).root_system()
Root system of type ['A', 4]
```

type()

Returns the type of self, or None if unknown. This method should be overridden in any subclass.

EXAMPLES:

```
sage: from sage.combinat.root_system.cartan_type import CartanType_abstract
sage: C = CartanType_abstract()
sage: C.type() is None
True
```

class CartanType_simple()

cartan_matrix()
Returns the Cartan matrix associated with self.
EXAMPLES:

```
sage: CartanType(['A',4]).cartan_matrix()
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -1  2]
```

dual()
EXAMPLES:

```
sage: CartanType(["A", 3]).dual()
['A', 3]
sage: CartanType(["B", 3]).dual()
['C', 3]
```

dynkin_diagram()
Returns the Dynkin diagram associated with self.
EXAMPLES:

```
sage: CartanType(['A',4]).dynkin_diagram()
O---O---O---O
1   2   3   4
A4
```

is_irreducible()
EXAMPLES:

```
sage: CartanType(['A', 3]).is_irreducible()
True
```

type()
Returns the type of self.
EXAMPLES:

```
sage: CartanType(['A', 4]).type()
'A'
sage: CartanType(['A', 4, 1]).type()
'A'
```

class CartanType_simple_affine(*t*)
A class for affine simple Cartan types

classical()
Returns the classical Cartan type associated with self (which should be affine)
Caveat: only implemented for untwisted
EXAMPLES:

```
sage: CartanType(['A', 3, 1]).classical()
['A', 3]
sage: CartanType(['B', 3, 1]).classical()
['B', 3]
```

is_affine()
EXAMPLES:

```
sage: CartanType(['A', 3, 1]).is_affine()
True
```

is_crystalographic()
EXAMPLES:

```
sage: CartanType(['A', 3, 1]).is_crystalographic()
True
```

is_finite()
EXAMPLES:

```
sage: CartanType(['A', 3, 1]).is_finite()
False
```

is_simply_laced()
EXAMPLES:

```
sage: CartanType(['A', 3, 1]).is_simply_laced()
True
sage: CartanType(['D', 4, 3]).is_simply_laced()
False
sage: CartanType(['D', 4, 1]).is_simply_laced()
True
sage: CartanType(['B', 4, 1]).is_simply_laced()
False
```

rank()
EXAMPLES:

```
sage: CartanType(['D', 4, 3]).rank()
3
sage: CartanType(['B', 4, 1]).rank()
4
```

class **CartanType_simple_finite**(*t*)
A class for finite simple Cartan types

affine()
Returns the corresponding untwisted affine Cartan type
EXAMPLES:

```
sage: CartanType(['A',3]).affine()
['A', 3, 1]
```

dual()
EXAMPLES:

```
sage: CartanType(['A',3]).dual()
['A', 3]
sage: CartanType(['D',4]).dual()
['D', 4]
sage: CartanType(['E',8]).dual()
```

```
['E', 8]
sage: CartanType(['B',3]).dual()
['C', 3]
sage: CartanType(['C',2]).dual()
['B', 2]
```

is_affine()
EXAMPLES:

```
sage: CartanType(["A", 3]).is_affine()
False
```

is_crystalographic()
EXAMPLES:

```
sage: CartanType(["A", 3]).is_crystalographic()
True
sage: CartanType(["I", 2]).is_crystalographic()
False
```

is_finite()
EXAMPLES:

```
sage: CartanType(["A", 3]).is_finite()
True
```

is_simply_laced()
EXAMPLES:

```
sage: CartanType(['A',3]).is_simply_laced()
True
sage: CartanType(['B',3]).is_simply_laced()
False
```

rank()
EXAMPLES:

```
sage: CartanType(["A", 3]).rank()
3
```

17.34.2 Dynkin diagrams

DynkinDiagram(**args*)
INPUT:

- `ct` - A Cartan Type Returns a Dynkin diagram for type ct.

The edge multiplicities are encoded as edge labels. This uses the convention in Kac / Fulton Harris Representation theory wikipedia http://en.wikipedia.org/wiki/Dynkin_diagram, that is for i != j:

```
j --k--> i <==> a_ij = -k
           <==> -scalar(coroot[i], root[j]) = k
           <==> multiple arrows point from the longer root
                to the shorter one
```

TODO: say something about the node labelling conventions.

EXAMPLES:

```
sage: DynkinDiagram(['A', 4])
 O---O---O---O
 1   2   3   4
 A4
sage: DynkinDiagram(['A',1],['A',1])
 O
 1
 O
 2
 A1xA1
sage: R = RootSystem("A2xB2xF4")
sage: DynkinDiagram(R)
 O---O
 1   2
 O=>=O
 3   4
 O---O=>=O---O
 5   6   7   8
 A2xB2xF4
```

class DynkinDiagram_class(*t*)

add_edge(*i, j, label=1*)

EXAMPLES:

```
sage: from sage.combinat.root_system.dynkin_diagram import DynkinDiagram_class
sage: d = DynkinDiagram_class(CartanType(['A',3]))
sage: list(sorted(d.edges()))
[]
sage: d.add_edge(2, 3)
sage: list(sorted(d.edges()))
[(2, 3, 1), (3, 2, 1)]
```

cartan_matrix()

returns the Cartan matrix for this Dynkin diagram

EXAMPLES:

```
sage: DynkinDiagram(['C',3]).cartan_matrix()
[ 2 -1  0]
[-1  2 -2]
[ 0 -1  2]
```

cartan_type()

EXAMPLES:

```
sage: DynkinDiagram("A2","B2","F4").cartan_type()
A2xB2xF4
```

column(*j*)

Returns the j^{th} column $(a_{i,j})_i$ of the Cartan matrix corresponding to this Dynkin diagram, as a container (or iterator) of tuples $(i, a_{i,j})$

EXAMPLES:

```
sage: g = DynkinDiagram(["B",4])
sage: [ (i,a) for (i,a) in g.column(3) ]
[(3, 2), (2, -1), (4, -2)]
```

dual()

Returns the dual Dynkin diagram, obtained by reversing all edges.

EXAMPLES:

```
sage: D = DynkinDiagram(['C',3])
sage: D.edges()
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]
sage: D.dual()
O---O=>=O
1   2   3
B3
sage: D.dual().edges()
[(1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1)]
sage: D.dual() == DynkinDiagram(['B',3])
True
```

TESTS:

```
sage: D = DynkinDiagram(['A',0]); D
Dynkin diagram of type ['A', 0]
sage: D.edges()
[]
sage: D.dual()
Dynkin diagram of type ['A', 0]
sage: D.dual().edges()
[]
sage: D = DynkinDiagram(['A',1])
sage: D.edges()
[]
sage: D.dual()
O
1
A1
sage: D.dual().edges()
[]
```

dynkin_diagram()

EXAMPLES:

```
sage: DynkinDiagram(['C',3]).dynkin_diagram()
O---O=<=O
1   2   3
C3
```

index_set()

EXAMPLES:

```
sage: DynkinDiagram(['C',3]).index_set()
[1, 2, 3]
sage: DynkinDiagram("A2","B2","F4").index_set()
[1, 2, 3, 4, 5, 6, 7, 8]
```

rank()

Returns the index set for this Dynkin diagram

EXAMPLES:

```
sage: DynkinDiagram(['C',3]).rank()
3
sage: DynkinDiagram("A2","B2","F4").rank()
8
```

row(i)

Returns the i^{th} row $(a_{i,j})_j$ of the Cartan matrix corresponding to this Dynkin diagram, as a container (or

iterator) of tuples $(j, a_{i,j})$

EXAMPLES:

```
sage: g = DynkinDiagram(["C",4])
sage: [ (i,a) for (i,a) in g.row(3) ]
[(3, 2), (2, -1), (4, -2)]
```

dynkin_diagram(*t*)

Returns the Dynkin diagram of type t.

Note that this function is deprecated, and that you should use DynkinDiagram instead as this will be disappearing in the near future.

EXAMPLES:

```
sage: dynkin_diagram(["A", 3])
doctest:1: DeprecationWarning: dynkin_diagram is deprecated, use DynkinDiagram instead!
O---O---O
1   2   3
A3
```

dynkin_diagram_ascii_art(*t, shift=0, nolabel=False*)

Returns ascii art representing a Dynkin diagram of a finite Cartan type. Accessed through the __repr__ method of DynkinDiagram.

The optional parameter shift causes the indices to be shifted by that amount, for use in Dynkin diagrams of reducible types. The parameter nolabel, if set, inhibits the printing of the Cartan type name as part of the ascii art.

EXAMPLES:

```
sage: DynkinDiagram("E6")
        O 2
        |
        |
 O---O---O---O---O
 1   3   4   5   6
 E6
```

extended_dynkin_diagram_ascii_art(*t*)

Returns ascii art representing the extended Dynkin diagram of a finite Cartan type. This is also the Dynkin diagram of the associated untwisted affine root system.

EXAMPLES:

```
sage: DynkinDiagram(['E',6,1])
        O 0
        |
        |
        O 2
        |
        |
O---O---O---O---O
1   3   4   5   6
E6~
```

precheck(*t, letter=None, length=None, affine=None, n_ge=None, n=None*)

EXAMPLES:

```
sage: from sage.combinat.root_system.dynkin_diagram import precheck
sage: ct = CartanType(['A',4])
sage: precheck(ct, letter='C')
...
ValueError: t[0] must be = 'C'
sage: precheck(ct, affine=1)
...
ValueError: t[2] must be = 1
sage: precheck(ct, length=3)
...
ValueError: len(t) must be = 3
sage: precheck(ct, n=3)
...
ValueError: t[1] must be = 3
sage: precheck(ct, n_ge=5)
...
ValueError: t[1] must be >= 5
```

17.34.3 Cartan matrices

cartan_matrix(*t*)

Returns the Cartan matrix corresponding to type t.

EXAMPLES:

```
sage: cartan_matrix(['A', 4])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -1  2]
sage: cartan_matrix(['B', 6])
[ 2 -1  0  0  0  0]
[-1  2 -1  0  0  0]
[ 0 -1  2 -1  0  0]
[ 0  0 -1  2 -1  0]
[ 0  0  0 -1  2 -1]
[ 0  0  0  0 -2  2]
sage: cartan_matrix(['C', 4])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -2]
[ 0  0 -1  2]
sage: cartan_matrix(['D', 6])
[ 2 -1  0  0  0  0]
[-1  2 -1  0  0  0]
[ 0 -1  2 -1  0  0]
[ 0  0 -1  2 -1 -1]
[ 0  0  0 -1  2  0]
[ 0  0  0 -1  0  2]
sage: cartan_matrix(['E',6])
[ 2  0 -1  0  0  0]
[ 0  2  0 -1  0  0]
[-1  0  2 -1  0  0]
[ 0 -1 -1  2 -1  0]
[ 0  0  0 -1  2 -1]
[ 0  0  0  0 -1  2]
sage: cartan_matrix(['E',7])
```

```
[ 2  0 -1  0  0  0  0]
[ 0  2  0 -1  0  0  0]
[-1  0  2 -1  0  0  0]
[ 0 -1 -1  2 -1  0  0]
[ 0  0  0 -1  2 -1  0]
[ 0  0  0  0 -1  2 -1]
[ 0  0  0  0  0 -1  2]
sage: cartan_matrix(['E', 8])
[ 2  0 -1  0  0  0  0  0]
[ 0  2  0 -1  0  0  0  0]
[-1  0  2 -1  0  0  0  0]
[ 0 -1 -1  2 -1  0  0  0]
[ 0  0  0 -1  2 -1  0  0]
[ 0  0  0  0 -1  2 -1  0]
[ 0  0  0  0  0 -1  2 -1]
[ 0  0  0  0  0  0 -1  2]
sage: cartan_matrix(['F', 4])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -2  2 -1]
[ 0  0 -1  2]
```

This is different from MuPAD-Combinat, due to different node convention?

```
sage: cartan_matrix(['G', 2])
[ 2 -3]
[-1  2]
sage: cartan_matrix(['A', 3, 1])
[ 2 -1  0 -1]
[-1  2 -1  0]
[ 0 -1  2 -1]
[-1  0 -1  2]
sage: cartan_matrix(['B', 3, 1])
[ 2  0 -1  0]
[ 0  2 -1  0]
[-1 -1  2 -1]
[ 0  0 -2  2]
sage: cartan_matrix(['C', 3, 1])
[ 2 -1  0  0]
[-2  2 -1  0]
[ 0 -1  2 -2]
[ 0  0 -1  2]
sage: cartan_matrix(['D', 4, 1])
[ 2  0 -1  0  0]
[ 0  2 -1  0  0]
[-1 -1  2 -1 -1]
[ 0  0 -1  2  0]
[ 0  0 -1  0  2]
sage: cartan_matrix(['E', 6, 1])
[ 2  0 -1  0  0  0  0]
[ 0  2  0 -1  0  0  0]
[-1  0  2  0 -1  0  0]
[ 0 -1  0  2 -1  0  0]
[ 0  0 -1 -1  2 -1  0]
[ 0  0  0  0 -1  2 -1]
[ 0  0  0  0  0 -1  2]
sage: cartan_matrix(['E', 7, 1])
[ 2 -1  0  0  0  0  0  0]
```

```
[-1  2  0 -1  0  0  0  0]
[ 0  0  2  0 -1  0  0  0]
[ 0 -1  0  2 -1  0  0  0]
[ 0  0 -1 -1  2 -1  0  0]
[ 0  0  0  0 -1  2 -1  0]
[ 0  0  0  0  0 -1  2 -1]
[ 0  0  0  0  0  0 -1  2]
sage: cartan_matrix(['E', 8, 1])
[ 2  0  0  0  0  0  0  0 -1]
[ 0  2  0 -1  0  0  0  0  0]
[ 0  0  2  0 -1  0  0  0  0]
[ 0 -1  0  2 -1  0  0  0  0]
[ 0  0 -1 -1  2 -1  0  0  0]
[ 0  0  0  0 -1  2 -1  0  0]
[ 0  0  0  0  0 -1  2 -1  0]
[ 0  0  0  0  0  0 -1  2 -1]
[-1  0  0  0  0  0  0 -1  2]
sage: cartan_matrix(['F', 4, 1])
[ 2 -1  0  0  0]
[-1  2 -1  0  0]
[ 0 -1  2 -1  0]
[ 0  0 -2  2 -1]
[ 0  0  0 -1  2]
sage: cartan_matrix(['G', 2, 1])
[ 2  0 -1]
[ 0  2 -3]
[-1 -1  2]
```

17.34.4 Coxeter matrices

coxeter_matrix(*t*)

Returns the Coxeter matrix of type t.

EXAMPLES:

```
sage: coxeter_matrix(['A', 4])
[1 3 2 2]
[3 1 3 2]
[2 3 1 3]
[2 2 3 1]
sage: coxeter_matrix(['B', 4])
[1 3 2 2]
[3 1 3 2]
[2 3 1 4]
[2 2 4 1]
sage: coxeter_matrix(['C', 4])
[1 3 2 2]
[3 1 3 2]
[2 3 1 4]
[2 2 4 1]
sage: coxeter_matrix(['D', 4])
[1 3 2 2]
[3 1 3 3]
[2 3 1 2]
[2 3 2 1]
```

```
sage: coxeter_matrix(['E', 6])
[1 2 3 2 2 2]
[2 1 2 3 2 2]
[3 2 1 3 2 2]
[2 3 3 1 3 2]
[2 2 2 3 1 3]
[2 2 2 2 3 1]

sage: coxeter_matrix(['F', 4])
[1 3 2 2]
[3 1 4 2]
[2 4 1 3]
[2 2 3 1]

sage: coxeter_matrix(['G', 2])
[1 6]
[6 1]
```

coxeter_matrix_as_function(*t*)

Returns the coxeter matrix associated to the Cartan type t.

EXAMPLES:

```
sage: from sage.combinat.root_system.coxeter_matrix import coxeter_matrix_as_function
sage: f = coxeter_matrix_as_function(['A',4])
sage: matrix([[f(i,j) for j in range(1,5)] for i in range(1,5)])
[1 3 2 2]
[3 1 3 2]
[2 3 1 3]
[2 2 3 1]
```

17.34.5 Root systems

class RootSystem(*cartan_type, as_dual_of=None*)

Returns the root system associated to the Cartan type t.

EXAMPLES: We construct the root system for type B_3

```
sage: R=RootSystem(['B',3]); R
Root system of type ['B', 3]
```

R models the root system abstractly. It comes equipped with various realizations of the root and weight lattices, where all computation take place. Let us play first with the root lattice.

```
sage: space = R.root_lattice()
sage: space
Root lattice of the Root system of type ['B', 3]
```

It is the free $\mathbf{Z}$-module $\bigoplus_i \mathbf{Z}.\alpha_i$ spanned by the simple roots:

```
sage: space.base_ring()
Integer Ring
sage: list(space.basis())
[alpha[1], alpha[2], alpha[3]]
```

Let us do some computations with the simple roots:

```
sage: alpha = space.simple_roots()
sage: alpha[1] + alpha[2]
alpha[1] + alpha[2]
```

There is a canonical pairing between the root lattice and the coroot lattice:

```
sage: R.coroot_lattice()
Coroot lattice of the Root system of type ['B', 3]
```

We construct the simple coroots, and do some computations (see comments about duality below for some caveat).

```
sage: alphacheck = space.simple_coroots()
sage: list(alphacheck)
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

We can carry over the same computations in any of the other realizations of the root lattice, like the root space $\bigoplus_i \mathbf{Q}.\alpha_i$, the weight lattice $\bigoplus_i \mathbf{Z}.\Lambda_i$, the weight space $\bigoplus_i \mathbf{Q}.\Lambda_i$. For example:

```
sage: space = R.weight_space()
sage: space
Weight space over the Rational Field of the Root system of type ['B', 3]

sage: space.base_ring()
Rational Field
sage: list(space.basis())
[Lambda[1], Lambda[2], Lambda[3]]

sage: alpha = space.simple_roots()
sage: alpha[1] + alpha[2]
Lambda[1] + Lambda[2] - 2*Lambda[3]
```

The fundamental weights are the dual basis of the coroots:

```
sage: Lambda = space.fundamental_weights()
sage: Lambda[1]
Lambda[1]

sage: alphacheck = space.simple_coroots()
sage: list(alphacheck)
[alphacheck[1], alphacheck[2], alphacheck[3]]

sage: [Lambda[i].scalar(alphacheck[1]) for i in space.index_set()]
[1, 0, 0]
sage: [Lambda[i].scalar(alphacheck[2]) for i in space.index_set()]
[0, 1, 0]
sage: [Lambda[i].scalar(alphacheck[3]) for i in space.index_set()]
[0, 0, 1]
```

Let us use the simple reflections. In the weight space, they work as in the *number game*: firing the node i on an element x adds c times the simple root α_i, where c is the coefficient of i in x:

```
sage: s = space.simple_reflections()
sage: Lambda[1].simple_reflection(1)
-Lambda[1] + Lambda[2]
sage: Lambda[2].simple_reflection(1)
Lambda[2]
sage: Lambda[3].simple_reflection(1)
Lambda[3]
sage: (-2*Lambda[1] + Lambda[2] + Lambda[3]).simple_reflection(1)
2*Lambda[1] - Lambda[2] + Lambda[3]
```

It can be convenient to manipulate the simple reflections themselves:

```
sage: s = space.simple_reflections()
sage: s[1](Lambda[1])
-Lambda[1] + Lambda[2]
sage: s[1](Lambda[2])
Lambda[2]
sage: s[1](Lambda[3])
Lambda[3]
```

The root system may also come equipped with an ambient space, that is a simultaneous realization of the weight lattice and the coroot lattice in a Euclidean vector space. This is implemented on a type by type basis, and is not always available. When the coefficients permit it, this is also available as an ambient lattice.

TODO: Demo: signed permutations realization of type B

The root system is aware of its dual root system:

```
sage: R.dual
Dual of root system of type ['B', 3]
```

R.dual is really the root system of type C_3:

```
sage: R.dual.cartan_type()
['C', 3]
```

And the coroot lattice that we have been manipulating before is really implemented as the root lattice of the dual root system:

```
sage: R.dual.root_lattice()
Coroot lattice of the Root system of type ['B', 3]
```

In particular, the coroots for the root lattice are in fact the roots of the coroot lattice:

```
sage: list(R.root_lattice().simple_coroots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
sage: list(R.coroot_lattice().simple_roots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
sage: list(R.dual.root_lattice().simple_roots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

The coweight lattice and space are defined similarly. Note that, to limit confusion, all the output have been tweaked appropriately.

TESTS:

```
sage: R = RootSystem(['C',3])
sage: R == loads(dumps(R))
True
sage: L = R.ambient_space()
sage: s = L.simple_reflections()
sage: s = L.simple_projections() # todo: not implemented
sage: L == loads(dumps(L))
True
sage: L = R.root_space()
sage: s = L.simple_reflections()
sage: L == loads(dumps(L))
True

sage: all(RootSystem(T).check() for T in CartanType.samples(finite=True,crystalographic=True))
True
```

ambient_lattice()

Returns the usual ambient lattice for this root_system, if it exists and is implemented, and None otherwise. This is a $\mathbf{Z}$-module, endowed with its canonical euclidean scalar product, which embeds simultaneously the root lattice and the coroot lattice (what about the weight lattice?)

EXAMPLES:

```
sage: RootSystem(['A',4]).ambient_lattice()
Ambient lattice of the Root system of type ['A', 4]

sage: RootSystem(['B',4]).ambient_lattice()
sage: RootSystem(['C',4]).ambient_lattice()
sage: RootSystem(['D',4]).ambient_lattice()
sage: RootSystem(['E',6]).ambient_lattice()
sage: RootSystem(['F',4]).ambient_lattice()
sage: RootSystem(['G',2]).ambient_lattice()
```

ambient_space()

Returns the usual ambient space for this root_system, if it is implemented, and None otherwise. This is a $\mathbf{Q}$-module, endowed with its canonical euclidean scalar product, which embeds simultaneously the root lattice and the coroot lattice (what about the weight lattice?). An alternative base ring can be provided as an option; it must contain the smallest ring over which the ambient space can be defined ($\mathbf{Z}$ or $\mathbf{Q}$, depending on the type).

EXAMPLES:

```
sage: RootSystem(['A',4]).ambient_space()
Ambient space of the Root system of type ['A', 4]

sage: RootSystem(['B',4]).ambient_space()
Ambient space of the Root system of type ['B', 4]

sage: RootSystem(['C',4]).ambient_space()
Ambient space of the Root system of type ['C', 4]

sage: RootSystem(['D',4]).ambient_space()
Ambient space of the Root system of type ['D', 4]

sage: RootSystem(['E',6]).ambient_space()
Ambient space of the Root system of type ['E', 6]

sage: RootSystem(['F',4]).ambient_space()
Ambient space of the Root system of type ['F', 4]
```

```
sage: RootSystem(['G',2]).ambient_space()
Ambient space of the Root system of type ['G', 2]
```

cartan_matrix()

EXAMPLES:

```
sage: RootSystem(['A',3]).cartan_matrix()
[ 2 -1  0]
[-1  2 -1]
[ 0 -1  2]
```

cartan_type()

Returns the Cartan type of the root system.

EXAMPLES:

```
sage: R = RootSystem(['A',3])
sage: R.cartan_type()
['A', 3]
```

check()

Runs the checks on the root system.

EXAMPLES:

```
sage: RootSystem(["A",3]).check()
True
```

coroot_lattice()

Returns the coroot lattice associated to self.

EXAMPLES:

```
sage: RootSystem(['A',3]).coroot_lattice()
Coroot lattice of the Root system of type ['A', 3]
```

coroot_space(*base_ring=Rational Field*)

Returns the coroot space associated to self.

EXAMPLES:

```
sage: RootSystem(['A',3]).coroot_space()
Coroot space over the Rational Field of the Root system of type ['A', 3]
```

coweight_lattice()

Returns the coweight lattice associated to self.

EXAMPLES:

```
sage: RootSystem(['A',3]).coweight_lattice()
Coweight lattice of the Root system of type ['A', 3]
```

coweight_space(*base_ring=Rational Field*)

Returns the weight space associated to self.

EXAMPLES:

```
sage: RootSystem(['A',3]).coweight_space()
Coweight space over the Rational Field of the Root system of type ['A', 3]
```

dynkin_diagram()

Returns the Dynkin diagram of the root system.

EXAMPLES:

```
sage: R = RootSystem(['A',3])
sage: R.dynkin_diagram()
O---O---O
1   2   3
A3
```

index_set()

EXAMPLES:

```
sage: RootSystem(['A',3]).index_set()
[1, 2, 3]
```

is_finite()

Returns True if self is a finite root system.

EXAMPLES:

```
sage: RootSystem(["A",3]).is_finite()
True
sage: RootSystem(["A",3,1]).is_finite()
False
```

is_irreducible()

Returns True if self is an irreducible root system.

EXAMPLES:

```
sage: RootSystem(['A', 3]).is_irreducible()
True
sage: RootSystem("A2xB2").is_irreducible()
False
```

root_lattice()

Returns the root lattice associated to self.

EXAMPLES:

```
sage: RootSystem(['A',3]).root_lattice()
Root lattice of the Root system of type ['A', 3]
```

root_space()

Returns the root space associated to self.

EXAMPLES

```
sage: RootSystem(['A',3]).root_space()
Root space over the Rational Field of the Root system of type ['A', 3]
```

weight_lattice()

Returns the weight lattice associated to self.

EXAMPLES:

```
sage: RootSystem(['A',3]).weight_lattice()
Weight lattice of the Root system of type ['A', 3]
```

weight_space()

Returns the weight space associated to self.

EXAMPLES:

```
sage: RootSystem(['A',3]).weight_space()
Weight space over the Rational Field of the Root system of type ['A', 3]
```

WeylDim(*ct, coeffs*)

The Weyl Dimension Formula.

INPUT:

- `type` - a Cartan type
- `coeffs` - a list of nonnegative integers

The length of the list must equal the rank type[1]. A dominant weight hwv is constructed by summing the fundamental weights with coefficients from this list. The dimension of the irreducible representation of the semisimple complex Lie algebra with highest weight vector hwv is returned.

EXAMPLES:

For $SO(7)$, the Cartan type is B_3, so:

```
sage: WeylDim(['B',3],[1,0,0]) # standard representation of SO(7)
7
sage: WeylDim(['B',3],[0,1,0]) # exterior square
21
sage: WeylDim(['B',3],[0,0,1]) # spin representation of spin(7)
8
sage: WeylDim(['B',3],[1,0,1]) # sum of the first and third fundamental weights
48
sage: [WeylDim(['F',4],x) for x in [1,0,0,0],[0,1,0,0],[0,0,1,0],[0,0,0,1]]
[52, 1274, 273, 26]
sage: [WeylDim(['E', 6], x) for x in [0, 0, 0, 0, 0, 0], [0, 1, 0, 0, 0, 0], [0, 0, 0, 0, 0, 1],
[1, 78, 27, 351, 351, 351, 27, 650, 351]
```

17.34.6 Weyl Groups

WeylGroup(*x*)

Returns the Weyl group of type type.

INPUT:

- `ct` - a Cartan Type.

EXAMPLES: The following constructions yield the same result, namely a weight lattice and its corresponding Weyl group:

```
sage: G = WeylGroup(['F',4])
sage: L = G.lattice()
```

or alternatively and equivalently:

```
sage: L = RootSystem(['F',4]).ambient_space()
sage: G = L.weyl_group()
```

Either produces a weight lattice, with access to its roots and weights.

```
sage: G = WeylGroup(['F',4])
sage: G.order()
1152
sage: [s1,s2,s3,s4] = G.simple_reflections()
sage: w = s1*s2*s3*s4; w
[ 1/2  1/2  1/2  1/2]
[-1/2  1/2  1/2 -1/2]
[ 1/2  1/2 -1/2 -1/2]
[ 1/2 -1/2  1/2 -1/2]
sage: type(w)
<class 'sage.combinat.root_system.weyl_group.WeylGroupElement'>
```

```
sage: w.order()
12
sage: w.length() # length function on Weyl group
4

sage: L = G.lattice()
sage: fw = L.fundamental_weights(); fw
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4: (1, 0, 0, 0)}
sage: rho = sum(fw); rho
(11/2, 5/2, 3/2, 1/2)
sage: w.action(rho) # action of G on weight lattice
(5, -1, 3, 2)
```

class **WeylGroupElement**(*g*, *parent*)

Class for a Weyl Group elements

action(*v*)

Returns the action of self on the vector v.

EXAMPLES:

```
sage: w = WeylGroup(['A',2])
sage: s1 = w.simple_reflection(1)
sage: v = w.lattice()([1,0,0])
sage: s1.action(v)
(0, 1, 0)
```

lattice()

Returns the ambient lattice associated with self.

EXAMPLES:

```
sage: w = WeylGroup(['A',2])
sage: s1 = w.simple_reflection(1)
sage: s1.lattice()
Ambient space of the Root system of type ['A', 2]
```

length()

Returns the length of self, which is the smallest number of simple reflections into which the element can be decomposed.

EXAMPLES:

```
sage: w = WeylGroup(['A',3])
sage: s1 = w.simple_reflection(1)
sage: s2 = w.simple_reflection(2)
sage: s1.length()
1
sage: (s1*s2).length()
2
```

matrix()

Returns self as a matrix.

EXAMPLES:

```
sage: w = WeylGroup(['A',2])
sage: s1 = w.simple_reflection(1)
sage: m = s1.matrix(); m
[0 1 0]
[1 0 0]
[0 0 1]
```

```
sage: m.parent()
Full MatrixSpace of 3 by 3 dense matrices over Rational Field
```

parent()

Returns self's parent.

EXAMPLES:

```
sage: w = WeylGroup(['A',2])
sage: s1 = w.simple_reflection(1)
sage: s1.parent()
Weyl Group of type ['A', 2] (as a matrix group acting on the ambient space)
```

class **WeylGroup_gens**(*gens, L*)

Class for a Weyl Group with generators (simple reflections)

cartan_type()

Returns the CartanType associated to self.

EXAMPLES:

```
sage: G = WeylGroup(['F',4])
sage: G.cartan_type()
['F', 4]
```

character_table()

Returns the GAP character table as a string. For larger tables you may preface this with a command such as gap.eval("SizeScreen([120,40])") in order to widen the screen.

EXAMPLES:

```
sage: print WeylGroup(['A',3]).character_table()
CT1
<BLANKLINE>
     2  3  2  2  .  3
     3  1  .  .  1  .
<BLANKLINE>
       1a 4a 2a 3a 2b
<BLANKLINE>
X.1     1 -1 -1  1  1
X.2     3  1 -1  . -1
X.3     2  .  . -1  2
X.4     3 -1  1  . -1
X.5     1  1  1  1  1
```

gens()

Returns the generators of self, i.e. the simple reflections.

EXAMPLES:

```
sage: G = WeylGroup(['A',3])
sage: G.gens()
[[0 1 0 0]
 [1 0 0 0]
 [0 0 1 0]
 [0 0 0 1],
 [1 0 0 0]
 [0 0 1 0]
 [0 1 0 0]
 [0 0 0 1],
 [1 0 0 0]
 [0 1 0 0]
```

```
 [0 0 0 1]
 [0 0 1 0]]
```

lattice()
Returns the ambient lattice of self's type.
EXAMPLES:

```
sage: G = WeylGroup(['F',4])
sage: G.lattice()
Ambient space of the Root system of type ['F', 4]
```

list()
Returns a list of the elements of self.
EXAMPLES:

```
sage: G = WeylGroup(['A',1])
sage: G.list()
[[0 1]
 [1 0], [1 0]
 [0 1]]
```

long_element()
Returns the long Weyl group element.
EXAMPLES:

```
sage: [WeylGroup(t).long_element().length() for t in ['A',5],['B',3],['C',3],['D',4],['G',2]
[15, 9, 9, 12, 6, 24, 36]
```

simple_reflection(i)
Returns the i^{th} simple reflection.
EXAMPLES:

```
sage: G = WeylGroup(['F',4])
sage: G.simple_reflection(1)
[1 0 0 0]
[0 0 1 0]
[0 1 0 0]
[0 0 0 1]
```

simple_reflections()
Returns the list of the simple reflections of self.
EXAMPLES:

```
sage: G = WeylGroup(['F',4])
sage: [s1,s2,s3,s4] = G.simple_reflections()
sage: w = s1*s2*s3*s4; w
[ 1/2  1/2  1/2  1/2]
[-1/2  1/2  1/2 -1/2]
[ 1/2  1/2 -1/2 -1/2]
[ 1/2 -1/2  1/2 -1/2]
sage: s4^2==G.unit()
True
sage: type(w)
<class 'sage.combinat.root_system.weyl_group.WeylGroupElement'>
```

unit()
Returns the unit element of the Weyl group
EXAMPLES:

```
sage: e = WeylGroup(['A',3]).unit(); e
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: type(e)
<class 'sage.combinat.root_system.weyl_group.WeylGroupElement'>
```

17.34.7 Weyl Characters

class WeightRing (*A, prefix=None*)

base_ring()
Returns the base ring.
EXAMPLES:

```
sage: R = WeylCharacterRing(['A',3], base_ring = CC); R.base_ring()
Complex Field with 53 bits of precision
```

cartan_type()
Returns the Cartan Type.
EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: WeightRing(A2).cartan_type()
['A', 2]
```

lattice()
Returns the weight lattice realization associated to self.
EXAMPLES:

```
sage: E8 = WeylCharacterRing(['E',8])
sage: e8 = WeightRing(E8)
sage: e8.lattice()
Ambient space of the Root system of type ['E', 8]
```

wt_repr(*wt*)
Returns a string representing the irreducible character with highest weight vectr wt.
EXAMPLES:

```
sage: G2 = WeylCharacterRing(['G',2])
sage: g2 = WeightRing(G2)
sage: g2.wt_repr([1,0,0])
'g2(1,0,0)'
```

class WeightRingElement (*A, mdict*)
A class for weights, and linear combinations of weights. See WeightRing? for more information.

cartan_type()
Returns the Cartan Type.
EXAMPLES:

```
sage: A2=WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: a2([0,1,0]).cartan_type()
['A', 2]
```

character()

Assuming that self is invariant under the Weyl group, this will express it as a linear combination of characters. If self is not Weyl group invariant, this method will not terminate.

EXAMPLES:

```
sage: A2 = WeylCharacterRing(['A',2])
sage: a2 = WeightRing(A2)
sage: W = a2.lattice().weyl_group()
sage: mu = a2(2,1,0)
sage: nu = sum(mu.weyl_group_action(w) for w in W)
sage: nu
a2(0,1,2) + a2(0,2,1) + a2(1,0,2) + a2(1,2,0) + a2(2,0,1) + a2(2,1,0)
sage: nu.character()
-2*A2(1,1,1) + A2(2,1,0)
```

mlist()

Returns a list of weights in self with their multiplicities.

EXAMPLES:

```
sage: G2 = WeylCharacterRing(['G',2])
sage: g2 = WeightRing(G2)
sage: pr = sum(g2(a) for a in g2.lattice().positive_roots())
sage: sorted(pr.mlist())
[[(1, -2, 1), 1],  [(1, -1, 0), 1],  [(1, 1, -2), 1],  [(1, 0, -1), 1],  [(2, -1, -1), 1],
```

weyl_group_action(*w*)

Returns the actionof the Weyl group element w on self.

EXAMPLES:

```
sage: G2 = WeylCharacterRing(['G',2])
sage: g2 = WeightRing(G2)
sage: L = g2.lattice()
sage: [fw1, fw2] = L.fundamental_weights()
sage: sum(g2(fw2).weyl_group_action(w) for w in L.weyl_group())
2*g2(-2,1,1) + 2*g2(-1,-1,2) + 2*g2(-1,2,-1) + 2*g2(1,-2,1) + 2*g2(1,1,-2) + 2*g2(2,-1,-1)
```

class WeylCharacter(*A, hdict, mdict*)

A class for Weyl Characters. Let K be a compact Lie group, which we assume is semisimple and simply-connected. Its complexified Lie algebra L is the Lie algebra of a complex analytic Lie group G. The following three categories are equivalent: representations of K; representations of L; and analytic representations of G. In every case, there is a parametrization of the irreducible representations by their highest weight vectors. For this theory of Weyl, see (for example) J. F. Adams, Lectures on Lie groups; Broecker and Tom Dieck, Representations of Compact Lie groups; Bump, Lie Groups, Part I; Fulton and Harris, Representation Theory, Part IV; Goodman and Wallach, Representations and Invariants of the Classical Groups, Chapter 5; Hall, Lie Groups, Lie Algebras and Representations; Humphreys, Introduction to Lie Algebras and their representations; Procesi, Lie Groups; Samelson, Notes on Lie Algebras; Varadarajan, Lie groups, Lie algebras, and their representations; or Zhelobenko, Compact Lie Groups and their Representations.

There is associated with K, L or G as above a lattice, the weight lattice, whose elements (called weights) are characters of a Cartan subgroup or subalgebra. There is an action of the Weyl group W on the lattice, and elements of a fixed fundamental domain for W, the positive Weyl chamber, are called dominant. There is for each representation a unique highest dominant weight that occurs with nonzero multiplicity with respect to a certain partial order, and it is called the highest weight vector.

EXAMPLES:

```
sage: L = RootSystem(['A',2]).ambient_space()
sage: [fw1,fw2] = L.fundamental_weights()
sage: R = WeylCharacterRing(['A',2], prefix="R")
```

```
sage: [R(1),R(fw1),R(fw2)]
[R(0,0,0), R(1,0,0), R(1,1,0)]
```

Here R(1), R(fw1) and R(fw2) are irreducible representations with highest weight vectors 0, and the first two fundamental weights.

A Weyl character is a character (not necessarily irreducible) of a reductive Lie group or algebra. It is represented by a pair of dictionaries. The mdict is a dictionary of weight multiplicities. The hdict is a dictionary of highest weight vectors of the irreducible characters that occur in its decomposition into irreducibles, with the multiplicities in this decomposition.

For type A (also G_2, F_4, E_6 and E_7) we will take as the weight lattice not the weight lattice of the semisimple group, but for a larger one. For type A, this means we are concerned with the representation theory of K=U(n) or G=GL(n,CC) rather than SU(n) or SU(n,CC). This is useful since the representation theory of GL(n) is ubiquitous, and also since we may then represent the fundamental weights (in root_system.py) by vectors with integer entries. If you are only interested in SL(3), say, use WeylCharacterRing(['A',2]) as above but be aware that R([a,b,c]) and R([a+1,b+1,c+1]) represent the same character of SL(3) since R([1,1,1]) is the determinant.

branch(*S, rule='default'*)

Returns the restriction of the character to the subalgebra. If no rule is specified, we will try to specify one.

INPUT:

- `S` - a Weyl character ring for a Lie subgroup or subalgebra
- `rule` - a branching rule.

See branch_weyl_character? for more information about branching rules.

EXAMPLES:

```
sage: B3 = WeylCharacterRing(['B',3])
sage: A2 = WeylCharacterRing(['A',2])
sage: [B3(w).branch(A2,rule="levi") for w in B3.lattice().fundamental_weights()]
[A2(0,0,-1) + A2(0,0,0) + A2(1,0,0),
 A2(0,-1,-1) + A2(0,0,-1) + A2(0,0,0) + A2(1,0,-1) + A2(1,0,0) + A2(1,1,0),
 A2(-1/2,-1/2,-1/2) + A2(1/2,-1/2,-1/2) + A2(1/2,1/2,-1/2) + A2(1/2,1/2,1/2)]
```

cartan_type()

Returns the Cartan Type.

EXAMPLES:

```
sage: A2=WeylCharacterRing("A2")
sage: A2([1,0,0]).cartan_type()
['A', 2]
```

check(*verbose=False*)

To check the correctness of an element, we compare the theoretical dimension computed Weyl character formula with the actual one obtained by adding up the multiplicities.

EXAMPLES:

```
sage: F4 = WeylCharacterRing(['F',4])
sage: [F4(x).check(verbose = true) for x in F4.lattice().fundamental_weights()]
[[52, 52], [1274, 1274], [273, 273], [26, 26]]
```

degree()

The degree of the character, that is, the dimension of module.

EXAMPLES:

```
sage: B3 = WeylCharacterRing(['B',3])
sage: [B3(x).degree() for x in B3.lattice().fundamental_weights()]
[7, 21, 8]
```

hlist()
Returns a list of highest weight vectors and multiplicities of the irreducible characters in self.
EXAMPLES:

```
sage: B3 = WeylCharacterRing(['B',3])
sage: B3(1/2,1/2,1/2).hlist()
[[(1/2, 1/2, 1/2), 1]]
```

mlist()
Returns a list of weights in self with their multiplicities.
EXAMPLES:

```
sage: B3 = WeylCharacterRing(['B',3])
sage: sorted(B3(1/2,1/2,1/2).mlist())
[[(-1/2, -1/2, -1/2), 1],  [(-1/2, -1/2, 1/2), 1],  [(-1/2, 1/2, -1/2), 1],  [(-1/2, 1/2, 1/
```

parent()
EXAMPLES:

```
sage: B3 = WeylCharacterRing(['B',3])
sage: B3(2).parent()
The Weyl Character Ring of Type [B,3] with Integer Ring coefficients
```

WeylCharacterRing(*ct, base_ring=Integer Ring, prefix=None, cache=False*)
A class for rings of Weyl characters. The Weyl character is a character of a semisimple (or reductive) Lie group or algebra. They form a ring, in which the addition and multiplication correspond to direct sum and tensor product of representations.
INPUT:

- `ct` - The Cartan Type

OPTIONAL ARGUMENTS:

- `base_ring` - (default: **Z**)
- `prefix` (default an automatically generated prefix based on Cartan type)
- `cache` - (default False) setting cache = True is a substantial speedup at the expense of some memory.

If no prefix specified, one is generated based on the Cartan type. It is good to name the ring after the prefix, since then it can parse its own output.
EXAMPLES:

```
sage: G2 = WeylCharacterRing(['G',2])
sage: [fw1,fw2] = G2.lattice().fundamental_weights()
sage: 2*G2(2*fw1+fw2)
2*G2(4,-1,-3)
sage: 2*G2(4,-1,-3)
2*G2(4,-1,-3)
sage: G2(4,-1,-3).degree()
189
```

Note that since the ring was named G_2 after its default prefix, it was able to parse its own output. You do not have to use the default prefix. Thus:
EXAMPLES:

```
sage: R = WeylCharacterRing(['B',3], prefix='R')
sage: chi = R(R.lattice().fundamental_weights()[3]); chi
R(1/2,1/2,1/2)
sage: R(1/2,1/2,1/2) == chi
True
```

The multiplication in R corresponds to the product of characters, which you can use to determine the decomposition of tensor products into irreducibles. For example, let us compute the tensor product of the standard and spin representations of Spin(7).

EXAMPLES:

```
sage: B3 = WeylCharacterRing(['B',3])
sage: [fw1,fw2,fw3]=B3.lattice().fundamental_weights()
sage: [B3(fw1).degree(),B3(fw3).degree()]
[7, 8]
sage: B3(fw1)*B3(fw3)
B3(1/2,1/2,1/2) + B3(3/2,1/2,1/2)
```

The name of the irreducible representation encodes the highest weight vector.

TESTS:

```
sage: F4 = WeylCharacterRing(['F',4], cache = True)
sage: [fw1,fw2,fw3,fw4] = F4.lattice().fundamental_weights()
sage: chi = F4(fw4); chi, chi.degree()
(F4(1,0,0,0), 26)
sage: chi^2
F4(0,0,0,0) + F4(1,0,0,0) + F4(1,1,0,0) + F4(3/2,1/2,1/2,1/2) + F4(2,0,0,0)
sage: [x.degree() for x in [F4(0,0,0,0), F4(1,0,0,0), F4(1,1,0,0), F4(3/2,1/2,1/2,1/2), F4(2,0,0
[1, 26, 52, 273, 324]
```

You can produce a list of the irreducible elements of an irreducible character.

EXAMPLES:

```
sage: R = WeylCharacterRing(['A',2], prefix = R)
sage: sorted(R([2,1,0]).mlist())
[[(1, 1, 1), 2],  [(1, 2, 0), 1],  [(1, 0, 2), 1],  [(2, 1, 0), 1],  [(2, 0, 1), 1],  [(0, 1, 2)
```

class **WeylCharacterRing_class**(*ct, base_ring, prefix, cache*)

base_ring()

Returns the base ring.

EXAMPLES:

```
sage: R = WeylCharacterRing(['A',3], base_ring = CC); R.base_ring()
Complex Field with 53 bits of precision
```

cartan_type()

Returns the Cartan Type.

EXAMPLES:

```
sage: WeylCharacterRing("A2").cartan_type()
['A', 2]
```

char_from_weights(*mdict*)

Return the hdict given just a dictionary of weight multiplicities.

This will not terminate unless the dictionary of weight multiplicities is Weyl group invariant.

EXAMPLES:

```
sage: B3 = WeylCharacterRing(['B',3])
sage: m = B3(1,0,0)._mdict
sage: B3.char_from_weights(m)
{(1, 0, 0): 1}
```

irr_repr(*hwv*)

Return a string representing the irreducible character with highest weight vectr hwv.

EXAMPLES:

```
sage: A2 = WeylCharacterRing(['A',2])
sage: A2.irr_repr([2,1,0])
'A2(2,1,0)'
```

lattice()

Returns the weight lattice associated to self.

EXAMPLES:

```
sage: WeylCharacterRing(['E',8]).lattice()
Ambient space of the Root system of type ['E', 8]
```

branch_weyl_character(*chi, R, S, rule='default'*)

A Branching rule describes the restriction of representations from a Lie group or algebra G to a smaller one. See for example, R. C. King, Branching rules for classical Lie groups using tensor and spinor methods. J. Phys. A 8 (1975), 429-449 or Howe, Tan and Willenbring, Stable branching rules for classical symmetric pairs, Trans. Amer. Math. Soc. 357 (2005), no. 4, 1601-1626.

INPUT:

- `chi` - a character of G
- `R` - the Weyl Character Ring of G
- `S` - the Weyl Character Ring of H
- `rule` - a set of r dominant weights in H where r is the rank of G.

You may use a predefined rule by specifying rule = one of"levi", "automorphic", "symmetric", "extended", "triality" or "miscellaneous". The use of these rules will be explained next. After the examples we will explain how to write your own branching rules for cases that we have omitted. (Rules for the exceptional groups have not yet been coded.)

To explain the predefined rules we survey the most important branching rules. These may be classified into several cases, and once this is understood, the detailed classification can be read off from the Dynkin diagrams. Dynkin classified the maximal subgroups of Lie groups in Mat. Sbornik N.S. 30(72):349-462 (1952).

We will list these for the cases where the Dynkin diagram of S is connected. This excludes branching rules such as A3 -> A1 x A1, which are not yet implemented.

LEVI TYPE. These can be read off from the Dynkin diagram. If removing a node from the Dynkin diagram produces another Dynkin diagram, there is a branching rule. Currently we require that the smaller diagram be connected. For these rules use the option rule="levi":

```
['A',r] -> ['A',r-1]
['B',r] -> ['A',r-1]
['B',r] -> ['B',r-1]
['C',r] -> ['A',r-1]
['C',r] -> ['C',r-1]
['D',r] -> ['A',r-1]
['D',r] -> ['D',r-1]
['E',r] -> ['A',r-1] r = 6,7,8 (not implemented yet)
['E',r] -> ['D',r-1] r = 6,7,8 (not implemented yet)
['E',r] -> ['E',r-1] r = 6,7 (not implemented yet)
['F',4] -> ['B',3] (not implemented yet)
['F',4] -> ['C',3] (not implemented yet)
['G',2] -> ['A',1] (short root) (not implemented yet)
```

The other Levi branching rule from G_2 -> A_1 corresponding to the long root is available by first branching G_2 -> A_2 then branching to A1.

AUTOMORPHIC TYPE. If the Dynkin diagram has a symmetry, then there is an automorphism that is a special case of a branching rule. There is also an exotic"triality" automorphism of D4 having order 3. Use rule="automorphic" or rule="triality"

['A',r] - ['A',r] ['D',r] - ['D',r] ['E',6] - ['E',6] (not implemented yet)

SYMMETRIC TYPE. Related to the automorphic type, when the Dynkin diagram has a symmetry there is a branching rule to the subalgebra (or subgroup) of invariants under the automorphism. Use rule="symmetric".

['A',2r+1] - ['B',r] ['A',2r] - ['C',r] ['D',r] - ['B',r-1] ['E',6] - ['F',4] (not implemented yet) ['D',4] - ['G',2] (not implemented yet)

EXTENDED TYPE. If removing a node from the extended Dynkin diagram results in a Dynkin diagram, then there is a branching rule. Use rule="extended" for these.

['G',2] - ['A',2] (not implemented yet) ['B',r] - ['D',r] ['F',4] - ['B',4] (not implemented yet) ['E',7] - ['A',7] (not implemented yet) ['E',8] - ['A',8] (not implemented yet)

MISCELLANEOUS: Use rule="miscellaneous" for the following rule, which does not fit into the above framework.

['B',3] - ['G',2] (Not implemented yet.)

ISOMORPHIC TYPE: Although not usually referred to as a branching rule, the effects of the accidental isomorphisms may be handled using rule="isomorphic"

['B',2] - ['C',2] ['C',2] - ['B',2] ['A',3] - ['D',3] ['D',3] - ['A',3]

EXAMPLES: (Levi type)

```
sage: A2 = WeylCharacterRing(['A',2])
sage: B2 = WeylCharacterRing(['B',2])
sage: C2 = WeylCharacterRing(['C',2])
sage: A3 = WeylCharacterRing(['A',3])
sage: B3 = WeylCharacterRing(['B',3])
sage: C3 = WeylCharacterRing(['C',3])
sage: D3 = WeylCharacterRing(['D',3])
sage: A4 = WeylCharacterRing(['A',4])
sage: D4 = WeylCharacterRing(['D',4])
sage: A5 = WeylCharacterRing(['A',5])
sage: D5 = WeylCharacterRing(['D',5])
sage: [B3(w).branch(A2,rule="levi") for w in B3.lattice().fundamental_weights()]
[A2(0,0,-1) + A2(0,0,0) + A2(1,0,0),
 A2(0,-1,-1) + A2(0,0,-1) + A2(0,0,0) + A2(1,0,-1) + A2(1,0,0) + A2(1,1,0),
 A2(-1/2,-1/2,-1/2) + A2(1/2,-1/2,-1/2) + A2(1/2,1/2,-1/2) + A2(1/2,1/2,1/2)]
```

The last example must be understood as follows. The representation of B3 being branched is spin, which is not a representation of SO(7) but of its double cover spin(7). The group A2 is really GL(3) and the double cover of SO(7) induces a cover of GL(3) that is trivial over SL(3) but not over the center of GL(3). The weight lattice for this GL(3) consists of triples (a,b,c) of half integers such that a-b and b-c are in **Z**, and this is reflected in the last decomposition.

```
sage: [C3(w).branch(A2,rule="levi") for w in C3.lattice().fundamental_weights()]
[A2(0,0,-1) + A2(1,0,0),
 A2(0,-1,-1) + A2(1,0,-1) + A2(1,1,0),
 A2(-1,-1,-1) + A2(1,-1,-1) + A2(1,1,-1) + A2(1,1,1)]
sage: [D4(w).branch(A3,rule="levi") for w in D4.lattice().fundamental_weights()]
[A3(0,0,0,-1) + A3(1,0,0,0),
 A3(0,0,-1,-1) + A3(0,0,0,0) + A3(1,0,0,-1) + A3(1,1,0,0),
 A3(1/2,-1/2,-1/2,-1/2) + A3(1/2,1/2,1/2,-1/2),
 A3(-1/2,-1/2,-1/2,-1/2) + A3(1/2,1/2,-1/2,-1/2) + A3(1/2,1/2,1/2,1/2)]
```

```
sage: [B3(w).branch(B2,rule="levi") for w in B3.lattice().fundamental_weights()]
[2*B2(0,0) + B2(1,0), B2(0,0) + 2*B2(1,0) + B2(1,1), 2*B2(1/2,1/2)]
sage: C3 = WeylCharacterRing(['C',3])
sage: [C3(w).branch(C2,rule="levi") for w in C3.lattice().fundamental_weights()]
[2*C2(0,0) + C2(1,0),
 C2(0,0) + 2*C2(1,0) + C2(1,1),
 C2(1,0) + 2*C2(1,1)]
sage: [D5(w).branch(D4,rule="levi") for w in D5.lattice().fundamental_weights()]
[2*D4(0,0,0,0) + D4(1,0,0,0),
 D4(0,0,0,0) + 2*D4(1,0,0,0) + D4(1,1,0,0),
 D4(1,0,0,0) + 2*D4(1,1,0,0) + D4(1,1,1,0),
 D4(1/2,1/2,1/2,-1/2) + D4(1/2,1/2,1/2,1/2),
 D4(1/2,1/2,1/2,-1/2) + D4(1/2,1/2,1/2,1/2)]
```

EXAMPLES: (Automorphic type, including D4 triality)

```
sage: [A3(chi).branch(A3,rule="automorphic") for chi in A3.lattice().fundamental_weights()]
[A3(0,0,0,-1), A3(0,0,-1,-1), A3(0,-1,-1,-1)]
sage: [D4(chi).branch(D4,rule="automorphic") for chi in D4.lattice().fundamental_weights()]
[D4(1,0,0,0), D4(1,1,0,0), D4(1/2,1/2,1/2,1/2), D4(1/2,1/2,1/2,-1/2)]
sage: [D4(chi).branch(D4,rule="triality") for chi in D4.lattice().fundamental_weights()]
[D4(1/2,1/2,1/2,-1/2), D4(1,1,0,0), D4(1/2,1/2,1/2,1/2), D4(1,0,0,0)]
```

EXAMPLES: (Symmetric type)

```
sage: [w.branch(B2,rule="symmetric") for w in [A4(1,0,0,0,0),A4(1,1,0,0,0),A4(1,1,1,0,0),A4(2,0,
[B2(1,0), B2(1,1), B2(1,1), B2(0,0) + B2(2,0)]
sage: [A5(w).branch(C3,rule="symmetric") for w in A5.lattice().fundamental_weights()]
[C3(1,0,0),
 C3(0,0,0) + C3(1,1,0),
 C3(1,0,0) + C3(1,1,1),
 C3(0,0,0) + C3(1,1,0),
 C3(1,0,0)]
sage: [A5(w).branch(D3,rule="symmetric") for w in A5.lattice().fundamental_weights()]
[D3(1,0,0), D3(1,1,0), D3(1,1,-1) + D3(1,1,1), D3(1,1,0), D3(1,0,0)]
sage: [D4(x).branch(B3,rule="symmetric") for x in D4.lattice().fundamental_weights()]
[B3(0,0,0) + B3(1,0,0),
 B3(1,0,0) + B3(1,1,0),
 B3(1/2,1/2,1/2),
 B3(1/2,1/2,1/2)]
```

EXAMPLES: (Extended type)

```
sage: [B3(x).branch(D3,rule="extended") for x in B3.lattice().fundamental_weights()]
[D3(0,0,0) + D3(1,0,0),
 D3(1,0,0) + D3(1,1,0),
 D3(1/2,1/2,-1/2) + D3(1/2,1/2,1/2)]
```

EXAMPLES: (Isomorphic type)

```
sage: [B2(x).branch(C2, rule="isomorphic") for x in B2.lattice().fundamental_weights()]
[C2(1,1), C2(1,0)]
sage: [C2(x).branch(B2, rule="isomorphic") for x in C2.lattice().fundamental_weights()]
[B2(1/2,1/2), B2(1,0)]
sage: [A3(x).branch(D3,rule="isomorphic") for x in A3.lattice().fundamental_weights()]
[D3(1/2,1/2,1/2), D3(1,0,0), D3(1/2,1/2,-1/2)]
sage: [D3(x).branch(A3,rule="isomorphic") for x in D3.lattice().fundamental_weights()]
[A3(1/2,1/2,-1/2,-1/2), A3(1/4,1/4,1/4,-3/4), A3(3/4,-1/4,-1/4,-1/4)]
```

Here A3(x,y,z,w) can be understood as a representation of SL(4). The weights x,y,z,w and x+t,y+t,z+t,w+t represent the same representation of SL(4) - though not of GL(4) - since A3(x+t,y+t,z+t,w+t) is the same as A3(x,y,z,w) tensored with det^t. So as a representation of SL(4), A3(1/4,1/4,1/4,-3/4) is the same as A3(1,1,1,0). The exterior square representation SL(4) -> GL(6) admits an invariant symmetric bilinear form, so is a representation SL(4) -> SO(6) that lifts to an isomorphism SL(4) -> Spin(6). Conversely, there are two isomorphisms SO(6) -> SL(4), of which we've selected one.

You may also write your own rules. We may arrange a Cartan subalgebra U of H to be contained in a Cartan subalgebra T of G. This embedding must be chosen in a particular way - the restriction of the positive Weyl chamber in G.lattice() must be contained in the positive Weyl chamber in H.lattice(). The RULE is the adjoint of this embedding U - T, which is a mapping from the dual space of T, which is the weight space of G, to the weight space of H.

EXAMPLES:

```
sage: A3 = WeylCharacterRing(['A',3])
sage: C2 = WeylCharacterRing(['C',2])
sage: rule = lambda x : [x[0]-x[3],x[1]-x[2]]
sage: branch_weyl_character(A3([1,1,0,0]),A3,C2,rule)
C2(0,0) + C2(1,1)
sage: A3(1,1,0,0).branch(C2, rule) == C2(0,0) + C2(1,1)
True
```

irreducible_character_freudenthal(*hwv, L, debug=False*)

Returns the dictionary of multiplicities for the irreducible character with highest weight lamb. The weight multiplicities are computed by the Freudenthal multiplicity formula. The algorithm is based on recursion relation that is stated, for example, in Humphrey's book on Lie Algebras. The multiplicities are invariant under the Weyl group, so to compute them it would be sufficient to compute them for the weights in the positive Weyl chamber. However after some testing it was found to be faster to compute every weight using the recursion, since the use of the Weyl group is expensive in its current implementation.

INPUT:

- `hwv` - a dominant weight in a weight lattice.
- `L` - the ambient lattice

17.35 Crystals

17.35.1 Crystals

Let T be a CartanType with index set I, and W be a realization of the type T weight lattice.

A type T crystal C is a colored oriented graph equipped with a weight function from the nodes to some realization of the type T weight lattice such that:

- Each edge is colored with a label in $i \in I$.
- For each $i \in I$, each node x has:
  - at most one i-successor $f_i(x)$;
  - at most one i-predecessor $e_i(x)$.

  Furthermore, when they exist,
  - $f_i(x)$.weight() = x.weight() - α_i;
  - $e_i(x)$.weight() = x.weight() + α_i.

This crystal actually models a representation of a Lie algebra if it satisfies some further local conditions due to Stembridge, see J. Stembridge, *A local characterization of simply-laced crystals*, Trans. Amer. Math. Soc. 355 (2003), no. 12, 4807-4823.

EXAMPLES:

We construct the type A_5 crystal on letters (or in representation theoretic terms, the highest weight crystal of type A_5 corresponding to the highest weight Λ_1)

```
sage: C = CrystalOfLetters(['A',5]); C
The crystal of letters for type ['A', 5]
```

It has a single highest weight element:

```
sage: C.highest_weight_vectors()
[1]
```

A crystal is a CombinatorialClass; and we can count and list its elements in the usual way:

```
sage: C.cardinality()
6
sage: C.list()
[1, 2, 3, 4, 5, 6]
```

as well as use it in for loops

```
sage: [x for x in C]
[1, 2, 3, 4, 5, 6]
```

Here are some more elaborate crystals (see their respective documentations):

```
sage: Tens = TensorProductOfCrystals(C, C)
sage: Spin = CrystalOfSpins(['B', 3])
sage: Tab  = CrystalOfTableaux(['A', 3], shape = [2,1,1])
sage: Fast = FastCrystal(['B', 2], shape = [3/2, 1/2])
```

One can get (currently) crude plotting via:

```
sage: Tab.plot()
```

For rank two crystals, there is an alternative method of getting metapost pictures. For more information see C.metapost?

Caveat: this crystal library, although relatively featureful for classical crystals, is still in an early development stage, and the syntax details may be subject to changes.

TODO:

- Vocabulary and conventions:
  - elements or vectors of a crystal?
  - For a classical crystal: connected / highest weight / irreducible
  - ...
- More introductory doc explaining the mathematical background
- Layout instructions for plot() for rank 2 types

- Streamlining the latex output
- Littelmann paths and/or alcove paths (this would give us the exceptional types)
- RestrictionOfCrystal / DirectSumOfCrystals
- Crystal.crystal_morphism
- Affine crystals
- Kirillov-Reshetikhin crystals

Most of the above features (except Littelmann/alcove paths) are in MuPAD-Combinat (see lib/COMBINAT/crystals.mu), which could provide inspiration.

class ClassicalCrystal()

The abstract class of classical crystals

cardinality()

Returns the number of elements of the crystal, using Weyl's dimension formula on each connected component

EXAMPLES:

```
sage: from sage.combinat.crystals.crystals import ClassicalCrystal
sage: C = CrystalOfLetters(['A', 5])
sage: ClassicalCrystal.cardinality(C)
6
```

highest_weight_vector()

Returns the highest weight vector if there is a single one; otherwise, raises an error.

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: C.highest_weight_vector()
1
```

highest_weight_vectors()

Returns a list of the highest weight vectors of self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: C.highest_weight_vectors()
[1]

sage: C = CrystalOfLetters(['A',2])
sage: T = TensorProductOfCrystals(C,C,C,generators=[[C(2),C(1),C(1)],[C(1),C(2),C(1)]])
sage: T.highest_weight_vectors()
[[2, 1, 1], [1, 2, 1]]
```

list()

The default implementation of list which builds the list from the iterator.

EXAMPLES:

```
sage: class C(CombinatorialClass):
...       def __iter__(self):
...           return iter([1,2,3])
...
sage: C().list() #indirect doctest
[1, 2, 3]
```

class Crystal()

The abstract class of crystals

Derived subclasses should implement the following:

- either a method cartan_type or an attribute _cartan_type
- module_generators: a list (or container) of distinct elements which generate the crystal using f_i

Lambda()

Returns the fundamentals weights in the weight lattice realization for the root system associated to self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['A', 5])
sage: C.Lambda()
Finite family {1: (1, 0, 0, 0, 0, 0), 2: (1, 1, 0, 0, 0, 0), 3: (1, 1, 1, 0, 0, 0), 4: (1, 1
```

cartan_type()

Returns the Cartan type of the associated crystal

EXAMPLES:: sage: C = CrystalOfLetters(['A',2]) sage: C.cartan_type() ['A', 2]

character(*R*)

INPUT: R, a WeylCharacterRing. Produces the character of the crystal.

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',2])
sage: T = TensorProductOfCrystals(C, C)
sage: A2 = WeylCharacterRing(C.cartan_type()); A2
The Weyl Character Ring of Type [A,2] with Integer Ring coefficients
sage: chi = T.character(A2); chi
A2(1,1,0) + A2(2,0,0)
sage: chi.check(verbose = true)
[9, 9]
```

check()

Runs sanity checks on the crystal:

- Checks that count, list, and __iter__ are consistent. For a ClassicalCrystal, this in particular checks that the number of elements returned by the brute force listing and the iterator __iter__ are consistent with the Weyl dimension formula.
- Should check Stembridge's rules, etc.

EXAMPLES:

```
sage: C = CrystalOfLetters(['A', 5])
sage: C.check()
True
```

digraph()

Returns the DiGraph associated to self.

EXAMPLES:

```
sage: from sage.combinat.crystals.crystals import Crystal
sage: C = CrystalOfLetters(['A', 5])
sage: Crystal.digraph(C)
Digraph on 6 vertices
```

dot_tex()

Returns a dot_tex version of self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',2])
sage: C.dot_tex()
'digraph G { \n  node [ shape=plaintext ];\n  N_0 [ label = " ", texlbl = "$\\text{1}$" ];\n
```

index_set()

Returns the index set of the Dynkin diagram underlying the given crystal

EXAMPLES: sage: C = CrystalOfLetters(['A', 5]) sage: C.index_set() [1, 2, 3, 4, 5]

latex()

Returns the crystal graph as a bit of latex. This can be exported to a file with self.latex_file('filename').

This requires dot2tex to be installed in sage-python.

Here some tips for installation:

- Install graphviz = 2.14
- Download pyparsing-1.4.11.tar.gz pydot-0.9.10.tar.gz dot2tex-2.7.0.tar.gz (see the dot2tex web page for download links) (note that the most recent version of pydot may not work. Be sure to install the 0.9.10 version.) Install each of them using the standard python install, but using sage-python:

```
# FIX ACCORDING TO YOUR Sage INSTALL
export sagedir=/opt/sage/
export sagepython=$sagedir/local/bin/sage-python

# Use downloaded version nums
for package in pyparsing-1.4.11 pydot-0.9.10 dot2tex-2.7.0; do\
        tar zxvf $package.tar.gz;\
        cd $package;\
        sudo $sagepython setup.py install;\
        cd ..;\
    done
```

- Install pgf-2.00 inside your latex tree In short:
  - untaring in /usr/share/texmf/tex/generic
  - clean out remaining pgf files from older version
  - run texhash

You should be done! To test, go to the dot2tex-2.7.0/examples directory, and type:

```
$sagedir//local/bin/dot2tex balls.dot > balls.tex
pdflatex balls.tex
open balls.pdf \#your favorite viewer here
```

EXAMPLES:

```
sage: C = CrystalOfLetters(['A', 5])
sage: C.latex() #optional requires dot2tex
...
```

latex_file(*filename*)

Exports a file, suitable for pdflatex, to 'filename'. This requires a proper installation of dot2tex in sage-python. For more information see the documentation for self.latex().

EXAMPLES:

```
sage: C = CrystalOfLetters(['A', 5])
sage: C.latex_file('/tmp/test.tex') #optional requires dot2tex
```

list()

Returns a list of the elements of self obtained by continually apply the f_i operators to the module generators of self.

EXAMPLES:

```
sage: from sage.combinat.crystals.crystals import Crystal
sage: C = CrystalOfLetters(['A', 5])
sage: l = Crystal.list(C)
sage: l.sort(); l
[1, 2, 3, 4, 5, 6]
```

metapost (*filename, thicklines=False, labels=True, scaling_factor=1.0, tallness=1.0*)

Use C.metapost("filename.mp",[options]) where options can be:

thicklines = True (for thicker edges) labels = False (to suppress labeling of the vertices) scaling_factor=value, where value is a floating point number, 1.0 by default. Increasing or decreasing the scaling factor changes the size of the image. tallness=1.0. Increasing makes the image taller without increasing the width.

Root operators e(1) or f(1) move along red lines, e(2) or f(2) along green. The highest weight is in the lower left. Vertices with the same weight are kept close together. The concise labels on the nodes are strings introduced by Berenstein and Zelevinsky and Littelmann; see Littelmann's paper Cones, Crystals, Patterns, sections 5 and 6.

For Cartan types B2 or C2, the pattern has the form

a2 a3 a4 a1

where c*a2 = a3 = 2*a4 =0 and a1=0, with c=2 for B2, c=1 for C2. Applying e(2) a1 times, e(1) a2 times, e(2) a3 times, e(1) a4 times returns to the highest weight. (Observe that Littelmann writes the roots in opposite of the usual order, so our e(1) is his e(2) for these Cartan types.) For type A2, the pattern has the form

a3 a2 a1

where applying e(1) a1 times, e(2) a2 times then e(3) a1 times returns to the highest weight. These data determine the vertex and may be translated into a Gelfand-Tsetlin pattern or tableau.

EXAMPLES:

```
sage: C = CrystalOfLetters(['A', 2])
sage: C.metapost('/tmp/test.mp') #optional

sage: C = CrystalOfLetters(['A', 5])
sage: C.metapost('/tmp/test.mp')
...
NotImplementedError
```

plot (***options*)

Returns the plot of self as a directed graph.

EXAMPLES:

```
sage: C = CrystalOfLetters(['A', 5])
sage: show_default(False) #do not show the plot by default
sage: C.plot()
Graphics object consisting of 17 graphics primitives
```

weight_lattice_realization()

Returns the weight lattice realization for the root system associated to self. This default implementation uses the ambient space of the root system.

EXAMPLES:

```
sage: C = CrystalOfLetters(['A', 5])
sage: C.weight_lattice_realization()
Ambient space of the Root system of type ['A', 5]
```

class **CrystalBacktracker** (*crystal*)

class **CrystalElement**()

The abstract class of crystal elements

Sub classes should implement at least:

- x.e(i) (returning $e_i(x)$)
- x.f(i) (returning $f_i(x)$)
- x.weight()

Epsilon()

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: C(0).Epsilon()
(0, 0, 0, 0, 0, 0)
sage: C(1).Epsilon()
(0, 0, 0, 0, 0, 0)
sage: C(2).Epsilon()
(1, 0, 0, 0, 0, 0)
```

Phi()

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: C(0).Phi()
(0, 0, 0, 0, 0, 0)
sage: C(1).Phi()
(1, 0, 0, 0, 0, 0)
sage: C(2).Phi()
(1, 1, 0, 0, 0, 0)
```

cartan_type()

Returns the cartan type associated to self

EXAMPLES:: sage: C = CrystalOfLetters(['A', 5]) sage: C(1).cartan_type() ['A', 5]

e(i)

Returns $e_i(x)$ if it exists or None otherwise. This is to be implemented by subclasses of CrystalElement.

TESTS:

```
sage: from sage.combinat.crystals.crystals import CrystalElement
sage: C = CrystalOfLetters(['A',5])
sage: CrystalElement.e(C(1), 1)
...
NotImplementedError
```

epsilon(i)

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: C(1).epsilon(1)
0
sage: C(2).epsilon(1)
1
```

f(i)

Returns $f_i(x)$ if it exists or None otherwise. This is to be implemented by subclasses of CrystalElement.

TESTS:

```
sage: from sage.combinat.crystals.crystals import CrystalElement
sage: C = CrystalOfLetters(['A',5])
sage: CrystalElement.f(C(1), 1)
...
NotImplementedError
```

index_set()
EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: C(1).index_set()
[1, 2, 3, 4, 5]
```

is_highest_weight()
Returns True if self is a highest weight.
EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: C(1).is_highest_weight()
True
sage: C(2).is_highest_weight()
False
```

phi(i)
EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: C(1).phi(1)
1
sage: C(2).phi(1)
0
```

s(i)
Returns the reflection of self along its i-string
EXAMPLES:

```
sage: C = CrystalOfTableaux(['A',2], shape=[2,1])
sage: b=C(rows=[[1,1],[3]])
sage: b.s(1)
[[2, 2], [3]]
sage: b=C(rows=[[1,2],[3]])
sage: b.s(2)
[[1, 2], [3]]
sage: T=CrystalOfTableaux(['A',2],shape=[4])
sage: t=T(rows=[[1,2,2,2]])
sage: t.s(1)
[[1, 1, 1, 2]]
```

weight()
EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: C(1).weight()
(1, 0, 0, 0, 0, 0)
```

17.35.2 Crystals of letters

class ClassicalCrystalOfLetters(*cartan_type, element_class, element_print_style=None, dual=None*)
A generic class for classical crystals of letters.

All classical crystals of letters should be instances of this class or of subclasses. To define a new crystal of letters, one only needs to implement a class for the elements (which subclasses Letter and CrystalElement), with appropriate e and f operations. If the module generator is not 1, one also needs to define the subclass ClassicalCrystalOfLetters for the crystal itself.

The basic assumption is that crystals of letters are small, but used intensively as building blocks. Therefore, we explicitly build in memory the list of all elements, the crystal graph and its transitive closure, so as to make the following operations constant time: list, cmp, (todo: phi, epsilon, e, f with caching)

digraph()

Returns the directed graph associated to self.

EXAMPLES:

```
sage: CrystalOfLetters(['A',5]).digraph()
Digraph on 6 vertices
```

list()

Returns a list of the elements of self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: C.list()
[1, 2, 3, 4, 5, 6]
```

lt_elements(*x, y*)

Returns True if and only if there is a path from x to y in the crystal graph, when x is not equal to y.

Because the crystal graph is classical, it is a directed acyclic graph which can be interpreted as a poset. This function implements the comparison function of this poset.

EXAMPLES:

```
sage: C = CrystalOfLetters(['A', 5])
sage: x = C(1)
sage: y = C(2)
sage: C.lt_elements(x,y)
True
sage: C.lt_elements(y,x)
False
sage: C.lt_elements(x,x)
False
sage: C = CrystalOfLetters(['D', 4])
sage: C.lt_elements(C(4),C(-4))
False
sage: C.lt_elements(C(-4),C(4))
False
```

CrystalOfLetters(*cartan_type, element_print_style=None, dual=None*)

Returns the crystal of letters of the given type.

For classical types, this is a combinatorial model for the crystal with highest weight Lambda_1 (the first fundamental weight).

Any irreducible classical crystal appears as the irreducible component of the tensor product of several copies of this crystal (plus possibly one copy of the spin crystal, see CrystalOfSpins). See M. Kashiwara, T. Nakashima, *Crystal graphs for representations of the 'q'-analogue of classical Lie algebras*, J. Algebra **165** (1994), no. 2, 295-345. Elements of this irreducible component have a fixed shape, and can be fit inside a tableau shape. Otherwise said, any irreducible classical crystal is isomorphic to a crystal of tableaux with cells filled by elements of the crystal of letters (possibly tensored with the crystal of spins).

INPUT:

- `T` - A CartanType

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: C.list()
[1, 2, 3, 4, 5, 6]
sage: C.cartan_type()
['A', 5]
```

For type E6, one can also specify how elements are printed. This option is usually set to None and the default representation is used. If one chooses the option 'compact', the elements are printed in the more compact convention with 27 letters +abcdefghijklmnopqrstuvwxyz and the 27 letters -ABCDEFGHIJKLMNOPQRSTUVWXYZ for the dual crystal.

EXAMPLES:

```
sage: C = CrystalOfLetters(['E',6], element_print_style = 'compact')
sage: C.list()
[+, a, b, c, d, e, f, g, h, i, j, k, l, m, n, o, p, q, r, s, t, u, v, w, x, y, z]
sage: C = CrystalOfLetters(['E',6], element_print_style = 'compact', dual = True)
sage: C.list()
[-, A, B, C, D, E, F, G, H, I, J, K, L, M, N, O, P, Q, R, S, T, U, V, W, X, Y, Z]
```

class **Crystal_of_letters_type_A_element** (*parent, value*)

Type A crystal of letters elements

TESTS:

```
sage: C = CrystalOfLetters (['A',3])
sage: C.list()
[1, 2, 3, 4]
sage: [ [x < y for y in C] for x in C ]
[[False, True, True, True],
 [False, False, True, True],
 [False, False, False, True],
 [False, False, False, False]]

sage: C = CrystalOfLetters(['A',5])
sage: C(1) < C(1), C(1) < C(2), C(1) < C(3), C(2) < C(1)
(False, True, True, False)

sage: C.check()
True
```

e (*i*)

Returns the action of e_i on self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',4])
sage: [[c,i,c.e(i)] for i in C.index_set() for c in C if c.e(i) is not None]
[[2, 1, 1], [3, 2, 2], [4, 3, 3], [5, 4, 4]]
```

f (*i*)

Returns the action of f_i on self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',4])
sage: [[c,i,c.f(i)] for i in C.index_set() for c in C if c.f(i) is not None]
[[1, 1, 2], [2, 2, 3], [3, 3, 4], [4, 4, 5]]
```

weight()
Returns the weight of self.
EXAMPLES:

```
sage: [v.weight() for v in CrystalOfLetters(['A',3])]
[(1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1)]
```

class **Crystal_of_letters_type_B_element**(*parent, value*)
Type B crystal of letters elements
TESTS:

```
sage: C = CrystalOfLetters (['B',3])
sage: C.check()
True
```

e(*i*)
Returns the action of e_i on self.
EXAMPLES:

```
sage: C = CrystalOfLetters(['B',4])
sage: [[c,i,c.e(i)] for i in C.index_set() for c in C if c.e(i) is not None]
[[2, 1, 1],
 [-1, 1, -2],
 [3, 2, 2],
 [-2, 2, -3],
 [4, 3, 3],
 [-3, 3, -4],
 [0, 4, 4],
 [-4, 4, 0]]
```

f(*i*)
Returns the actions of f_i on self.
EXAMPLES:

```
sage: C = CrystalOfLetters(['B',4])
sage: [[c,i,c.f(i)] for i in C.index_set() for c in C if c.f(i) is not None]
[[1, 1, 2],
 [-2, 1, -1],
 [2, 2, 3],
 [-3, 2, -2],
 [3, 3, 4],
 [-4, 3, -3],
 [4, 4, 0],
 [0, 4, -4]]
```

weight()
Returns the weight of self.
EXAMPLES:

```
sage: [v.weight() for v in CrystalOfLetters(['B',3])]
[(1, 0, 0),
 (0, 1, 0),
 (0, 0, 1),
 (0, 0, 0),
 (0, 0, -1),
 (0, -1, 0),
 (-1, 0, 0)]
```

class **Crystal_of_letters_type_C_element** (*parent, value*)

Type C crystal of letters elements

TESTS:

```
sage: C = CrystalOfLetters (['C',3])
sage: C.list()
[1, 2, 3, -3, -2, -1]
sage: [ [x < y for y in C] for x in C ]
[[False, True, True, True, True, True],
 [False, False, True, True, True, True],
 [False, False, False, True, True, True],
 [False, False, False, False, True, True],
 [False, False, False, False, False, True],
 [False, False, False, False, False, False]]
sage: C.check()
True
```

e (*i*)

Returns the action of e_i on self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['C',4])
sage: [[c,i,c.e(i)] for i in C.index_set() for c in C if c.e(i) is not None]
[[2, 1, 1],
 [-1, 1, -2],
 [3, 2, 2],
 [-2, 2, -3],
 [4, 3, 3],
 [-3, 3, -4],
 [-4, 4, 4]]
```

f (*i*)

Retursn the action of f_i on self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['C',4])
sage: [[c,i,c.f(i)] for i in C.index_set() for c in C if c.f(i) is not None]
[[1, 1, 2],
 [-2, 1, -1],
 [2, 2, 3],
 [-3, 2, -2],
 [3, 3, 4],
 [-4, 3, -3],
 [4, 4, -4]]
```

weight ()

Returns the weight of self.

EXAMPLES:

```
sage: [v.weight() for v in CrystalOfLetters(['C',3])]
[(1, 0, 0), (0, 1, 0), (0, 0, 1), (0, 0, -1), (0, -1, 0), (-1, 0, 0)]
```

class **Crystal_of_letters_type_D_element** (*parent, value*)

Type D crystal of letters elements

TESTS:

```
sage: C = CrystalOfLetters(['D',4])
sage: C.list()
```

```
[1, 2, 3, 4, -4, -3, -2, -1]
sage: C.check()
True
```

e(*i*)

Returns the action of e_i on self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['D',5])
sage: [[c,i,c.e(i)] for i in C.index_set() for c in C if c.e(i) is not None]
[[2, 1, 1],
 [-1, 1, -2],
 [3, 2, 2],
 [-2, 2, -3],
 [4, 3, 3],
 [-3, 3, -4],
 [5, 4, 4],
 [-4, 4, -5],
 [-5, 5, 4],
 [-4, 5, 5]]
```

f(*i*)

Returns the action of f_i on self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['D',5])
sage: [[c,i,c.f(i)] for i in C.index_set() for c in C if c.f(i) is not None]
[[1, 1, 2],
 [-2, 1, -1],
 [2, 2, 3],
 [-3, 2, -2],
 [3, 3, 4],
 [-4, 3, -3],
 [4, 4, 5],
 [-5, 4, -4],
 [4, 5, -5],
 [5, 5, -4]]
```

weight()

Returns the weight of self.

EXAMPLES:

```
sage: [v.weight() for v in CrystalOfLetters(['D',4])]
[(1, 0, 0, 0),
 (0, 1, 0, 0),
 (0, 0, 1, 0),
 (0, 0, 0, 1),
 (0, 0, 0, -1),
 (0, 0, -1, 0),
 (0, -1, 0, 0),
 (-1, 0, 0, 0)]
```

class **Crystal_of_letters_type_E6_element**(*parent, value*)

Type E_6 crystal of letters elements. This crystal corresponds to the highest weight crystal $B(\Lambda_1)$.

TESTS:

```
sage: C = CrystalOfLetters(['E',6])
sage: C.module_generators
```

```
[[1]]
sage: C.list()
[[1], [-1, 3], [-3, 4], [-4, 2, 5], [-2, 5], [-5, 2, 6], [-2, -5, 4, 6],
[-4, 3, 6], [-3, 1, 6], [-1, 6], [-6, 2], [-2, -6, 4], [-4, -6, 3, 5],
[-3, -6, 1, 5], [-1, -6, 5], [-5, 3], [-3, -5, 1, 4], [-1, -5, 4], [-4, 1, 2],
[-1, -4, 2, 3], [-3, 2], [-2, -3, 4], [-4, 5], [-5, 6], [-6], [-2, 1], [-1, -2, 3]]
sage: C.check()
True
sage: all(b.f(i).e(i) == b for i in C.index_set() for b in C if b.f(i) is not None)
True
sage: all(b.e(i).f(i) == b for i in C.index_set() for b in C if b.e(i) is not None)
True
sage: G = C.digraph()
sage: G.show(edge_labels=true, figsize=12, vertex_size=1)
```

e(*i*)

Returns the action of e_i on self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['E',6])
sage: C([-1,3]).e(1)
[1]
sage: C([-2,-3,4]).e(2)
[-3, 2]
sage: C([1]).e(1)
```

f(*i*)

Returns the action of f_i on self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['E',6])
sage: C([1]).f(1)
[-1, 3]
sage: C([-6]).f(1)
```

weight()

Returns the weight of self.

EXAMPLES:

```
sage: [v.weight() for v in CrystalOfLetters(['E',6])]
[(0, 0, 0, 0, 0, -2/3, -2/3, 2/3),
(-1/2, 1/2, 1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
(1/2, -1/2, 1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
(1/2, 1/2, -1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
(-1/2, -1/2, -1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
(1/2, 1/2, 1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
(-1/2, -1/2, 1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
(-1/2, 1/2, -1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
(1/2, -1/2, -1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
(0, 0, 0, 0, 1, 1/3, 1/3, -1/3),
(1/2, 1/2, 1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
(-1/2, -1/2, 1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
(-1/2, 1/2, -1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
(1/2, -1/2, -1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
(0, 0, 0, 1, 0, 1/3, 1/3, -1/3),
(-1/2, 1/2, 1/2, -1/2, -1/2, -1/6, -1/6, 1/6),
(1/2, -1/2, 1/2, -1/2, -1/2, -1/6, -1/6, 1/6),
(0, 0, 1, 0, 0, 1/3, 1/3, -1/3),
```

```
(1/2, 1/2, -1/2, -1/2, -1/2, -1/6, -1/6, 1/6),
(0, 1, 0, 0, 0, 1/3, 1/3, -1/3),
(1, 0, 0, 0, 0, 1/3, 1/3, -1/3),
(0, -1, 0, 0, 0, 1/3, 1/3, -1/3),
(0, 0, -1, 0, 0, 1/3, 1/3, -1/3),
(0, 0, 0, -1, 0, 1/3, 1/3, -1/3),
(0, 0, 0, 0, -1, 1/3, 1/3, -1/3),
(-1/2, -1/2, -1/2, -1/2, -1/2, -1/6, -1/6, 1/6),
(-1, 0, 0, 0, 0, 1/3, 1/3, -1/3)]
```

class **Crystal_of_letters_type_E6_element_dual** (*parent, value*)

Type E_6 crystal of letters elements. This crystal corresponds to the highest weight crystal $B(\Lambda_6)$. This crystal is dual to $B(\Lambda_1)$ of type E_6.

TESTS:

```
sage: C = CrystalOfLetters(['E',6], dual = True)
sage: C.module_generators
[[6]]
sage: all(b==b.retract(b.lift()) for b in C)
True
sage: C.list()
[[6], [5, -6], [4, -5], [2, 3, -4], [3, -2], [1, 2, -3], [2, -1], [1, 4, -2, -3],
[4, -1, -2], [1, 5, -4], [3, 5, -1, -4], [5, -3], [1, 6, -5], [3, 6, -1, -5], [4, 6, -3, -5],
[2, 6, -4], [6, -2], [1, -6], [3, -1, -6], [4, -3, -6], [2, 5, -4, -6], [5, -2, -6], [2, -5],
[4, -2, -5], [3, -4], [1, -3], [-1]]
sage: C.check()
True
sage: all(b.f(i).e(i) == b for i in C.index_set() for b in C if b.f(i) is not None)
True
sage: all(b.e(i).f(i) == b for i in C.index_set() for b in C if b.e(i) is not None)
True
sage: G = C.digraph()
sage: G.show(edge_labels=true, figsize=12, vertex_size=1)
```

e (*i*)

Returns the action of e_i on self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['E',6], dual = True)
sage: C([-1]).e(1)
[1, -3]
```

f (*i*)

Returns the action of f_i on self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['E',6], dual = True)
sage: C([6]).f(6)
[5, -6]
sage: C([6]).f(1)
```

lift ()

Lifts an element of self to the crystal of letters CrystalOfLetters(['E',6]) by taking its inverse weight.

EXAMPLES:

```
sage: C = CrystalOfLetters(['E',6], dual = True)
sage: b=C.module_generators[0]
```

```
sage: b.lift()
[-6]
```

retract(*p*)

Retracts element p, which is an element in CrystalOfLetters(['E',6]) to an element in CrystalOfLetters(['E',6], dual = True) by taking its inverse weight.

EXAMPLES:

```
sage: C = CrystalOfLetters(['E',6])
sage: Cd = CrystalOfLetters(['E',6], dual = True)
sage: b = Cd.module_generators[0]
sage: p = C([-1,3])
sage: b.retract(p)
[1, -3]
sage: b.retract(None)
```

weight()

Returns the weight of self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['E',6], dual = True)
sage: b=C.module_generators[0]
sage: b.weight()
(0, 0, 0, 0, 1, -1/3, -1/3, 1/3)
sage: [v.weight() for v in C]
[(0, 0, 0, 0, 1, -1/3, -1/3, 1/3),
(0, 0, 0, 1, 0, -1/3, -1/3, 1/3),
(0, 0, 1, 0, 0, -1/3, -1/3, 1/3),
(0, 1, 0, 0, 0, -1/3, -1/3, 1/3),
(-1, 0, 0, 0, 0, -1/3, -1/3, 1/3),
(1, 0, 0, 0, 0, -1/3, -1/3, 1/3),
(1/2, 1/2, 1/2, 1/2, 1/2, 1/6, 1/6, -1/6),
(0, -1, 0, 0, 0, -1/3, -1/3, 1/3),
(-1/2, -1/2, 1/2, 1/2, 1/2, 1/6, 1/6, -1/6),
(0, 0, -1, 0, 0, -1/3, -1/3, 1/3),
(-1/2, 1/2, -1/2, 1/2, 1/2, 1/6, 1/6, -1/6),
(1/2, -1/2, -1/2, 1/2, 1/2, 1/6, 1/6, -1/6),
(0, 0, 0, -1, 0, -1/3, -1/3, 1/3),
(-1/2, 1/2, 1/2, -1/2, 1/2, 1/6, 1/6, -1/6),
(1/2, -1/2, 1/2, -1/2, 1/2, 1/6, 1/6, -1/6),
(1/2, 1/2, -1/2, -1/2, 1/2, 1/6, 1/6, -1/6),
(-1/2, -1/2, -1/2, -1/2, 1/2, 1/6, 1/6, -1/6),
(0, 0, 0, 0, -1, -1/3, -1/3, 1/3),
(-1/2, 1/2, 1/2, 1/2, -1/2, 1/6, 1/6, -1/6),
(1/2, -1/2, 1/2, 1/2, -1/2, 1/6, 1/6, -1/6),
(1/2, 1/2, -1/2, 1/2, -1/2, 1/6, 1/6, -1/6),
(-1/2, -1/2, -1/2, 1/2, -1/2, 1/6, 1/6, -1/6),
(1/2, 1/2, 1/2, -1/2, -1/2, 1/6, 1/6, -1/6),
(-1/2, -1/2, 1/2, -1/2, -1/2, 1/6, 1/6, -1/6),
(-1/2, 1/2, -1/2, -1/2, -1/2, 1/6, 1/6, -1/6),
(1/2, -1/2, -1/2, -1/2, -1/2, 1/6, 1/6, -1/6),
(0, 0, 0, 0, 0, 2/3, 2/3, -2/3)]
```

class **Crystal_of_letters_type_G_element**(*parent, value*)

Type G2 crystal of letters elements

TESTS:

```
sage: C = CrystalOfLetters(['G',2])
sage: C.list()
[1, 2, 3, 0, -3, -2, -1]
sage: C.check()
True
```

e(*i*)

Returns the action of e_i on self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['G',2])
sage: [[c,i,c.e(i)] for i in C.index_set() for c in C if c.e(i) is not None]
[[2, 1, 1],
 [0, 1, 3],
 [-3, 1, 0],
 [-1, 1, -2],
 [3, 2, 2],
 [-2, 2, -3]]
```

f(*i*)

Returns the action of f_i on self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['G',2])
sage: [[c,i,c.f(i)] for i in C.index_set() for c in C if c.f(i) is not None]
[[1, 1, 2],
 [3, 1, 0],
 [0, 1, -3],
 [-2, 1, -1],
 [2, 2, 3],
 [-3, 2, -2]]
```

weight()

Returns the weight of self.

EXAMPLES:

```
sage: [v.weight() for v in CrystalOfLetters(['G',2])]
[(1, 0, -1), (1, -1, 0), (0, 1, -1), (0, 0, 0), (0, -1, 1), (-1, 1, 0), (-1, 0, 1)]
```

class Letter(*parent, value*)

A class for letters

parent()

Returns the parent of self.

EXAMPLES:

```
sage: from sage.combinat.crystals.letters import Letter
sage: Letter(ZZ, 1).parent()
Integer Ring
```

17.35.3 Spin Crystals

These are the crystals associated with the three spin representations: the spin representations of odd orthogonal groups (or rather their double covers); and the + and - spin representations of the even orthogonal groups.

We follow Kashiwara and Nakashima (Journal of Algebra 165, 1994) in representing the elements of the spin Crystal by sequences of signs +/-. Two other representations are available as attributes internal_repn and signature of the crystal element.

- A numerical internal representation, an integer N such that if N-1 is written in binary and the 1's are replaced by −, the 0's by +
- The signature, which is a list in which + is replaced by +1 and − by -1.

CrystalOfSpins(*ct*)

Return the spin crystal of the given type B.

This is a combinatorial model for the crystal with highest weight $Lambda_n$ (the n-th fundamental weight). It has 2^n elements, here called Spins. See also CrystalOfLetters, CrystalOfSpinsPlus and CrystalOfSpinsMinus.

INPUT:

- `['B',n]` - A CartanType of type B.

EXAMPLES:

```
sage: C = CrystalOfSpins(['B',3])
sage: C.list()
[[1, 1, 1],
 [1, 1, -1],
 [1, -1, 1],
 [-1, 1, 1],
 [1, -1, -1],
 [-1, 1, -1],
 [-1, -1, 1],
 [-1, -1, -1]]
 sage: C.cartan_type()
 ['B', 3]

sage: [x.signature() for x in C]
['+++', '++-', '+-+', '-++', '+--', '-+-', '--+', '---']
```

TESTS:

```
sage: TensorProductOfCrystals(C,C,generators=[[C.list()[0],C.list()[0]]]).cardinality()
35
```

CrystalOfSpinsMinus(*ct*)

Return the minus spin crystal of the given type D.

This is the crystal with highest weight $Lambda_{n-1}$ (the (n-1)-st fundamental weight).

INPUT:

- `['D',n]` - A CartanType of type D.

EXAMPLES:

```
sage: E = CrystalOfSpinsMinus(['D',4])
sage: E.list()
 [[1, 1, 1, -1],
  [1, 1, -1, 1],
  [1, -1, 1, 1],
  [-1, 1, 1, 1],
  [1, -1, -1, -1],
  [-1, 1, -1, -1],
  [-1, -1, 1, -1],
  [-1, -1, -1, 1]]
sage: [x.signature() for x in E]
['+++-', '++-+', '+-++', '-+++', '+---', '-+--', '--+-', '---+']
```

TESTS:

```
sage: len(TensorProductOfCrystals(E,E,generators=[[E[0],E[0]]]).list())
35
sage: D = CrystalOfSpinsPlus(['D',4])
sage: len(TensorProductOfCrystals(D,E,generators=[[D.list()[0],E.list()[0]]]).list())
56
```

CrystalOfSpinsPlus(*ct*)

Return the plus spin crystal of the given type D.

This is the crystal with highest weight $Lambda_n$ (the n-th fundamental weight).

INPUT:

- `['D',n]` - A CartanType of type D.

EXAMPLES:

```
sage: D = CrystalOfSpinsPlus(['D',4])
sage: D.list()
[[1, 1, 1, 1],
 [1, 1, -1, -1],
 [1, -1, 1, -1],
 [-1, 1, 1, -1],
 [1, -1, -1, 1],
 [-1, 1, -1, 1],
 [-1, -1, 1, 1],
 [-1, -1, -1, -1]]

sage: [x.signature() for x in D]
['++++', '++--', '+-+-', '-++-', '+--+', '-+-+', '--++', '----']
```

TESTS:

```
sage: D.check()
True
```

class GenericCrystalOfSpins(*ct, element_class, case*)

cmp_elements(*x, y*)

Returns True if and only if there is a path from x to y in the crystal graph.

Because the crystal graph is classical, it is a directed acyclic graph which can be interpreted as a poset. This function implements the comparison function of this poset.

EXAMPLES:

```
sage: C = CrystalOfSpins(['B',3])
sage: x = C([1,1,1])
sage: y = C([-1,-1,-1])
sage: C.cmp_elements(x,y)
-1
sage: C.cmp_elements(y,x)
1
sage: C.cmp_elements(x,x)
0
```

digraph()

Returns the directed graph associated to self.

EXAMPLES:

```
sage: CrystalOfSpins(['B',3]).digraph()
Digraph on 8 vertices
```

list()
Returns a list of the elements of self.
EXAMPLES:

```
sage: CrystalOfSpins(['B',3]).list()
[[1, 1, 1],
 [1, 1, -1],
 [1, -1, 1],
 [-1, 1, 1],
 [1, -1, -1],
 [-1, 1, -1],
 [-1, -1, 1],
 [-1, -1, -1]]
```

class Spin(*parent, value*)

parent()
Returns the parent of self.
EXAMPLES:

```
sage: C = CrystalOfSpins(['B',3])
sage: C([1,1,1]).parent()
The crystal of spins for type ['B', 3]
```

signature()
Returns the signature of self.
EXAMPLES:

```
sage: C = CrystalOfSpins(['B',3])
sage: C([1,1,1]).signature()
'+++'
sage: C([1,1,-1]).signature()
'++-'
```

class Spin_crystal_type_B_element(*parent, value*)
Type B spin representation crystal element

e(*i*)
Returns the action of e_i on self.
EXAMPLES:

```
sage: C = CrystalOfSpins(['B',3])
sage: [[C[m].e(i) for i in range(1,4)] for m in range(8)]
[[None, None, None],
 [None, None, [1, 1, 1]],
 [None, [1, 1, -1], None],
 [[1, -1, 1], None, None],
 [None, None, [1, -1, 1]],
 [[1, -1, -1], None, [-1, 1, 1]],
 [None, [-1, 1, -1], None],
 [None, None, [-1, -1, 1]]]
```

f(*i*)
Returns the action of f_i on self.
EXAMPLES:

```
sage: C = CrystalOfSpins(['B',3])
sage: [[C[m].f(i) for i in range(1,4)] for m in range(8)]
[[None, None, [1, 1, -1]],
 [None, [1, -1, 1], None],
 [[-1, 1, 1], None, [1, -1, -1]],
 [None, None, [-1, 1, -1]],
 [[-1, 1, -1], None, None],
 [None, [-1, -1, 1], None],
 [None, None, [-1, -1, -1]],
 [None, None, None]]
```

class **Spin_crystal_type_D_element**(*parent, value*)

Type D spin representation crystal element

e(*i*)

Returns the action of e_i on self.

EXAMPLES:

```
sage: D = CrystalOfSpinsPlus(['D',4])
sage: [[D.list()[m].e(i) for i in range(1,4)] for m in range(8)]
[[None, None, None],
 [None, None, None],
 [None, [1, 1, -1, -1], None],
 [[1, -1, 1, -1], None, None],
 [None, None, [1, -1, 1, -1]],
 [[1, -1, -1, 1], None, [-1, 1, 1, -1]],
 [None, [-1, 1, -1, 1], None],
 [None, None, None]]

sage: E = CrystalOfSpinsMinus(['D',4])
sage: [[E[m].e(i) for i in range(1,4)] for m in range(8)]
[[None, None, None],
 [None, None, [1, 1, 1, -1]],
 [None, [1, 1, -1, 1], None],
 [[1, -1, 1, 1], None, None],
 [None, None, None],
 [[1, -1, -1, -1], None, None],
 [None, [-1, 1, -1, -1], None],
 [None, None, [-1, -1, 1, -1]]]
```

f(*i*)

Returns the action of f_i on self.

EXAMPLES:

```
sage: D = CrystalOfSpinsPlus(['D',4])
sage: [[D.list()[m].f(i) for i in range(1,4)] for m in range(8)]
[[None, None, None],
 [None, [1, -1, 1, -1], None],
 [[-1, 1, 1, -1], None, [1, -1, -1, 1]],
 [None, None, [-1, 1, -1, 1]],
 [[-1, 1, -1, 1], None, None],
 [None, [-1, -1, 1, 1], None],
 [None, None, None],
 [None, None, None]]

sage: E = CrystalOfSpinsMinus(['D',4])
sage: [[E[m].f(i) for i in range(1,4)] for m in range(8)]
[[None, None, [1, 1, -1, 1]],
 [None, [1, -1, 1, 1], None],
```

```
[[-1, 1, 1, 1], None, None],
[None, None, None],
[[-1, 1, -1, -1], None, None],
[None, [-1, -1, 1, -1], None],
[None, None, [-1, -1, -1, 1]],
[None, None, None]]
```

17.35.4 Tensor Products of Crystals

class **CrystalOfTableaux**(*type, shape=None, shapes=None*)

Crystals of tableaux. Input: a Cartan Type type and "shape", a partition of length <= type[1]. Produces a classical crystal with the given Cartan Type and highest weight corresponding to the given shape.

If the type is ['D',r] then the shape is permitted to have a negative value in the r-th position. Thus if shape='[s_1,s_2,...,s_r]' then s_r may be negative but in any case $s1 \geq s2 \geq ...s_{r-1} \geq |s_r|$. This crystal is related to $[s_1, \cdots, |s_r|]$ by the outer automorphism of SO(2r).

Note that crystals of tableaux are constructed using an embedding into tensor products following Kashiwara and Nakashima [Kashiwara, Masaki; Nakashima, Toshiki, *Crystal graphs for representations of the q-analogue of classical Lie algebras*, J. Algebra 165 (1994), no. 2, 295-345.]. Sage's tensor product rule for crystals differs from that of Kashiwara and Nakashima by reversing the order of the tensor factors. Sage produces the same crystals of tableaux as Kashiwara and Nakashima. With Sage's convention, the tensor product of crystals is the same as the monoid operation on tableaux and hence the plactic monoid.

EXAMPLES:

We create the crystal of tableaux for type A_2, with highest weight given by the partition [2,1,1]:

```
sage: Tab = CrystalOfTableaux(['A',3], shape = [2,1,1])
```

Here is the list of its elements:

```
sage: Tab.list()
[[[1, 1], [2], [3]], [[1, 2], [2], [3]], [[1, 3], [2], [3]],
 [[1, 4], [2], [3]], [[1, 4], [2], [4]], [[1, 4], [3], [4]],
 [[2, 4], [3], [4]], [[1, 1], [2], [4]], [[1, 2], [2], [4]],
 [[1, 3], [2], [4]], [[1, 3], [3], [4]], [[2, 3], [3], [4]],
 [[1, 1], [3], [4]], [[1, 2], [3], [4]], [[2, 2], [3], [4]]]
```

One can get (currently) crude plotting via:

```
#         sage: Tab.plot()  # random
```

One can get instead get a LaTeX drawing ready to be copy-pasted into a LaTeX file:

```
#         sage: Tab.latex() # random
```

See sage.combinat.crystals.crystals? for general help on using crystals

Internally, a tableau of a given Cartan type is represented as a tensor product of letters of the same type. The order in which the tensor factors appear is by reading the columns of the tableaux left to right, top to bottom (in French notation). As an example:

```
sage: T = CrystalOfTableaux(['A',2], shape = [3,2])
sage: T.module_generators[0]
[[1, 1, 1], [2, 2]]
sage: T.module_generators[0]._list
[2, 1, 2, 1, 1]
```

To create a tableau, one can use:

```
sage: Tab = CrystalOfTableaux(['A',3], shape = [2,2])
sage: Tab(rows=[[1,2],[3,4]])
[[1, 2], [3, 4]]
sage: Tab(columns=[[3,1],[4,2]])
[[1, 2], [3, 4]]
```

FIXME: do we want to specify the columns increasingly or decreasingly That is, should this be Tab(columns = [[1,3],[2,4]])

TODO: make this fully consistent with Tableau!

TESTS:

Base cases:

```
sage: T = CrystalOfTableaux(['A',2], shape = [])
sage: T.list()
[[]]
sage: T = CrystalOfTableaux(['C',2], shape = [1])
sage: T.check()
True
sage: T.list()
[[[1]], [[2]], [[-2]], [[-1]]]
sage: T = CrystalOfTableaux(['A',2], shapes = [[],[1],[2]])
sage: T.list()
[[], [[1]], [[2]], [[3]], [[1, 1]], [[1, 2]], [[2, 2]], [[1, 3]], [[2, 3]], [[3, 3]]]
sage: T.module_generators
([], [[1]], [[1, 1]])
sage: T = CrystalOfTableaux(['B',2],shape=[3])
sage: T(rows=[[1,1,0]])
[[1, 1, 0]]
```

Input tests:

```
sage: Tab = CrystalOfTableaux(['A',3], shape = [2,2])
sage: C = Tab.letters
sage: Tab(rows    = [[1,2],[3,4]])._list == [C(3),C(1),C(4),C(2)]
True
sage: Tab(columns = [[3,1],[4,2]])._list == [C(3),C(1),C(4),C(2)]
True
```

And for compatibility with TensorProductOfCrystal we should also allow as input the internal list / sequence of elements:

```
sage: Tab(list    = [3,1,4,2])._list     == [C(3),C(1),C(4),C(2)]
True
sage: Tab(3,1,4,2)._list                 == [C(3),C(1),C(4),C(2)]
True
```

Type D, illustrating that the last parameter in the shape can be negative:

```
sage: C = CrystalOfTableaux(['D',4],shape=[1,1,1,-1])
sage: C.cardinality()
35
sage: C.check()
True
```

The next example checks whether a given tableau is in fact a valid type C tableau or not:

sage: T = CrystalOfTableaux(['C',3], shape = [2,2,2]) sage: t = T(rows=[[1,3],[2,-3],[3,-1]]) sage: t in T.list() True sage: t = T(rows=[[2,3],[3,-3],[-3,-2]]) sage: t in T.list() False

cartan_type()

Returns the Cartan type of the associated crystal

EXAMPLES:: sage: T = CrystalOfTableaux(['A',3], shape = [2,2]) sage: T.cartan_type() ['A', 3]

module_generator(*shape*)

This yields the module generator (or highest weight element) of a classical crystal of given shape. The module generator is the unique tableau with equal shape and content.

EXAMPLE: sage: T = CrystalOfTableaux(['D',3], shape = [1,1]) sage: T.module_generator([1,1]) [[1], [2]]

class CrystalOfTableauxElement(*parent, *args, **options*)

to_tableau()

Returns the Tableau object corresponding to self.

EXAMPLES:

```
sage: T = CrystalOfTableaux(['A',3], shape = [2,2])
sage: t = T(rows=[[1,2],[3,4]]).to_tableau(); t
[[1, 2], [3, 4]]
sage: type(t)
<class 'sage.combinat.tableau.Tableau_class'>
sage: type(t[0][0])
<type 'sage.rings.integer.Integer'>
sage: T = CrystalOfTableaux(['D',3], shape = [1,1])
sage: t=T(rows=[[-3],[3]]).to_tableau(); t
[[-3], [3]]
sage: t=T(rows=[[3],[-3]]).to_tableau(); t
[[3], [-3]]
```

class CrystalOfWords()

Auxiliary class to provide a call method to create tensor product elements. This class is shared with several tensor product classes and is also used in CrystalOfTableaux to allow tableaux of different tensor product structures in column-reading (and hence different shapes) to be considered elements in the same crystal.

class FullTensorProductOfClassicalCrystals(**crystals, **options*)

class FullTensorProductOfCrystals(**crystals, **options*)

cardinality()

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',2])
sage: T = TensorProductOfCrystals(C,C)
sage: T.cardinality()
9
```

list()

The default implementation of list which builds the list from the iterator.

EXAMPLES:

```
sage: class C(CombinatorialClass):
...       def __iter__(self):
...           return iter([1,2,3])
...
sage: C().list() #indirect doctest
[1, 2, 3]
```

class ImmutableListWithParent(*parent, list*)

A class for lists having a parent

Specification: any subclass C should implement __init__ which accepts the following form C(parent, list = list)

EXAMPLES: We create an immutable list whose parent is the class list:

```
sage: from sage.combinat.crystals.tensor_product import ImmutableListWithParent
sage: l = ImmutableListWithParent(list, [1,2,3])
sage: l._list
[1, 2, 3]
sage: l.parent()
<type 'list'>
sage: l.sibling([2,1]) == ImmutableListWithParent(list, [2,1])
True
sage: l.reversed()
[3, 2, 1]
sage: l.set_index(1,4)
[1, 4, 3]
```

parent()

EXAMPLES:

```
sage: from sage.combinat.crystals.tensor_product import ImmutableListWithParent
sage: l = ImmutableListWithParent(list, [1,2,3])
sage: l.parent()
<type 'list'>
```

reversed()

Returns the sibling of self which is obtained by reversing the elements of self.

EXAMPLES:

```
sage: from sage.combinat.crystals.tensor_product import ImmutableListWithParent
sage: l = ImmutableListWithParent(list, [1,2,3])
sage: l.reversed()
[3, 2, 1]
```

set_index(*k, value*)

Returns the sibling of self obtained by setting the k^{th} entry of self to value.

EXAMPLES:

```
sage: from sage.combinat.crystals.tensor_product import ImmutableListWithParent
sage: l = ImmutableListWithParent(list, [1,2,3])
sage: l.set_index(0,2)
[2, 2, 3]
sage: l.set_index(1,4)
[1, 4, 3]
sage: _.parent()
<type 'list'>
```

sibling(*l*)

Returns an ImmutableListWithParent object whose list is l and whose parent is the same as self's parent.

Note that the implementation of this function makes an assumption about the constructor for subclasses.

EXAMPLES:

```
sage: from sage.combinat.crystals.tensor_product import ImmutableListWithParent
sage: l = ImmutableListWithParent(list, [1,2,3])
sage: m = l.sibling([2,3,4]); m
[2, 3, 4]
```

```
sage: m.parent()
<type 'list'>
```

class **TensorProductOfClassicalCrystalsWithGenerators**(**crystals, **options*)

TensorProductOfCrystals(**crystals, **options*)

Tensor product of crystals.

Given two crystals B and B' of the same type, one can form the tensor product $B \otimes B'$. As a set $B \otimes B'$ is the Cartesian product $B \times B'$. The crystal operators f_i and e_i act on $b \otimes b' \in B \otimes B'$ as follows:

f_i(b otimes b') = begin{cases} f_i(b) otimes b' & text{if $varepsilon_i(b) ge varphi_i(b')$}\ b otimes f_i(b') & text{otherwise} end{cases}

and

e_i(b otimes b') = begin{cases} b otimes e_i(b') & text{if $varepsilon_i(b) le varphi_i(b')$}\ e_i(b) otimes b' & text{otherwise.} end{cases}

Note that this is the opposite of Kashiwara's convention for tensor products of crystals.

EXAMPLES:

We construct the type A_2-crystal generated by $2 \otimes 1 \otimes 1$:

```
sage: C = CrystalOfLetters(['A',2])
sage: T = TensorProductOfCrystals(C,C,C,generators=[[C(2),C(1),C(1)]])
```

It has 8 elements:

```
sage: T.list()
[[2, 1, 1], [2, 1, 2], [2, 1, 3], [3, 1, 3], [3, 2, 3], [3, 1, 1], [3, 1, 2], [3, 2, 2]]
```

One can also check the Cartan type of the crystal:

```
sage: T.cartan_type()
['A', 2]
```

Other examples include crystals of tableaux (which internally are represented as tensor products obtained by reading the tableaux columnwise):

```
sage: C = CrystalOfTableaux(['A',3], shape=[1,1,0])
sage: D = CrystalOfTableaux(['A',3], shape=[1,0,0])
sage: T = TensorProductOfCrystals(C,D, generators=[[C(rows=[[1], [2]]), D(rows=[[1]])], [C(rows=
sage: T.cardinality()
24
sage: T.check()
True
sage: T.module_generators
[[[[1], [2]], [[1]]], [[[2], [3]], [[1]]]]
sage: [x.weight() for x in T.module_generators]
[(2, 1, 0, 0), (1, 1, 1, 0)]
```

If no module generators are specified, we obtain the full tensor product:

```
sage: C=CrystalOfLetters(['A',2])
sage: T=TensorProductOfCrystals(C,C)
sage: T.list()
[[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1], [3, 2], [3, 3]]
sage: T.cardinality()
9
```

For a tensor product of crystals without module generators, the default implementation of module_generators contains all elements in the tensor product of the crystals. If there is a subset of elements in the tensor product that still generates the crystal, this needs to be implemented for the specific crystal separately:

```
sage: T.module_generators.list()
[[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1], [3, 2], [3, 3]]
```

For classical highest weight crystals, it is also possible to list all highest weight elements:

```
sage: C = CrystalOfLetters(['A',2])
sage: T = TensorProductOfCrystals(C,C,C,generators=[[C(2),C(1),C(1)],[C(1),C(2),C(1)]])
sage: T.highest_weight_vectors()
[[2, 1, 1], [1, 2, 1]]
```

class **TensorProductOfCrystalsElement** (*parent, list*)

A class for elements of tensor products of crystals

e (*i*)

Returns the action of e_i on self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: T = TensorProductOfCrystals(C,C)
sage: T(C(1),C(2)).e(1) == T(C(1),C(1))
True
sage: T(C(2),C(1)).e(1) == None
True
sage: T(C(2),C(2)).e(1) == T(C(1),C(2))
True
```

epsilon (*i*)

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: T = TensorProductOfCrystals(C,C)
sage: T(C(1),C(1)).epsilon(1)
0
sage: T(C(1),C(2)).epsilon(1)
1
sage: T(C(2),C(1)).epsilon(1)
0
```

f (*i*)

Returns the action of f_i on self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: T = TensorProductOfCrystals(C,C)
sage: T(C(1),C(1)).f(1)
[1, 2]
sage: T(C(1),C(2)).f(1)
[2, 2]
```

```
sage: T(C(2),C(1)).f(1) is None
True
```

phi(*i*)

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: T = TensorProductOfCrystals(C,C)
sage: T(C(1),C(1)).phi(1)
2
sage: T(C(1),C(2)).phi(1)
1
sage: T(C(2),C(1)).phi(1)
0
```

positions_of_unmatched_minus(*i, dual=False, reverse=False*)

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: T = TensorProductOfCrystals(C,C)
sage: T(C(2),C(1)).positions_of_unmatched_minus(1)
[]
sage: T(C(1),C(2)).positions_of_unmatched_minus(1)
[0]
```

positions_of_unmatched_plus(*i*)

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',5])
sage: T = TensorProductOfCrystals(C,C)
sage: T(C(2),C(1)).positions_of_unmatched_plus(1)
[]
sage: T(C(1),C(2)).positions_of_unmatched_plus(1)
[1]
```

weight()

Returns the weight of self.

EXAMPLES:

```
sage: C = CrystalOfLetters(['A',3])
sage: T = TensorProductOfCrystals(C,C)
sage: T(C(1),C(2)).weight()
(1, 1, 0, 0)
```

class **TensorProductOfCrystalsWithGenerators**(**crystals, **options*)

17.35.5 Fast Rank Two Crystals

class **FastCrystal**(*ct, shape, format='string'*)

An alternative implementation of rank 2 crystals. The root operators are implemented in memory by table lookup. This means that in comparison with the Crystals of Tableaux, these crystals are slow to instantiate but faster for computation. Implemented for types A2, B2 and C2.

Input: CartanType and a shape. The CartanType is ['A',2], ['B',2] or ['C',2]. The shape is of the form [l1,l2] where l1 and l2 are either integers or (in type B) half integers such that l1-l2 is integral. It is assumed that l1 >= l2 >= 0. If l1 and l2 are integers, this will produce the a crystal isomorphic to the one obtained by CrystalOfTableaux(type, shape=[l1,l2]). Furthermore FastCrystal(['B', 2], l1+1/2, l2+1/2) produces a crystal isomorphic to the following crystal T:

```
C = CrystalOfTableaux(['B',2], shape=[l1,l2])
D = CrystalOfSpins(['B',2])
T = TensorProductOfCrystals(C,D,C.list()[0],D.list()[0])
```

The representation of elements is in term of the Berenstein-Zelevinsky-Littelmann strings [a1, a2, ...] described under metapost in crystals.py. Alternative representations may be obtained by the options format="dual_string" or format="simple". In the simple format, the element is represented by and integer, and in the dual_string format, it is represented by the Berenstein-Zelevinsky-Littelmann string, but the underlying decomposition of the long Weyl group element into simple reflections is changed.

TESTS:

```
sage: C = FastCrystal(['A',2],shape=[4,1])
sage: C.cardinality()
24
sage: C.cartan_type()
['A', 2]
sage: C.check()
True
sage: C = FastCrystal(['B',2],shape=[4,1])
sage: C.cardinality()
154
sage: C.check()
True
sage: C = FastCrystal(['B',2],shape=[3/2,1/2])
sage: C.cardinality()
16
sage: C.check()
True
sage: C = FastCrystal(['C',2],shape=[2,1])
sage: C.cardinality()
16
sage: C = FastCrystal(['C',2],shape=[3,1])
sage: C.cardinality()
35
sage: C.check()
True
```

cmp_elements(*x*, *y*)

Returns True if and only if there is a path from x to y in the crystal graph.

Because the crystal graph is classical, it is a directed acyclic graph which can be interpreted as a poset. This function implements the comparison function of this poset.

EXAMPLES:

```
sage: C = FastCrystal(['A',2],shape=[2,1])
sage: x = C(0)
sage: y = C(1)
sage: C.cmp_elements(x,y)
-1
sage: C.cmp_elements(y,x)
1
sage: C.cmp_elements(x,x)
0
```

digraph()

Returns the digraph associated to self.

EXAMPLES:

```
sage: C = FastCrystal(['A',2],shape=[2,1])
sage: C.digraph()
Digraph on 8 vertices
```

list()
Returns a list of the elements of self.
EXAMPLES:

```
sage: C = FastCrystal(['A',2],shape=[2,1])
sage: C.list()
[[0, 0, 0],
 [1, 0, 0],
 [0, 1, 1],
 [0, 2, 1],
 [1, 2, 1],
 [0, 1, 0],
 [1, 1, 0],
 [2, 1, 0]]
```

class **FastCrystalElement**(*parent, value, format*)

e(*i*)
Returns the action of e_i on self.
EXAMPLES:

```
sage: C = FastCrystal(['A',2],shape=[2,1])
sage: C(1).e(1)
[0, 0, 0]
sage: C(0).e(1) is None
True
```

f(*i*)
Returns the action of f_i on self.
EXAMPLES:

```
sage: C = FastCrystal(['A',2],shape=[2,1])
sage: C(6).f(1)
[1, 2, 1]
sage: C(7).f(1) is None
True
```

parent()
Returns the parent of self.
EXAMPLES:

```
sage: C = FastCrystal(['A',2],shape=[2,1])
sage: C[0].parent()
The fast crystal for A2 with shape [2,1]
```

weight()
Returns the weight of self.
EXAMPLES:

```
sage: [v.weight() for v in FastCrystal(['A',2], shape=[2,1])]
[(2, 1, 0), (1, 2, 0), (1, 1, 1), (1, 0, 2), (0, 1, 2), (2, 0, 1), (1, 1, 1), (0, 2, 1)]
sage: [v.weight() for v in FastCrystal(['B',2], shape=[1,0])]
[(1, 0), (0, 1), (0, 0), (0, -1), (-1, 0)]
sage: [v.weight() for v in FastCrystal(['B',2], shape=[1/2,1/2])]
```

```
[(1/2, 1/2), (1/2, -1/2), (-1/2, 1/2), (-1/2, -1/2)]
sage: [v.weight() for v in FastCrystal(['C',2], shape=[1,0])]
[(1, 0), (0, 1), (0, -1), (-1, 0)]
sage: [v.weight() for v in FastCrystal(['C',2], shape=[1,1])]
[(1, 1), (1, -1), (0, 0), (-1, 1), (-1, -1)]
```

17.36 Posets

17.36.1 Posets

class FinitePoset (*digraph, elements=None*)

Note: A class that inherits from this class needs to define _element_type. This is the class of the elements that the inheriting class contains. For example, for this class, FinitePoset, _element_type is PosetElement.

antichains()

Returns a list of all antichains of the poset.

An antichain of a poset is a collection of elements of the poset that are pairwise incomparable.

EXAMPLES:

```
sage: Posets.PentagonPoset().antichains()
[[], [0], [1], [2], [3], [4], [1, 2], [1, 3]]
sage: Posets.AntichainPoset(3).antichains()
[[], [2], [1], [0], [1, 0], [2, 1], [2, 0], [2, 1, 0]]
sage: Posets.ChainPoset(3).antichains()
[[], [0], [1], [2]]
```

bottom()

Returns the bottom element of the poset, if it exists.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.bottom() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.bottom()
0
```

closed_interval(*x, y*)

Returns a list of the elements z such that $x \leq z \leq y$. The order is that induced by the ordering in `self.linear_extension()`.

EXAMPLES:

```
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: P = Poset(dag)
sage: I = set(map(P,[2,5,6,4,7]))
sage: I == set(P.closed_interval(2,7))
True
```

cover_relations(*element=None*)

Returns the list of pairs [u,v] of elements of the poset such that u v is a cover relation (that is, u v and there does not exist z such that u z v).

EXAMPLES:

```
sage: Q = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: Q.cover_relations()
[[1, 2], [0, 2], [2, 3], [3, 4]]
```

cover_relations_iterator()

Returns an iterator for the cover relations of the poset.

EXAMPLES:

```
sage: Q = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: type(Q.cover_relations_iterator())
<type 'generator'>
sage: [z for z in Q.cover_relations_iterator()]
[[1, 2], [0, 2], [2, 3], [3, 4]]
```

covers(*x*, *y*)

Returns True if y covers x and False otherwise.

EXAMPLES:

```
sage: Q = Poset([[1,5],[2,6],[3],[4],[],[6,3],[4]])
sage: Q.covers(Q(1),Q(6))
True
sage: Q.covers(Q(1),Q(4))
False
```

dual()

Returns the dual poset of the given poset.

EXAMPLE:

```
sage: P = Poset([[1,2],[4],[3],[4],[]])
sage: P.dual()
Finite poset containing 5 elements
```

graphviz_string(*graph_string='graph'*, *edge_string='–'*)

Returns a representation in the DOT language, ready to render in graphviz.

REFERENCES:

- http://www.graphviz.org/doc/info/lang.html

EXAMPLES:

```
sage: P = Poset({'a':['b'],'b':['d'],'c':['d'],'d':['f'],'e':['f'],'f':[]})
sage: print P.graphviz_string()
graph {
"f";"d";"b";"a";"c";"e";
"f"--"e";"d"--"c";"b"--"a";"d"--"b";"f"--"d";
}
```

has_bottom()

Returns True if the poset has a unique minimal element.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.has_bottom()
False
sage: Q = Poset({0:[1],1:[]})
sage: Q.has_bottom()
True
```

has_top()

Returns True if the poset contains a unique maximal element, and False otherwise.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.has_top()
False
sage: Q = Poset({0:[1],1:[]})
sage: Q.has_top()
True
```

hasse_diagram()

Returns the Hasse_diagram of the poset as a Sage DiGraph object.

EXAMPLES:

```
sage: Q = Poset({5:[2,3], 1:[3,4], 2:[0], 3:[0], 4:[0]})
sage: Q.hasse_diagram()
Digraph on 6 vertices

sage: P = Poset({'a':['b'],'b':['d'],'c':['d'],'d':['f'],'e':['f'],'f':[]})
sage: H = P.hasse_diagram()
sage: P.cover_relations()
[[e, f], [c, d], [a, b], [b, d], [d, f]]
sage: H.edges()
[(a, b, None), (c, d, None), (b, d, None), (e, f, None), (d, f, None)]
```

interval(*x*, *y*)

Returns a list of the elements z such that $x \leq z \leq y$. The order is that induced by the ordering in `self.linear_extension()`.

INPUT:

- `x` - any element of the poset
- `y` - any element of the poset

EXAMPLES:

```
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: P = Poset(dag)
sage: I = set(map(P,[2,5,6,4,7]))
sage: I == set(P.interval(2,7))
True

sage: dg = DiGraph({"a":["b","c"], "b":["d"], "c":["d"]})
sage: P = Poset(dg)
sage: P.interval("a","d")
[a, c, b, d]
```

is_bounded()

Returns True if the poset contains a unique maximal element and a unique minimal element, and False otherwise.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.is_bounded()
False
sage: Q = Poset({0:[1],1:[]})
sage: Q.is_bounded()
True
```

is_chain()

Returns True if the poset is totally ordered, and False otherwise.

EXAMPLES:

```
sage: L = Poset({0:[1],1:[2],2:[3],3:[4]})
sage: L.is_chain()
True
sage: V = Poset({0:[1,2]})
sage: V.is_chain()
False
```

is_gequal(*x, y*)

Returns True if x is greater than or equal to y in the poset, and False otherwise.

EXAMPLES:

```
sage: Q = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x,y,z = Q(0),Q(1),Q(4)
sage: Q.is_gequal(x,y)
False
sage: Q.is_gequal(y,x)
False
sage: Q.is_gequal(x,z)
False
sage: Q.is_gequal(z,x)
True
sage: Q.is_gequal(z,y)
True
sage: Q.is_gequal(z,z)
True
```

is_graded()

Returns True if the poset is graded, and False otherwise.

A poset is *graded* if it admits a rank function.

EXAMPLES:

```
sage: P = Poset([[1],[2],[3],[4],[]])
sage: P.is_graded()
True
sage: Q = Poset([[1,5],[2,6],[3],[4],[],[6,3],[4]])
sage: Q.is_graded()
False
```

is_greater_than(*x, y*)

Returns True if x is greater than but not equal to y in the poset, and False otherwise.

EXAMPLES:

```
sage: Q = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x,y,z = Q(0),Q(1),Q(4)
sage: Q.is_greater_than(x,y)
False
sage: Q.is_greater_than(y,x)
False
sage: Q.is_greater_than(x,z)
False
sage: Q.is_greater_than(z,x)
True
sage: Q.is_greater_than(z,y)
True
sage: Q.is_greater_than(z,z)
False
```

is_join_semilattice()

Returns True is the poset has a join operation, and False otherwise.

EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: P.is_join_semilattice()
True

sage: P = Poset([[1,2],[3],[3],[]])
sage: P.is_join_semilattice()
True

sage: P = Poset({0:[2,3],1:[2,3]})
sage: P.is_join_semilattice()
False
```

is_lequal(*x*, *y*)

Returns True if x is less than or equal to y in the poset, and False otherwise.

EXAMPLES:

```
sage: Q = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x,y,z = Q(0),Q(1),Q(4)
sage: Q.is_lequal(x,y)
False
sage: Q.is_lequal(y,x)
False
sage: Q.is_lequal(x,z)
True
sage: Q.is_lequal(y,z)
True
sage: Q.is_lequal(z,z)
True
```

is_less_than(*x*, *y*)

Returns True if x is less than but not equal to y in the poset, and False otherwise.

EXAMPLES:

```
sage: Q = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x,y,z = Q(0),Q(1),Q(4)
sage: Q.is_less_than(x,y)
False
sage: Q.is_less_than(y,x)
False
sage: Q.is_less_than(x,z)
True
sage: Q.is_less_than(y,z)
True
sage: Q.is_less_than(z,z)
False
```

is_meet_semilattice()

Returns True if self has a meet operation, and False otherwise.

EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: P.is_meet_semilattice()
True

sage: P = Poset([[1,2],[3],[3],[]])
sage: P.is_meet_semilattice()
True
```

```
sage: P = Poset({0:[2,3],1:[2,3]})
sage: P.is_meet_semilattice()
False
```

is_ranked()

Returns True if the poset is ranked, and False otherwise.

A poset is {ranked} if it admits a rank function.

EXAMPLES:

```
sage: P = Poset([[1],[2],[3],[4],[]])
sage: P.is_ranked()
True
sage: Q = Poset([[1,5],[2,6],[3],[4],[],[6,3],[4]])
sage: Q.is_ranked()
False
```

join_matrix()

Returns a matrix whose (i,j) entry is k, where self.linear_extension()[k] is the join (least upper bound) of self.linear_extension()[i] and self.linear_extension()[j].

EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: J = P.join_matrix(); J
[0 1 2 3 4 5 6 7]
[1 1 3 3 7 7 7 7]
[2 3 2 3 4 6 6 7]
[3 3 3 3 7 7 7 7]
[4 7 4 7 4 7 7 7]
[5 7 6 7 7 5 6 7]
[6 7 6 7 7 6 6 7]
[7 7 7 7 7 7 7 7]
sage: J[P(4).vertex,P(3).vertex] == P(7).vertex
True
sage: J[P(5).vertex,P(2).vertex] == P(5).vertex
True
sage: J[P(5).vertex,P(2).vertex] == P(2).vertex
False
```

lequal_matrix(***kwds*)

Computes the matrix whose [i,j] entry is 1 if self.linear_extension()[i] self.linear_extension()[j] 0 otherwise.

EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: LEQM = P.lequal_matrix(); LEQM
[1 1 1 1 1 1 1 1]
[0 1 0 1 0 0 0 1]
[0 0 1 1 1 0 1 1]
[0 0 0 1 0 0 0 1]
[0 0 0 0 1 0 0 1]
[0 0 0 0 0 1 1 1]
[0 0 0 0 0 0 1 1]
[0 0 0 0 0 0 0 1]
sage: LEQM[1,3]
1
sage: P.linear_extension()[1] < P.linear_extension()[3]
True
sage: LEQM[2,5]
```

```
0
sage: P.linear_extension()[2] < P.linear_extension()[5]
False
```

level_sets()

Returns a list l such that l[i+1] is the set of minimal elements of the poset obtained by removing the elements in l[0], l[1], ..., l[i].

EXAMPLES:

```
sage: P = Poset({0:[1,2],1:[3],2:[3],3:[]})
sage: [len(x) for x in P.level_sets()]
[1, 2, 1]

sage: Q = Poset({0:[1,2], 1:[3], 2:[4], 3:[4]})
sage: [len(x) for x in Q.level_sets()]
[1, 2, 1, 1]
```

linear_extension()

Returns a linear extension of the poset.

EXAMPLES:

```
sage: B = Posets.BooleanLattice(3)
sage: B.linear_extension()
[0, 1, 2, 3, 4, 5, 6, 7]
```

linear_extensions()

Returns a list of all the linear extensions of the poset.

EXAMPLES:

```
sage: D = Poset({ 0:[1,2], 1:[3], 2:[3,4] })
sage: D.linear_extensions()
[[0, 1, 2, 3, 4], [0, 1, 2, 4, 3], [0, 2, 1, 3, 4], [0, 2, 1, 4, 3], [0, 2, 4, 1, 3]]
```

list()

List the elements of the poset. This just returns the result of `linear_extension()`.

EXAMPLES:

```
sage: D = Poset({ 0:[1,2], 1:[3], 2:[3,4] })
sage: D.list()
[0, 1, 2, 3, 4]
sage: type(D.list()[0])
<class 'sage.combinat.posets.elements.PosetElement'>
```

lower_covers(*y*)

Returns a list of lower covers of the element y. An lower cover of y is an element x such that y x is a cover relation.

EXAMPLES:

```
sage: Q = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: map(Q.lower_covers,Q.list())
[[], [], [1, 0], [2], [3]]
```

lower_covers_iterator(*y*)

Returns an iterator for the lower covers of the element y. An lower cover of y is an element x such that y x is a cover relation.

EXAMPLES:

```
sage: Q = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: type(Q.lower_covers_iterator(0))
<type 'generator'>
```

maximal_elements()

Returns a list of the maximal elements of the poset.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.maximal_elements()
[4]
```

meet_matrix()

Returns a matrix whose (i,j) entry is k, where self.linear_extension()[k] is the meet (greatest lower bound) of self.linear_extension()[i] and self.linear_extension()[j].

EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: M = P.meet_matrix(); M
[0 0 0 0 0 0 0 0]
[0 1 0 1 0 0 0 1]
[0 0 2 2 2 0 2 2]
[0 1 2 3 2 0 2 3]
[0 0 2 2 4 0 2 4]
[0 0 0 0 0 5 5 5]
[0 0 2 2 2 5 6 6]
[0 1 2 3 4 5 6 7]
sage: M[P(4).vertex,P(3).vertex] == P(0).vertex
True
sage: M[P(5).vertex,P(2).vertex] == P(2).vertex
True
sage: M[P(5).vertex,P(2).vertex] == P(5).vertex
False
```

minimal_elements()

Returns a list of the minimal elements of the poset.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P(0) in P.minimal_elements()
True
sage: P(1) in P.minimal_elements()
True
sage: P(2) in P.minimal_elements()
True
```

mobius_function(*x*, *y*)

Returns the value of the Mobius function of the poset on the elements x and y.

EXAMPLES:

```
sage: P = Poset([[1,2,3],[4],[4],[4],[]])
sage: P.mobius_function(P(0),P(4))
2
sage: sum([P.mobius_function(P(0),v) for v in P])
0
sage: sum([abs(P.mobius_function(P(0),v)) \
...        for v in P])
6
sage: for u,v in P.cover_relations_iterator():
```

```
...     if P.mobius_function(u,v) != -1:
...         print "Bug in mobius_function!"

sage: Q = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: Q.mobius_function(Q(0),Q(-1))
0
sage: Q.mobius_function(Q(0),Q(5))
0
sage: Q.mobius_function(Q(2),Q(7))
2
sage: Q.mobius_function(Q(3),Q(3))
1
sage: sum([Q.mobius_function(Q(0),v) for v in Q])
0
```

mobius_function_matrix()

Returns a matrix whose (i,j) entry is the value of the Mobius function evaluated at self.linear_extension()[i] and self.linear_extension()[j].

EXAMPLES:

```
sage: P = Poset([[4,2,3],[],[1],[1],[1]])
sage: x,y = (P.linear_extension()[0],P.linear_extension()[1])
sage: P.mobius_function(x,y)
-1
sage: M = P.mobius_function_matrix(); M
[ 1 -1 -1 -1  2]
[ 0  1  0  0 -1]
[ 0  0  1  0 -1]
[ 0  0  0  1 -1]
[ 0  0  0  0  1]
sage: M[0,4]
2
sage: M[0,1]
-1
```

open_interval(x, y)

Returns a list of the elements z such that $x < z < y$. The order is that induced by the ordering in `self.linear_extension()`.

EXAMPLES:

```
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: P = Poset(dag)
sage: I = set(map(P,[5,6,4]))
sage: I == set(P.open_interval(2,7))
True

sage: dg = DiGraph({"a":["b","c"], "b":["d"], "c":["d"]})
sage: P = Poset(dg)
sage: P.open_interval("a","d")
[c, b]
```

order_complex()

Returns the order complex associated to this poset.

The order complex is the simplical complex with vertices equal to the elements of the poset, and faces given by the chains.

EXAMPLES:

```
sage: P = Posets.BooleanLattice(3)
sage: S = P.order_complex(); S
Simplicial complex with vertex set (0, 1, 2, 3, 4, 5, 6, 7) and 6 facets
sage: S.f_vector()
[1, 8, 19, 18, 6]
sage: S.homology()      # S is contractible
{0: 0, 1: 0, 2: 0, 3: 0}
sage: Q = P.subposet([1,2,3,4,5,6])
sage: Q.order_complex().homology()    # a circle
{0: 0, 1: Z}
```

order_filter(*elements*)

Returns the order filter generated by a list of elements.

I is an order filter if, for any x in I and y such that $y \geq x$, then y is in I.

EXAMPLES:

```
sage: B = Posets.BooleanLattice(4)
sage: B.order_filter([3,8])
[8, 9, 10, 3, 11, 12, 13, 14, 7, 15]
```

order_ideal(*elements*)

Returns the order ideal generated by a list of elements.

I is an order ideal if, for any x in I and y such that $y \leq x$, then y is in I.

EXAMPLES:

```
sage: B = Posets.BooleanLattice(4)
sage: B.order_ideal([7,10])
[0, 8, 1, 2, 10, 3, 4, 5, 6, 7]
```

plot(*label_elements=True, element_labels=None, label_font_size=12, label_font_color='black', vertex_size=300, vertex_colors=None, **kwds*)

Returns a Graphic object corresponding the Hasse diagram of the poset. Optionally, it is labelled.

INPUT:

- `label_elements` - whether to display element labels
- `element_labels` - a dictionary of element labels

EXAMPLES:

```
sage: D = Poset({ 0:[1,2], 1:[3], 2:[3,4] })
sage: D.plot(label_elements=False)
sage: D.plot()
sage: type(D.plot())
<class 'sage.plot.plot.Graphics'>
sage: elm_labs = {0:'a', 1:'b', 2:'c', 3:'d', 4:'e'}
sage: D.plot(element_labels=elm_labs)

sage: P = Poset({})
sage: P.plot()

sage: P = Poset(DiGraph('E@ACA@?'))
sage: P.plot()
```

principal_order_filter(*x*)

Returns the order filter generated by an element `x`.

EXAMPLES:

```
sage: B = Posets.BooleanLattice(4)
sage: B.principal_order_filter(2)
[2, 10, 3, 11, 6, 14, 7, 15]
```

principal_order_ideal(*x*)
Returns the order ideal generated by an element x.
EXAMPLES:

```
sage: B = Posets.BooleanLattice(4)
sage: B.principal_order_ideal(6)
[0, 2, 4, 6]
```

random_subposet(*p*)
Returns a random subposet that contains each element with probability p.
EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: Q = P.random_subposet(.25)
```

rank(*element=None*)
Returns the rank of an element, or the rank of the poset if element is None. (The rank of a poset is the length of the longest chain of elements of the poset.)
EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: P.rank(5)
2
sage: P.rank()
3
sage: Q = Poset([[1,2],[3],[],[]])

sage: P = Posets.SymmetricGroupBruhatOrderPoset(4)

sage: [(v,P.rank(v)) for v in P]
[(1234, 0),
 (2134, 1),
...
 (4231, 5),
 (4321, 6)]
```

rank_function()
Returns a rank function of the poset, if it exists.
A *rank function* of a poset P is a function r from that maps elements of P to integers and satisfies: $r(x) = r(y) + 1$ if x covers y.
EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: P.rank_function() is not None
True
sage: r = P.rank_function()
sage: for u,v in P.cover_relations_iterator():
...     if r(v) != r(u) + 1:
...         print "Bug in rank_function!"

sage: Q = Poset([[1,2],[4],[3],[4],[]])
sage: Q.rank_function() is None
True
```

show(*label_elements=True, element_labels=None, label_font_size=12, label_font_color='black', vertex_size=300, vertex_colors=None, **kwds*)
Shows the Graphics object corresponding the Hasse diagram of the poset. Optionally, it is labelled.
INPUT:

- label_elements - whether to display element labels

- `element_labels` - a dictionary of element labels

EXAMPLES:

```
sage: D = Poset({ 0:[1,2], 1:[3], 2:[3,4] })
sage: D.plot(label_elements=False)
sage: D.show()
sage: elm_labs = {0:'a', 1:'b', 2:'c', 3:'d', 4:'e'}
sage: D.show(element_labels=elm_labs)
```

size()

Returns the number of elements in the poset.

EXAMPLES:

```
sage: Poset([[1,2,3],[4],[4],[4],[]]).size()
5
```

subposet(*elements*)

Returns the poset containing elements with partial order induced by that of self.

EXAMPLES:

```
sage: P = Poset({"a":["c","d"], "b":["d","e"], "c":["f"], "d":["f"], "e":["f"]})
sage: P.subposet(["a","b","f"])
Finite poset containing 3 elements

sage: P = posets.BooleanLattice(2)
sage: above = P.principal_order_filter(0)
sage: Q = P.subposet(above)
sage: above_new = Q.principal_order_filter(Q.list()[0])
sage: Q.subposet(above_new)
Finite poset containing 4 elements
```

top()

Returns the top element of the poset, if it exists.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.top() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.top()
1
```

upper_covers(*y*)

Returns a list of upper covers of the element y. An upper cover of y is an element x such that y x is a cover relation.

EXAMPLES:

```
sage: Q = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: map(Q.upper_covers,Q.list())
[[2], [2], [3], [4], []]
```

upper_covers_iterator(*y*)

Returns an iterator for the upper covers of the element y. An upper cover of y is an element x such that y x is a cover relation.

EXAMPLES:

```
sage: Q = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: type(Q.upper_covers_iterator(0))
<type 'generator'>
```

class FinitePosets_n(*n*)

The Combinatorial Class of all posets on n vertices.

cardinality(*from_iterator=False*)

Return the cardinality of this object.

Note: By default, this returns pre-computed values obtained from the On-Line Encyclopedia of Integer Sequences (A000112). To override this, use pass the argument `from_iterator=True`.

EXAMPLES:

```
sage: P = Posets(3)
sage: P.cardinality()
5
sage: P.cardinality(from_iterator=True)
5
```

Poset(*data=None, element_labels=None, cover_relations=False*)

Construct a poset from various forms of input data.

INPUT:

1. A two-element list or tuple (E, R), where E is a collection of elements of the poset and R is the set of relations. Elements of R are two-element lists/tuples/iterables. If cover_relations=True, then R is assumed to be the cover relations of the poset. If E is empty, then E is taken to be the set of elements appearing in the relations R.
2. A two-element list or tuple (E, f), where E is the set of elements of the poset and f is a function such that f(x,y) is True if x <= y and False otherwise for all pairs of elements in E. If cover_relations=True, then f(x,y) should be True if and only if x is covered by y, and False otherwise.
3. A dictionary, list or tuple of upper covers: data[x] is an list of the elements that cover the element x in the poset.

   Note: If data is a list or tuple of length 2, then it is handled by the above cases.
4. An acyclic, loop-free and multi-edge free DiGraph. If cover_relations is True, then the edges of the digraph correspond to cover relations in the poset. If cover_relations is False, then the cover relations are computed.
5. A previously constructed poset (the poset itself is returned).

- **element_labels – (default: None) an optional list or** dictionary of objects that label the poset elements.
- `cover_relations` - (default: False) If True, then the data is assumed to describe a directed acyclic graph whose arrows are cover relations. If False, then the cover relations are first computed.

OUTPUT:

FinitePoset – an instance of the FinitePoset class.

EXAMPLES:

1. Elements and cover relations:

```
sage: elms = [1,2,3,4,5,6,7]
sage: rels = [[1,2],[3,4],[4,5],[2,5]]
sage: Poset((elms, rels), cover_relations = True)
Finite poset containing 7 elements
```

Elements and non-cover relations:

```
sage: elms = [1,2,3,4]
sage: rels = [[1,2],[1,3],[1,4],[2,3],[2,4],[3,4]]
sage: P = Poset( [elms,rels] ,cover_relations=False); P
```

```
Finite poset containing 4 elements
sage: P.cover_relations()
[[1, 2], [2, 3], [3, 4]]
```

2.Elements and function: the standard permutations of [1, 2, 3, 4] with the Bruhat order:

```
sage: elms = Permutations(4)
sage: fcn = lambda p,q : p.bruhat_lequal(q)
sage: Poset((elms, fcn))
Finite poset containing 24 elements
```

With a function that identifies the cover relations: the set partitions of {1, 2, 3} ordered by refinement:

```
sage: elms = SetPartitions(3)
sage: def fcn(A, B):
...     if len(A) != len(B)+1:
...         return False
...     for a in A:
...         if not any(set(a).issubset(b) for b in B):
...             return False
...     return True
sage: Poset((elms, fcn), cover_relations=True)
Finite poset containing 5 elements
```

3.A dictionary of upper covers:

```
sage: Poset({'a':['b','c'], 'b':['d'], 'c':['d'], 'd':[]})
Finite poset containing 4 elements
```

A list of upper covers:

```
sage: Poset([[1,2],[4],[3],[4],[]])
Finite poset containing 5 elements
```

A list of upper covers and a dictionary of labels:

```
sage: elm_labs = {0:"a",1:"b",2:"c",3:"d",4:"e"}
sage: P = Poset([[1,2],[4],[3],[4],[]],elm_labs)
sage: P.list()
[a, b, c, d, e]
```

Warning: The special case where the argument data is a list or tuple of length 2 is handled by the above cases. So you cannot use this method to input a 2-element poset.

4.An acyclic DiGraph.

```
sage: dag = DiGraph({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]})
sage: Poset(dag)
Finite poset containing 6 elements
```

Any directed acyclic graph without loops or multiple edges, as long as cover_relations=False:

```
sage: dig = DiGraph({0:[2,3], 1:[3,4,5], 2:[5], 3:[5], 4:[5]})
sage: dig.allows_multiple_edges()
False
sage: dig.allows_loops()
False
sage: dig.transitive_reduction() == dig
False
sage: Poset(dig, cover_relations=False)
Finite poset containing 6 elements
sage: Poset(dig, cover_relations=True)
```

```
...
ValueError: Hasse diagram is not transitively reduced.
```

class **Posets_all**()
The Combinatorial Class of all posets.

is_poset(*dig*)
Tests whether a directed graph is acyclic and transitively reduced.

EXAMPLES:

```
sage: from sage.combinat.posets.posets import is_poset
sage: dig = DiGraph({0:[2,3], 1:[3,4,5], 2:[5], 3:[5], 4:[5]})
sage: is_poset(dig)
False
sage: is_poset(dig.transitive_reduction())
True
```

17.36.2 Hasse diagrams of posets

class **HasseDiagram**(*data=None, pos=None, loops=None, format=None, boundary=, [], weighted=None, implementation='networkx', sparse=True, vertex_labels=True, **kwds*)
The Hasse diagram of a poset. This is just a transitively-reduced, directed, acyclic graph without loops or multiple edges.

Note: We assume that `range(n)` is a linear extension of the poset. That is, `range(n)` is the vertex set and a topological sort of the digraph.

This should not be called directly, use Poset instead; all type checking happens there.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]}); H
Hasse diagram of a poset containing 4 elements
sage: H == loads(dumps(H))
True
```

antichains()
Returns a list of all antichains of the poset.

An antichain of a poset is a collection of elements of the poset that are pairwise incomparable.

Note: This algorithm is based on Freese-Jezek-Nation p226

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[4],2:[3],3:[4]})
sage: H.antichains()
[[], [0], [1], [2], [3], [4], [1, 2], [1, 3]]

sage: H = HasseDiagram({0:[],1:[],2:[]})
sage: H.antichains()
[[], [0], [1], [2], [1, 2], [0, 1], [0, 2], [0, 1, 2]]

sage: H = HasseDiagram({0:[1],1:[2],2:[3],3:[4]})
sage: H.antichains()
[[], [0], [1], [2], [3], [4]]
```

bottom()

Returns the bottom element of the poset, if it exists.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.bottom() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.bottom()
0
```

closed_interval(*x, y*)

Returns a list of the elements z such that x = z = y. The order is that induced by the ordering in self.linear_extension.

EXAMPLES:

```
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: set([2,5,6,4,7]) == set(H.closed_interval(2,7))
True
```

complements()

Returns a list `l` such that `l[i]` is a complement of `i` in `self`.

A complement of `x` is an element `y` such that the meet of `x` and `y` is the bottom element of `self` and the join of `x` and `y` is the top element of `self`.

EXAMPLES:: sage: from sage.combinat.posets.hasse_diagram import HasseDiagram sage: H = HasseDiagram({0:[1,2,3],1:[4],2:[4],3:[4]}) sage: H.complements() [4, 3, 3, 2, 0]
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[4]}) sage: H.complements() [4, None, None, None, 0]

cover_relations(*element=None*)

TESTS:: sage: from sage.combinat.posets.hasse_diagram import HasseDiagram sage: H = HasseDiagram({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]}) sage: H.cover_relations() [(0, 2), (0, 3), (1, 3), (1, 4), (2, 5), (3, 5), (4, 5)]

cover_relations_iterator()

TESTS:: sage: from sage.combinat.posets.hasse_diagram import HasseDiagram sage: H = HasseDiagram({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]}) sage: list(H.cover_relations_iterator()) [(0, 2), (0, 3), (1, 3), (1, 4), (2, 5), (3, 5), (4, 5)]

covers(*x, y*)

Returns True if y covers x and False otherwise.

EXAMPLES:

```
sage: Q = Poset([[1,5],[2,6],[3],[4],[],[6,3],[4]])
sage: Q.covers(Q(1),Q(6))
True
sage: Q.covers(Q(1),Q(4))
False
```

dual()

Returns a poset that is dual to the given poset.

EXAMPLE:

```
sage: P = Poset([[1,2],[4],[3],[4],[]])
sage: P.dual()
Finite poset containing 5 elements
```

has_bottom()

Returns True if the poset has a unique minimal element.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.has_bottom()
False
sage: Q = Poset({0:[1],1:[]})
sage: Q.has_bottom()
True
```

has_top()

Returns `True` if the poset contains a unique maximal element, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.has_top()
False
sage: Q = Poset({0:[1],1:[]})
sage: Q.has_top()
True
```

interval(*x*, *y*)

Returns a list of the elements z such that x <= z <= y. The order is that induced by the ordering in self.linear_extension.

INPUT:

- `x` - any element of the poset
- `y` - any element of the poset

EXAMPLES:

```
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: I = set([2,5,6,4,7])
sage: I == set(H.interval(2,7))
True
```

is_bounded()

Returns True if the poset contains a unique maximal element and a unique minimal element, and False otherwise.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.is_bounded()
False
sage: Q = Poset({0:[1],1:[]})
sage: Q.is_bounded()
True
```

is_chain()

Returns True if the poset is totally ordered, and False otherwise.

EXAMPLES:

```
sage: L = Poset({0:[1],1:[2],2:[3],3:[4]})
sage: L.is_chain()
True
sage: V = Poset({0:[1,2]})
```

```
sage: V.is_chain()
False
```

is_complemented_lattice()

Returns `True` if `self` is the Hasse diagram of a complemented lattice, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2,3],1:[4],2:[4],3:[4]})
sage: H.is_complemented_lattice()
True

sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[4]})
sage: H.is_complemented_lattice()
False
```

is_distributive_lattice()

Returns `True` if `self` is the Hasse diagram of a distributive lattice, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.is_distributive_lattice()
False
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3]})
sage: H.is_distributive_lattice()
True
sage: H = HasseDiagram({0:[1,2,3],1:[4],2:[4],3:[4]})
sage: H.is_distributive_lattice()
False
```

is_distributive_lattice_fastest()

This function is deprecated and will be removed in a future version of Sage. Please use `self.is_distributive_lattice()` instead.

TESTS:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.is_distributive_lattice_fastest()
doctest:1: DeprecationWarning: is_distributive_lattice_fastest is deprecated, use is_distrib
False
```

is_gequal(*x*, *y*)

Returns `True` if `x` is greater than or equal to `y`, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: Q = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x,y,z = 0,1,4
sage: Q.is_gequal(x,y)
False
sage: Q.is_gequal(y,x)
False
sage: Q.is_gequal(x,z)
False
sage: Q.is_gequal(z,x)
True
sage: Q.is_gequal(z,y)
True
```

```
sage: Q.is_gequal(z,z)
True
```

is_graded()

Returns True if the poset is graded, and False otherwise.

A poset is {graded} if it admits a rank function.

EXAMPLES:

```
sage: P = Poset([[1],[2],[3],[4],[]])
sage: P.is_graded()
True
sage: Q = Poset([[1,5],[2,6],[3],[4],[],[6,3],[4]])
sage: Q.is_graded()
False
```

is_greater_than(*x*, *y*)

Returns `True` if `x` is greater than but not equal to `y`, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: Q = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x,y,z = 0,1,4
sage: Q.is_greater_than(x,y)
False
sage: Q.is_greater_than(y,x)
False
sage: Q.is_greater_than(x,z)
False
sage: Q.is_greater_than(z,x)
True
sage: Q.is_greater_than(z,y)
True
sage: Q.is_greater_than(z,z)
False
```

is_join_semilattice()

Returns `True` if `self` has a join operation, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.is_join_semilattice()
True
sage: H = HasseDiagram({0:[2,3],1:[2,3]})
sage: H.is_join_semilattice()
False
sage: H = HasseDiagram({0:[2,3],1:[2,3],2:[4],3:[4]})
sage: H.is_join_semilattice()
False
```

is_lequal(*i*, *j*)

Returns True if i is less than or equal to j in the poset, and False otherwise.

Note: If the `leq_matrix` has been computed, then this method is redefined to use the cached matrix (see `_alternate_is_lequal`).

TESTS:: sage: from sage.combinat.posets.hasse_diagram import HasseDiagram sage: H = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]}) sage: x,y,z = 0, 1, 4 sage: H.is_lequal(x,y) False sage: H.is_lequal(y,x) False sage: H.is_lequal(x,z) True sage: H.is_lequal(y,z) True sage: H.is_lequal(z,z) True

is_less_than(*x*, *y*)

Returns True if `x` is less than or equal to `y` in the poset, and False otherwise.

TESTS:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x,y,z = 0, 1, 4
sage: H.is_less_than(x,y)
False
sage: H.is_less_than(y,x)
False
sage: H.is_less_than(x,z)
True
sage: H.is_less_than(y,z)
True
sage: H.is_less_than(z,z)
False
```

is_linear_extension(*lin_ext=None*)

TESTS:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: H.is_linear_extension(range(4))
True
sage: H.is_linear_extension([3,2,1,0])
False
```

is_meet_semilattice()

Returns `True` if `self` has a meet operation, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.is_meet_semilattice()
True

sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: H.is_meet_semilattice()
True

sage: H = HasseDiagram({0:[2,3],1:[2,3]})
sage: H.is_meet_semilattice()
False
```

is_ranked()

Returns True if the poset is ranked, and False otherwise.

A poset is *ranked* if it admits a rank function.

EXAMPLES:

```
sage: P = Poset([[1],[2],[3],[4],[]])
sage: P.is_ranked()
True
sage: Q = Poset([[1,5],[2,6],[3],[4],[],[6,3],[4]])
sage: Q.is_ranked()
False
```

join_matrix()

Returns the matrix of joins of `self`. The `(x,y)`-entry of this matrix is the join of `x` and `y` in `self`.

This algorithm is modelled after the algorithm of Freese-Jezek-Nation (p217).

Note: Once the matrix has been computed, it is stored in `self._join_matrix`. Delete this attribute if you want to recompute the matrix.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.join_matrix()
[0 1 2 3 4 5 6 7]
[1 1 4 7 4 7 7 7]
[2 4 2 6 4 5 6 7]
[3 7 6 3 7 7 6 7]
[4 4 4 7 4 7 7 7]
[5 7 5 7 7 5 7 7]
[6 7 6 6 7 7 6 7]
[7 7 7 7 7 7 7 7]
```

TESTS:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2,3],1:[2,3]})
sage: H.join_matrix()
...
ValueError: Not a join-semilattice: no top element.

sage: H = HasseDiagram({0:[2,3],1:[2,3],2:[4],3:[4]})
sage: H.join_matrix()
...
ValueError: No join for x=...
```

lequal_matrix(*ring=Integer Ring, sparse=True*)

Computes a matrix whose `[i,j]` entry is 1 if `self.linear_extension[i] <= self.linear_extension[j]` and 0 otherwise. The matrix is stored in the attribute `_leq_matrix` and the method `__lt__` is redefined to use this matrix.

EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: H = P._hasse_diagram
sage: hasattr(H,'_leq_matrix')
False
sage: H.lequal_matrix()
[1 1 1 1 1 1 1 1]
[0 1 0 1 0 0 0 1]
[0 0 1 1 1 0 1 1]
[0 0 0 1 0 0 0 1]
[0 0 0 0 1 0 0 1]
[0 0 0 0 0 1 1 1]
[0 0 0 0 0 0 1 1]
[0 0 0 0 0 0 0 1]
sage: hasattr(H,'_leq_matrix')
True
```

level_sets()

Returns a list l such that l[i+1] is the set of minimal elements of the poset obtained by removing the elements in l[0], l[1], ..., l[i].

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: [len(x) for x in H.level_sets()]
```

```
[1, 2, 1]

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2], 1:[3], 2:[4], 3:[4]})
sage: [len(x) for x in H.level_sets()]
[1, 2, 1, 1]
```

linear_extension()

TESTS:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: H.linear_extension()
[0, 1, 2, 3]
```

linear_extensions()

TESTS:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: H.linear_extensions()
[[0, 1, 2, 3], [0, 2, 1, 3]]
```

lower_covers_iterator(*element*)

Returns the list of elements that are covered by `element`.

EXAMPLES:: sage: from sage.combinat.posets.hasse_diagram import HasseDiagram sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]}) sage: list(H.lower_covers_iterator(0)) [] sage: list(H.lower_covers_iterator(4)) [1, 2]

maximal_elements()

Returns a list of the maximal elements of the poset.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.maximal_elements()
[4]
```

meet_matrix()

Returns the matrix of meets of self. The `(x,y)`-entry of this matrix is the meet of `x` and `y` in `self`.

This algorithm is modelled after the algorithm of Freese-Jezek-Nation (p217).

Note: Once the matrix has been computed, it is stored in self._meet_matrix. Delete this attribute if you want to recompute the matrix.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.meet_matrix()
[0 0 0 0 0 0 0 0]
[0 1 0 0 1 0 0 1]
[0 0 2 0 2 2 2 2]
[0 0 0 3 0 0 3 3]
[0 1 2 0 4 2 2 4]
[0 0 2 0 2 5 2 5]
[0 0 2 3 2 2 6 6]
[0 1 2 3 4 5 6 7]
```

TESTS:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2,3],1:[2,3]})
sage: H.meet_matrix()
...
ValueError: Not a meet-semilattice: no bottom element.

sage: H = HasseDiagram({0:[1,2],1:[3,4],2:[3,4]})
sage: H.meet_matrix()
...
ValueError: No meet for x=...
```

minimal_elements()

Returns a list of the minimal elements of the poset.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P(0) in P.minimal_elements()
True
sage: P(1) in P.minimal_elements()
True
sage: P(2) in P.minimal_elements()
True
```

mobius_function(*i*, *j*)

Returns the value of the M"obius function of the poset on the elements `i` and `j`.

EXAMPLES:

```
sage: P = Poset([[1,2,3],[4],[4],[4],[]])
sage: H = P._hasse_diagram
sage: H.mobius_function(0,4)
2
sage: for u,v in P.cover_relations_iterator():
...     if P.mobius_function(u,v) != -1:
...         print "Bug in mobius_function!"
```

mobius_function_matrix()

Returns a matrix whose `(x, y)` entry is the value of the M"obius function of self evaluated on `x` and `y`.

Note: Once this matrix has been computed, it is stored in `self._mobius_function_matrix`. Delete this attribute if you want to recompute the matrix.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.mobius_function_matrix()
[ 1 -1 -1 -1  1  0  1  0]
[ 0  1  0  0 -1  0  0  0]
[ 0  0  1  0 -1 -1 -1  2]
[ 0  0  0  1  0  0 -1  0]
[ 0  0  0  0  1  0  0 -1]
[ 0  0  0  0  0  1  0 -1]
[ 0  0  0  0  0  0  1 -1]
[ 0  0  0  0  0  0  0  1]
sage: hasattr(H,'_mobius_function_matrix')
True
```

open_interval(*x*, *y*)

Returns a list of the elements z such that $x < z < y$. The order is that induced by the ordering in `self.linear_extension`.

EXAMPLES:

```
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: set([5,6,4]) == set(H.open_interval(2,7))
True
sage: H.open_interval(7,2)
[]
```

order_filter(*elements*)

Returns the order filter generated by a list of elements.

I is an order filter if, for any x in I and y such that $y \geq x$, then y is in I.

EXAMPLES:

```
sage: H = Posets.BooleanLattice(4)._hasse_diagram
sage: H.order_filter([3,8])
[3, 7, 8, 9, 10, 11, 12, 13, 14, 15]
```

order_ideal(*elements*)

Returns the order ideal generated by a list of elements.

I is an order ideal if, for any x in I and y such that $y \leq x$, then y is in I.

EXAMPLES:

```
sage: H = Posets.BooleanLattice(4)._hasse_diagram
sage: H.order_ideal([7,10])
[0, 1, 2, 3, 4, 5, 6, 7, 8, 10]
```

plot(*label_elements=True, element_labels=None, label_font_size=12, label_font_color='black', **kwds*)

Returns a Graphics object corresponding to the Hasse diagram.

EXAMPLES:

```
sage: uc = [[2,3], [], [1], [1], [1], [3,4]]
sage: elm_lbls = Permutations(3).list()
sage: P = Poset(uc,elm_lbls)
sage: H = P._hasse_diagram
sage: levels = H.level_sets()
sage: heights = dict([[i, levels[i]] for i in range(len(levels))])
sage: type(H.plot(label_elements=True))
<class 'sage.plot.plot.Graphics'>

sage: P = Posets.SymmetricGroupBruhatIntervalPoset([0,1,2,3], [2,3,0,1])
sage: P._hasse_diagram.plot()
```

principal_order_filter(*i*)

Returns the order filter generated by `i`.

EXAMPLES:

```
sage: H = Posets.BooleanLattice(4)._hasse_diagram
sage: H.principal_order_filter(2)
[2, 3, 6, 7, 10, 11, 14, 15]
```

principal_order_ideal(*i*)

Returns the order ideal generated by i.

EXAMPLES:

```
sage: H = Posets.BooleanLattice(4)._hasse_diagram
sage: H.principal_order_ideal(6)
[0, 2, 4, 6]
```

rank(*element=None*)

Returns the rank of `element`, or the rank of the poset if `element` is `None`. (The rank of a poset is the length of the longest chain of elements of the poset.)

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.rank(5)
2
sage: H.rank()
3
sage: Q = HasseDiagram({0:[1,2],1:[3],2:[],3:[]})
sage: Q.rank()
2
sage: Q.rank(1)
1
```

rank_function()

Returns a rank function of the poset, if it exists.

A *rank function* of a poset P is a function r from that maps elements of P to integers and satisfies: $r(x) = r(y) + 1$ if x covers y.

EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: P.rank_function() is not None
True
sage: r = P.rank_function()
sage: for u,v in P.cover_relations_iterator():
...     if r(v) != r(u) + 1:
...         print "Bug in rank_function!"

sage: Q = Poset([[1,2],[4],[3],[4],[]])
sage: Q.rank_function() is None
True
```

show(*label_elements=True, element_labels=None, label_font_size=12, label_font_color='black', vertex_size=300, vertex_colors=None, **kwds*)

Shows the Graphics object corresponding to the Hasse diagram. Optionally, it is labelled.

INPUT:

- `label_elements` - whether to display element labels
- `element_labels` - a dictionary of element labels

EXAMPLES:

```
sage: uc = [[2,3], [], [1], [1], [1], [3,4]]
sage: elm_lbls = Permutations(3).list()
sage: P = Poset(uc,elm_lbls)
sage: H = P._hasse_diagram
sage: levels = H.level_sets()
sage: heights = dict([[i, levels[i]] for i in range(len(levels))])
sage: H.show(label_elements=True)
```

size()

Returns the number of elements in the poset.

EXAMPLES:

```
sage: Poset([[1,2,3],[4],[4],[4],[]]).size()
5
```

top()
Returns the top element of the poset, if it exists.
EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.top() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.top()
1
```

upper_covers_iterator(*element*)
Returns the list of elements that cover `element`.
EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: list(H.upper_covers_iterator(0))
[1, 2, 3]
sage: list(H.upper_covers_iterator(7))
[]
```

17.36.3 Elements of posets, lattices, semilattices, etc.

class JoinSemilatticeElement(*poset, element, vertex*)

class LatticePosetElement(*poset, element, vertex*)

class MeetSemilatticeElement(*poset, element, vertex*)

class PosetElement(*poset, element, vertex*)

17.36.4 SemiLattices and Lattices

class FiniteJoinSemilattice(*digraph, elements=None*)
We assume that the argument passed to FiniteJoinSemilattice is the poset of a join-semilattice (i.e. a poset with least upper bound for each pair of elements).
TESTS:

```
sage: J = JoinSemilattice([[1,2],[3],[3]])
sage: J == loads(dumps(J))
True
```

```
sage: P = Poset([[1,2],[3],[3]])
sage: J = JoinSemilattice(P)
sage: J == loads(dumps(J))
True
```

join(*x, y*)
Return the join of `self` and `other` in the lattice.
EXAMPLES:

```
sage: D = Posets.DiamondPoset(5)
sage: D(1) + D(2)
4
sage: D(1) + D(1)
```

```
1
sage: D(1) + D(4)
4
sage: D(1) + D(0)
1
```

class **FiniteLatticePoset**(*digraph, elements=None*)

We assume that the argument passed to FiniteLatticePoset is the poset of a lattice (i.e. a poset with greatest lower bound and least upper bound for each pair of elements).

TESTS:

```
sage: L = LatticePoset([[1,2],[3],[3]])
sage: L == loads(dumps(L))
True

sage: P = Poset([[1,2],[3],[3]])
sage: L = LatticePoset(P)
sage: L == loads(dumps(L))
True
```

complements()

Returns a list of the elements of the lattice.

A complement of `x` is an element `y` such that the meet of `x` and `y` is the bottom element of `self` and the join of `x` and `y` is the top element of `self`.

EXAMPLES:

```
sage: L = LatticePoset({0:[1,2,3],1:[4],2:[4],3:[4]})
sage: L.complements()
[4, 3, 3, 2, 0]

sage: L = LatticePoset({0:[1,2],1:[3],2:[3],3:[4]})
sage: L.complements()
[4, None, None, None, 0]
```

is_complemented()

Returns `True` if `self` is a complemented lattice, and `False` otherwise.

EXAMPLES:

```
sage: L = LatticePoset({0:[1,2,3],1:[4],2:[4],3:[4]})
sage: L.is_complemented()
True

sage: L = LatticePoset({0:[1,2],1:[3],2:[3],3:[4]})
sage: L.is_complemented()
False
```

is_distributive()

Returns `True` if the lattice is distributive, and `False` otherwise.

EXAMPLES:

```
sage: L = LatticePoset({0:[1,2],1:[3],2:[3]})
sage: L.is_distributive()
True
sage: L = LatticePoset({0:[1,2,3],1:[4],2:[4],3:[4]})
sage: L.is_distributive()
False
```

class **FiniteMeetSemilattice**(*digraph, elements=None*)

..note:: We assume that the argument passed to MeetSemilattice is the poset of a meet-semilattice (i.e. a poset with greatest lower bound for each pair of elements).

TESTS:

```
sage: M = MeetSemilattice([[1,2],[3],[3]])
sage: M == loads(dumps(M))
True
```

```
sage: P = Poset([[1,2],[3],[3]])
sage: M = MeetSemilattice(P)
sage: M == loads(dumps(M))
True
```

meet (*x*, *y*)

Return the meet of `self` and `other` in the lattice.

EXAMPLES:

```
sage: D = Posets.DiamondPoset(5)
sage: D(1) * D(2)
0
sage: D(1) * D(1)
1
sage: D(1) * D(0)
0
sage: D(1) * D(4)
1
```

JoinSemilattice (*data*)

Construct a join semi-lattice from various forms of input data.

INPUT:

- `data` - any data that defines a poset that is also a join semilattice. See the documentation for `Poset`.

EXAMPLES:

Using data that defines a poset:

```
sage: JoinSemilattice([[1,2],[3],[3]])
Finite join-semilattice containing 4 elements
```

Using a previously constructed poset:

```
sage: P = Poset([[1,2],[3],[3]])
sage: J = JoinSemilattice(P); J
Finite join-semilattice containing 4 elements
sage: type(J)
<class 'sage.combinat.posets.lattices.FiniteJoinSemilattice'>
```

If the data is not a lattice, then an error is raised:

```
sage: elms = [1,2,3,4,5,6,7]
sage: rels = [[1,2],[3,4],[4,5],[2,5]]
sage: JoinSemilattice((elms, rels))
...
ValueError: Not a join semilattice.
```

LatticePoset(*data*)

Construct a lattice from various forms of input data.

INPUT:

- `data` - any data that defines a poset. See the documentation for `Poset`.

OUTPUT:

FiniteLatticePoset – an instance of FiniteLatticePoset

EXAMPLES:

Using data that defines a poset:

```
sage: LatticePoset([[1,2],[3],[3]])
Finite lattice containing 4 elements
```

Using a previously constructed poset:

```
sage: P = Poset([[1,2],[3],[3]])
sage: L = LatticePoset(P); L
Finite lattice containing 4 elements
sage: type(L)
<class 'sage.combinat.posets.lattices.FiniteLatticePoset'>
```

If the data is not a lattice, then an error is raised:

```
sage: elms = [1,2,3,4,5,6,7]
sage: rels = [[1,2],[3,4],[4,5],[2,5]]
sage: LatticePoset((elms, rels))
...
ValueError: Not a lattice.
```

MeetSemilattice(*data*)

Construct a meet semi-lattice from various forms of input data.

INPUT:

- `data` - any data that defines a poset that is also a meet semilattice. See the documentation for `Poset`.

EXAMPLES:

Using data that defines a poset:

```
sage: MeetSemilattice([[1,2],[3],[3]])
Finite meet-semilattice containing 4 elements
```

Using a previously constructed poset:

```
sage: P = Poset([[1,2],[3],[3]])
sage: L = MeetSemilattice(P); L
Finite meet-semilattice containing 4 elements
sage: type(L)
<class 'sage.combinat.posets.lattices.FiniteMeetSemilattice'>
```

If the data is not a lattice, then an error is raised:

```
sage: elms = [1,2,3,4,5,6,7]
sage: rels = [[1,2],[3,4],[4,5],[2,5]]
sage: MeetSemilattice((elms, rels))
...
ValueError: Not a meet semilattice.
```

17.36.5 Some examples of posets and lattices.

AntichainPoset(**args, **kwds*)
This function is deprecated and will be removed in a future version of Sage. Please use `Posets.AntichainPoset` instead.

TESTS:: sage: AntichainPoset(3) doctest:1: DeprecationWarning: AntichainPoset is deprecated, use Posets.AntichainPoset instead! Finite poset containing 3 elements

BooleanLattice(**args, **kwds*)
This function is deprecated and will be removed in a future version of Sage. Please use `Posets.BooleanLattice` instead.

TESTS:: sage: BooleanLattice(3) doctest:1: DeprecationWarning: BooleanLattice is deprecated, use Posets.BooleanLattice instead! Finite lattice containing 8 elements

ChainPoset(**args, **kwds*)
This function is deprecated and will be removed in a future version of Sage. Please use `Posets.ChainPoset` instead.

TESTS:: sage: ChainPoset(3) doctest:1: DeprecationWarning: ChainPoset is deprecated, use Posets.ChainPoset instead! Finite lattice containing 3 elements

DiamondPoset(**args, **kwds*)
This function is deprecated and will be removed in a future version of Sage. Please use `Posets.DiamondPoset` instead.

TESTS:: sage: DiamondPoset(3) doctest:1: DeprecationWarning: DiamondPoset is deprecated, use Posets.DiamondPoset instead! Finite lattice containing 3 elements

PentagonPoset(**args, **kwds*)
This function is deprecated and will be removed in a future version of Sage. Please use `Posets.PentagonPoset` instead.

TESTS:: sage: PentagonPoset() doctest:1: DeprecationWarning: PentagonPoset is deprecated, use Posets.PentagonPoset instead! Finite lattice containing 5 elements

PosetOfIntegerCompositions(**args, **kwds*)
This function is deprecated and will be removed in a future version of Sage. Please use `Posets.IntegerCompositions` instead.

TESTS:: sage: PosetOfIntegerCompositions(3) doctest:1: DeprecationWarning: PosetOfIntegerCompositions is deprecated, use Posets.IntegerCompositions instead! Finite poset containing 4 elements

PosetOfIntegerPartitions(**args, **kwds*)
This function is deprecated and will be removed in a future version of Sage. Please use `Posets.IntegerPartitions` instead.

TESTS:: sage: PosetOfIntegerPartitions(3) doctest:1: DeprecationWarning: PosetOfIntegerPartitions is deprecated, use Posets.IntegerPartitions instead! Finite poset containing 3 elements

PosetOfRestrictedIntegerPartitions(**args, **kwds*)
This function is deprecated and will be removed in a future version of Sage. Please use `Posets.RestrictedIntegerPartitions` instead.

TESTS:: sage: PosetOfRestrictedIntegerPartitions(3) doctest:1: DeprecationWarning: PosetOfRestrictedIntegerPartitions is deprecated, use Posets.RestrictedIntegerPartitions instead! Finite poset containing 3 elements

class **PosetsGenerator**()

A collection of examples of posets.

EXAMPLES:: sage: P = Posets() sage: P == loads(dumps(P)) True

AntichainPoset(*n*)

Returns an antichain (a poset with no comparable elements) containing n elements.

EXAMPLES:

```
sage: A = Posets.AntichainPoset(6); A
Finite poset containing 6 elements
sage: for i in range(5):
...       for j in range(5):
...           if A.covers(A(i),A(j)):
...              print "TEST FAILED"
```

BooleanLattice(*n*)

Returns the Boolean lattice containing 2^n elements.

EXAMPLES:

```
sage: Posets.BooleanLattice(5)
Finite lattice containing 32 elements
```

ChainPoset(*n*)

Returns a chain (a totally ordered poset) containing n elements.

EXAMPLES:

```
sage: C = Posets.ChainPoset(6); C
Finite lattice containing 6 elements
sage: C.linear_extension()
[0, 1, 2, 3, 4, 5]
sage: for i in range(5):
...       for j in range(5):
...           if C.covers(C(i),C(j)) and j != i+1:
...              print "TEST FAILED"
```

DiamondPoset(*n*)

Returns the lattice of rank two containing n elements.

EXAMPLES:

```
sage: Posets.DiamondPoset(7)
Finite lattice containing 7 elements
```

IntegerCompositions(*n*)

Returns the poset of integer compositions of the integer n.

A composition of a positive integer n is a list of positive integers that sum to n. The order is reverse refinement: `[p_1,p_2,...,p_l] < [q_1,q_2,...,q_m]` if q consists of an integer composition of `p_1`, followed by an integer composition of `p_2`, and so on.

EXAMPLES:

```
sage: P = Posets.IntegerCompositions(7); P
Finite poset containing 64 elements
sage: len(P.cover_relations())
192
```

IntegerPartitions(*n*)

Returns the poset of integer partitions on the integer n.

A partition of a positive integer n is a non-increasing list of positive integers that sum to n. If p and q are integer partitions of n, then p covers q if and only if q is obtained from p by joining two parts of p (and sorting, if necessary).

EXAMPLES:

```
sage: P = Posets.IntegerPartitions(7); P
Finite poset containing 15 elements
sage: len(P.cover_relations())
28
```

PentagonPoset()

Return the "pentagon".

EXAMPLES:

```
sage: Posets.PentagonPoset()
Finite lattice containing 5 elements
```

RandomPoset(*n, p*)

Generate a random poset on n vertices according to a probability distribution p.

EXAMPLES:

```
sage: Posets.RandomPoset(17,.15)
Finite poset containing 17 elements
```

RestrictedIntegerPartitions(*n*)

Returns the poset of integer partitions on the integer n ordered by restricted refinement. That is, if p and q are integer partitions of n, then p covers q if and only if q is obtained from p by joining two distinct parts of p (and sorting, if necessary).

EXAMPLES:

```
sage: P = Posets.RestrictedIntegerPartitions(7); P
Finite poset containing 15 elements
sage: len(P.cover_relations())
17
```

SymmetricGroupBruhatIntervalPoset(*start, end*)

The poset of permutations with respect to Bruhat order.

INPUT:

- start - list permutation
- end - list permutation (same n, of course)

Note: Must have start <= end.

EXAMPLES:

Any interval is rank symmetric if and only if it avoids these permutations:

```
sage: P1 = Posets.SymmetricGroupBruhatIntervalPoset([0,1,2,3], [2,3,0,1])
sage: P2 = Posets.SymmetricGroupBruhatIntervalPoset([0,1,2,3], [3,1,2,0])
sage: ranks1 = [P1.rank(v) for v in P1]
sage: ranks2 = [P2.rank(v) for v in P2]
sage: [ranks1.count(i) for i in uniq(ranks1)]
[1, 3, 5, 4, 1]
sage: [ranks2.count(i) for i in uniq(ranks2)]
[1, 3, 5, 6, 4, 1]
```

SymmetricGroupBruhatOrderPoset(*n*)

The poset of permutations with respect to Bruhat order.

EXAMPLES:

```
sage: Posets.SymmetricGroupBruhatOrderPoset(4)
Finite poset containing 24 elements
```

SymmetricGroupWeakOrderPoset(*n, labels='permutations'*)

The poset of permutations with respect to weak order.

EXAMPLES:

```
sage: Posets.SymmetricGroupWeakOrderPoset(4)
Finite poset containing 24 elements
```

RandomPoset(**args, **kwds*)

This function is deprecated and will be removed in a future version of Sage. Please use `Posets.RandomPoset` instead.

TESTS:: sage: RandomPoset(17,.15) doctest:1: DeprecationWarning: RandomPoset is deprecated, use Posets.RandomPoset instead! Finite poset containing 17 elements

SymmetricGroupBruhatOrderPoset(**args, **kwds*)

This function is deprecated and will be removed in a future version of Sage. Please use `Posets.SymmetricGroupBruhatOrderPoset` instead.

TESTS:: sage: SymmetricGroupBruhatOrderPoset(3) doctest:1: DeprecationWarning: SymmetricGroupBruhatOrderPoset is deprecated, use Posets.SymmetricGroupBruhatOrderPoset instead! Finite poset containing 6 elements

SymmetricGroupWeakOrderPoset(**args, **kwds*)

This function is deprecated and will be removed in a future version of Sage. Please use `Posets.SymmetricGroupWeakOrderPoset` instead.

TESTS:: sage: SymmetricGroupWeakOrderPoset(3) doctest:1: DeprecationWarning: SymmetricGroupWeakOrderPoset is deprecated, use Posets.SymmetricGroupWeakOrderPoset instead! Finite poset containing 6 elements

17.37 Designs and Incidence Structures

17.37.1 Block designs.

A module to help with constructions and computations of block designs and other incidence structures.

A block design is an incidence structure consisting of a set of points P and a set of blocks B, where each block is considered as a subset of P. More precisely, a *block design* B is a class of k-element subsets of P such that the number r of blocks that contain any point x in P is independent of x, and the number lambda of blocks that contain any given t-element subset T is independent of the choice of T (see [1] for more). Such a block design is also called a t-(v,k,lambda)-design, and v (the number of points), b (the number of blocks), k, r, and lambda are the parameters of the design. (In Python, lambda is reserved, so we sometimes use lmbda or L instead.)

In Sage, sets are replaced by (ordered) lists and the standard representation of a block design uses P = [0,1,..., v-1], so a block design is specified by (v,B).

This software is released under the terms of the GNU General Public License, version 2 or above (your choice). For details on licencing, see the accompanying documentation.

- [2] What is a block design?, http://designtheory.org/library/extrep/html/node4.html (in 'The External Representation of Block Designs' by Peter J. Cameron, Peter Dobcsanyi, John P. Morgan, Leonard H. Soicher)

This is a significantly modified form of the module block_design.py (version 0.6) written by Peter Dobcsanyi peter@designtheory.org. Thanks go to Robert Miller for lots of good design suggestions.

Copyright 2007-2008 by Peter Dobcsanyi peter@designtheory.org, and David Joyner wdjoyner@gmail.com.

TODO: Implement DerivedDesign, ComplementaryDesign, Hadamard3Design

AffineGeometryDesign(*n, d, F*)

Input: n is the Euclidean dimension, so the number of points is $v = |F^n|$ (F = GF(q), some q) d is the dimension of the (affine) subspaces of $P = GF(q)^n$ which make up the blocks.

$AG_{n,d}(F)$, as it is sometimes denoted, is a 2 - (v, k, λ) design of points and d- flats (cosets of dimension n) in the affine geometry $AG_n(F)$, where

$$v = q^n,\ k = q^d, \lambda = \frac{(q^{n-1}-1)\cdots(q^{n+1-d}-1)}{(q^{n-1}-1)\cdots(q-1)}.$$

Wraps some functions used in GAP Design's PGPointFlatBlockDesign. Does *not* require GAP's Design.

EXAMPLES:

```
sage: BD = AffineGeometryDesign(3, 1, GF(2))
sage: BD.parameters()
(2, 8, 2, 2)
sage: BD.is_block_design()
(True, [2, 8, 2, 2])
sage: BD = AffineGeometryDesign(3, 2, GF(2))
sage: BD.parameters()
(2, 8, 4, 12)
sage: BD.is_block_design()
(True, [3, 8, 4, 4])
```

BlockDesign(*max_pt, blks, name=None, test=True*)

Returns an instance of the IncidenceStructure class. Requires each B in blks to be contained in range(max_pt). Does not test if the result is a block design.

EXAMPLES:

```
sage: BlockDesign(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]], name="Fano plane"
Incidence structure with 7 points and 7 blocks
sage: print BlockDesign(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]], name="Fano
Fano plane<points=[0, 1, 2, 3, 4, 5, 6], blocks=[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5], [1,
```

HadamardDesign(*n*)

As described in Section 1, p. 10, in [CvL]. The input n must have the property that there is a Hadamard matrix of order n+1 (and that a construction of that Hadamard matrix has been implemented...).

EXAMPLES:

```
sage: HadamardDesign(7)
Incidence structure with 7 points and 7 blocks
sage: print HadamardDesign(7)
HadamardDesign<points=[0, 1, 2, 3, 4, 5, 6], blocks=[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5],
```

REFERENCES:

•[CvL] P. Cameron, J. H. van Lint, Designs, graphs, codes and their links, London Math. Soc., 1991.

ProjectiveGeometryDesign(*n, d, F, method=None*)

Input: n is the projective dimension, so the number of points is v = PPn(GF(q)) d is the dimension of the subspaces of P = PPn(GF(q)) which make up the blocks, so b is the number of d-dimensional subspaces of P

Wraps GAP Design's PGPointFlatBlockDesign. Does *not* require GAP's Design.

EXAMPLES:

```
sage: ProjectiveGeometryDesign(2, 1, GF(2))
Incidence structure with 7 points and 7 blocks
sage: BD = ProjectiveGeometryDesign(2, 1, GF(2), method="gap")      # requires optional gap pack
sage: BD.is_block_design()                                          # requires optional gap package
(True, [2, 7, 3, 1])
```

WittDesign(*n*)

Input: n is in 9,10,11,12,21,22,23,24.

Wraps GAP Design's WittDesign. If n=24 then this function returns the large Witt design W24, the unique (up to isomorphism) 5-(24,8,1) design. If n=12 then this function returns the small Witt design W12, the unique (up to isomorphism) 5-(12,6,1) design. The other values of n return a block design derived from these.

REQUIRES: GAP's Design package.

EXAMPLES:

```
sage: BD = WittDesign(9)    # requires optional gap package
sage: BD.parameters()       # requires optional gap package
(2, 9, 3, 1)
sage: BD                    # requires optional gap package
Incidence structure with 9 points and 12 blocks
sage: print BD              # requires optional gap package
WittDesign<points=[0, 1, 2, 3, 4, 5, 6, 7, 8], blocks=[[0, 1, 7], [0, 2, 5], [0, 3, 4], [0, 6, 8
sage: BD = WittDesign(12)   # requires optional gap package
sage: BD.parameters(t=5)    # requires optional gap package
(5, 12, 6, 1)
```

tdesign_params(*t, v, k, L*)

Return the design's parameters: (t, v, b, r , k, L). Note t must be given.

EXAMPLES:

```
sage: BD = BlockDesign(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
sage: from sage.combinat.designs.block_design import tdesign_params
sage: tdesign_params(2,7,3,1)
(2, 7, 7, 3, 3, 1)
```

17.37.2 Incidence structures.

An incidence structure is specified by a list of points, blocks, and an incidence matrix ([1], [2]).

Classes:

IncidenceStructure

This software is released under the terms of the GNU General Public License, version 2 or above (your choice). For details on licencing, see the accompanying documentation.

REFERENCES:

- [1] Block designs and incidence structures from wikipedia, http://en.wikipedia.org/wiki/Block_design http://en.wikipedia.org/wiki/Incidence_structure
- [2] E. Assmus, J. Key, Designs and their codes, CUP, 1992.

This is a significantly modified form of part of the module block_design.py (version 0.6) written by Peter Dobcsanyi peter@designtheory.org.

class IncidenceStructure(*pts, blks, inc_mat=None, name=None, test=True*)

This the base class for block designs.

automorphism_group()

Returns the subgroup of the automorphism group of the incidence graph which respects the P B partition. This is (isomorphic to) the automorphism group of the block design, although the degrees differ.

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import BlockDesign
sage: BD = BlockDesign(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
sage: G = BD.automorphism_group(); G
Permutation Group with generators [(4,5)(6,7), (4,6)(5,7), (2,3)(6,7), (2,4)(3,5), (1,2)(5,6
sage: BD = BlockDesign(4,[[0],[0,1],[1,2],[3,3]],test=False)
sage: G = BD.automorphism_group(); G
Permutation Group with generators [()]
sage: BD = BlockDesign(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
sage: G = BD.automorphism_group(); G
Permutation Group with generators [(4,5)(6,7), (4,6)(5,7), (2,3)(6,7), (2,4)(3,5), (1,2)(5,6
```

block_design_checker(*t, v, k, lmbda, type=None*)

This is *not* a wrapper for GAP Design's IsBlockDesign. The GAP Design function IsBlockDesign http://www.gap-system.org/Manuals/pkg/design/htm/CHAP004.htmSSEC001.1 apparently simply checks the record structure and no mathematical properties. Instead, the function below checks some necessary (but not sufficient) "easy" identities arising from the identity.

INPUT:

- `t` - the t as in "t-design"
- `v` - the number of points
- `k` - the number of blocks incident to a point
- `lmbda` - each t-tuple of points should be incident with lmbda blocks
- `type` - can be 'simple' or 'binary' or 'connected' Depending on the option, this wraps IsBinaryBlockDesign, IsSimpleBlockDesign, or IsConnectedBlockDesign.
  - –Binary: no block has a repeated element.
  - –Simple: no block is repeated.
  - –Connected: its incidence graph is a connected graph.

WRNING: This is very fast but can return false positives.

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import BlockDesign
sage: BD = BlockDesign(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
sage: BD.parameters()
(2, 7, 3, 1)
sage: BD.block_design_checker(2, 7, 3, 1)
True
sage: BD.block_design_checker(2, 7, 3, 1,"binary")
True
sage: BD.block_design_checker(2, 7, 3, 1,"connected")
True
sage: BD.block_design_checker(2, 7, 3, 1,"simple")
True
```

block_sizes()

Return a list of block's sizes.

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import BlockDesign
sage: BD = BlockDesign(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
```

```
sage: BD.block_sizes()
[3, 3, 3, 3, 3, 3, 3]
```

blocks()

Return the list of blocks.

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import BlockDesign
sage: BD = BlockDesign(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
sage: BD.blocks()
[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6], [2, 4, 5]]
```

dual_design(*method=None*)

Wraps GAP Design's DualBlockDesign (see [1]). The dual of a block design may not be a block design.

Also can be called with `dual_design`.

REQUIRES: method="gap" option requires GAP's Design package. method=None option does *not* require GAP's Design.

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import BlockDesign
sage: D = BlockDesign(4, [[0,2],[1,2,3],[2,3]], test=False)
sage: D
Incidence structure with 4 points and 3 blocks
sage: D.dual_design()
Incidence structure with 3 points and 4 blocks
sage: print D.dual_design(method="gap")       # optional - gap_design
IncidenceStructure<points=[0, 1, 2], blocks=[[0], [0, 1, 2], [1], [1, 2]]>
sage: BD = IncidenceStructure(range(7),[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4
sage: BD
Incidence structure with 7 points and 7 blocks
sage: print BD.dual_design(method="gap")          # optional - gap_design
IncidenceStructure<points=[0, 1, 2, 3, 4, 5, 6], blocks=[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1
sage: BD.dual_incidence_structure()
Incidence structure with 7 points and 7 blocks
```

REFERENCE:

- Soicher, Leonard, Design package manual, available at http://www.gap-system.org/Manuals/pkg/design/htm/CHAP003.htm

dual_incidence_structure(*method=None*)

Wraps GAP Design's DualBlockDesign (see [1]). The dual of a block design may not be a block design.

Also can be called with `dual_design`.

REQUIRES: method="gap" option requires GAP's Design package. method=None option does *not* require GAP's Design.

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import BlockDesign
sage: D = BlockDesign(4, [[0,2],[1,2,3],[2,3]], test=False)
sage: D
Incidence structure with 4 points and 3 blocks
sage: D.dual_design()
Incidence structure with 3 points and 4 blocks
sage: print D.dual_design(method="gap")       # optional - gap_design
IncidenceStructure<points=[0, 1, 2], blocks=[[0], [0, 1, 2], [1], [1, 2]]>
sage: BD = IncidenceStructure(range(7),[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4
sage: BD
Incidence structure with 7 points and 7 blocks
```

```
sage: print BD.dual_design(method="gap")          # optional - gap_design
IncidenceStructure<points=[0, 1, 2, 3, 4, 5, 6], blocks=[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1
sage: BD.dual_incidence_structure()
Incidence structure with 7 points and 7 blocks
```

REFERENCE:

- Soicher, Leonard, Design package manual, available at http://www.gap-system.org/Manuals/pkg/design/htm/CHAP003.htm

incidence_graph()

Returns the incidence graph of the design, where the incidence matrix of the design is the adjacency matrix of the graph.

EXAMPLE:

```
sage: BD = IncidenceStructure(range(7),[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4
sage: BD.incidence_graph()
Bipartite graph on 14 vertices
sage: A = BD.incidence_matrix()
sage: Graph(block_matrix([A*0,A,A.transpose(),A*0])) == BD.incidence_graph()
True
```

REFERENCE:

- Sage Reference Manual on Graphs

incidence_matrix()

Return the incidence matrix A of the design. A is a (v x b) matrix defined by: A[i,j] = 1 if i is in block B_j 0 otherwise

EXAMPLES:

```
sage: BD = IncidenceStructure(range(7),[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4
sage: BD.block_sizes()
[3, 3, 3, 3, 3, 3, 3]
sage: BD.incidence_matrix()
[1 1 1 0 0 0 0]
[1 0 0 1 1 0 0]
[1 0 0 0 0 1 1]
[0 1 0 1 0 1 0]
[0 1 0 0 1 0 1]
[0 0 1 1 0 0 1]
[0 0 1 0 1 1 0]
```

is_block_design()

Returns a pair True, pars if the incidence structure is a t-design, for some t, where pars is the list of parameters [t, v, k, lmbda]. The largest possible t is returned, provided t=10.

EXAMPLES:

```
sage: BD = IncidenceStructure(range(7),[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4
sage: BD.is_block_design()
(True, [2, 7, 3, 1])
sage: BD.block_design_checker(2, 7, 3, 1)
True
sage: BD = WittDesign(9)         # requires optional gap package
sage: BD.is_block_design()       # requires optional gap package
(True, [2, 9, 3, 1])
sage: BD = WittDesign(12)        # requires optional gap package
sage: BD.is_block_design()       # requires optional gap package
(True, [5, 12, 6, 1])
sage: BD = AffineGeometryDesign(3, 1, GF(2))
```

```
sage: BD.is_block_design()
(True, [2, 8, 2, 2])
```

parameters(*t=2*)

Returns (t,v,k,lambda). Does not check if the input is a block design. Uses t=2 by default.

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import BlockDesign
sage: BD = BlockDesign(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]], name="Fa
sage: BD.parameters()
(2, 7, 3, 1)
sage: BD.parameters(t=3)
(3, 7, 3, 0)
```

points()

Returns the list of points.

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import BlockDesign
sage: BD = BlockDesign(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
sage: BD.points()
[0, 1, 2, 3, 4, 5, 6]
```

points_from_gap()

Literally pushes this block design over to GAP and returns the points of that. Other than debugging, usefulness is unclear.

REQUIRES: GAP's Design package.

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import BlockDesign
sage: BD = BlockDesign(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
sage: BD.points_from_gap()      # requires optional gap package
[1, 2, 3, 4, 5, 6, 7]
```

IncidenceStructureFromMatrix(*M, name=None*)

M must be a (0,1)-matrix. Creates a set of "points" from the rows and a set of "blocks" from the columns.

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import BlockDesign
sage: BD1 = BlockDesign(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
sage: M = BD1.incidence_matrix()
sage: BD2 = IncidenceStructureFromMatrix(M)
sage: BD1 == BD2
True
```

coordinatewise_product(*L*)

L is a list of n-vectors or lists all of length n with a common parent. This returns the vector whose i-th coordinate is the product of the i-th coordinates of the vectors.

EXAMPLES:

```
sage: from sage.combinat.designs.incidence_structures import coordinatewise_product
sage: L = [[1,2,3],[-1,-1,-1],[5,7,11]]
sage: coordinatewise_product(L)
[-5, -14, -33]
```

17.38 Combinatorial Species

17.38.1 Power Series

Streams or Infinite Arrays

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html. In particular, the relevant section for this file can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse12.html.

Stream(*x=None, const=None*)

Returns a stream.

EXAMPLES: We can create a constant stream by just passing a

```
sage: from sage.combinat.species.stream import Stream
sage: s = Stream(const=0)
sage: [s[i] for i in range(10)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
```

class **Stream_class**(*gen=None, const=None, func=None*)

EXAMPLES:

```
sage: from sage.combinat.species.stream import Stream
sage: from itertools import izip
sage: s = Stream(const=0)
sage: len(s)
1
sage: [x for (x,i) in izip(s, range(4))]
[0, 0, 0, 0]
sage: len(s)
1
```

```
sage: s = Stream(const=4)
sage: g = iter(s)
sage: l1 = [x for (x,i) in izip(g, range(10))]
sage: l = [4 for k in range(10)]
sage: l == l1
True
```

```
sage: h = lambda l: 1 if len(l) < 2 else l[-1] + l[-2]
sage: fib = Stream(h)
sage: [x for (x,i) in izip(fib, range(11))]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]
```

```
sage: s = Stream()
sage: l = Stream([1, 0])
sage: y = Stream([0,1,0])
sage: s.set_gen(iter(l + y * s * s))
sage: [x for (x,i) in izip(s, range(6))]
[1, 1, 2, 5, 14, 42]
```

```
sage: r = [4, 3, 5, 2, 6, 1, 1, 1, 1, 1]
sage: l = [4, 3, 5, 2, 6, 1]
sage: s = Stream(l)
sage: s[3] = -1
```

```
sage: [x for (x,i) in izip(s, r)]
[4, 3, 5, -1, 6, 1, 1, 1, 1, 1]
sage: s[5] = -2
sage: [x for (x,i) in izip(s, r)]
[4, 3, 5, -1, 6, -2, 1, 1, 1, 1]
sage: s[6] = -3
sage: [x for (x,i) in izip(s, r)]
[4, 3, 5, -1, 6, -2, -3, 1, 1, 1]
sage: s[8] = -4
sage: [x for (x,i) in izip(s, r)]
[4, 3, 5, -1, 6, -2, -3, 1, -4, 1]
sage: a = Stream(const=0)
sage: a[2] = 3
sage: [x for (x,i) in izip(a, range(4))]
[0, 0, 3, 0]
```

data()

Returns a list of all the coefficients computed so far.

EXAMPLES:

```
sage: from sage.combinat.species.stream import Stream, _integers_from
sage: s = Stream(_integers_from(3))
sage: s.data()
[]
sage: s[5]
8
sage: s.data()
[3, 4, 5, 6, 7, 8]
```

is_constant()

Returns True if and only if

EXAMPLES:

```
sage: from sage.combinat.species.stream import Stream
sage: s = Stream([1,2,3])
sage: s.is_constant()
False
sage: s[3]
3
sage: s.data()
[1, 2, 3]
sage: s.is_constant()
True
```

TESTS:

```
sage: l = [2,3,5,7,11,0]
sage: s = Stream(l)
sage: s.is_constant()
False
sage: s[3]
7
sage: s.is_constant()
False
sage: s[5]
0
sage: s.is_constant()
False
sage: s[6]
```

```
0
sage: s.is_constant()
True

sage: s = Stream(const='I am constant.')
sage: s.is_constant()
True
```

map(*f*)

EXAMPLES:

```
sage: from sage.combinat.species.stream import Stream
sage: s = Stream(ZZ)
sage: square = lambda x: x^2
sage: ss = s.map(square)
sage: [ss[i] for i in range(10)]
[0, 1, 1, 4, 4, 9, 9, 16, 16, 25]
```

TESTS:

```
sage: from itertools import izip
sage: f = lambda l: 0 if len(l) == 0 else l[-1] + 1
sage: o = Stream(f)
sage: [x for (x,i) in izip(o, range(10))]
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
sage: double = lambda z: 2*z
sage: t = o.map(double)
sage: [x for (x,i) in izip(t, range(10))]
[0, 2, 4, 6, 8, 10, 12, 14, 16, 18]

sage: double = lambda z: 2*z
sage: o = Stream([0,1,2,3])
sage: [x for (x,i) in izip(o, range(6))]
[0, 1, 2, 3, 3, 3]
sage: t = o.map(double)
sage: [x for (x,i) in izip(t, range(6))]
[0, 2, 4, 6, 6, 6]
```

number_computed()

Returns the number of coefficients computed so far.

EXAMPLES:

```
sage: from sage.combinat.species.stream import Stream
sage: l = [4,3,5,7,4,1,9,7]
sage: s = Stream(l)
sage: s[3]
7
sage: len(s)
4
sage: s[3]
7
sage: len(s)
4
sage: s[1]
3
sage: len(s)
4
sage: s[4]
4
```

```
sage: len(s)
5
```

TESTS:

```
sage: l = ['Hello', ' ', 'World', '!']
sage: s = Stream(l)
sage: len(s)
0
sage: s[2]
'World'
sage: len(s)
3
sage: u = ""
sage: for i in range(len(s)): u += s[i]
sage: u
'Hello World'
sage: v = ""
sage: for i in range(10): v += s[i]
sage: v
'Hello World!!!!!!!'
sage: len(s)
4
```

set_gen(*gen*)

EXAMPLES:

```
sage: from sage.combinat.species.stream import Stream
sage: from itertools import izip
sage: fib = Stream()
sage: def g():
...           yield 1
...           yield 1
...           n = 0
...           while True:
...               yield fib[n] + fib[n+1]
...               n += 1

sage: fib.set_gen(g())
sage: [x for (x,i) in izip(fib, range(11))]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]

sage: l = [4,3,5,2,6,1]
sage: s = Stream(l)
sage: s[3]
2
sage: len(s)
4
sage: g = iter(l)
sage: s.set_gen(g)
sage: s[5]
3
sage: len(s)
6
```

stretch(*k*)

EXAMPLES:

```
sage: from sage.combinat.species.stream import Stream
sage: s = Stream(range(1, 10))
```

```
sage: s2 = s.stretch(2)
sage: [s2[i] for i in range(10)]
[1, 0, 2, 0, 3, 0, 4, 0, 5, 0]
```

Series Order

This file provides some utility classes which are useful when working with unknown, known, and infinite series orders for univariate power series.

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html. In particular, the relevant section for this file can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatsu30.html.

class **InfiniteSeriesOrder**()

class **SeriesOrderElement**()

class **UnknownSeriesOrder**()

bounded_decrement(*x*)

EXAMPLES:

```
sage: from sage.combinat.species.series_order import *
sage: u = UnknownSeriesOrder()
sage: bounded_decrement(u)
Unknown series order
sage: bounded_decrement(4)
3
sage: bounded_decrement(0)
0
```

increment(*x*)

EXAMPLES:

```
sage: from sage.combinat.species.series_order import *
sage: u = UnknownSeriesOrder()
sage: increment(u)
Unknown series order
sage: increment(2)
3
```

Lazy Power Series

This file provides an implementation of lazy univariate power series, which uses the stream class for its internal data structure. The lazy power series keep track of their approximate order as much as possible without forcing the computation of any additional coefficients. This is required for recursively defined power series.

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html. In particular, the relevant section for this file can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse9.html.

class **LazyPowerSeries**(*A*, *stream=None*, *order=None*, *aorder=None*, *aorder_changed=True*, *is_initialized=False*, *name=None*)

add(*y*)

EXAMPLES: Test Plus 1

```
sage: from sage.combinat.species.series import *
sage: from sage.combinat.species.stream import Stream
sage: L = LazyPowerSeriesRing(QQ)
sage: gs0 = L([0])
sage: gs1 = L([1])
sage: sum1 = gs0 + gs1
sage: sum2 = gs1 + gs1
sage: sum3 = gs1 + gs0
sage: [gs0.coefficient(i) for i in range(11)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
sage: [gs1.coefficient(i) for i in range(11)]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: [sum1.coefficient(i) for i in range(11)]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: [sum2.coefficient(i) for i in range(11)]
[2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2]
sage: [sum3.coefficient(i) for i in range(11)]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
```

Test Plus 2

```
sage: gs1 = L([1,2,4,8,0])
sage: gs2 = L([-1, 0,-1,-9,22,0])
sage: sum = gs1 + gs2
sage: sum2 = gs2 + gs1
sage: [ sum.coefficient(i) for i in range(5) ]
[0,  2, 3, -1, 22]
sage: [ sum.coefficient(i) for i in range(5, 11) ]
[0, 0, 0, 0, 0, 0]
sage: [ sum2.coefficient(i) for i in range(5) ]
[0,  2, 3, -1, 22]
sage: [ sum2.coefficient(i) for i in range(5, 11) ]
[0, 0, 0, 0, 0, 0]
```

coefficient(*n*)

Returns the coefficient of xn in self.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L(ZZ)
sage: [f.coefficient(i) for i in range(5)]
[0, 1, -1, 2, -2]
```

coefficients(*n*)

Returns the first n coefficients of self.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L([1,2,3,0])
sage: f.coefficients(5)
[1, 2, 3, 0, 0]
```

compose(*y*)

Returns the composition of this power series and the power series y.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: s = L([1])
sage: t = L([0,0,1])
```

```
sage: u = s(t)
sage: u.coefficients(11)
[1, 0, 1, 1, 2, 3, 5, 8, 13, 21, 34]
```

Test Compose 2

```
sage: s = L([1])
sage: t = L([0,0,1,0])
sage: u = s(t)
sage: u.aorder
0
sage: u.order
Unknown series order
sage: u.coefficients(10)
[1, 0, 1, 0, 1, 0, 1, 0, 1, 0]
sage: u.aorder
0
sage: u.order
0
```

Test Compose 3 s = 1/(1-x), t = x/(1-x) s(t) = (1-x)/(1-2x)

```
sage: s = L([1])
sage: t = L([0,1])
sage: u = s(t)
sage: u.coefficients(14)
[1, 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096]
```

composition(*y*)

Returns the composition of this power series and the power series y.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: s = L([1])
sage: t = L([0,0,1])
sage: u = s(t)
sage: u.coefficients(11)
[1, 0, 1, 1, 2, 3, 5, 8, 13, 21, 34]
```

Test Compose 2

```
sage: s = L([1])
sage: t = L([0,0,1,0])
sage: u = s(t)
sage: u.aorder
0
sage: u.order
Unknown series order
sage: u.coefficients(10)
[1, 0, 1, 0, 1, 0, 1, 0, 1, 0]
sage: u.aorder
0
sage: u.order
0
```

Test Compose 3 s = 1/(1-x), t = x/(1-x) s(t) = (1-x)/(1-2x)

```
sage: s = L([1])
sage: t = L([0,1])
sage: u = s(t)
sage: u.coefficients(14)
```

```
[1, 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096]
```

compute_aorder(**args, **kwargs*)

The default compute_aorder does nothing.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L(1)
sage: a.compute_aorder() is None
True
```

compute_coefficients(*i*)

Computes all the coefficients of self up to i.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L([1,2,3])
sage: a.compute_coefficients(5)
sage: a
1 + 2*x + 3*x^2 + 3*x^3 + 3*x^4 + 3*x^5 + ...
```

define(*x*)

EXAMPLES: Test Recursive 0

```
sage: L = LazyPowerSeriesRing(QQ)
sage: one = L(1)
sage: monom = L.gen()
sage: s = L()
sage: s._name = 's'
sage: s.define(one+monom*s)
sage: s.aorder
0
sage: s.order
Unknown series order
sage: [s.coefficient(i) for i in range(6)]
[1, 1, 1, 1, 1, 1]
```

Test Recursive 1

```
sage: s = L()
sage: s._name = 's'
sage: s.define(one+monom*s*s)
sage: s.aorder
0
sage: s.order
Unknown series order
sage: [s.coefficient(i) for i in range(6)]
[1, 1, 2, 5, 14, 42]
```

Test Recursive 1b

```
sage: s = L()
sage: s._name = 's'
sage: s.define(monom + s*s)
sage: s.aorder
1
sage: s.order
Unknown series order
sage: [s.coefficient(i) for i in range(7)]
[0, 1, 1, 2, 5, 14, 42]
```

Test Recursive 2

```
sage: s = L()
sage: s._name = 's'
sage: t = L()
sage: t._name = 't'
sage: s.define(one+monom*t*t*t)
sage: t.define(one+monom*s*s)
sage: [s.coefficient(i) for i in range(9)]
[1, 1, 3, 9, 34, 132, 546, 2327, 10191]
sage: [t.coefficient(i) for i in range(9)]
[1, 1, 2, 7, 24, 95, 386, 1641, 7150]
```

Test Recursive 2b

```
sage: s = L()
sage: s._name = 's'
sage: t = L()
sage: t._name = 't'
sage: s.define(monom + t*t*t)
sage: t.define(monom + s*s)
sage: [s.coefficient(i) for i in range(9)]
[0, 1, 0, 1, 3, 3, 7, 30, 63]
sage: [t.coefficient(i) for i in range(9)]
[0, 1, 1, 0, 2, 6, 7, 20, 75]
```

Test Recursive 3

```
sage: s = L()
sage: s._name = 's'
sage: s.define(one+monom*s*s*s)
sage: [s.coefficient(i) for i in range(10)]
[1, 1, 3, 12, 55, 273, 1428, 7752, 43263, 246675]
```

derivative()

EXAMPLES:

```
sage: from sage.combinat.species.stream import Stream
sage: L = LazyPowerSeriesRing(QQ)
sage: one = L(1)
sage: monom = L.gen()
sage: s = L([1])
sage: u = s.derivative()
sage: u.coefficients(10)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]

sage: s = L()
sage: s._name = 's'
sage: s.define(one+monom*s*s)
sage: u = s.derivative()
sage: u.coefficients(5) #[1*1, 2*2, 3*5, 4*14, 5*42]
[1, 4, 15, 56, 210]

sage: s = L([1])
sage: t = L([0,1])
sage: u = s(t).derivative()
sage: v = (s.derivative().compose(t))*t.derivative()
sage: u.coefficients(11)
[1, 4, 12, 32, 80, 192, 448, 1024, 2304, 5120, 11264]
sage: v.coefficients(11)
[1, 4, 12, 32, 80, 192, 448, 1024, 2304, 5120, 11264]
```

```
sage: s = L(); s._name='s'
sage: t = L(); t._name='t'
sage: s.define(monom+t*t*t)
sage: t.define(monom+s*s)
sage: u = (s*t).derivative()
sage: v = s.derivative()*t + s*t.derivative()
sage: u.coefficients(10)
[0, 2, 3, 4, 30, 72, 133, 552, 1791, 4260]
sage: v.coefficients(10)
[0, 2, 3, 4, 30, 72, 133, 552, 1791, 4260]
sage: u.coefficients(10) == v.coefficients(10)
True

sage: f = L._new_initial(2, Stream([0,0,4,5,6,0]))
sage: d = f.derivative()
sage: d.get_aorder()
1
sage: d.coefficients(5)
[0, 8, 15, 24, 0]
```

exponential()

TESTS:

```
sage: def inv_factorial():
...       q = 1
...       yield 0
...       yield q
...       n = 2
...       while True:
...           q = q / n
...           yield q
...           n += 1
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L(inv_factorial()) #e^(x)-1
sage: u = f.exponential()
sage: g = inv_factorial()
sage: z1 = [1,1,2,5,15,52,203,877,4140,21147,115975]
sage: l1 = [z*g.next() for z in z1]
sage: l1 = [1] + l1[1:]
sage: u.coefficients(11)
[1, 1, 1, 5/6, 5/8, 13/30, 203/720, 877/5040, 23/224, 1007/17280, 4639/145152]
sage: l1 == u.coefficients(11)
True
```

get_aorder()

Returns the approximate order of self.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L.gen()
sage: a.get_aorder()
1
```

get_order()

Returns the order of self.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L.gen()
```

```
sage: a.get_order()
1
```

get_stream()

Returns self's underlying Stream object.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L.gen()
sage: s = a.get_stream()
sage: [s[i] for i in range(5)]
[0, 1, 0, 0, 0]
```

initialize_coefficient_stream(*compute_coefficients*)

Initializes the coefficient stream.

INPUT: compute_coefficients

TESTS:

```
sage: from sage.combinat.species.series_order import inf, unk
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L()
sage: compute_coefficients = lambda ao: iter(ZZ)
sage: f.order = inf
sage: f.aorder = inf
sage: f.initialize_coefficient_stream(compute_coefficients)
sage: f.coefficients(5)
[0, 0, 0, 0, 0]

sage: f = L()
sage: compute_coefficients = lambda ao: iter(ZZ)
sage: f.order = 1
sage: f.aorder = 1
sage: f.initialize_coefficient_stream(compute_coefficients)
sage: f.coefficients(5)
[0, 1, -1, 2, -2]
```

integral(*integration_constant=0*)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: zero = L(0)
sage: s = zero
sage: t = s.integral()
sage: t.is_zero()
True

sage: s = zero
sage: t = s.integral(1)
sage: t.coefficients(6)
[1, 0, 0, 0, 0, 0]
sage: t._stream.is_constant()
True

sage: s = L.term(1, 0)
sage: t = s.integral()
sage: t.coefficients(6)
[0, 1, 0, 0, 0, 0]
sage: t._stream.is_constant()
True
```

```
sage: s = L.term(1,0)
sage: t = s.integral(1)
sage: t.coefficients(6)
[1, 1, 0, 0, 0, 0]
sage: t._stream.is_constant()
True

sage: s = L.term(1, 4)
sage: t = s.integral()
sage: t.coefficients(10)
[0, 0, 0, 0, 0, 1/5, 0, 0, 0, 0]

sage: s = L.term(1,4)
sage: t = s.integral(1)
sage: t.coefficients(10)
[1, 0, 0, 0, 0, 1/5, 0, 0, 0, 0]
```

TESTS:

```
sage: from sage.combinat.species.stream import Stream
sage: f = L._new_initial(2, Stream([0,0,4,5,6,0]))
sage: i = f.derivative().integral()
sage: i.get_aorder()
2
sage: i.coefficients(5)
[0, 0, 4, 5, 6]
sage: i = f.derivative().integral(1)
sage: i.get_aorder()
0
sage: i.coefficients(5)
[1, 0, 4, 5, 6]
```

is_finite(*n=None*)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L([0,0,1,0,0]); a
O(1)
sage: a.is_finite()
False
sage: c = a[4]
sage: a.is_finite()
False
sage: a.is_finite(4)
False
sage: c = a[5]
sage: a.is_finite()
True
sage: a.is_finite(4)
True
```

is_zero()

Returns True if and only if self is zero.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: s = L([0,2,3,0])
sage: s.is_zero()
False
```

```
sage: s = L(0)
sage: s.is_zero()
True

sage: s = L([0])
sage: s.is_zero()
False
sage: s.coefficient(0)
0
sage: s.coefficient(1)
0
sage: s.is_zero()
True
```

iterator(*n=0, initial=None*)

Returns an iterator for the coefficients of self starting at n.

EXAMPLES:

```
sage: from sage.combinat.species.stream import Stream
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L(range(10))
sage: g = f.iterator(2)
sage: [g.next() for i in range(5)]
[2, 3, 4, 5, 6]
sage: g = f.iterator(2, initial=[0,0])
sage: [g.next() for i in range(5)]
[0, 0, 2, 3, 4]
```

refine_aorder()

Refines the approximate order of self as much as possible without computing any coefficients.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L([0,0,0,0,1])
sage: a.aorder
0
sage: a.coefficient(2)
0
sage: a.aorder
0
sage: a.refine_aorder()
sage: a.aorder
3

sage: a = L([0,0])
sage: a.aorder
0
sage: a.coefficient(5)
0
sage: a.refine_aorder()
sage: a.aorder
Infinite series order

sage: a = L([0,0,1,0,0,0])
sage: a[4]
0
sage: a.refine_aorder()
sage: a.aorder
2
```

restricted(*min=None, max=None*)

Returns the power series restricted to the coefficients starting at min and going up to, but not including max. If min is not specified, then it is assumed to be zero. If max is not specified, then it is assumed to be infinity.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: a = L([1])
sage: a.restricted().coefficients(10)
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: a.restricted(min=2).coefficients(10)
[0, 0, 1, 1, 1, 1, 1, 1, 1, 1]
sage: a.restricted(max=5).coefficients(10)
[1, 1, 1, 1, 1, 0, 0, 0, 0, 0]
sage: a.restricted(min=2, max=6).coefficients(10)
[0, 0, 1, 1, 1, 1, 0, 0, 0, 0]
```

set_approximate_order(*new_order*)

Sets the approximate order of self and returns True if the approximate order has changed otherwise it will return False.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L([0,0,0,3,2,1,0])
sage: f.get_aorder()
0
sage: f.set_approximate_order(3)
True
sage: f.set_approximate_order(3)
False
```

tail()

Returns the power series whose coefficients obtained by subtracting the constant term from this series and then dividing by x.

EXAMPLES:

```
sage: from sage.combinat.species.stream import Stream
sage: L = LazyPowerSeriesRing(QQ)
sage: f = L(range(20))
sage: g = f.tail()
sage: g.coefficients(10)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

times(*y*)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: gs0 = L(0)
sage: gs1 = L([1])

sage: prod0 = gs0 * gs1
sage: [prod0.coefficient(i) for i in range(11)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]

sage: prod1 = gs1 * gs0
sage: [prod1.coefficient(i) for i in range(11)]
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
```

```
sage: prod2 = gs1 * gs1
sage: [prod2.coefficient(i) for i in range(11)]
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11]

sage: gs1 = L([1,2,4,8,0])
sage: gs2 = L([-1, 0,-1,-9,22,0])

sage: prod1 = gs1 * gs2
sage: [prod1.coefficient(i) for i in range(11)]
[-1, -2, -5, -19, 0, 0, 16, 176, 0, 0, 0]

sage: prod2 = gs2 * gs1
sage: [prod2.coefficient(i) for i in range(11)]
[-1, -2, -5, -19, 0, 0, 16, 176, 0, 0, 0]
```

class **LazyPowerSeriesRing**(*R, element_class=None, names=None*)

gen(*i=0*)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: L.gen().coefficients(5)
[0, 1, 0, 0, 0]
```

identity_element()

Returns the one power series.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: L.identity_element()
1
```

ngens()

EXAMPLES:

```
sage: LazyPowerSeriesRing(QQ).ngens()
1
```

product_generator(*g*)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: s1 = L([1,1,0])
sage: s2 = L([1,0,1,0])
sage: s3 = L([1,0,0,1,0])
sage: s4 = L([1,0,0,0,1,0])
sage: s5 = L([1,0,0,0,0,1,0])
sage: s6 = L([1,0,0,0,0,0,1,0])
sage: s = [s1, s2, s3, s4, s5, s6]
sage: def g():
...       for a in s:
...           yield a
sage: p = L.product_generator(g())
sage: p.coefficients(26)
[1, 1, 1, 2, 2, 3, 4, 4, 4, 5, 5, 5, 5, 4, 4, 4, 3, 2, 2, 1, 1, 1, 0, 0, 0, 0]

sage: def m(n):
...       yield 1
...       while True:
```

```
...            for i in range(n-1):
...                yield 0
...            yield 1
...
sage: def s(n):
...        q = 1/n
...        yield 0
...        while True:
...            for i in range(n-1):
...                yield 0
...            yield q
...

sage: def lhs_gen():
...        n = 1
...        while True:
...            yield L(m(n))
...            n += 1
...

sage: def rhs_gen():
...        n = 1
...        while True:
...            yield L(s(n))
...            n += 1
...
sage: lhs = L.product_generator(lhs_gen())
sage: rhs = L.sum_generator(rhs_gen()).exponential()
sage: lhs.coefficients(10)
[1, 1, 2, 3, 5, 7, 11, 15, 22, 30]
sage: rhs.coefficients(10)
[1, 1, 2, 3, 5, 7, 11, 15, 22, 30]
```

sum(*a*)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: l = [L(ZZ)]*3
sage: L.sum(l).coefficients(10)
[0, 3, -3, 6, -6, 9, -9, 12, -12, 15]
```

sum_generator(*g*)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: g = [L([1])]*6 + [L(0)]
sage: t = L.sum_generator(g)
sage: t.coefficients(10)
[1, 2, 3, 4, 5, 6, 6, 6, 6, 6]

sage: s = L([1])
sage: def g():
...        while True:
...            yield s
sage: t = L.sum_generator(g())
sage: t.coefficients(9)
[1, 2, 3, 4, 5, 6, 7, 8, 9]
```

term(*r*, *n*)

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: L.term(0,0)
0
sage: L.term(3,2).coefficients(5)
[0, 0, 3, 0, 0]
```

zero_element()

Returns the zero power series.

EXAMPLES:

```
sage: L = LazyPowerSeriesRing(QQ)
sage: L.zero_element()
0
```

uninitialized()

EXAMPLES:

```
sage: from sage.combinat.species.series import uninitialized
sage: uninitialized()
...
RuntimeError: we should never be here
```

Generating Series

This file makes a number of extensions to lazy power series by endowing them with some semantic content for how they're to be interpreted.

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html. In particular, the relevant section for this file can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse10.html. One notable difference is that we use power-sum symmetric functions as the coefficients of our cycle index series.

TESTS:

```
sage: from sage.combinat.species.stream import Stream, _integers_from
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: p = SFAPower(QQ)
sage: CIS = CycleIndexSeriesRing(QQ)

sage: geo1 = CIS((p([1])^i  for i in _integers_from(0)))
sage: geo2 = CIS((p([2])^i  for i in _integers_from(0)))
sage: s = geo1 * geo2
sage: s[0]
p[]
sage: s[1]
p[1] + p[2]
sage: s[2]
p[1, 1] + p[2, 1] + p[2, 2]
sage: s[3]
p[1, 1, 1] + p[2, 1, 1] + p[2, 2, 1] + p[2, 2, 2]
```

Whereas the coefficients of the above test are homogeneous with respect to total degree, the following test groups with respect to weighted degree where each variable x_i has weight i.

```
sage: def g():
...       for i in _integers_from(0):
...           yield p([2])^i
...           yield p(0)
sage: geo1 = CIS((p([1])^i  for i in _integers_from(0)))
sage: geo2 = CIS(g())
sage: s = geo1 * geo2
sage: s[0]
p[]
sage: s[1]
p[1]
sage: s[2]
p[1, 1] + p[2]
sage: s[3]
p[1, 1, 1] + p[2, 1]
sage: s[4]
p[1, 1, 1, 1] + p[2, 1, 1] + p[2, 2]
```

class CycleIndexSeries (*A, stream=None, order=None, aorder=None, aorder_changed=True, is_initialized=False, name=None*)

coefficient_cycle_type (*t*)

Returns the coefficient of a cycle type t.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: p = SFAPower(QQ)
sage: CIS = CycleIndexSeriesRing(p)
sage: f = CIS([0, p([1]), 2*p([1,1]),3*p([2,1])])
sage: f.coefficient_cycle_type([1])
1
sage: f.coefficient_cycle_type([1,1])
2
sage: f.coefficient_cycle_type([2,1])
3
```

count (*t*)

Returns the number of structures corresponding to a certain cycle type.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: p = SFAPower(QQ)
sage: CIS = CycleIndexSeriesRing(p)
sage: f = CIS([0, p([1]), 2*p([1,1]),3*p([2,1])])
sage: f.count([1])
1
sage: f.count([1,1])
4
sage: f.count([2,1])
6
```

functorial_composition (*g*)

Returns the functorial composition of self and g.

If F, G, and H are combinatorial species such that ' H = F Box G ', $then the cycle index series ' Z_H = Z_F \Box Z_G$ is defined as

EXAMPLES:

```
sage: S = species.SimpleGraphSpecies()
sage: S.cycle_index_series().coefficients(5)
[p[],
 p[1],
 p[1, 1] + p[2],
 4/3*p[1, 1, 1] + 2*p[2, 1] + 2/3*p[3],
 8/3*p[1, 1, 1, 1] + 4*p[2, 1, 1] + 2*p[2, 2] + 4/3*p[3, 1] + p[4]]
```

generating_series()

EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: cis = P.cycle_index_series()
sage: f = cis.generating_series()
sage: f.coefficients(5)
[1, 1, 1, 5/6, 5/8]
```

isotype_generating_series()

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: cis = P.cycle_index_series()
sage: f = cis.isotype_generating_series()
sage: f.coefficients(10)
[1, 1, 2, 3, 5, 7, 11, 15, 22, 30]
```

stretch(k)

Returns the stretch of a cycle index series by a positive integer k.

If

$$f = \sum_{n=0}^{\infty} f_n(x_1, x_2, \ldots, x_n),$$

then the stretch g of f by k is

$$g = \sum_{n=0}^{\infty} f_n(x_k, x_{2k}, \ldots, x_{nk}).$$

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: p = SFAPower(QQ)
sage: CIS = CycleIndexSeriesRing(p)
sage: f = CIS([p([1])])
sage: f.stretch(3).coefficients(10)
[p[3], 0, 0, p[3], 0, 0, p[3], 0, 0, p[3]]
```

weighted_composition(*y_species*)

Returns the composition of this cycle index series with the cycle index series of y_species where y_species is a weighted species. Note that this is basically the same algorithm as composition except we can't use the optimization that the powering of cycle index series commutes with 'stretching'.

EXAMPLES:

```
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: E_cis = E.cycle_index_series()
sage: E_cis.weighted_composition(C).coefficients(4)
[p[], p[1], p[1, 1] + p[2], p[1, 1, 1] + p[2, 1] + p[3]]
sage: E(C).cycle_index_series().coefficients(4)
[p[], p[1], p[1, 1] + p[2], p[1, 1, 1] + p[2, 1] + p[3]]
```

class `CycleIndexSeriesRing_class`(*R*)

class `ExponentialGeneratingSeries`(*A, stream=None, order=None, aorder=None, aorder_changed=True, is_initialized=False, name=None*)

`count`(*n*)

Returns the number of structures of size n.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ)
sage: f = R([1])
sage: [f.count(i) for i in range(7)]
[1, 1, 2, 6, 24, 120, 720]
```

`counts`(*n*)

Returns the number of structures on a set for size i for i in range(n).

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.counts(5)
[0, 1, 4, 18, 96]
```

`functorial_composition`(*y*)

Returns the exponential generating series which is the functorial composition of self with y.

If $f = \sum_{n=0}^{\infty} f_n \frac{x^n}{n!}$ and $g = \sum_{n=0}^{\infty} f_n \frac{x^n}{n!}$, then functorial composition $f \Box g$ is defined as

$$f \Box g = \sum_{n=0}^{\infty} f_{g_n} \frac{x^n}{n!}$$

REFERENCES:

•Section 2.2 of BLL.

EXAMPLES:

```
sage: G = species.SimpleGraphSpecies()
sage: g = G.generating_series()
sage: g.coefficients(10)
[1, 1, 1, 4/3, 8/3, 128/15, 2048/45, 131072/315, 2097152/315, 536870912/2835]
```

class `ExponentialGeneratingSeriesRing_class`(*R*)

class `OrdinaryGeneratingSeries`(*A, stream=None, order=None, aorder=None, aorder_changed=True, is_initialized=False, name=None*)

`count`(*n*)

Returns the number of structures on a set of size n.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.count(10)
10
```

`counts`(*n*)

Returns the number of structures on a set for size i for i in range(n).

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.counts(10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

class **OrdinaryGeneratingSeriesRing_class**(*R*)

factorial_gen()

A generator for the factorials starting at 0.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import factorial_gen
sage: g = factorial_gen()
sage: [g.next() for i in range(5)]
[1, 1, 2, 6, 24]
```

17.38.2 Basic Species

Combinatorial Species

This file defines the main classes for working with combinatorial species, operations on them, as well as some implementations of basic species required for other constructions.

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html. In particular, the relevant section for this file can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse8.html.

Weighted Species:

As a first application of weighted species, we count unlabeled ordered trees by total number of nodes and number of internal nodes. To achieve this, we assign a weight of 1 to the leaves and of q to internal nodes:

```
sage: q = QQ['q'].gen()
sage: leaf = species.SingletonSpecies()
sage: internal_node = species.SingletonSpecies(weight=q)
sage: L = species.LinearOrderSpecies(min=1)
sage: T = species.CombinatorialSpecies()
sage: T.define(leaf + internal_node*L(T))
sage: T.isotype_generating_series().coefficients(6)
[0, 1, q, q^2 + q, q^3 + 3*q^2 + q, q^4 + 6*q^3 + 6*q^2 + q]
```

Consider the following:

```
sage: T.isotype_generating_series().coefficient(4)
q^3 + 3*q^2 + q
```

This means that, among the trees on 4 nodes, one has a single internal node, three have two internal nodes, and one has three internal nodes.

class **GenericCombinatorialSpecies**(*min=None, max=None, weight=None*)

algebraic_equation_system()

Returns a system of algebraic equations satisfied by this species. The nodes are numbered in the order that they appear as vertices of the associated digraph.

EXAMPLES:

```
sage: B = species.BinaryTreeSpecies()
sage: B.algebraic_equation_system()
[-node3^2 + node1, -node1 + node3 - z]

sage: B.digraph().vertices()
[Combinatorial species,
 Product of (Combinatorial species) and (Combinatorial species),
 Singleton species,
 Sum of (Singleton species) and (Product of (Combinatorial species) and (Combinatorial speci

sage: B.algebraic_equation_system()[0].parent()
Multivariate Polynomial Ring in node0, node1, node2, node3 over Fraction Field of Univariate
```

composition(*g*)

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: S(S)
Composition of (Set species) and (Set species)
```

cycle_index_series()

Returns the cycle index series for this species.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: g = P.cycle_index_series()
sage: g.coefficients(4)
[p[], p[1], p[1, 1] + p[2], p[1, 1, 1] + p[2, 1] + p[3]]
```

digraph()

Returns a directed graph where the vertices are the individual species that make up this one.

EXAMPLES:

```
sage: X = species.SingletonSpecies()
sage: B = species.CombinatorialSpecies()
sage: B.define(X+B*B)
sage: g = B.digraph(); g
Multi-digraph on 4 vertices

sage: g, labels = g.canonical_label(certify=True)
sage: list(sorted(labels.items()))
[(Combinatorial species, 0),
 (Product of (Combinatorial species) and (Combinatorial species), 2),
 (Singleton species, 1),
 (Sum of (Singleton species) and (Product of (Combinatorial species) and (Combinatorial spec
sage: g.edges()
[(0, 3, None), (2, 0, None), (2, 0, None), (3, 1, None), (3, 2, None)]
```

functorial_composition(*g*)

Returns the functorial composition of self with g.

EXAMPLES:

```
sage: E = species.SetSpecies()
sage: E2 = E.restricted(min=2, max=3)
sage: WP = species.SubsetSpecies()
sage: P2 = E2*E
sage: G = WP.functorial_composition(P2)
```

```
sage: G.isotype_generating_series().coefficients(5)
[1, 1, 2, 4, 11]
```

generating_series()

Returns the generating series for this species. This is an exponential generating series so the nth coefficient of the series corresponds to the number of labeled structures with n labels divided by n!.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: g = P.generating_series()
sage: g.coefficients(4)
[1, 1, 1, 1]
sage: g.counts(4)
[1, 1, 2, 6]
sage: P.structures([1,2,3]).list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
sage: len(_)
6
```

is_weighted()

Returns True if this species has a nontrivial weighting associated with it.

EXAMPLES:

```
sage: C = species.CycleSpecies()
sage: C.is_weighted()
False
```

isotype_generating_series()

Returns the isotype generating series for this species. The nth coefficient of this series corresponds to the number of isomorphism types for the structures on n labels.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: g = P.isotype_generating_series()
sage: g.coefficients(4)
[1, 1, 2, 3]
sage: g.counts(4)
[1, 1, 2, 3]
sage: P.isotypes([1,2,3]).list()
[[2, 3, 1], [2, 1, 3], [1, 2, 3]]
sage: len(_)
3
```

isotypes(*labels, structure_class=None*)

EXAMPLES:

```
sage: F = CombinatorialSpecies()
sage: F.isotypes([1,2,3]).list()
...
NotImplementedError
```

product(*g*)

Returns the product of self and g.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: F = P * P; F
Product of (Permutation species) and (Permutation species)
```

restricted(*min=None, max=None*)

EXAMPLES:

```
sage: S = species.SetSpecies().restricted(min=3); S
Set species with min=3
sage: S.structures([1,2]).list()
[]
sage: S.generating_series().coefficients(5)
[0, 0, 0, 1/6, 1/24]
```

structures(*labels, structure_class=None*)

EXAMPLES:

```
sage: F = CombinatorialSpecies()
sage: F.structures([1,2,3]).list()
...
NotImplementedError
```

sum(*g*)

Returns the sum of self and g.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: F = P + P; F
Sum of (Permutation species) and (Permutation species)
sage: F.structures([1,2]).list()
[[1, 2], [2, 1], [1, 2], [2, 1]]
```

weight_ring()

Returns the ring in which the weights of this species occur.

By default, this is just the field of rational numbers.

EXAMPLES:

```
sage: species.SetSpecies().weight_ring()
Rational Field
```

weighted(*weight*)

Returns a version of this species with the specified weight.

EXAMPLES:

```
sage: t = ZZ['t'].gen()
sage: C = species.CycleSpecies(); C
Cyclic permutation species
sage: C.weighted(t)
Cyclic permutation species with weight=t
```

Recursive Species

class **CombinatorialSpecies**()

define(*x*)

Defines self to be equal to the combinatorial species x. This is used to define combinatorial species recursively. All of the real work is done by calling the .set() method for each of the series associated to self.

EXAMPLES: The species of linear orders L can be recursively defined by $L = 1 + X * L$ where 1 represents the empty set species and X represents the singleton species.

```
sage: X = species.SingletonSpecies()
sage: E = species.EmptySetSpecies()
sage: L = CombinatorialSpecies()
sage: L.define(E+X*L)
sage: L.generating_series().coefficients(4)
[1, 1, 1, 1]
sage: L.structures([1,2,3]).cardinality()
6
sage: L.structures([1,2,3]).list()
[1*(2*(3*{})),
 1*(3*(2*{})),
 2*(1*(3*{})),
 2*(3*(1*{})),
 3*(1*(2*{})),
 3*(2*(1*{}))]

sage: L = species.LinearOrderSpecies()
sage: L.generating_series().coefficients(4)
[1, 1, 1, 1]
sage: L.structures([1,2,3]).cardinality()
6
sage: L.structures([1,2,3]).list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

TESTS:

```
sage: A = CombinatorialSpecies()
sage: A.define(E+X*A*A)
sage: A.generating_series().coefficients(6)
[1, 1, 2, 5, 14, 42]
sage: A.generating_series().counts(6)
[1, 1, 4, 30, 336, 5040]
sage: len(A.structures([1,2,3,4]).list())
336
sage: A.isotype_generating_series().coefficients(6)
[1, 1, 2, 5, 14, 42]
sage: len(A.isotypes([1,2,3,4]).list())
14

sage: A = CombinatorialSpecies()
sage: A.define(X+A*A)
sage: A.generating_series().coefficients(6)
[0, 1, 1, 2, 5, 14]
sage: A.generating_series().counts(6)
[0, 1, 2, 12, 120, 1680]
sage: len(A.structures([1,2,3]).list())
12
sage: A.isotype_generating_series().coefficients(6)
[0, 1, 1, 2, 5, 14]
sage: len(A.isotypes([1,2,3,4]).list())
5

sage: X2 = X*X
sage: X5 = X2*X2*X
sage: A = CombinatorialSpecies()
sage: B = CombinatorialSpecies()
sage: C = CombinatorialSpecies()
sage: A.define(X5+B*B)
sage: B.define(X5+C*C)
```

```
sage: C.define(X2+C*C+A*A)
sage: A.generating_series().coefficients(Integer(10))
[0, 0, 0, 0, 0, 1, 0, 0, 1, 2]
sage: A.generating_series().coefficients(15)
[0, 0, 0, 0, 0, 1, 0, 0, 1, 2, 5, 4, 14, 10, 48]
sage: B.generating_series().coefficients(15)
[0, 0, 0, 0, 1, 1, 2, 0, 5, 0, 14, 0, 44, 0, 138]
sage: C.generating_series().coefficients(15)
[0, 0, 1, 0, 1, 0, 2, 0, 5, 0, 15, 0, 44, 2, 142]

sage: F = CombinatorialSpecies()
sage: F.define(E+X+(X*F+X*X*F))
sage: F.generating_series().counts(10)
[1, 2, 6, 30, 192, 1560, 15120, 171360, 2217600, 32296320]
sage: F.generating_series().coefficients(10)
[1, 2, 3, 5, 8, 13, 21, 34, 55, 89]
sage: F.isotype_generating_series().coefficients(10)
[1, 2, 3, 5, 8, 13, 21, 34, 55, 89]
```

weight_ring()

EXAMPLES:

```
sage: F = species.CombinatorialSpecies()
sage: F.weight_ring()
Rational Field

sage: X = species.SingletonSpecies()
sage: E = species.EmptySetSpecies()
sage: L = CombinatorialSpecies()
sage: L.define(E+X*L)
sage: L.weight_ring()
Rational Field
```

class **CombinatorialSpeciesStructure**(*parent, s, **options*)

Characteristic Species

class **CharacteristicSpeciesStructure**(*parent, labels, list*)

automorphism_group()

Returns the group of permutations whose action on this structure leave it fixed. For the characteristic species, there is only one structure, so every permutation is in its automorphism group.

EXAMPLES:

```
sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.automorphism_group()
Symmetric group of order 3! as a permutation group
```

canonical_label()

EXAMPLES:

```
sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.canonical_label()
```

```
{'a', 'b', 'c'}
```

transport(*perm*)

Returns the transport of this structure along the permutation perm.

EXAMPLES:

```
sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
{'a', 'b', 'c'}
```

class CharacteristicSpecies_class(*n, min=None, max=None, weight=None*)

class EmptySetSpecies_class(*min=None, max=None, weight=None*)

class SingletonSpecies_class(*min=None, max=None, weight=None*)

Cycle Species

CycleSpecies(**args, **kwds*)

Returns the species of cycles.

EXAMPLES:

```
sage: C = species.CycleSpecies(); C
Cyclic permutation species
sage: C.structures([1,2,3,4]).list()
[(1, 2, 3, 4),
 (1, 2, 4, 3),
 (1, 3, 2, 4),
 (1, 3, 4, 2),
 (1, 4, 2, 3),
 (1, 4, 3, 2)]
```

TESTS: We check to verify that the caching of species is actually working.

```
sage: species.CycleSpecies() is species.CycleSpecies()
True
```

class CycleSpeciesStructure(*parent, labels, list*)

automorphism_group()

Returns the group of permutations whose action on this structure leave it fixed.

EXAMPLES:

```
sage: P = species.CycleSpecies()
sage: a = P.structures([1, 2, 3, 4]).random_element(); a
(1, 2, 3, 4)
sage: a.automorphism_group()
Permutation Group with generators [(1,2,3,4)]

sage: [a.transport(perm) for perm in a.automorphism_group()]
[(1, 2, 3, 4), (1, 2, 3, 4), (1, 2, 3, 4), (1, 2, 3, 4)]
```

canonical_label()

EXAMPLES:

```
sage: P = species.CycleSpecies()
sage: P.structures(["a","b","c"]).random_element().canonical_label()
('a', 'b', 'c')
```

permutation_group_element()
Returns this cycle as a permutation group element.
EXAMPLES:

```
sage: F = species.CycleSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
('a', 'b', 'c')
sage: a.permutation_group_element()
(1,2,3)
```

transport(*perm*)
Returns the transport of this structure along the permutation perm.
EXAMPLES:

```
sage: F = species.CycleSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
('a', 'b', 'c')
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
('a', 'c', 'b')
```

class CycleSpecies_class(*min=None, max=None, weight=None*)

Partition Species

PartitionSpecies(**args, **kwds*)
Returns the species of partitions.
EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: P.generating_series().coefficients(5)
[1, 1, 1, 5/6, 5/8]
sage: P.isotype_generating_series().coefficients(5)
[1, 1, 2, 3, 5]
```

class PartitionSpeciesStructure(*parent, labels, list*)

automorphism_group()
Returns the group of permutations whose action on this set partition leave it fixed.
EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.automorphism_group()
Permutation Group with generators [(1,2)]
```

canonical_label()
EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.canonical_label() for s in S]
[{{'a', 'b', 'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a'}, {'b'}, {'c'}}]
```

change_labels(*labels*)

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.change_labels([1,2,3])
{{1, 2}, {3}}
```

transport(*perm*)

Returns the transport of this set partition along the permutation perm. For set partitions, this is the direct product of the automorphism groups for each of the blocks.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.transport(p)
{{2, 4}, {3}}
```

class **PartitionSpecies_class**(*min=None, max=None, weight=None*)

Permutation species

PermutationSpecies(**args, **kwds*)

Returns the species of permutations.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: P.generating_series().coefficients(5)
[1, 1, 1, 1, 1]
sage: P.isotype_generating_series().coefficients(5)
[1, 1, 2, 3, 5]
```

class **PermutationSpeciesStructure**(*parent, labels, list*)

automorphism_group()

Returns the group of permutations whose action on this structure leave it fixed.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"]).random_element(); a
['a', 'c', 'b', 'd']
```

```
sage: a.automorphism_group()
Permutation Group with generators [(2,3), (1,4)]

sage: [a.transport(perm) for perm in a.automorphism_group()]
[['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd']]
```

canonical_label()

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.canonical_label() for s in S]
[['a', 'b', 'c'],
 ['b', 'a', 'c'],
 ['b', 'a', 'c'],
 ['b', 'c', 'a'],
 ['b', 'c', 'a'],
 ['b', 'a', 'c']]
```

permutation_group_element()

Returns self as a permutation group element.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"]).random_element(); a
['a', 'c', 'b', 'd']
sage: a.permutation_group_element()
(2,3)
```

transport(*perm*)

Returns the transport of this structure along the permutation perm.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"]).random_element(); a
['a', 'c', 'b', 'd']
sage: a.transport(p)
['a', 'd', 'c', 'b']
```

class **PermutationSpecies_class**(*min=None, max=None, weight=None*)

Linear-order Species

LinearOrderSpecies(**args, **kwds*)

Returns the species of linear orders.

EXAMPLES:

```
sage: L = species.LinearOrderSpecies()
sage: L.generating_series().coefficients(5)
[1, 1, 1, 1, 1]
```

class **LinearOrderSpeciesStructure**(*parent, labels, list*)

automorphism_group()
Returns the group of permutations whose action on this structure leave it fixed. For the species of linear orders, there is no non-trivial automorphism.

EXAMPLES:

```
sage: F = species.LinearOrderSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
['a', 'b', 'c']
sage: a.automorphism_group()
Symmetric group of order 1! as a permutation group
```

canonical_label()
EXAMPLES:

```
sage: P = species.LinearOrderSpecies()
sage: s = P.structures(["a", "b", "c"]).random_element()
sage: s.canonical_label()
['a', 'b', 'c']
```

transport(*perm*)
Returns the transport of this structure along the permutation perm.

EXAMPLES:

```
sage: F = species.LinearOrderSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
['a', 'b', 'c']
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
['b', 'a', 'c']
```

class **LinearOrderSpecies_class**(*min=None, max=None, weight=None*)

Set Species

SetSpecies(**args, **kwds*)
Returns the species of sets.

EXAMPLES:

```
sage: E = species.SetSpecies()
sage: E.structures([1,2,3]).list()
[{1, 2, 3}]
sage: E.isotype_generating_series().coefficients(4)
[1, 1, 1, 1]
```

class **SetSpeciesStructure**(*parent, labels, list*)

automorphism_group()
Returns the group of permutations whose action on this set leave it fixed. For the species of sets, there is only one isomorphism class, so every permutation is in its automorphism group.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.automorphism_group()
Symmetric group of order 3! as a permutation group
```

canonical_label()
EXAMPLES:

```
sage: S = species.SetSpecies()
sage: a = S.structures(["a","b","c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.canonical_label()
{'a', 'b', 'c'}
```

transport(*perm*)
Returns the transport of this set along the permutation perm.
EXAMPLES:

```
sage: F = species.SetSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
{'a', 'b', 'c'}
```

class **SetSpecies_class**(*min=None, max=None, weight=None*)

Subset Species

SubsetSpecies(**args, **kwds*)
Returns the species of subsets.
EXAMPLES:

```
sage: S = species.SubsetSpecies()
sage: S.generating_series().coefficients(5)
[1, 2, 2, 4/3, 2/3]
sage: S.isotype_generating_series().coefficients(5)
[1, 2, 3, 4, 5]
```

class **SubsetSpeciesStructure**(*parent, labels, list*)

automorphism_group()
Returns the group of permutations whose action on this subset leave it fixed.
EXAMPLES:

```
sage: F = species.SubsetSpecies()
sage: a = F.structures([1,2,3,4])[6]; a
{1, 3}
sage: a.automorphism_group()
Permutation Group with generators [(2,4), (1,3)]

sage: [a.transport(g) for g in a.automorphism_group()]
[{1, 3}, {1, 3}, {1, 3}, {1, 3}]
```

canonical_label()
EXAMPLES:

```
sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.canonical_label() for s in S]
[{}, {'a'}, {'a'}, {'a'}, {'a', 'b'}, {'a', 'b'}, {'a', 'b'}, {'a', 'b', 'c'}]
```

complement()
EXAMPLES:

```
sage: F = species.SubsetSpecies()
sage: a = F.structures(["a", "b", "c"])[5]; a
{'a', 'c'}
sage: a.complement()
{'b'}
```

labels()
EXAMPLES:

```
sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.labels() for s in S]
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]
```

transport(*perm*)
Returns the transport of this subset along the permutation perm.
EXAMPLES:

```
sage: F = species.SubsetSpecies()
sage: a = F.structures(["a", "b", "c"])[5]; a
{'a', 'c'}
sage: p = PermutationGroupElement((1,2))
sage: a.transport(p)
{'b', 'c'}
sage: p = PermutationGroupElement((1,3))
sage: a.transport(p)
{'a', 'c'}
```

class **SubsetSpecies_class**(*min=None, max=None, weight=None*)

Examples of Combinatorial Species

17.38.3 Operations on Species

Sum species

class **SumSpeciesStructure**(*parent, s, **options*)

class **SumSpecies_class**(*F, G, min=None, max=None, weight=None*)

weight_ring()
Returns the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you add elements of the weight rings for each of the operands.
EXAMPLES:

```
sage: S = species.SetSpecies()
sage: C = S+S
sage: C.weight_ring()
Rational Field

sage: S = species.SetSpecies(weight=QQ['t'].gen())
sage: C = S + S
sage: C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

Sum species

class ProductSpeciesStructure(*parent, labels, subset, left, right*)

automorphism_group()
EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures([1,2,3,4]).random_element(); a
{1}*{2, 3, 4}
sage: a.automorphism_group()
Permutation Group with generators [(2,3), (2,3,4)]

sage: [a.transport(g) for g in a.automorphism_group()]
[{1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4}]

sage: a = F.structures([1,2,3,4]).random_element(); a
{2, 3}*{1, 4}
sage: [a.transport(g) for g in a.automorphism_group()]
[{2, 3}*{1, 4}, {2, 3}*{1, 4}, {2, 3}*{1, 4}, {2, 3}*{1, 4}]
```

canonical_label()
EXAMPLES:

```
sage: S = species.SetSpecies()
sage: F = S * S
sage: S = F.structures(['a','b','c']).list(); S
[{}*{'a', 'b', 'c'},
 {'a'}*{'b', 'c'},
 {'b'}*{'a', 'c'},
 {'c'}*{'a', 'b'},
 {'a', 'b'}*{'c'},
 {'a', 'c'}*{'b'},
 {'b', 'c'}*{'a'},
 {'a', 'b', 'c'}*{}]

sage: F.isotypes(['a','b','c']).cardinality()
4
sage: [s.canonical_label() for s in S]
[{}*{'a', 'b', 'c'},
 {'a'}*{'b', 'c'},
 {'a'}*{'b', 'c'},
 {'a'}*{'b', 'c'},
 {'a', 'b'}*{'c'},
 {'a', 'b'}*{'c'},
 {'a', 'b'}*{'c'},
 {'a', 'b', 'c'}*{}]
```

change_labels(*labels*)
EXAMPLES:

```
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures(['a','b','c']).random_element(); a
{}*{'a', 'b', 'c'}
sage: a.change_labels([1,2,3])
{}*{1, 2, 3}
```

transport(*perm*)

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures(['a','b','c'])[4]; a
{'a', 'b'}*{'c'}
sage: a.transport(p)
{'a', 'c'}*{'b'}
```

class **ProductSpecies_class**(*F, G, min=None, max=None, weight=None*)

weight_ring()

Returns the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you multiply (and add) elements of the weight rings for each of the operands.

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: C = S*S
sage: C.weight_ring()
Rational Field

sage: S = species.SetSpecies(weight=QQ['t'].gen())
sage: C = S*S
sage: C.weight_ring()
Univariate Polynomial Ring in t over Rational Field

sage: S = species.SetSpecies()
sage: C = (S*S).weighted(QQ['t'].gen())
sage: C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

Composition species

class **CompositionSpeciesStructure**(*parent, labels, pi, f, gs*)

change_labels(*labels*)

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: S = L.structures(['a','b','c']).list()
sage: a = S[2]; a
F-structure: {{'a', 'c'}, {'b'}}; G-structures: [('a', 'c'), ('b')]
sage: a.change_labels([1,2,3])
F-structure: {{1, 3}, {2}}; G-structures: [(1, 3), (2)]
```

transport(*perm*)
EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: S = L.structures(['a','b','c']).list()
sage: a = S[2]; a
F-structure: {{'a', 'c'}, {'b'}}; G-structures: [('a', 'c'), ('b')]
sage: a.transport(p)
F-structure: {{'a', 'b'}, {'c'}}; G-structures: [('a', 'c'), ('b')]
```

class CompositionSpecies_class(*F, G, min=None, max=None, weight=None*)

weight_ring()
Returns the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you multiply (and add) elements of the weight rings for each of the operands.
EXAMPLES:

```
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: L.weight_ring()
Rational Field
```

Functorial composition species

class FunctorialCompositionSpecies_class(*F, G, min=None, max=None, weight=None*)

weight_ring()
Returns the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you multiply (and add) lements of the weight rings for each of the operands.
EXAMPLES:

```
sage: G = species.SimpleGraphSpecies()
sage: G.weight_ring()
Rational Field
```

class FunctorialCompositionStructure(*parent, labels, list*)

17.38.4 Miscellaneous

Species structures

We will illustrate the use of the structure classes using the "balls and bars" model for integer compositions. An integer composition of 6 such as [2, 1, 3] can be represented in this model as 'oooooo' where the 6 o's correspond to the balls and the 2 's correspond to the bars. If BB is our species for this model, the it satisfies the following recursive definition:

BB = o + o*BB + o*|*BB

Here we define this species using the default structures:

```
sage: ball = species.SingletonSpecies(); o = var('o')
sage: bar = species.EmptySetSpecies()
sage: BB = CombinatorialSpecies()
```

```
sage: BB.define(ball + ball*BB + ball*bar*BB)
sage: BB.isotypes([o]*3).list()
[o*(o*o), o*((o*{})*o), (o*{})*(o*o), (o*{})*((o*{})*o)]
```

If we ignore the parentheses, we can read off that the integer compositions are [3], [2, 1], [1, 2], and [1, 1, 1].

class GenericSpeciesStructure(*parent, labels, list*)

change_labels(*labels*)

EXAMPLES:

```
sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.change_labels([1,2,3]) for s in S]
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
```

is_isomorphic(*x*)

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: a = S.structures([1,2,3]).random_element(); a
{1, 2, 3}
sage: b = S.structures(['a','b','c']).random_element(); b
{'a', 'b', 'c'}
sage: a.is_isomorphic(b)
True
```

labels()

EXAMPLES:

```
sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.labels() for s in S]
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]
```

class IsotypesWrapper(*species, labels, structure_class*)

class SimpleIsotypesWrapper(*species, labels, structure_class*)

class SimpleStructuresWrapper(*species, labels, structure_class*)

class SpeciesStructure()

parent()

Returns the species that this structure is associated with.

EXAMPLES:

```
sage: L = species.LinearOrderSpecies()
sage: a,b = L.structures([1,2])
sage: a.parent()
Linear order species
```

class SpeciesStructureWrapper(*parent, s, **options*)

canonical_label()

EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: s = (P+P).structures([1,2,3]).random_element(); s
```

```
{{1, 3}, {2}}
sage: s.canonical_label()
{{1, 2}, {3}}
```

labels()

EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: s = (P+P).structures([1,2,3]).random_element(); s
{{1, 3}, {2}}
sage: s.labels()
[{1, 3}, {2}]
sage: type(_)
<type 'list'>
```

transport(*perm*)

EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: s = (P+P).structures([1,2,3]).random_element(); s
{{1, 3}, {2}}
sage: s.transport(PermutationGroupElement((2,3)))
{{1, 2}, {3}}
```

class **SpeciesWrapper**(*species, labels, iterator, generating_series, name, structure_class*)

cardinality()

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: F.structures([1,2,3]).cardinality()
1
```

class **StructuresWrapper**(*species, labels, structure_class*)

Miscellaneous Functions

accept_size(*f*)

The purpose of this decorator is to change calls like species.SetSpecies(size=1) to species.SetSpecies(min=1, max=2). This is to make caching species easier and to restrict the number of parameters that the lower level code needs to know about.

EXAMPLES:

```
sage: from sage.combinat.species.misc import accept_size
sage: def f(*args, **kwds):
...       print args, list(sorted(kwds.items()))
sage: f = accept_size(f)
sage: f(min=1)
() [('min', 1)]
sage: f(size=2)
() [('max', 3), ('min', 2)]
```

change_support(*perm, support, change_perm=None*)

Changes the support of a permutation defined on [1, ..., n] to support.

EXAMPLES:

```
sage: from sage.combinat.species.misc import change_support
sage: p = PermutationGroupElement((1,2,3)); p
(1,2,3)
sage: change_support(p, [3,4,5])
(3,4,5)
```

17.39 Developer Tools

17.39.1 Backtracking

This library contains generic tools for constructing large sets whose elements can be enumerated by exploring a search space with a (lazy) tree or graph structure.

- `SearchForest`: Depth first search through a tree described by a `children` function.
- `GenericBacktracker`: Depth first search through a tree described by a `children` function, with branch pruning, etc.
- `TransitiveIdeal`: Depth first search through a graph described by a `neighbours` relation.
- `TransitiveIdealGraded`: Breath first search through a graph described by a `neighbours` relation.

TODO:

1. Find a good and consistent naming scheme! Do we want to emphasize the underlying graph/tree structure? The branch & bound aspect? The transitive closure of a relation point of view?
2. Do we want `TransitiveIdeal(relation, generators)` or `TransitiveIdeal(generators, relation)`? The code needs to be standardized once the choice is made.

class `GenericBacktracker`(*initial_data, initial_state*)

A generic backtrack tool for exploring a search space organized as a tree, with branch pruning, etc.

See also `SearchForest` and `TransitiveIdeal` for handling simple special cases.

class `SearchForest`(*roots, children*)

Returns the set of nodes of the forest having the given roots, and where `children(x)` returns the children of the node `x` of the forest.

See also `GenericBacktracker`, `TransitiveIdeal`, and `TransitiveIdealGraded`.

INPUT:

- `roots`: a list (or iterable)
- `children`: a function returning a list (or iterable)

EXAMPLES:

A generator object for binary sequencences of length 3, listed:

```
sage: list(SearchForest([[]], lambda l: [l+[0], l+[1]] if len(l) < 3 else []))
[[], [0], [0, 0], [0, 0, 0], [0, 0, 1], [0, 1], [0, 1, 0], [0, 1, 1], [1], [1, 0], [1, 0, 0], [1
```

A generator object for ordered sequences of length 2 from a 4-set, sampled:

```
sage: tb = SearchForest([[]], lambda l: [l + [i] for i in range(4) if i not in l] if len(l) < 2
sage: tb[0]
[]
sage: tb[16]
[3, 2]
```

class `TransitiveIdeal`(*succ, generators*)

Generic tool for constructing ideals of a relation.

INPUT:

- `relation`: a function (or callable) returning a list (or iterable)
- `generators`: a list (or iterable)

Returns the set S of elements that can be obtained by repeated application of `relation` on the elements of `generators`.

Consider `relation` as modeling a directed graph (possibly with loops, cycles, or circuits). Then S is the ideal generated by `generators` under this relation.

Enumerating the elements of S is achieved by depth first search through the graph. The time complexity is $O(n + m)$ where n is the size of the ideal, and m the number of edges in the relation. The memory complexity is the depth, that is the maximal distance between a generator and an element of S.

See also `SearchForest` and `TransitiveIdealGraded`.

EXAMPLES:

```
sage: [i for i in TransitiveIdeal(lambda i: [i+1] if i<10 else [], [0])]
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]

sage: [i for i in TransitiveIdeal(lambda i: [mod(i+1,3)], [0])]
[0, 1, 2]
sage: [i for i in TransitiveIdeal(lambda i: [mod(i+2,3)], [0])]
[0, 2, 1]
sage: [i for i in TransitiveIdeal(lambda i: [mod(i+2,10)], [0])]
[0, 2, 4, 6, 8]
sage: [i for i in TransitiveIdeal(lambda i: [mod(i+3,10),mod(i+5,10)], [0])]
[0, 3, 8, 1, 4, 5, 6, 7, 9, 2]
sage: [i for i in TransitiveIdeal(lambda i: [mod(i+4,10),mod(i+6,10)], [0])]
[0, 4, 8, 2, 6]
sage: [i for i in TransitiveIdeal(lambda i: [mod(i+3,9)], [0,1])]
[0, 1, 3, 4, 6, 7]

sage: [p for p in TransitiveIdeal(lambda x:[x],[Permutation([3,1,2,4]), Permutation([2,1,3,4])])]
[[2, 1, 3, 4], [3, 1, 2, 4]]
```

We now illustrate that the enumeration is done lazily, by depth first search:

```
sage: C = TransitiveIdeal(lambda x: [x-1, x+1], (-10, 0, 10))
sage: f = C.__iter__()
sage: [ f.next() for i in range(6) ]
[0, 1, 2, 3, 4, 5]
```

We compute all the permutations of 3:

```
sage: [p for p in TransitiveIdeal(attrcall("permutohedron_succ"), [Permutation([1,2,3])])]
[[1, 2, 3], [2, 1, 3], [1, 3, 2], [2, 3, 1], [3, 2, 1], [3, 1, 2]]
```

We compute all the permutations which are larger than [3,1,2,4], [2,1,3,4] in the right permutohedron:

```
sage: [p for p in TransitiveIdeal(attrcall("permutohedron_succ"), [Permutation([3,1,2,4]), Permu
[[2, 1, 3, 4], [2, 1, 4, 3], [2, 4, 1, 3], [4, 2, 1, 3], [4, 2, 3, 1], [4, 3, 2, 1], [3, 1, 2, 4
```

class TransitiveIdealGraded(*succ, generators*)

Generic tool for constructing ideals of a relation.

INPUT:

- `relation`: a function (or callable) returning a list (or iterable)
- `generators`: a list (or iterable)

Returns the set S of elements that can be obtained by repeated application of `relation` on the elements of `generators`.

Consider `relation` as modeling a directed graph (possibly with loops, cycles, or circuits). Then S is the ideal generated by `generators` under this relation.

Enumerating the elements of S is achieved by breath first search through the graph; hence elements are enumerated by increasing distance from the generators. The time complexity is $O(n + m)$ where n is the size of the ideal, and m the number of edges in the relation. The memory complexity is the depth, that is the maximal distance between a generator and an element of S.

See also `SearchForest` and `TransitiveIdeal`.

EXAMPLES:

```
sage: [i for i in TransitiveIdealGraded(lambda i: [i+1] if i<10 else [], [0])]
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

We now illustrates that the enumeration is done lazily, by breath first search:

```
sage: C = TransitiveIdealGraded(lambda x: [x-1, x+1], (-10, 0, 10))
sage: f = C.__iter__()
```

The elements at distance 0 from the generators:

```
sage: sorted([ f.next() for i in range(3) ])
[-10, 0, 10]
```

The elements at distance 1 from the generators:

```
sage: sorted([ f.next() for i in range(6) ])
[-11, -9, -1, 1, 9, 11]
```

The elements at distance 2 from the generators:

```
sage: sorted([ f.next() for i in range(6) ])
[-12, -8, -2, 2, 8, 12]
```

The enumeration order between elements at the same distance is not specified.

We compute all the permutations which are larger than [3,1,2,4] or [2,1,3,4] in the permutohedron:

```
sage: [p for p in TransitiveIdealGraded(attrcall("permutohedron_succ"), [Permutation([3,1,2,4]),
[[3, 1, 2, 4], [2, 1, 3, 4], [2, 1, 4, 3], [3, 2, 1, 4], [2, 3, 1, 4], [3, 1, 4, 2], [2, 3, 4, 1
```

search_forest_iterator(*roots, children*)

Returns an iterator on the nodes of the forest having the given roots, and where `children(x)` returns the children of the node `x` of the forest. Note that every node of the tree is returned, not simply the leaves.

INPUT:

- `roots`: a list (or iterable)
- `children`: a function returning a list (or iterable)

EXAMPLES:

Search tree where leaves are binary sequences of length 3:

```
sage: from sage.combinat.backtrack import search_forest_iterator
sage: list(search_forest_iterator([[]], lambda l: [l+[0], l+[1]] if len(l) < 3 else []))
[[], [0], [0, 0], [0, 0, 0], [0, 0, 1], [0, 1], [0, 1, 0], [0, 1, 1], [1], [1, 0], [1, 0, 0], [1
```

Search tree where leaves are ordered sequences of length 2 from a 4-set:

```
sage: from sage.combinat.backtrack import search_forest_iterator
sage: list(search_forest_iterator([[]], lambda l: [l + [i] for i in range(4) if i not in l] if l
[[], [0], [0, 1], [0, 2], [0, 3], [1], [1, 0], [1, 2], [1, 3], [2], [2, 0], [2, 1], [2, 3], [3],
```

17.39.2 Output functions

tex_from_array(*a*)

EXAMPLES:

```
sage: from sage.combinat.output import tex_from_array
sage: print tex_from_array([[1,2,3],[4,5]])
{\def\lr#1{\multicolumn{1}{|@{\hspace{.6ex}}c@{\hspace{.6ex}}|}{\raisebox{-.3ex}{$#1$}}}
\raisebox{-.6ex}{$\begin{array}[b]{ccc}
\cline{1-1}\cline{2-2}\cline{3-3}
\lr{1}&\lr{2}&\lr{3}\\
\cline{1-1}\cline{2-2}\cline{3-3}
\lr{4}&\lr{5}\\
\cline{1-1}\cline{2-2}
\end{array}$}
}
```

17.39.3 Low-level permutations

class PermutationsNK(*n, k*)

cardinality()

Returns the number of permutations of k things from a list of n things.

EXAMPLES:

```
sage: from sage.combinat.permutation_nk import PermutationsNK
sage: PermutationsNK(3,2).cardinality()
6
sage: PermutationsNK(5,4).cardinality()
120
```

random_element()

Returns a random permutation of k things from range(n).

EXAMPLES:

```
sage: from sage.combinat.permutation_nk import PermutationsNK
sage: PermutationsNK(3,2).random_element()
[0, 1]
```

17.39.4 Low-level splits

SplitNK(*n*, *k*)

Returns the combinatorial class of splits of a the set range(n) into a set of size k and a set of size n-k.

EXAMPLES:

```
sage: from sage.combinat.split_nk import SplitNK
sage: S = SplitNK(5,2); S
Splits of {0, ..., 4} into a set of size 2 and one of size 3
sage: S.first()
[[0, 1], [2, 3, 4]]
sage: S.last()
[[3, 4], [0, 1, 2]]
sage: S.list()
[[[0, 1], [2, 3, 4]],
 [[0, 2], [1, 3, 4]],
 [[0, 3], [1, 2, 4]],
 [[0, 4], [1, 2, 3]],
 [[1, 2], [0, 3, 4]],
 [[1, 3], [0, 2, 4]],
 [[1, 4], [0, 2, 3]],
 [[2, 3], [0, 1, 4]],
 [[2, 4], [0, 1, 3]],
 [[3, 4], [0, 1, 2]]]
```

class SplitNK_nk(*n*, *k*)

cardinality()

Returns the number of choices of set partitions of range(n) into a set of size k and a set of size n-k.

EXAMPLES:

```
sage: from sage.combinat.split_nk import SplitNK
sage: SplitNK(5,2).cardinality()
10
```

random_element()

Returns a random set partition of range(n) into a set of size k and a set of size n-k.

EXAMPLES:

```
sage: from sage.combinat.split_nk import SplitNK
sage: SplitNK(5,2).random_element()
[[0, 2], [1, 3, 4]]
```

17.39.5 Low-level Combinations

class ChooseNK(*n*, *k*)

Low level combinatorial class of all possible choices of k elements out of range(n) without repetitions.

This is a low-level combinatorial class, with a simplistic interface by design. It aim at speed. It's element are returned as plain list of python int.

EXAMPLES:

```
sage: from sage.combinat.choose_nk import ChooseNK
sage: c = ChooseNK(4,2)
sage: c.first()
[0, 1]
```

```
sage: c.list()
[[0, 1], [0, 2], [0, 3], [1, 2], [1, 3], [2, 3]]
sage: type(c.list()[1])
<type 'list'>
sage: type(c.list()[1][1])
<type 'int'>
```

cardinality()

Returns the number of choices of k things from a list of n things.

EXAMPLES:

```
sage: from sage.combinat.choose_nk import ChooseNK
sage: ChooseNK(3,2).cardinality()
3
sage: ChooseNK(5,2).cardinality()
10
```

random_element()

Returns a random choice of k things from range(n).

EXAMPLES:

```
sage: from sage.combinat.choose_nk import ChooseNK
sage: ChooseNK(5,2).random_element()
[0, 2]
```

rank(*x*)

EXAMPLES:

```
sage: from sage.combinat.choose_nk import ChooseNK
sage: c52 = ChooseNK(5,2)
sage: range(c52.cardinality()) == map(c52.rank, c52)
True
```

unrank(*r*)

EXAMPLES:

```
sage: from sage.combinat.choose_nk import ChooseNK
sage: c52 = ChooseNK(5,2)
sage: c52.list() == map(c52.unrank, range(c52.cardinality()))
True
```

from_rank(*r*, *n*, *k*)

Returns the combination of rank r in the subsets of range(n) of size k when listed in lexicographic order.

The algorithm used is based on combinadics and James McCaffrey's MSDN article. See: http://en.wikipedia.org/wiki/Combinadic

EXAMPLES:

```
sage: import sage.combinat.choose_nk as choose_nk
sage: choose_nk.from_rank(0,3,0)
[]
sage: choose_nk.from_rank(0,3,1)
[0]
sage: choose_nk.from_rank(1,3,1)
[1]
sage: choose_nk.from_rank(2,3,1)
[2]
sage: choose_nk.from_rank(0,3,2)
[0, 1]
```

```
sage: choose_nk.from_rank(1,3,2)
[0, 2]
sage: choose_nk.from_rank(2,3,2)
[1, 2]
sage: choose_nk.from_rank(0,3,3)
[0, 1, 2]
```

rank(*comb*, *n*)

Returns the rank of comb in the subsets of range(n) of size k.

The algorithm used is based on combinadics and James McCaffrey's MSDN article. See: http://en.wikipedia.org/wiki/Combinadic

EXAMPLES:

```
sage: import sage.combinat.choose_nk as choose_nk
sage: choose_nk.rank([], 3)
0
sage: choose_nk.rank([0], 3)
0
sage: choose_nk.rank([1], 3)
1
sage: choose_nk.rank([2], 3)
2
sage: choose_nk.rank([0,1], 3)
0
sage: choose_nk.rank([0,2], 3)
1
sage: choose_nk.rank([1,2], 3)
2
sage: choose_nk.rank([0,1,2], 3)
0
```

17.39.6 Low-level multichoose

class MultichooseNK(*n*, *k*)

cardinality()

Returns the number of multichoices of k things from a list of n things.

EXAMPLES:

```
sage: MultichooseNK(3,2).cardinality()
6
```

random_element()

Returns a random multichoice of k things from range(n).

EXAMPLES:

```
sage: MultichooseNK(5,2).random_element()
[0, 2]
sage: MultichooseNK(5,2).random_element()
[0, 1]
```

17.39.7 Tools

transitive_ideal (*f, x*)

Given an initial value x and a successor function f, return a list containing x and all of its successors. The successor function should return a list of all the successors of f.

Note that if x has an infinite number of successors, transitive_ideal won't return.

EXAMPLES:

```
sage: f = lambda x: [x-1] if x > 0 else []
sage: sage.combinat.tools.transitive_ideal(f, 10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

17.39.8 Generators

concat (*gens*)

Returns a generator that is the concatenation of the generators in the list.

EXAMPLES:

```
sage: list(sage.combinat.generator.concat([[1,2,3],[4,5,6]]))
[1, 2, 3, 4, 5, 6]
```

element (*element, n=1*)

Returns a generator that yield a single element n times.

EXAMPLES:

```
sage: list(sage.combinat.generator.element(1))
[1]
sage: list(sage.combinat.generator.element(1, n=3))
[1, 1, 1]
```

map (*f, gen*)

Returns a generator that returns f(g) for g in gen.

EXAMPLES:

```
sage: f = lambda x: x*2
sage: list(sage.combinat.generator.map(f,[4,5,6]))
[8, 10, 12]
```

select (*f, gen*)

Returns a generator for all the elements g of gen such that f(g) is True.

EXAMPLES:

```
sage: f = lambda x: x % 2 == 0
sage: list(sage.combinat.generator.select(f,range(7)))
[0, 2, 4, 6]
```

successor (*initial, succ*)

Given an initial value and a successor function, yield the initial value and each following successor. The generator will continue to generate values until the successor function yields None.

EXAMPLES:

```
sage: f = lambda x: x+1 if x < 10 else None
sage: list(sage.combinat.generator.successor(0,f))
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

17.39.9 Rankers

from_list(*l*)

Returns a ranker from the list l.

INPUT:

- `l` - a list

OUTPUT:

- `[rank, unrank]` - functions

EXAMPLES:

```
sage: import sage.combinat.ranker as ranker
sage: l = [1,2,3]
sage: r,u = ranker.from_list(l)
sage: r(1)
0
sage: r(3)
2
sage: u(2)
3
sage: u(0)
1
```

on_fly()

Returns a pair of enumeration functions rank / unrank.

rank assigns on the fly an integer, starting from 0, to any object passed as argument. The object should be hashable. unrank is the inverse function; it returns None for indices that have not yet been assigned.

EXAMPLES:

```
sage: [rank, unrank] = sage.combinat.ranker.on_fly()
sage: rank('a')
0
sage: rank('b')
1
sage: rank('c')
2
sage: rank('a')
0
sage: unrank(2)
'c'
sage: unrank(3)
sage: rank('d')
3
sage: unrank(3)
'd'
```

TODO: add tests as in combinat::rankers

rank_from_list(*l*)
Returns a rank function given a list l.

EXAMPLES:

```
sage: import sage.combinat.ranker as ranker
sage: l = [1,2,3]
sage: r = ranker.rank_from_list(l)
sage: r(1)
0
sage: r(3)
2
```

unrank_from_list(*l*)
Returns an unrank function from a list.

EXAMPLES:

```
sage: import sage.combinat.ranker as ranker
sage: l = [1,2,3]
sage: u = ranker.unrank_from_list(l)
sage: u(2)
3
sage: u(0)
1
```

17.40 Words

17.40.1 Alphabets

Alphabet(*data=None, name=None*)
Returns an object representing an ordered alphabet.

EXAMPLES:

```
sage: Alphabet("ab")
Ordered Alphabet ['a', 'b']
sage: Alphabet([0,1,2])
Ordered Alphabet [0, 1, 2]
sage: Alphabet(name="positive integers")
Ordered Alphabet of Positive Integers
sage: Alphabet(name="PP")
Ordered Alphabet of Positive Integers
sage: Alphabet(name="natural numbers")
Ordered Alphabet of Natural Numbers
sage: Alphabet(name="NN")
Ordered Alphabet of Natural Numbers
```

OrderedAlphabet(*data=None, name=None*)
Returns an object representing an ordered alphabet.

EXAMPLES:

```
sage: Alphabet("ab")
Ordered Alphabet ['a', 'b']
sage: Alphabet([0,1,2])
Ordered Alphabet [0, 1, 2]
```

```
sage: Alphabet(name="positive integers")
Ordered Alphabet of Positive Integers
sage: Alphabet(name="PP")
Ordered Alphabet of Positive Integers
sage: Alphabet(name="natural numbers")
Ordered Alphabet of Natural Numbers
sage: Alphabet(name="NN")
Ordered Alphabet of Natural Numbers
```

class **OrderedAlphabet_Finite**(*alphabet*)

rank(*letter*)

Returns the index of letter in self.

INPUT:

- `letter` - a letter contained in this alphabet

OUTPUT:

- `integer` - the integer mapping for the letter

EXAMPLES:

```
sage: from sage.combinat.words.alphabet import OrderedAlphabet_Finite
sage: OrderedAlphabet_Finite('abcd').rank('a')
0
sage: OrderedAlphabet_Finite('abcd').rank('d')
3
sage: OrderedAlphabet_Finite('abcd').rank('e')
...
IndexError: letter not in alphabet: 'e'
sage: OrderedAlphabet_Finite('abcd').rank('')
...
IndexError: letter not in alphabet: ''
```

string_rep()

Returns the string representation of the alphabet.

TESTS:

```
sage: from sage.combinat.words.alphabet import OrderedAlphabet_Finite
sage: OrderedAlphabet_Finite('cba').string_rep()
"['c', 'b', 'a']"
sage: OrderedAlphabet_Finite([1, 3, 2]).string_rep()
'[1, 3, 2]'
```

unrank(*n*)

Returns the letter in position n of the alphabet self.

INPUT:

- `n` - a nonnegative integer

OUTPUT: the (n+1)-th object output by iter(self)

EXAMPLES:

```
sage: from sage.combinat.words.alphabet import OrderedAlphabet_Finite
sage: OrderedAlphabet_Finite('abcd').unrank(0)
'a'
sage: OrderedAlphabet_Finite('abcd').unrank(3)
'd'
sage: OrderedAlphabet_Finite('abcd').unrank(5)
```

```
...
IndexError: list index out of range
```

class OrderedAlphabet_Infinite()

cardinality()

Return the number of elements in self.

OUTPUT: +Infinity

EXAMPLES:

```
sage: from sage.combinat.words.alphabet import OrderedAlphabet_Infinite
sage: OrderedAlphabet_Infinite().cardinality()
+Infinity
```

list()

Returns NotImplementedError since we cannot list all the nonnegative integers.

TESTS:

```
sage: from sage.combinat.words.alphabet import OrderedAlphabet_Infinite
sage: OrderedAlphabet_Infinite().list()
...
NotImplementedError
```

class OrderedAlphabet_NaturalNumbers()

The alphabet of nonnegative integers, ordered in the usual way.

TESTS:

```
sage: from sage.combinat.words.alphabet import OrderedAlphabet_NaturalNumbers
sage: NN = OrderedAlphabet_NaturalNumbers()
sage: NN == loads(dumps(NN))
True
```

next(*n*)

Returns the letter following n in the alphabet self.

INPUT:

- n - nonnegative integer

OUTPUT: n+1

EXAMPLES:

```
sage: from sage.combinat.words.alphabet import OrderedAlphabet_NaturalNumbers
sage: NN = OrderedAlphabet_NaturalNumbers()
sage: NN.next(0)
1
sage: NN.next(117)
118
sage: NN.next(-1)
...
ValueError: letter(=-1) not in the alphabet
```

rank(*letter*)

Returns the index of letter in self.

INPUT:

- `letter` - a letter contained in this alphabet

OUTPUT:

- `integer` - the integer mapping for the letter

EXAMPLES:

```
sage: from sage.combinat.words.alphabet import OrderedAlphabet_NaturalNumbers
sage: NN = OrderedAlphabet_NaturalNumbers()
sage: NN.rank(0)
0
sage: NN.rank(17)
17
```

TESTS:

```
sage: NN.rank(-1)
...
ValueError: letter(=-1) not in the alphabet
sage: NN.rank("a")
...
ValueError: letter(=a) not in the alphabet
```

string_rep()

Returns the string representation of the alphabet.

TESTS:

```
sage: from sage.combinat.words.alphabet import OrderedAlphabet_NaturalNumbers
sage: OrderedAlphabet_NaturalNumbers().string_rep()
'Natural Numbers'
```

unrank(*n*)

Returns the letter in position n in self, which in this case is n.

INPUT:

- n - nonnegative integer

OUTPUT:

- n - nonnegative integer

EXAMPLES:

```
sage: from sage.combinat.words.alphabet import OrderedAlphabet_NaturalNumbers
sage: NN = OrderedAlphabet_NaturalNumbers()
sage: NN.unrank(0)
0
sage: NN.unrank(17)
17
```

TESTS:

```
sage: NN.unrank(-1)
...
ValueError: -1 is not a nonnegative integer
sage: NN.unrank("a")
...
ValueError: a is not a nonnegative integer
```

class **OrderedAlphabet_PositiveIntegers**()

The alphabet of nonnegative integers, ordered in the usual way.

TESTS:

```
sage: from sage.combinat.words.alphabet import OrderedAlphabet_PositiveIntegers
sage: PP = OrderedAlphabet_PositiveIntegers()
sage: PP == loads(dumps(PP))
True
```

next(*n*)

Returns the letter following n in the alphabet self.

INPUT:

- n - positive integer

OUTPUT: n+1

EXAMPLES:

```
sage: from sage.combinat.words.alphabet import OrderedAlphabet_PositiveIntegers
sage: PP = OrderedAlphabet_PositiveIntegers()
sage: PP.next(1)
2
sage: PP.next(117)
118
sage: PP.next(0)
...
ValueError: letter(=0) not in the alphabet
```

rank(*letter*)

Returns the index of letter in self.

INPUT:

- letter - a positive integer

OUTPUT: letter-1

EXAMPLES:

```
sage: from sage.combinat.words.alphabet import OrderedAlphabet_PositiveIntegers
sage: OrderedAlphabet_PositiveIntegers().rank(1)
0
sage: OrderedAlphabet_PositiveIntegers().rank(8)
7
```

TESTS:

```
sage: OrderedAlphabet_PositiveIntegers().rank(-1)
...
TypeError: -1 not in alphabet
```

string_rep()

Returns the string representation of the alphabet.

TESTS:

```
sage: from sage.combinat.words.alphabet import OrderedAlphabet_PositiveIntegers
sage: OrderedAlphabet_PositiveIntegers().string_rep()
'Positive Integers'
```

unrank(*i*)

Returns the i-th letter in self, where the first letter is the 0-th letter.

INPUT:

- i - an integer

OUTPUT: i+1

EXAMPLES:

```
sage: from sage.combinat.words.alphabet import OrderedAlphabet_PositiveIntegers
sage: OrderedAlphabet_PositiveIntegers().unrank(0)
1
sage: OrderedAlphabet_PositiveIntegers().unrank(7)
8
```

class OrderedAlphabet_class()
Generic class for ordered alphabets.

17.40.2 Shuffle products

class ShuffleProduct_overlapping(*w1, w2*)

class ShuffleProduct_overlapping_r(*w1, w2, r*)

class ShuffleProduct_shifted(*w1, w2*)

class ShuffleProduct_w1w2(*w1, w2*)

cardinality()
Returns the number of words in the shuffle product of w1 and w2.
It is given by binomial(len(w1)+len(w2), len(w1)).
EXAMPLES:

```
sage: from sage.combinat.words.shuffle_product import ShuffleProduct_w1w2
sage: w, u = map(Words("abcd"), ["ab", "cd"])
sage: S = ShuffleProduct_w1w2(w,u)
sage: S.cardinality()
6
```

17.40.3 Suffix Tries and Suffix Trees

class ImplicitSuffixTree(*word*)

active_state()
Returns the active state of the suffix tree.
EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.active_state()
(0, (6, 6))
```

edge_iterator()
Returns an iterator over the edges of the suffix tree. The edge from u to v labelled by (i,j) is returned as the tuple (u,v,(i,j)).
EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: sorted( ImplicitSuffixTree(Word("aaaaa")).edge_iterator() )
[(0, 1, (0, None))]
sage: sorted( ImplicitSuffixTree(Word([0,1,0,1])).edge_iterator() )
[(0, 1, (0, None)), (0, 2, (1, None))]
sage: sorted( ImplicitSuffixTree(Word()).edge_iterator() )
[]
```

factor_iterator(*n=None*)
Generate distinct factors of self.
INPUT:

- n - an integer, or None.

OUTPUT: If n is an integer, returns an iterator over all distinct factors of length n. If n is None, returns an iterator generating all distinct factors.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: sorted( ImplicitSuffixTree(Word("cacao")).factor_iterator() )
[word: , word: a, word: ac, word: aca, word: acao, word: ao, word: c, word: ca, word: cac, w
sage: sorted( ImplicitSuffixTree(Word("cacao")).factor_iterator(1) )
[word: a, word: c, word: o]
sage: sorted( ImplicitSuffixTree(Word("cacao")).factor_iterator(2) )
[word: ac, word: ao, word: ca]
sage: sorted( ImplicitSuffixTree(Word([0,0,0])).factor_iterator() )
[word: , word: 0, word: 00, word: 000]
sage: sorted( ImplicitSuffixTree(Word([0,0,0])).factor_iterator(2) )
[word: 00]
sage: sorted( ImplicitSuffixTree(Word([0,0,0])).factor_iterator(0) )
[word: ]
sage: sorted( ImplicitSuffixTree(Word()).factor_iterator() )
[word: ]
sage: sorted( ImplicitSuffixTree(Word()).factor_iterator(2) )
[]
```

number_of_factors(*n=None*)

Count the number of distinct factors of self.word().

INPUT:

- n - an integer, or None.

OUTPUT: If n is an integer, returns the number of distinct factors of length n. If n is None, returns the total number of distinct factors.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: t = ImplicitSuffixTree(Word([1,2,1,3,1,2,1]))
sage: t.number_of_factors()
22
sage: t.number_of_factors(1)
3
sage: t.number_of_factors(9)
0
sage: t.number_of_factors(0)
1

sage: t = ImplicitSuffixTree(Word("cacao"))
sage: t.number_of_factors()
13
sage: map(t.number_of_factors, range(10))
[1, 3, 3, 3, 2, 1, 0, 0, 0, 0]

sage: t = ImplicitSuffixTree(Word("c"*1000))
sage: t.number_of_factors()
1001
sage: t.number_of_factors(17)
1
sage: t.number_of_factors(0)
1

sage: ImplicitSuffixTree(Word()).number_of_factors()
1
```

```
sage: blueberry = ImplicitSuffixTree(Word("blueberry"))
sage: blueberry.number_of_factors()
43
sage: map(blueberry.number_of_factors, range(10))
[1, 6, 8, 7, 6, 5, 4, 3, 2, 1]
```

plot(*word_labels=False, layout='tree', tree_root=0, tree_orientation='up', vertex_colors=None, edge_labels=True, *args, **kwds*)

Returns a Graphics object corresponding to the transition graph of the suffix tree.

INPUT:

- `word_labels` - if False, labels the edges by pairs (i, j); if True, labels the edges by word[i:j].

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: ImplicitSuffixTree(Word('cacao')).plot(word_labels=True)
sage: ImplicitSuffixTree(Word('cacao')).plot(word_labels=False)
```

TESTS:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: type(ImplicitSuffixTree(Word('cacao')).plot(word_labels=True))
<class 'sage.plot.plot.Graphics'>
sage: type(ImplicitSuffixTree(Word('cacao')).plot(word_labels=False))
<class 'sage.plot.plot.Graphics'>
```

process_letter(*letter*)

Modifies the current implicit suffix tree producing the implicit suffix tree for self.word() + letter.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: w = Words("aco")("cacao")
sage: t = ImplicitSuffixTree(w[:-1]); t
Implicit Suffix Tree of the word: caca
sage: t.process_letter(w[-1]); t
Implicit Suffix Tree of the word: cacao

sage: W = Words([0,1])
sage: s = ImplicitSuffixTree(W([0,1,0,1])); s
Implicit Suffix Tree of the word: 0101
sage: s.process_letter(W([1])[0]); s
Implicit Suffix Tree of the word: 01011
```

show(*word_labels=None, *args, **kwds*)

Displays the output of self.plot().

INPUT:

- `word_labels` - if False, labels the edges by pairs (i, j); if True, labels the edges by word[i:j].

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: w = Words("cao")("cacao")
sage: t = ImplicitSuffixTree(w)
sage: t.show(word_labels=True)
sage: t.show(word_labels=False)
```

states()

Returns the states (explicit nodes) of the suffix tree.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.states()
[0, 1, 2, 3, 4, 5, 6, 7]
```

suffix_link(*state*)

Evaluates the suffix link map of the implicit suffix tree on state. Note that the suffix link is not defined for all states.

The suffix link of a state x' that corresponds to the suffix x is defined to be -1 is x' is the root (0) and y' otherwise, where y' is the state corresponding to the suffix x[1:].

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.suffix_link(3)
5
sage: t.suffix_link(5)
0
sage: t.suffix_link(0)
-1
sage: t.suffix_link(-1)
Traceback (most recent call last):
    ...
TypeError: there is no suffix link from -1
```

to_digraph(*word_labels=False*)

Returns a DiGraph object of the transition graph of the suffix tree.

word_labels - if False, labels the edges by pairs (i, j); if True, labels the edges by word[i:j].

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.to_digraph()
Digraph on 8 vertices
```

to_explicit_suffix_tree()

Converts self to an explicit suffix tree. It is obtained by processing an end of string letter as if it were a regular letter, except that no new leaf nodes are created (thus, the only thing that happens is that some implicit nodes become explicit).

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: w = Words("aco")("cacao")
sage: t = ImplicitSuffixTree(w[:-1])
sage: t.to_explicit_suffix_tree()

sage: W = Words([0,1])
sage: s = ImplicitSuffixTree(W([0,1,0,1, 1]))
sage: s.to_explicit_suffix_tree()
```

transition_function(*word, node=0*)

Returns the node obtained by starting from node and following the edges labelled by the letters of word. Returns ("explicit", end_node) if we end at end_node, or ("implicit", (edge, d)) if we end d spots along an edge.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words([0,1,2])
sage: t = ImplicitSuffixTree(W([0,1,0,1,2]))
sage: t.transition_function(W([0,1,0]))
('implicit', (3, 1), 1)
sage: t.transition_function(W([0,1,2]))
('explicit', 4)
sage: t.transition_function(W([0,1,2]), 5)
('explicit', 2)
sage: t.transition_function(W([0,1]), 5)
('implicit', (5, 2), 2)
```

transition_function_dictionary()

Returns the transition function as a dictionary of dictionaries. The format is consistent with the input format for DiGraph.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: W = Words("aco")
sage: t = ImplicitSuffixTree(W("cac"))
sage: t.transition_function_dictionary()
{0: {1: (0, None), 2: (1, None)}}

sage: W = Words([0,1])
sage: t = ImplicitSuffixTree(W([0,1,0]))
sage: t.transition_function_dictionary()
{0: {1: (0, None), 2: (1, None)}}
```

trie_type_dict()

Returns a dictionary in a format compatible with that of the suffix trie transition function.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree, SuffixTrie
sage: W = Words("ab")
sage: t = ImplicitSuffixTree(W("aba"))
sage: t.trie_type_dict() == dict([[(0, W("a")), 4], [(0, W("b")), 3], [(3, W("a")), 2], [(4,
True
```

uncompactify()

Returns the tree obtained from self by splitting edges so that they are labelled by exactly one letter. The resulting tree is isomorphic to the suffix trie.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree, SuffixTrie
sage: abbab = Words("ab")("abbab")
sage: s = SuffixTrie(abbab)
sage: t = ImplicitSuffixTree(abbab)
sage: t.uncompactify().is_isomorphic(s.to_digraph())
True
```

word()

Returns the word whose implicit suffix tree this is.

TEST:

```
sage: from sage.combinat.words.suffix_trees import ImplicitSuffixTree
sage: ImplicitSuffixTree(Word([0,1,0,1,0])).word() == Word([0,1,0,1,0])
True
```

NaiveSuffixTree(*word*)

Given a word, constructs the suffix tree of the word using a naive algorithm. Useful for testing.

INPUT:

- `word` - any word

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import NaiveSuffixTree
sage: W = Words('abco')
sage: s = NaiveSuffixTree(W("abacabaabaca")); s
Suffix Tree of the word: abacabaabaca

sage: s = NaiveSuffixTree(W("cacao")); s
Suffix Tree of the word: cacao
sage: s.edges()
[(0, 3, word: ca), (0, 5, word: a), (0, 7, word: o), (3, 1, word: cao), (3, 4, word: o), (5, 2,

sage: W = Words([0,1])
sage: s = NaiveSuffixTree(W([0,1,0,1,1])); s
Suffix Tree of the word: 01011
sage: s.edges()
[(0, 3, word: 01), (0, 5, word: 1), (3, 1, word: 011), (3, 4, word: 1), (5, 2, word: 011), (5, 6
```

class **NaiveSuffixTreeClass**(*data=None, pos=None, loops=None, format=None, boundary=, [], weighted=None, implementation='networkx', sparse=True, vertex_labels=True, **kwds*)

naive_process_suffix(*suffix*)

Helper function for constructing the suffix tree.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import NaiveSuffixTreeClass
sage: W = Words([0,1,2])
sage: NST = NaiveSuffixTreeClass({0:[]})
sage: NST.set_vertex(0,{'position':0,'suffix':True})
sage: NST.naive_process_suffix(W([0,1,1,2,0])); NST
Suffix Tree of the word: 01120
```

node_to_word(*node*)

Returns the word obtained by reading the edge labels from the root to node.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import NaiveSuffixTree
sage: NaiveSuffixTree(Word("abacabaabaca")).node_to_word(17)
word: ca
sage: NaiveSuffixTree(Word("cacao")).node_to_word(0)
word:
sage: NaiveSuffixTree(Word([0,1,1,0,1,0,0,1])).node_to_word(10)
word: 001
```

plot(*layout='tree', tree_root=0, tree_orientation='up', vertex_colors=None, edge_labels=True, *args, **kwds*)

Returns a Graphics object associated to self.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import NaiveSuffixTree
sage: NaiveSuffixTree(Word("abacabaabaca")).plot()
```

TESTS:

```
sage: from sage.combinat.words.suffix_trees import NaiveSuffixTree
sage: type(NaiveSuffixTree(Word("abacabaabaca")).plot())
<class 'sage.plot.plot.Graphics'>
```

word()

Returns the word whose suffix tree this is.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import NaiveSuffixTree
sage: NaiveSuffixTree(Word("abcba")).word()
word: abcba
```

word_to_node(*node, word*)

Returns the node obtained by starting from node and following the edges labelled by the letters of word. Returns ("node", node2, word2) if we end at node2, or ("implicit", edge, word2) if we end in the middle of an edge (called an implicit node), where word2 is the suffix of word that does not match any more edge labels.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import NaiveSuffixTree
sage: W = Words("abc")
sage: NST = NaiveSuffixTree(W("abacabaabaca"))
sage: NST.word_to_node(0, W("ca"))
('node', 17, word: )
sage: NST.word_to_node(0, W("cab"))
('implicit', ((17, 5, word: baabaca), 1), word: )
sage: NST.word_to_node(17, W("b"))
('implicit', ((17, 5, word: baabaca), 1), word: )
sage: NST.word_to_node(15, W("baabacabca"))
('node', 4, word: bca)
```

class **SuffixTrie**(*word*)

active_state()

Returns the active state of the suffix trie. This is the state corresponding to the word as a suffix of itself.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w)
sage: t.active_state()
8

sage: u = Words([0,1])([0,1,1,0,1,0,0,1])
sage: s = SuffixTrie(u)
sage: s.active_state()
22
```

final_states()

Returns the set of final states of the suffix trie. These are the states corresponding to the suffixes of self.word(). They are obtained be repeatedly following the suffix link from the active state until we reach 0.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w)
```

```
sage: t.final_states() == Set([8, 9, 10, 11, 12, 0])
True
```

has_suffix(*word*)

Return True if and only if word is a suffix of self.word().

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w)
sage: [t.has_suffix(w[i:]) for i in range(len(w)+1)]
[True, True, True, True, True, True]
sage: [t.has_suffix(w[:i]) for i in range(len(w)+1)]
[True, False, False, False, False, True]
```

node_to_word(*state=0*)

Returns the word obtained by reading the edge labels from 0 to state.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("abc")("abcba")
sage: t = SuffixTrie(w)
sage: t.node_to_word(10)
word: abcba
sage: t.node_to_word(7)
word: abcb
```

plot(*layout='tree', tree_root=0, tree_orientation='up', vertex_colors=None, edge_labels=True, *args, **kwds*)

Returns a Graphics object corresponding to the transition graph of the suffix trie.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: SuffixTrie(Word("cacao")).plot()
```

TESTS:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: type(SuffixTrie(Word("cacao")).plot())
<class 'sage.plot.plot.Graphics'>
```

process_letter(*letter*)

Modify self to produce the suffix trie for self.word() + letter.

NOTE: letter must occur within the alphabet of the word.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("ab")("ababba")
sage: t = SuffixTrie(w); t
Suffix Trie of the word: ababba
sage: t.process_letter("a"); t
Suffix Trie of the word: ababbaa
```

TESTS:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w); t
Suffix Trie of the word: cacao
sage: t.process_letter("d")
Traceback (most recent call last):
```

```
    ...
IndexError: letter not in alphabet: 'd'
```

show(**args, **kwds*)

Displays the output of self.plot().

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cac")
sage: t = SuffixTrie(w)
sage: t.show()
```

states()

Returns the states of the automaton defined by the suffix trie.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words([0,1])([0,1,1])
sage: t = SuffixTrie(w)
sage: t.states()
[0, 1, 2, 3, 4]

sage: u = Words("aco")("cacao")
sage: s = SuffixTrie(u)
sage: s.states()
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11]
```

suffix_link(*state*)

Evaluates the suffix link map of the suffix trie on state. Note that the suffix link map is not defined on -1.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w)
sage: map(t.suffix_link, range(13))
[-1, 0, 3, 0, 5, 1, 7, 2, 9, 10, 11, 12, 0]
sage: t.suffix_link(0)
-1
```

TESTS:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cacao")
sage: t = SuffixTrie(w)
sage: t.suffix_link([1])
Traceback (most recent call last):
    ...
TypeError: [1] is not an integer
sage: t.suffix_link(-1)
Traceback (most recent call last):
    ...
TypeError: suffix link is not defined for -1
sage: t.suffix_link(17)
Traceback (most recent call last):
    ...
TypeError: 17 is not a state
```

to_digraph()

Returns a DiGraph object of the transition graph of the suffix trie.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("cao")("cac")
sage: t = SuffixTrie(w)
sage: d = t.to_digraph(); d
Digraph on 6 vertices
sage: d.adjacency_matrix()
[0 1 0 1 0 0]
[0 0 1 0 0 0]
[0 0 0 0 1 0]
[0 0 0 0 0 1]
[0 0 0 0 0 0]
[0 0 0 0 0 0]
```

transition_function(*node, word*)

Returns the state reached by beginning at node and following the arrows in the transition graph labelled by the letters of word.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words([0,1])([0,1,0,1,1])
sage: t = SuffixTrie(w)
sage: [t.transition_function(u,letter) == v \
        for ((u,letter),v) in t._transition_function.iteritems()] \
        == [True] * len(t._transition_function)
True
```

word()

Returns the word whose suffix tree this is.

EXAMPLES:

```
sage: from sage.combinat.words.suffix_trees import SuffixTrie
sage: w = Words("abc")("abcba")
sage: t = SuffixTrie(w)
sage: t.word()
word: abcba
sage: t.word() == w
True
```

17.40.4 Word morphisms

class WordMorphism(*data, codomain=None*)

TESTS:

```
sage: wm = WordMorphism('a->ab,b->ba')
sage: wm == loads(dumps(wm))
True
```

codomain()

Returns the domain of the images.

EXAMPLES

```
sage: WordMorphism('a->ab,b->a').codomain()
Words over Ordered Alphabet ['a', 'b']
sage: WordMorphism('6->ab,y->5,0->asd').codomain()
Words over Ordered Alphabet ['5', 'a', 'b', 'd', 's']
```

conjugate(*pos*)

Returns the morphism where each image of self is conjugate of parameter pos.

Retourne le morphisme dont toutes les images ont etes conjuguees de pos.

EXAMPLES

```
sage: m = WordMorphism('a->abcde')
sage: m.conjugate(0) == m
True
sage: print m.conjugate(1)
WordMorphism: a->bcdea
sage: print m.conjugate(3)
WordMorphism: a->deabc
sage: print WordMorphism('').conjugate(4)
WordMorphism:
sage: m = WordMorphism('a->abcde,b->xyz')
sage: print m.conjugate(2)
WordMorphism: a->cdeab, b->zxy
```

domain()

Returns domain of self.

EXAMPLES:

```
sage: WordMorphism('a->ab,b->a').domain()
Words over Ordered Alphabet ['a', 'b']
sage: WordMorphism('b->ba,a->ab').domain()
Words over Ordered Alphabet ['a', 'b']
sage: WordMorphism('6->ab,y->5,0->asd').domain()
Words over Ordered Alphabet ['0', '6', 'y']
```

fixed_point(*letter*)

Returns the fixed point of self beginning by the given letter.

A fixed point of morphism φ is a word w such that $\varphi(w) = w$.

INPUT:

- `self` - an endomorphism, must be prolongable on letter
- `letter` - in the domain of self, the first letter of the fixed point.

OUTPUT:

- `word` - the fixed point of self beginning with letter.

EXAMPLES:

1. Infinite fixed point:

```
sage: WordMorphism('a->ab,b->ba').fixed_point(letter='a')
Fixed point beginning with 'a' of the morphism WordMorphism: a->ab, b->ba
sage: WordMorphism('a->ab,b->a').fixed_point(letter='a')
Fixed point beginning with 'a' of the morphism WordMorphism: a->ab, b->a
sage: WordMorphism('a->ab,b->b,c->ba').fixed_point(letter='a')
Fixed point beginning with 'a' of the morphism WordMorphism: a->ab, b->b, c->ba
```

2. Infinite fixed point of an erasing morphism:

```
sage: WordMorphism('a->ab,b->,c->ba').fixed_point(letter='a')
Fixed point beginning with 'a' of the morphism WordMorphism: a->ab, b->, c->ba
```

3. Finite fixed point:

```
sage: WordMorphism('a->ab,b->b,c->ba').fixed_point(letter='b')
word: b
```

4. Finite fixed point of an erasing morphism:

```
sage: m = WordMorphism('a->abc,b->,c->')
sage: fp = m.fixed_point('a'); fp
Fixed point beginning with 'a' of the morphism WordMorphism: a->abc, b->, c->
sage: fp[:10]
word: abc
sage: m = WordMorphism('a->ba,b->')
sage: m('ba')
word: ba
sage: m.fixed_point('a') #todo: not implemented
word: ba
```

5. Fixed point of a power of a morphism:

```
sage: m = WordMorphism('a->ba,b->ab')
sage: (m^2).fixed_point(letter='a')
Fixed point beginning with 'a' of the morphism WordMorphism: a->abba, b->baab
```

TESTS:

```
sage: WordMorphism('a->ab,b->,c->ba').fixed_point(letter='b')
...
TypeError: self must be prolongable on b
sage: WordMorphism('a->ab,b->,c->ba').fixed_point(letter='c')
...
TypeError: self must be prolongable on c
sage: WordMorphism('a->ab,b->,c->ba').fixed_point(letter='d')
...
TypeError: letter (=d) is not in the domain alphabet (=Ordered Alphabet ['a', 'b', 'c'])
sage: WordMorphism('a->aa,b->aac').fixed_point(letter='a')
...
TypeError: self (=WordMorphism: a->aa, b->aac) is not a endomorphism
```

has_conjugate_in_classP (*f=None*)

Returns True if self has a conjugate in class f-P.

DEFINITION: Let Σ be an alphabet and f be an involution on Σ. "We say that a morphism φ is in class f-P if there exists an f-palindrome $p \in$ f - Pal(Σ^*) and for each $\alpha \in \Sigma$ there exists an f-palindrome $q_\alpha \in$ f - Pal(Σ^*) such that $\varphi(\alpha) = pq_\alpha$." [2]

We say that a morphism φ' est de classe $f - P'$ if there exists a morphism φ conjugate of φ' such that φ is in class f-P. [2]

INPUT:

- `f` - involution (default: None) on the alphabet of self. It must be something that WordMorphism's contructor understand (dict, str, ...).

OUTPUT:

- `boolean` - True if f is None and if self has a conjugate in class P; True otherwise and if self has a conjugate in class f-P; False otherwise.

REFERENCES:

- [1] Hof, A., O. Knill et B. Simon, Singular continuous spectrum for palindromic Schrödinger operators, Commun. Math. Phys. 174 (1995) 149-159.
- [2] Labbé, Sébastien. Propriétés combinatoires des f-palindromes, Mémoire de maîtrise en Mathématiques, Montréal, UQAM, 2008, 109 pages.

EXAMPLES:

```
sage: fibo = WordMorphism('a->ab,b->a')
sage: fibo.has_conjugate_in_classP()
True
```

```
sage: (fibo^2).is_in_classP()
False
sage: (fibo^2).has_conjugate_in_classP()
True
```

has_left_conjugate()

Returns true if all the non empty images of self begins with the same letter.

Retourne vrai si toutes les images non vides commencent par la meme lettre.

EXAMPLES:

```
sage: m = WordMorphism('a->abcde,b->xyz')
sage: m.has_left_conjugate()
False
sage: WordMorphism('b->xyz').has_left_conjugate()
True
sage: WordMorphism('').has_left_conjugate()
True
sage: WordMorphism('a->,b->xyz').has_left_conjugate()
True
sage: WordMorphism('a->abbab,b->abb').has_left_conjugate()
True
sage: WordMorphism('a->abbab,b->abb,c->').has_left_conjugate()
True
```

has_right_conjugate()

Returns true if all the non empty images of self ends with the same letter.

Retourne vrai si toutes les images non vide terminent par la meme lettre.

EXAMPLES:

```
sage: m = WordMorphism('a->abcde,b->xyz')
sage: m.has_right_conjugate()
False
sage: WordMorphism('b->xyz').has_right_conjugate()
True
sage: WordMorphism('').has_right_conjugate()
True
sage: WordMorphism('a->,b->xyz').has_right_conjugate()
True
sage: WordMorphism('a->abbab,b->abb').has_right_conjugate()
True
sage: WordMorphism('a->abbab,b->abb,c->').has_right_conjugate()
True
```

images()

Returns the list of all the images of the letters of the alphabet under self.

EXAMPLES

```
sage: WordMorphism('a->ab,b->a').images()
[word: ab, word: a]
sage: WordMorphism('6->ab,y->5,0->asd').images()
[word: 5, word: asd, word: ab]
```

incidence_matrix()

Returns the incidence matrix of the morphism. The order of the rows and column are given by the order defined on the alphabet of the domain and the codomain.

The matrix returned is over the integers. If a different ring is desired, use either the change_ring function or the matrix function.

EXAMPLES:

```
sage: m = WordMorphism('a->abc,b->a,c->c')
sage: m.incidence_matrix()
[1 1 0]
[1 0 0]
[1 0 1]
sage: m = WordMorphism('a->abc,b->a,c->c,d->abbccccabca,e->abc')
sage: m.incidence_matrix()
[1 1 0 3 1]
[1 0 0 3 1]
[1 0 1 5 1]
```

is_empty()

Returns True if the cardinality of the domain is zero and False otherwise.

EXAMPLES:

```
sage: WordMorphism('').is_empty()
True
sage: WordMorphism('a->a').is_empty()
False
```

is_endomorphism()

Returns True if the codomain is a subset of the domain.

EXAMPLES

```
sage: WordMorphism('a->ab,b->a').is_endomorphism()
True
sage: WordMorphism('6->ab,y->5,0->asd').is_endomorphism()
False
sage: WordMorphism('a->a,b->aa,c->aaa').is_endomorphism()
True
sage: Wabc = Words('abc')
sage: m = WordMorphism('a->a,b->aa,c->aaa',codomain = Wabc)
sage: m.is_endomorphism()
True
```

is_erasing()

Returns True if self is an erasing morphism, i.e. the image of a letter is the empty word.

EXAMPLES

```
sage: WordMorphism('a->ab,b->a').is_erasing()
False
sage: WordMorphism('6->ab,y->5,0->asd').is_erasing()
False
sage: WordMorphism('6->ab,y->5,0->asd,7->').is_erasing()
True
sage: WordMorphism('').is_erasing()
False
```

is_identity()

Returns True if self is the identity morphism.

EXAMPLES:

```
sage: m = WordMorphism('a->a,b->b,c->c,d->e')
sage: m.is_identity()
False
sage: WordMorphism('a->a,b->b,c->c').is_identity()
True
sage: WordMorphism('a->a,b->b,c->cb').is_identity()
False
```

```
sage: m = WordMorphism('a->b,b->c,c->a')
sage: (m^2).is_identity()
False
sage: (m^3).is_identity()
True
sage: (m^4).is_identity()
False
sage: WordMorphism('').is_identity()
True
sage: WordMorphism({0:[0],1:[1]}).is_identity()
True
```

is_in_classP (*f=None*)

Returns True if self is in class P (or f-P).

DEFINITION: "[Let A be an alphabet] We say that a primitive substitution S is in the *class P* if there exists a palindrome p and for each $b \in A$ a palindrome q_b such that $S(b) = pq_b$ for all $b \in A$." [1]

Let Σ be an alphabet and f be an involution on Σ. "We say that a morphism φ is in class f-P if there exists an f-palindrome $p \in$ f - Pal(Σ^*) and for each $\alpha \in \Sigma$ there exists an f-palindrome $q_\alpha \in$ f - Pal(Σ^*) such that $\varphi(\alpha) = pq_\alpha$." [2]

INPUT:

- `f` - involution (default: None) on the alphabet of self. It must be something that WordMorphism's contructor understand (dict, str, ...).

OUTPUT:

- `boolean` - True if f is None and if self is in class P; True otherwise and if self is in class f-P; False otherwise.

REFERENCES:

- [1] Hof, A., O. Knill et B. Simon, Singular continuous spectrum for palindromic Schrödinger operators, Commun. Math. Phys. 174 (1995) 149-159.
- [2] Labbé, Sébastien. Propriétés combinatoires des f-palindromes, Mémoire de maîtrise en Mathématiques, Montréal, UQAM, 2008, 109 pages.

EXAMPLES:

```
sage: WordMorphism('a->bbaba,b->bba').is_in_classP()
True
sage: tm = WordMorphism('a->ab,b->ba')
sage: tm.is_in_classP()
False
sage: f='a->b,b->a'
sage: tm.is_in_classP(f=f)
True
sage: (tm^2).is_in_classP()
True
sage: (tm^2).is_in_classP(f=f)
False
sage: fibo = WordMorphism('a->ab,b->a')
sage: fibo.is_in_classP()
True
sage: fibo.is_in_classP(f=f)
False
sage: (fibo^2).is_in_classP()
False
sage: f='a->b,b->a,c->c'
sage: WordMorphism('a->acbcc,b->acbab,c->acbba').is_in_classP (f)
True
```

is_involution()

Returns True if self is an involution, i.e. its square is the identity.

EXAMPLES:

```
sage: WordMorphism('a->b,b->a').is_involution()
True
sage: WordMorphism('').is_involution()
True
sage: WordMorphism({0:[1],1:[0]}).is_involution()
True
```

is_primitive()

Returns True if self is primitive.

INPUT:

- `self` - an endomorphism

-In English: A morphism φ is *primitive* if there exists an positive integer k such that for all $\alpha \in \Sigma$, $\varphi^k(\alpha)$ contains all the letters of Σ.

-En français: Un morphisme φ est *primitif* s'il existe un nombre naturel k tel que pour tout $\alpha \in \Sigma$, $\varphi^k(\alpha)$ contient toutes les lettres de Σ.

EXAMPLES:

```
sage: tm = WordMorphism('a->ab,b->ba')
sage: tm.is_primitive()
True
sage: fibo = WordMorphism('a->ab,b->a');
sage: fibo.is_primitive()
True
sage: m = WordMorphism('a->bb,b->aa')
sage: m.is_primitive()
False
sage: f = WordMorphism({0:[1],1:[0]})
sage: f.is_primitive()
False
sage: m = WordMorphism('a->bb,b->aac')
sage: m.is_primitive()
...
TypeError: self (=WordMorphism: a->bb, b->aac) is not a endomorphism
sage: m = WordMorphism('a->,b->',codomain=Words('ab'))
sage: m.is_primitive()
False
sage: m = WordMorphism('a->,b->')
sage: m.is_primitive()
False
```

is_prolongable(*letter*)

Returns True if self is prolongable on letter.

A morphism φ is prolongable on a letter a if a is a prefix of $\varphi(a)$.

INPUT:

- `self` - the codomain must be an instance of Words
- `letter` - in the domain alphabet

OUTPUT:

- `boolean` - if self is prolongable on letter.

EXAMPLES:

```
sage: WordMorphism('a->ab,b->a').is_prolongable(letter='a')
True
sage: WordMorphism('a->ab,b->a').is_prolongable(letter='b')
False
sage: WordMorphism('a->ba,b->ab').is_prolongable(letter='b')
False
sage: (WordMorphism('a->ba,b->ab')^2).is_prolongable(letter='b')
True
sage: WordMorphism('a->ba,b->').is_prolongable(letter='b')
False
sage: WordMorphism('a->bb,b->aac').is_prolongable(letter='a')
False
```

TESTS:

```
sage: WordMorphism('a->ab,b->b,c->ba').is_prolongable(letter='d')
...
TypeError: letter (=d) is not in the domain alphabet (=Ordered Alphabet ['a', 'b', 'c'])
sage: n0, n1 = matrix(2,[1,1,1,0]), matrix(2,[2,1,1,0])
sage: n = {'a':n0, 'b':n1}
sage: WordMorphism(n).is_prolongable(letter='a') #todo: not implemented
...
TypeError: codomain of self must be an instance of Words
```

letter_iterator(*letter*)

Returns an iterator of the letters of the fixed point of self starting with letter.

If w is the word, then this iterator: outputs the elements of morphism[w[i]], appends morphism[w[i+1]] to w, increments i.

INPUT:

- `self` - an endomorphism, must be prolongable on letter
- `letter` - in the domain of self

OUTPUT:

- `iterator` - iterator of the fixed point

EXAMPLES:

```
sage: m = WordMorphism('a->abc,b->,c->')
sage: list(m.letter_iterator('b'))
...
TypeError: self must be prolongable on b
sage: list(m.letter_iterator('a'))
['a', 'b', 'c']
sage: m = WordMorphism('a->aa,b->aac')
sage: list(m.letter_iterator('a'))
...
TypeError: self (=WordMorphism: a->aa, b->aac) is not a endomorphism
```

list_fixed_points()

Returns the list of all fixed points of self.

EXAMPLES

```
sage: WordMorphism('a->ab,b->ba').list_fixed_points() #not implemented
[Fixed point beginning with 'a' of the morphism WordMorphism: a->ab, b->ba,
Fixed point beginning with 'b' of the morphism WordMorphism: a->ab, b->ba]
```

list_of_conjugates()

Retourne une liste des morphismes conjugues du receveur obtenus en conjuguant les prefixes (et suffixes) communs de chacune des images.

Returns the list of all the conjugate morphisms of self obtain by taking the conjugate of the common prefixes and suffixes of all the images.

DEFINITION (from [1]): Recall from Lothaire [2] (Section 2.3.4) that φ is *right conjugate* of φ', noted $\varphi \triangleleft \varphi'$, if there exists $u \in \Sigma^*$ such that

$$\varphi(\alpha)u = u\varphi'(\alpha), \quad \text{for all } \alpha \in \Sigma$$

, or equivalently that $\varphi(x)u = u\varphi'(x)$, for all words $x \in \Sigma^*$. Clearly, this relation is not symmetric so that we say that two morphisms φ and φ' are *conjugate*, noted $\varphi \bowtie \varphi'$, if $\varphi \triangleleft \varphi'$ or $\varphi' \triangleleft \varphi$. It is easy to see that conjugacy of morphisms is an equivalence relation.

REFERENCES:

- [2] M. Lothaire, Algebraic Combinatorics on words, Cambridge University Press, 2002.

EXAMPLES:

```
sage: m = WordMorphism('a->abbab,b->abb')
sage: map(str, m.list_of_conjugates())
['WordMorphism: a->babba, b->bab',
'WordMorphism: a->abbab, b->abb',
'WordMorphism: a->bbaba, b->bba',
'WordMorphism: a->babab, b->bab',
'WordMorphism: a->ababb, b->abb',
'WordMorphism: a->babba, b->bba',
'WordMorphism: a->abbab, b->bab']
sage: m = WordMorphism('a->aaa,b->aa')
sage: map(str, m.list_of_conjugates())
['WordMorphism: a->aaa, b->aa']
sage: WordMorphism('').list_of_conjugates()
[Morphism from Words over Ordered Alphabet [] to Words over Ordered Alphabet []]
sage: m = WordMorphism('a->aba,b->aba')
sage: map(str, m.list_of_conjugates())
['WordMorphism: a->baa, b->baa',
'WordMorphism: a->aab, b->aab',
'WordMorphism: a->aba, b->aba']
sage: m = WordMorphism('a->abb,b->abbab,c->')
sage: map(str, m.list_of_conjugates())
['WordMorphism: a->bab, b->babba, c->',
'WordMorphism: a->abb, b->abbab, c->',
'WordMorphism: a->bba, b->bbaba, c->',
'WordMorphism: a->bab, b->babab, c->',
'WordMorphism: a->abb, b->ababb, c->',
'WordMorphism: a->bba, b->babba, c->',
'WordMorphism: a->bab, b->abbab, c->']
```

reversal()

Returns the reversal of self.

EXAMPLES

```
sage: print WordMorphism('6->ab,y->5,0->asd').reversal()
WordMorphism: 0->dsa, 6->ba, y->5
sage: print WordMorphism('a->ab,b->a').reversal()
WordMorphism: a->ba, b->a
```

17.40.5 Words of all kinds

AUTHORS:

- Arnaud Bergeron
- Amy Glen
- Sébastien Labbé
- Franco Saliola

EXAMPLES:

We define the set of words over 'a' and 'b'.

```
sage: W = Words('ab'); W
Words over Ordered Alphabet ['a', 'b']
```

Then we can build some words in the set:

```
sage: W('abba')
word: abba
```

If you try to use letters that are not the alphabet of the set you get an error:

```
sage: W([1, 2])
...
IndexError: letter not in alphabet: 1
```

You can also build infinite words backed by a function or an iterator!

```
sage: def f(n):
...       if n % 2 == 1:
...           return 'a'
...       else:
...           return 'b'
...
sage: W(f)
Infinite word over ['a', 'b']
```

class AbstractFiniteWord(*parent, word, mapping=None, format=None, part=slice(None, None, None)*)

class AbstractInfiniteWord(*parent, word, mapping=None, format=None, part=slice(None, None, None)*)

class AbstractWord(*parent, word, mapping=None, format=None, part=slice(None, None, None)*)

coerce(*other*)

Returns a pair of words with a common parent or raises an exception.

This function begins by checking if both words have the same parent. If this is the case, then no work is done and both words are returned as-is.

Otherwise it will attempt to convert other to the domain of self. If that fails, it will attempt to convert self to the domain of other. If both attempts fail, it raises a TypeError to signal failure.

EXAMPLES:

```
sage: W1 = Words('abc'); W2 = Words('ab')
sage: w1 = W1('abc'); w2 = W2('abba'); w3 = W1('baab')
sage: w1.parent() is w2.parent()
False
sage: a, b = w1.coerce(w2)
sage: a.parent() is b.parent()
True
```

parent()

Returns the parent object from which the word was created.

EXAMPLES:

```
sage: from sage.combinat.words.word import AbstractWord
sage: W = Words('ab')
sage: w = AbstractWord(W, '')
sage: w.parent()
Words over Ordered Alphabet ['a', 'b']
sage: w.parent() is W
True
```

size_of_alphabet()

Returns the size of the alphabet of the word.

TESTS:

```
sage: from sage.combinat.words.word import AbstractWord
sage: AbstractWord(Words('ab'), '').size_of_alphabet()
2
sage: AbstractWord(Words('abc'), '').size_of_alphabet()
3
```

class **FiniteWord_over_Alphabet**(*parent, *args, **kwds*)

class **FiniteWord_over_OrderedAlphabet**(*parent, *args, **kwds*)

BWT()

Returns the Burrows-Wheeler Transform (BWT) of self.

The *Burrows-Wheeler transform* of a finite word w is obtained from w by first listing the conjugates of w in lexicographic order and then concatenating the final letters of the conjugates in this order. See [1].

EXAMPLES:

```
sage: W = Words('abc')
sage: W('abaccaaba').BWT()
word: cbaabaaca
sage: W('abaab').BWT()
word: bbaaa
sage: W('bbabbaca').BWT()
word: cbbbbaaa
sage: W('aabaab').BWT()
word: bbaaaa
sage: Word().BWT()
word:
sage: W('a').BWT()
word: a
```

REFERENCES:

- [1] M. Burrows, D.J. Wheeler, "A block-sorting lossless data compression algorithm", HP Lab Technical Report, 1994, available at http://www.hpl.hp.com/techreports/Compaq-DEC/SRC-RR-124.html

apply_morphism(*morphism*)

Returns the word obtained by applying the morphism to self.

INPUT:

- `morphism` - Can be an instance of WordMorphism, or anything that can be used to construct one.

EXAMPLES:

```
sage: w = Word("ab")
sage: d = {'a':'ab', 'b':'ba'}
```

```
sage: w.apply_morphism(d)
word: abba
sage: w.apply_morphism(WordMorphism(d))
word: abba
```

apply_permutation_to_letters(*permutation*)

Return the word obtained by applying permutation to the letters of the alphabet of self.

EXAMPLES:

```
sage: w = Words('abcd')('abcd')
sage: p = [2,1,4,3]
sage: w.apply_permutation_to_letters(p)
word: badc
sage: u = Words('dabc')('abcd')
sage: u.apply_permutation_to_letters(p)
word: dcba
sage: w.apply_permutation_to_letters(Permutation(p))
word: badc
sage: w.apply_permutation_to_letters(PermutationGroupElement(p))
word: badc
```

apply_permutation_to_positions(*permutation*)

Return the word obtained by permuting the positions of the letters in self.

EXAMPLES:

```
sage: w = Words('abcd')('abcd')
sage: w.apply_permutation_to_positions([2,1,4,3])
word: badc
sage: u = Words('dabc')('abcd')
sage: u.apply_permutation_to_positions([2,1,4,3])
word: badc
sage: w.apply_permutation_to_positions(Permutation([2,1,4,3]))
word: badc
sage: w.apply_permutation_to_positions(PermutationGroupElement([2,1,4,3]))
word: badc
```

border()

Returns the longest word that is both a proper prefix and a proper suffix of self.

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('121212').border()
word: 1212
sage: W('12321').border()
word: 1
sage: W().border() is None
True
```

charge(*check=True*)

EXAMPLES:

```
sage: Word([1,1,2,2,3]).charge()
0
sage: Word([3,1,1,2,2]).charge()
1
sage: Word([2,1,1,2,3]).charge()
1
sage: Word([2,1,1,3,2]).charge()
2
```

```
sage: Word([3,2,1,1,2]).charge()
2
sage: Word([2,2,1,1,3]).charge()
3
sage: Word([3,2,2,1,1]).charge()
4
```

TESTS:

```
sage: Word([3,3,2,1,1]).charge()
...
ValueError: the evaluation of the word must be a partition
```

colored_vector(*x=0, y=0, width='default', height=1, cmap='hsv', thickness=1*)

Returns a vector (Graphics object) illustrating self. Each letter is represented by a colored rectangle. There is a unique color for each letter of the alphabet.

INPUT:

- `x` - (default: 0) bottom left x-coordinate of the vector
- `y` - (default: 0) bottom left y-coordinate of the vector
- `width` - (default: 'default') width of the vector. By default, the width is the length of self.
- `height` - (default: 1) height of the vector
- `thickness` - (default: 1) thickness of the contour
- `cmap` - (default: 'hsv') color map

OUTPUT: Graphics

EXAMPLES:

```
sage: Word(range(20)).colored_vector()

sage: Word(range(100)).colored_vector(0,0,10,1)

sage: Words(range(100))(range(10)).colored_vector()

sage: w = Word('abbabaab')
sage: w.colored_vector()

sage: w.colored_vector(cmap='autumn')
```

TESTS:

```
sage: Word(range(100)).colored_vector(cmap='jolies')
...
RuntimeError: Color map jolies not known
sage: Word(range(100)).colored_vector(cmap='__doc__')
...
RuntimeError: Color map __doc__ not known
```

commutes_with(*other*)

Returns True if self commutes with other, and False otherwise.

EXAMPLES:

```
sage: W = Words('12')
sage: W('12').commutes_with(W('12'))
True
sage: W('12').commutes_with(W('11'))
False
sage: W().commutes_with(W('21'))
True
```

complete_return_words(*fact*)

Returns the set of complete return words of fact in self.

This is the set of all factors starting by the given factor and ending just after the next occurrence of this factor. See for instance [1].

EXAMPLES:

```
sage: W = Words('123')
sage: W('21331233213231').complete_return_words(W('2')) == set([W('213312'), W('2332'), W('2
True
sage: W('').complete_return_words(W('213')) == set()
True
sage: W('121212').complete_return_words(W('1212')) == set([W('121212')])
True
```

REFERENCES:

- [1] J. Justin, L. Vuillon, Return words in Sturmian and episturmian words, Theor. Inform. Appl. 34 (2000) 343-356.

conjugate(*pos*)

Returns the conjugate at pos of self.

pos can be any integer, the distance used is the modulo by the length of self.

EXAMPLES:

```
sage: W = Words('12')
sage: W('12112').conjugate(1)
word: 21121
sage: W().conjugate(2)
word:
sage: W('12112').conjugate(8)
word: 12121
sage: W('12112').conjugate(-1)
word: 21211
```

conjugate_position(*other*)

Returns the position where self is conjugate with other. Returns None if there is no such position.

EXAMPLES:

```
sage: W = Words('123')
sage: W('12113').conjugate_position(W('31211'))
1
sage: W('12131').conjugate_position(W('12113')) is None
True
sage: W().conjugate_position(W('123')) is None
True
```

conjugates()

Returns the set of conjugates of self.

TESTS:

```
sage: W = Words('abc')
sage: W('cbbca').conjugates() == set([W('cacbb'),W('bbcac'),W('acbbc'),W('cbbca'),W('bcacb')
True
sage: W('abcabc').conjugates() == set([W('abcabc'),W('bcabca'),W('cabcab')])
True
sage: W().conjugates() == set([W()])
True
sage: W('a').conjugates() == set([W('a')])
True
```

count (*letter*)

Counts the number of occurrences of letter in self.

EXAMPLES:

```
sage: Words('ab')('abbabaab').count('a')
4
```

critical_exponent()

Returns the critical exponent of self.

The *critical exponent* of a word is the supremum of the order of all its (finite) factors. See [1].

EXAMPLES:

```
sage: Word('aaba').critical_exponent()
2
sage: Word('aabaa').critical_exponent()
2
sage: Word('aabaaba').critical_exponent()
7/3
sage: Word('ab').critical_exponent()
1
sage: Word('aba').critical_exponent()
3/2
sage: words.ThueMorseWord()[:20].critical_exponent()
2
```

REFERENCES:

- [1] F. Dejean. Sur un théorème de Thue. J. Combinatorial Theory Ser. A 13:90–99, 1972.

crochemore_factorization()

Returns the Crochemore factorization of self as an ordered list of factors.

The *Crochemore factorization* of a finite word w is the unique factorization: $(x_1, x_2, \ldots, x_n)$ of w with each x_i satisfying either: C1. x_i is a letter that does not appear in $u = x_1 \ldots x_{i-1}$; C2. x_i is the longest prefix of $v = x_i \ldots x_n$ that also has an occurrence beginning within $u = x_1 \ldots x_{i-1}$. See [1].

This is not a very good implementation, and should be improved.

EXAMPLES:

```
sage: x = Words('ab')('abababb')
sage: x.crochemore_factorization()
(a.b.abab.b)
sage: mul(x.crochemore_factorization()) == x
True
sage: y = Words('abc')('abaababacabba')
sage: y.crochemore_factorization()
(a.b.a.aba.ba.c.ab.ba)
sage: mul(y.crochemore_factorization()) == y
True
sage: x = Words([0, 1])([0,1,0,1,0,1,1])
sage: x.crochemore_factorization()
(0.1.0101.1)
sage: mul(x.crochemore_factorization()) == x
True
```

REFERENCES:

- [1] M. Crochemore, Recherche linéaire d'un carré dans un mot, C. R. Acad. Sci. Paris Sér. I Math. 296 (1983) 14 781-784.

defect (*f=None*)

Returns the defect of self.

The *defect* of a finite word w is given by $D(w) = |w| + 1 - |PAL(w)|$, where $PAL(w)$ denotes the set of palindromic factors of w (including the empty word). See [1].

INPUT:

- `f` - involution (default: None) on the alphabet of self. It must be something that WordMorphism's constructor understands (dict, str, ...).

OUTPUT:

- `integer` - If f is None, the palindromic defect of self; otherwise, the f-palindromic defect of self.

EXAMPLES:

```
sage: words.ThueMorseWord()[:100].defect()
16
sage: words.FibonacciWord()[:100].defect()
0
sage: W = Words('01')
sage: W('000000000000').defect()
0
sage: W('011010011001').defect()
2
sage: W('0101001010001').defect()
0
sage: W().defect()
0
sage: Word('abbabaabbaababba').defect()
2
sage: Word('abbabaabbaababba').defect('a->b,b->a')
4
```

REFERENCES:

- [1] S. Brlek, S. Hamel, M. Nivat, C. Reutenauer, On the Palindromic Complexity of Infinite Words, in J. Berstel, J. Karhumaki, D. Perrin, Eds, Combinatorics on Words with Applications, International Journal of Foundation of Computer Science, Vol. 15, No. 2 (2004) 293-306.

deg_inv_lex_less (*other, weights=None*)

Returns True if the word self is degree inverse lexicographically less than other.

EXAMPLES:

```
sage: W = Words([1,2,3,4])
sage: W([1,2,4]).deg_inv_lex_less(W([1,3,2]))
False
sage: W([3,2,1]).deg_inv_lex_less(W([1,2,3]))
True
```

deg_lex_less (*other, weights=None*)

Returns True if self is degree lexicographically less than other, and False otherwise. The weight of each letter in the ordered alphabet is given by weights, which defaults to [1, 2, 3, ...].

EXAMPLES:

```
sage: Word([1,2,3]).deg_lex_less(Word([1,3,2]))
True
sage: Word([3,2,1]).deg_lex_less(Word([1,2,3]))
False
sage: W = Words(range(5))
sage: W([1,2,4]).deg_lex_less(W([1,3,2]))
False
sage: Word("abba").deg_lex_less(Word("abbb"))
True
sage: Word("abba").deg_lex_less(Word("baba"))
True
sage: Word("abba").deg_lex_less(Word("aaba"))
False
```

```
sage: Word("abba").deg_lex_less(Word("aaba"),[1,0])
True
```

deg_rev_lex_less(*other, weights=None*)

Returns True if self is degree reverse lexicographically less than other.

EXAMPLES:

```
sage: Word([3,2,1]).deg_rev_lex_less(Word([1,2,3]))
False
sage: W = Words([1,2,3,4])
sage: W([1,2,4]).deg_rev_lex_less(W([1,3,2]))
False
sage: W([1,2,3]).deg_rev_lex_less(W([1,2,4]))
True
```

degree(*weights=None*)

Returns the weighted degree of self, where the weighted degree of each letter in the ordered alphabet is given by weights, which defaults to [1, 2, 3, ...].

INPUTS: weights - a list or tuple, or a dictionary keyed by the letters occurring in self.

EXAMPLES:

```
sage: Word([1,2,3]).degree()
6
sage: Word([3,2,1]).degree()
6
sage: Word("abba").degree()
6
sage: Word("abba").degree([0,2])
4
sage: Word("abba").degree([-1,-1])
-4
sage: Word("aabba").degree([1,1])
5
sage: Words([1,2,4])([1,2,4]).degree()
6
sage: Words([1,2,3,4])([1,2,4]).degree()
7
sage: Word("aabba").degree({'a':1,'b':2})
7
sage: Word([0,1,0]).degree({0:17,1:0})
34
```

delta()

Returns the delta equivalent of self.

This is the word composed of the length of consecutive runs of the same letter in a given word.

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('22112122').delta()
word: 22112
sage: W('555008').delta()
word: 321
sage: W().delta()
word:
```

delta_derivate(*W=None*)

Returns the derivative under delta for self.

EXAMPLES:

```
sage: W = Words('12')
sage: W('12211').delta_derivate()
word: 22
sage: W('1').delta_derivate(Words([1]))
word: 1
sage: W('2112').delta_derivate()
word: 2
sage: W('2211').delta_derivate()
word: 22
sage: W('112').delta_derivate()
word: 2
sage: W('11222').delta_derivate(Words([1, 2, 3]))
word: 3
```

delta_derivate_left(*W=None*)

Returns the derivative under delta for self.

EXAMPLES:

```
sage: W = Words('12')
sage: W('12211').delta_derivate_left()
word: 22
sage: W('1').delta_derivate_left(Words([1]))
word: 1
sage: W('2112').delta_derivate_left()
word: 21
sage: W('2211').delta_derivate_left()
word: 22
sage: W('112').delta_derivate_left()
word: 21
sage: W('11222').delta_derivate_left(Words([1, 2, 3]))
word: 3
```

delta_derivate_right(*W=None*)

Returns the right derivative under delta for self.

EXAMPLES:

```
sage: W = Words('12')
sage: W('12211').delta_derivate_right()
word: 122
sage: W('1').delta_derivate_right(Words([1]))
word: 1
sage: W('2112').delta_derivate_right()
word: 12
sage: W('2211').delta_derivate_right()
word: 22
sage: W('112').delta_derivate_right()
word: 2
sage: W('11222').delta_derivate_right(Words([1, 2, 3]))
word: 23
```

delta_inv(*W=None, s=None*)

Returns the inverse of the delta operator applied to self.

The letters in the returned word will start at the specified letter or the first one if None is specified (the default). The default alphabet is [1, 2].

EXAMPLES:

```
sage: W = Words([1, 2])
sage: W([2, 2, 1, 1]).delta_inv()
```

```
word: 112212
sage: W([1, 1, 1, 1]).delta_inv(Words('123'))
word: 1231
sage: W([2, 2, 1, 1, 2]).delta_inv(s=2)
word: 22112122
```

evaluation()

Returns a list a where a[i] is the number of occurrences in self of the i-th letter in self.alphabet().

NOTE: This is slightly different from self.parikh_vector() in that it truncates the list after the last nonzero output.

EXAMPLES:

```
sage: Words('ab')('aabaa').evaluation()
[4, 1]
sage: Words('bac')('aabaa').evaluation()
[1, 4]
sage: Words('bca')('aabaa').evaluation()
[1, 0, 4]
sage: Words('abc')('aabaa').evaluation()
[4, 1]
sage: Word('aabaacaccab').evaluation()
[6, 2, 3]
sage: Word().evaluation()
[]
sage: Words('abcde')('badbcdb').evaluation()
[1, 3, 1, 2]
sage: Word([1,2,2,1,3]).evaluation()
[2, 2, 1]
sage: P = Alphabet(name="positive integers")
sage: Words(P)([]).evaluation()
[]
```

evaluation_dict()

Returns a dictionary keyed by the letters occurring in self with values the number of occurrences of the letter.

EXAMPLES:

```
sage: Word([2,1,4,2,3,4,2]).evaluation_dict()
{1: 1, 2: 3, 3: 1, 4: 2}
sage: Word('badbcdb').evaluation_dict()
{'a': 1, 'c': 1, 'b': 3, 'd': 2}
sage: Word().evaluation_dict()
{}
```

evaluation_partition()

Returns the evaluation of the word w as a partition.

EXAMPLES:

```
sage: Word("acdabda").evaluation_partition()
[3, 2, 1, 1]
sage: Word([2,1,4,2,3,4,2]).evaluation_partition()
[3, 2, 1, 1]
```

evaluation_sparse()

Returns a list representing the evaluation of self. The entries of the list are two-element lists [a, n], where a is a letter occurring in self and n is the number of occurrences of a in self.

EXAMPLES:

```
sage: Word([4,4,2,5,2,1,4,1]).evaluation_sparse()
[(1, 2), (2, 2), (4, 3), (5, 1)]
sage: Words("acdb")("abcaccab").evaluation_sparse()
[('a', 3), ('c', 3), ('b', 2)]
```

exponent()

Returns the exponent of self.

OUTPUT:

- integer - the exponent

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('1231').exponent()
1
sage: W('121212').exponent()
3
sage: W().exponent()
0
```

factor_iterator(*n=None*)

Generates distinct factors of self.

INPUT:

- n - an integer, or None.

OUTPUT: If n is an integer, returns an iterator over all distinct factors of length n. If n is None, returns an iterator generating all distinct factors.

EXAMPLES:

```
sage: w = Words('123')('1213121')
sage: sorted( w.factor_iterator(0) )
[word: ]
sage: sorted( w.factor_iterator(10) )
[]
sage: sorted( w.factor_iterator(1) )
[word: 1, word: 2, word: 3]
sage: sorted( w.factor_iterator(4) )
[word: 1213, word: 1312, word: 2131, word: 3121]
sage: sorted( w.factor_iterator() )
[word: , word: 1, word: 12, word: 121, word: 1213, word: 12131, word: 121312, word: 1213121,

sage: u = Words([1,2,3])([1,2,1,2,3])
sage: sorted( u.factor_iterator(0) )
[word: ]
sage: sorted( u.factor_iterator(10) )
[]
sage: sorted( u.factor_iterator(1) )
[word: 1, word: 2, word: 3]
sage: sorted( u.factor_iterator(5) )
[word: 12123]
sage: sorted( u.factor_iterator() )
[word: , word: 1, word: 12, word: 121, word: 1212, word: 12123, word: 123, word: 2, word: 21

sage: xxx = Word("xxx")
sage: sorted( xxx.factor_iterator(0) )
[word: ]
sage: sorted( xxx.factor_iterator(4) )
[]
```

```
sage: sorted( xxx.factor_iterator(2) )
[word: xx]
sage: sorted( xxx.factor_iterator() )
[word: , word: x, word: xx, word: xxx]

sage: e = Word()
sage: sorted( e.factor_iterator(0) )
[word: ]
sage: sorted( e.factor_iterator(17) )
[]
sage: sorted( e.factor_iterator() )
[word: ]
```

TESTS:

```
sage: type( Words('cao')('cacao').factor_iterator() )
<type 'generator'>
```

factor_occurrences_in(*other*)

Returns an iterator over all occurrences (including overlapping ones) of self in other in their order of appearance.

EXAMPLES:

```
sage: W = Words('123')
sage: list(W('121').factor_occurrences_in(W('121213211213')))
[0, 2, 8]
```

factor_set()

Returns the set of factors of self.

EXAMPLES:

```
sage: Words('123')('1213121').factor_set()    # random
Set of elements of <generator object at 0xa8fde6c>
sage: sorted(  Words([1,2,3])([1,2,1,2,3]).factor_set()  )
[word: , word: 1, word: 12, word: 121, word: 1212, word: 12123, word: 123, word: 2, word: 21
sage: sorted(  Words("x")("xx").factor_set()  )
[word: , word: x, word: xx]
sage: set( Words([])().factor_set() )
set([word: ])
```

first_pos_in(*other*)

Returns the position of the first occurrence of self in other, or None if self is not a factor of other.

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('12').first_pos_in(W('131231'))
2
sage: W('32').first_pos_in(W('131231')) is None
True
```

freq()

Returns a table of the frequencies of the letters in self.

OUTPUT:

- `dict` - letters associated to their frequency

EXAMPLES:

```
sage: Words('123')('1213121').freq()     # keys appear in random order
{'1': 4, '2': 2, '3': 1}
```

TESTS:

```
sage: f = Words('123')('1213121').freq()
sage: f['1'] == 4
True
sage: f['2'] == 2
True
sage: f['3'] == 1
True
```

good_suffix_table()

Returns a table of the maximum skip you can do in order not to miss a possible occurrence of self in a word.

This is a part of the Boyer-Moore algorithm to find factors. See [1].

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('121321').good_suffix_table()
[5, 5, 5, 5, 3, 3, 1]
sage: W('12412').good_suffix_table()
[3, 3, 3, 3, 3, 1]
```

REFERENCES:

- [1] R.S. Boyer, J.S. Moore, A fast string searching algorithm, Communications of the ACM 20 (1977) 762-772.

implicit_suffix_tree()

Returns the implicit suffix tree of self.

The *suffix tree* of a word w is a compactification of the suffix trie for w. The compactification removes all nodes that have exactly one incoming edge and exactly one outgoing edge. It consists of two components: a tree and a word. Thus, instead of labelling the edges by factors of w, we can labelled them by indices of the occurrence of the factors in w.

See sage.combinat.words.suffix_trees.ImplicitSuffixTree? for more information.

EXAMPLES:

```
sage: w = Words("cao")("cacao")
sage: w.implicit_suffix_tree()
Implicit Suffix Tree of the word: cacao

sage: w = Words([0,1])([0,1,0,1,1])
sage: w.implicit_suffix_tree()
Implicit Suffix Tree of the word: 01011
```

inv_lex_less(*other*)

Returns True if self is inverse lexicographically less than other.

EXAMPLES:

```
sage: W = Words([1,2,3,4])
sage: W([1,2,4]).inv_lex_less(W([1,3,2]))
False
sage: W([3,2,1]).inv_lex_less(W([1,2,3]))
True
```

inversions()

Returns a list of the inversions of self. An inversion is a pair (i,j) of non-negative integers i j such that self[i] self[j].

EXAMPLES:

```
sage: Words([1,2,3])([1,2,3,2,2,1]).inversions()
[[1, 5], [2, 3], [2, 4], [2, 5], [3, 5], [4, 5]]
sage: Words([3,2,1])([1,2,3,2,2,1]).inversions()
[[0, 1], [0, 2], [0, 3], [0, 4], [1, 2]]
sage: Words('ab')('abbaba').inversions()
[[1, 3], [1, 5], [2, 3], [2, 5], [4, 5]]
sage: Words('ba')('abbaba').inversions()
[[0, 1], [0, 2], [0, 4], [3, 4]]
```

is_balanced(*q=1*)

Returns True if self is q-balanced, and False otherwise.

A finite or infinite word w is said to be *'q'-balanced* if for any two factors u, v of w of the same length, the difference between the number of x's in each of u and v is at most q for all letters x in the alphabet of w. A 1-balanced word is simply said to be balanced. See for instance [1] and Chapter 2 of [2].

INPUT:

- q - integer (default 1), the balance level

OUTPUT:

- boolean - the result

EXAMPLES:

```
sage: Words('123')('1213121').is_balanced()
True
sage: Words('12')('1122').is_balanced()
False
sage: Words('123')('121333121').is_balanced()
False
sage: Words('123')('121333121').is_balanced(2)
False
sage: Words('123')('121333121').is_balanced(3)
True
sage: Words('12')('121122121').is_balanced()
False
sage: Words('12')('121122121').is_balanced(2)
True
sage: Words('12')('121122121').is_balanced(-1)
...
TypeError: the balance level must be a positive integer
sage: Words('12')('121122121').is_balanced(0)
...
TypeError: the balance level must be a positive integer
sage: Words('12')('121122121').is_balanced('a')
...
TypeError: the balance level must be a positive integer
```

REFERENCES:

- [2] M. Lothaire, Algebraic Combinatorics On Words, vol. 90 of Encyclopedia of Mathematics and its Applications, Cambridge University Press, U.K., 2002.

is_cadence(*seq*)

Returns True if seq is a cadence of self, and False otherwise.

A *cadence* is an increasing sequence of indexes that all map to the same letter.

EXAMPLES:

```
sage: W = Words('123')
sage: W('121132123').is_cadence([0, 2, 6])
True
sage: W('121132123').is_cadence([0, 1, 2])
False
sage: W('121132123').is_cadence([])
True
```

is_conjugate_with(*other*)

Returns True if self is a conjugate of other, and False otherwise.

EXAMPLES:

```
sage: W = Words('123')
sage: W('11213').is_conjugate_with(W('31121'))
True
sage: W().is_conjugate_with(W('123'))
False
sage: W('112131').is_conjugate_with(W('11213'))
False
sage: W('12131').is_conjugate_with(W('11213'))
True
```

is_cube()

Returns True if self is a cube, and False otherwise.

EXAMPLES:

```
sage: W = Words('012')
sage: W('012012012').is_cube()
True
sage: W('01010101').is_cube()
False
sage: W().is_cube()
True
sage: W('012012').is_cube()
False
```

is_cube_free()

Returns True if self does not contain cubes, and False otherwise.

EXAMPLES:

```
sage: W = Words('123')
sage: W('12312').is_cube_free()
True
sage: W('32221').is_cube_free()
False
sage: W().is_cube_free()
True
```

is_empty()

Returns True if the length of self is zero, and False otherwise.

EXAMPLES:

```
sage: W=Words('ab')
sage: W().is_empty()
True
sage: W('a').is_empty()
False
```

is_factor_of(*other*)

Returns True if self is a factor of other, and False otherwise.

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('2113').is_factor_of(W('12312133213123321132123'))
True
sage: W('321').is_factor_of(W('12312412313123123312'))
False
```

is_full (*f=None*)

Returns True if self has defect 0, and False otherwise.

A word is *full* if its defect is zero (see [1]).

INPUT:

- `f` - involution (default: None) on the alphabet of self. It must be something that WordMorphism's constructor understands (dict, str, ...).

OUTPUT:

- `boolean` - If f is None, whether self is full; otherwise, whether self is full of f-palindromes.

EXAMPLES:

```
sage: words.ThueMorseWord()[:100].is_full()
False
sage: words.FibonacciWord()[:100].is_full()
True
sage: Words('0')('000000000000000').is_full()
True
sage: Words('01')('011010011001').is_full()
False
sage: Words('123456789')('2194').is_full()
True
sage: Word().is_full()
True
sage: Word().is_full('a->b,b->a')
True
sage: w = Word('ab')
sage: w.is_full()
True
sage: w.is_full('a->b,b->a')
False
```

REFERENCES:

is_lyndon()

Returns True if self is a Lyndon word, and False otherwise.

A *Lyndon word* is a non-empty word that is lexicographically smaller than all of its proper suffixes for the given order on its alphabet. That is, w is a Lyndon word if w is non-empty and for each factorization $w = uv$ (with u, v both non-empty), we have $w < v$.

Equivalently, w is a Lyndon word iff w is a non-empty word that is lexicographically smaller than all of its proper conjugates for the given order on its alphabet.

See for instance [1].

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('123132133').is_lyndon()
True
```

```
sage: W().is_lyndon()
True
sage: W('122112').is_lyndon()
False
```

REFERENCES:

- [1] M. Lothaire, Combinatorics On Words, vol. 17 of Encyclopedia of Mathematics and its Applications, Addison-Wesley, Reading, Massachusetts, 1983.

is_overlap()

Returns True if self is an overlap, and False otherwise.

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('12121').is_overlap()
True
sage: W('123').is_overlap()
False
sage: W('1231').is_overlap()
False
sage: W('123123').is_overlap()
False
sage: W('1231231').is_overlap()
True
sage: W().is_overlap()
False
```

is_palindrome(*f=None*)

Returns True if self is a palindrome (or a f -palindrome), and False otherwise.

- In French: Soit $f : \Sigma \to \Sigma$ une involution qui s'étend évidemment à un morphisme sur Σ^*. On dit que $w \in \Sigma^*$ est un *'f'-pseudo-palindrome* [1], ou plus simplement un *'f'-palindrome*, si $w = f(\tilde{w})$ (extrait de [2]).
- In English Let $f : \Sigma \to \Sigma$ be an involution that extends to a morphism on Σ^*. We say that $w \in \Sigma^*$ is a *'f'-palindrome* if $w = f(\tilde{w})$ [2].

Also called *'f' -pseudo-palindrome* [1].

INPUT:

- `f` - involution (default: None) on the alphabet of self. It must be something that WordMorphism's constructor understands (dict, str, ...).

OUTPUT:

- `boolean` - if f is None, whether self is a palindrome; otherwise, whether self is a f-palindrome.

EXAMPLES: Some palindromes...

```
sage: W=Words('abcdefghijklmnopqrstuvwxyz I')
sage: W('esope reste ici et se repose').is_palindrome()
False
sage: W('esoperesteicietserepose').is_palindrome()
True
sage: W('I saw I was I').is_palindrome()
True
sage: Word('abbcbba').is_palindrome()
True
sage: Word('abcbdba').is_palindrome()
False
```

Some f-palindromes... You can use a str:

```
sage: Word('aababb').is_palindrome('a->b,b->a')
True
sage: Word('abacbacbab').is_palindrome('a->b,b->a,c->c')
True
```

You can use WordMorphism:

```
sage: f = WordMorphism('a->b,b->a')
sage: Word('aababb').is_palindrome(f)
True
```

You can use a dictionary:

```
sage: f = {'a':'b','b':'a'}
sage: Word('aababb').is_palindrome(f)
True
sage: w = words.ThueMorseWord()[:8]; w
word: 01101001
sage: w.is_palindrome(f={0:[1],1:[0]})
True
```

self must be in the domain of the involution:

```
sage: f = WordMorphism('a->a')
sage: Word('aababb').is_palindrome(f)
...
ValueError: self must be in the domain of the given involution
```

The given involution must be an involution:

```
sage: f = WordMorphism('a->b,b->b')
sage: Word('abab').is_palindrome(f)
...
ValueError: f must be an involution
```

TESTS:

```
sage: Y = Words('ab')
sage: Y().is_palindrome()
True
sage: Y('a').is_palindrome()
True
sage: Y('ab').is_palindrome()
False
sage: Y('aba').is_palindrome()
True
sage: Y('aa').is_palindrome()
True
sage: E = 'a->b,b->a'
sage: Y().is_palindrome(E)
True
sage: Y('a').is_palindrome(E)
False
sage: Y('ab').is_palindrome(E)
True
sage: Y('aa').is_palindrome(E)
False
sage: Y('aba').is_palindrome(E)
False
sage: Y('abab').is_palindrome(E)
True
```

- [2] S. Labbé, Propriétés combinatoires des f-palindromes, Mémoire de maîtrise en Mathématiques, Montréal, UQAM, 2008, 109 pages.

is_prefix_of(*other*)

Returns True if self is a prefix of other, and False otherwise.

EXAMPLES:

```
sage: V = Words('0123456789')
sage: w = V('0123456789')
sage: y = V('012345')
sage: y.is_prefix_of(w)
True
sage: w.is_prefix_of(y)
False
sage: W = Words('ab')
sage: w.is_prefix_of(W())
False
sage: W().is_prefix_of(w)
True
sage: W().is_prefix_of(W())
True
```

is_primitive()

Returns True if self is primitive, and False otherwise.

A finite word w is *primitive* if it is not a positive integer power of a shorter word.

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('1231').is_primitive()
True
sage: W('111').is_primitive()
False
```

is_proper_prefix_of(*other*)

Returns True if self is a proper prefix of other, and False otherwise.

EXAMPLES:

```
sage: W = Words('123')
sage: W('12').is_proper_prefix_of(W('123'))
True
sage: W('12').is_proper_prefix_of(W('12'))
False
sage: W().is_proper_prefix_of(W('123'))
True
sage: W('123').is_proper_prefix_of(W('12'))
False
sage: W().is_proper_prefix_of(W())
False
```

is_proper_suffix_of(*other*)

Returns True if self is a proper suffix of other, and False otherwise.

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('23').is_proper_suffix_of(W('123'))
True
```

```
sage: W('12').is_proper_suffix_of(W('12'))
False
sage: W().is_proper_suffix_of(W('123'))
True
sage: W('123').is_proper_suffix_of(W('12'))
False
```

is_quasiperiodic()

Returns True if self is quasiperiodic, and False otherwise.

A finite or infinite word w is *quasiperiodic* if it can be constructed by concatenations and superpositions of one of its proper factors u, which is called a *quasiperiod* of w. See for instance [1], [2], and [3].

EXAMPLES:

```
sage: W = Words('abc')
sage: W('abaababaabaababaaba').is_quasiperiodic()
True
sage: W('abacaba').is_quasiperiodic()
False
sage: W('a').is_quasiperiodic()
False
sage: W().is_quasiperiodic()
False
sage: W('abaaba').is_quasiperiodic()
True
```

is_smooth_prefix()

Returns True if self is the prefix of a smooth word, and False otherwise.

Let $A_k = \{1, \ldots, k\}$, $k \geq 2$. An infinite word w in A_k^ω is said to be *smooth* if and only if for all positive integers m, $\Delta^m(w)$ is in A_k^ω, where $\Delta(w)$ is the word obtained from w by composing the length of consecutive runs of the same letter in w. See for instance [1] and [2].

INPUT:

- `self` - must be a word over the integers to get something other than False

OUTPUT:

- `boolean` - whether self is a smooth prefix or not

EXAMPLES:

```
sage: W = Words([1, 2])
sage: W([1, 1, 2, 2, 1, 2, 1, 1]).is_smooth_prefix()
True
sage: W([1, 2, 1, 2, 1, 2]).is_smooth_prefix()
False
```

REFERENCES:

- [2] S. Brlek, S. Dulucq, A. Ladouceur, L. Vuillon, Combinatorial properties of smooth infinite words, Theoret. Comput. Sci. 352 (2006) 306-317.

is_square()
Returns True if self is a square, and False otherwise.
EXAMPLES:

```
sage: W = Words('123')
sage: W('1212').is_square()
True
sage: W('1213').is_square()
False
sage: W('12123').is_square()
False
sage: W().is_square()
True
```

is_square_free()
Returns True if self does not contain squares, and False otherwise.
EXAMPLES:

```
sage: W = Words('123')
sage: W('12312').is_square_free()
True
sage: W('31212').is_square_free()
False
sage: W().is_square_free()
True
```

is_subword_of(*other*)
Returns True is self is a subword of other, and False otherwise.
EXAMPLES:

```
sage: W = Words('123')
sage: W().is_subword_of(W('123'))
True
sage: W('123').is_subword_of(W('3211333213233321'))
True
sage: W('321').is_subword_of(W('11122212112122133111222332'))
False
```

is_suffix_of(*other*)
Returns True if w is a suffix of other, and False otherwise.
EXAMPLES:

```
sage: W = Words('0123456789')
sage: w = W('0123456789')
sage: y = W('56789')
sage: y.is_suffix_of(w)
True
sage: w.is_suffix_of(y)
False
sage: W('579').is_suffix_of(w)
False
sage: W().is_suffix_of(y)
True
sage: w.is_suffix_of(W())
False
sage: W().is_suffix_of(W())
True
```

is_symmetric(*f=None*)
Returns True if self is symmetric (or f-symmetric), and False otherwise.

A word is *symmetric* (resp. *'f'-symmetric*) if it is the product of two palindromes (resp. f-palindromes). See [1] and [2].

INPUT:

- `f` - involution (default: None) on the alphabet of self. It must be something that WordMorphism's constructor understands (dict, str, ...).

OUTPUT:

- `boolean` - If f is None, whether self is symmetric; otherwise, whether self is f-symmetric.

EXAMPLES:

```
sage: W = Words('ab')
sage: W('abbabab').is_symmetric()
True
sage: W('ababa').is_symmetric()
True
sage: W('aababaabba').is_symmetric()
False
sage: W('aabbbaababba').is_symmetric()
False
sage: W('aabbbaababba').is_symmetric('a->b,b->a')
True
```

- [2] A. de Luca, A. De Luca, Pseudopalindrome closure operators in free monoids, Theoret. Comput. Sci. 362 (2006) 282-300.

iterated_palindromic_closure(*side='right', f=None*)

Returns the iterated (f-)palindromic closure of self.

INPUT:

- `side` - 'right' or 'left' (default: 'right') the direction of the closure
- `f` - involution (default: None) on the alphabet of self. It must be something that WordMorphism's constructor understands (dict, str, ...).

OUTPUT:

- `word` - If f is None, the right iterated palindromic closure of self; otherwise, the right iterated f-palindromic closure of self. If side is 'left', the left palindromic closure.

EXAMPLES:

```
sage: W = Words('123')
sage: W('123').iterated_palindromic_closure()
word: 1213121
sage: W('123').iterated_palindromic_closure(side='left')
word: 3231323
sage: W('1').iterated_palindromic_closure()
word: 1
sage: W().iterated_palindromic_closure()
word:
sage: W=Words('ab')
sage: W('ab').iterated_palindromic_closure(f='a->b,b->a')
word: abbaab
sage: W('ab').iterated_palindromic_closure(f='a->b,b->a',side='left')
word: abbaab
sage: W('aab').iterated_palindromic_closure(f='a->b,b->a')
word: ababbaabab
```

```
sage: W('aab').iterated_palindromic_closure(f='a->b,b->a',side='left')
word: abbaabbaab
```

TESTS:

```
sage: W('aab').iterated_palindromic_closure(f='a->b,b->a',side='leftt')
...
ValueError: side must be either 'left' or 'right' (not leftt)
sage: W('aab').iterated_palindromic_closure(f='a->b,b->b',side='left')
...
ValueError: f must be an involution
```

REFERENCES:

- [1] A. de Luca, A. De Luca, Pseudopalindrome closure operators in free monoids, Theoret. Comput. Sci. 362 (2006) 282-300.

lacunas (*f=None*)

Returns the list of all the lacunas of self.

A *lacuna* is a position in a word where the longest palindromic suffix is not unioccurrent (see [1]).

INPUT:

- `f` - involution (default: None) on the alphabet of self. It must be something that WordMorphism's constructor understands (dict, str, ...).

OUTPUT:

- `list` - list of all the lacunas of self.

EXAMPLES:

```
sage: words.ThueMorseWord()[:100].lacunas()
[8, 9, 24, 25, 32, 33, 34, 35, 36, 37, 38, 39, 96, 97, 98, 99]
sage: words.ThueMorseWord()[:50].lacunas(f={0:[1],1:[0]})
[0, 2, 4, 12, 16, 17, 18, 19, 48, 49]
```

REFERENCES:

- [1] A. Blondin-Massé, S. Brlek, S. Labbé, Palindromic lacunas of the Thue-Morse word, Proc. GASCOM 2008 (June 16-20 2008, Bibbiena, Arezzo-Italia), 53-67.

last_position_table()

Returns a table (of size 256) that contains the last position of each letter in self. The letters not present in the word will have a position of None.

EXAMPLES:

```
sage: Words('01234')('1231232').last_position_table()
[-1, 3, 6, 5, -1]
```

length_border()

Returns the length of the border of self.

The *border* of a word is the longest word that is both a proper prefix and a proper suffix of self.

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('121').length_border()
1
sage: W('1').length_border()
0
sage: W('1212').length_border()
2
sage: W('111').length_border()
2
sage: W().length_border() is None
True
```

lengths_lps (*f=None*)

Returns the list of the length of the longest palindromic suffix (lps) for each non-empty prefix of self.

It corresponds to the function G_w defined in [2].

INPUT:

- `f` - involution (default: None) on the alphabet of self. It must be something that WordMorphism's constructor understand (dict, str, ...).

OUTPUT:

- `list` - list of the length of the longest palindromic suffix (lps) for each non-empty prefix of self.

EXAMPLES:

```
sage: Word().lengths_lps()
[]
sage: Word('a').lengths_lps()
[1]
sage: Word('aaa').lengths_lps()
[1, 2, 3]
sage: Word('abbabaabbaab').lengths_lps()
[1, 1, 2, 4, 3, 3, 2, 4, 2, 4, 6, 8]
sage: Word('abbabaabbaab').lengths_lps(f='a->b,b->a')
[0, 2, 0, 2, 2, 4, 6, 8, 4, 6, 4, 6]
sage: Word([5,8,5,5,8,8,5,5,8,8,5,8,5]).lengths_lps(f={5:[8],8:[5]})
[0, 2, 2, 0, 2, 4, 6, 4, 6, 8, 10, 12, 4]
```

REFERENCES:

- [1] A. Blondin-Massé, S. Brlek, S. Labbé, Palindromic lacunas of the Thue-Morse word, Proc. GASCOM 2008 (June 16-20 2008, Bibbiena, Arezzo-Italia), 53-67.
- [2] A. Blondin-Massé, S. Brlek, A. Frosini, S. Labbé, S. Rinaldi, Reconstructing words from a fixed palindromic length sequence, Proc. TCS 2008, 5th IFIP International Conference on Theoretical Computer Science (September 8-10 2008, Milano, Italia), accepted.

lengths_unioccurrent_lps (*f=None*)

Returns the list of the lengths of the unioccurrent longest palindromic suffixes (lps) for each non-empty prefix of self. No unioccurrent lps are indicated by None.

It corresponds to the function H_w defined in [1] and [2].

INPUT:

- `f` - involution (default: None) on the alphabet of self. It must be something that WordMorphism's constructor understand (dict, str, ...).

OUTPUT:

- `list` - list of the length of the unioccurrent longest palindromic suffix (lps) for each non-empty prefix of self. No unioccurrent lps are indicated by None.

EXAMPLES:

```
sage: f = words.FibonacciWord()[:20]
sage: f.lengths_unioccurrent_lps() == f.lengths_lps()
True
sage: words.ThueMorseWord()[:20].lengths_unioccurrent_lps()
[1, 1, 2, 4, 3, 3, 2, 4, None, None, 6, 8, 10, 12, 14, 16, 6, 8, 10, 12]
sage: words.ThueMorseWord()[:15].lengths_unioccurrent_lps(f={1:[0],0:[1]})
[None, 2, None, 2, None, 4, 6, 8, 4, 6, 4, 6, None, 4, 6]
```

REFERENCES:

- [1] A. Blondin-Massé, S. Brlek, S. Labbé, Palindromic lacunas of the Thue-Morse word, Proc. GASCOM 2008 (June 16-20 2008, Bibbiena, Arezzo-Italia), 53-67.

- [2] A. Blondin-Massé, S. Brlek, A. Frosini, S. Labbé, S. Rinaldi, Reconstructing words from a fixed palindromic length sequence, Proc. TCS 2008, 5th IFIP International Conference on Theoretical Computer Science (September 8-10 2008, Milano, Italia), accepted.

lex_greater(*other*)

Returns True if self is lexicographically greater than other.

EXAMPLES:

```
sage: w = Word([1,2,3])
sage: u = Word([1,3,2])
sage: v = Word([3,2,1])
sage: w.lex_greater(u)
False
sage: v.lex_greater(w)
True
sage: a = Word("abba")
sage: b = Word("abbb")
sage: a.lex_greater(b)
False
sage: b.lex_greater(a)
True
```

lex_less(*other*)

Returns True if self is lexicographically less than other.

EXAMPLES:

```
sage: w = Word([1,2,3])
sage: u = Word([1,3,2])
sage: v = Word([3,2,1])
sage: w.lex_less(u)
True
sage: v.lex_less(w)
False
sage: a = Word("abba")
sage: b = Word("abbb")
sage: a.lex_less(b)
True
sage: b.lex_less(a)
False
```

longest_common_prefix(*other*)

Returns the longest common prefix of self and other.

EXAMPLES:

```
sage: W = Words('0123456789')
sage: w=W('12345')
sage: y=W('1236777')
sage: w.longest_common_prefix(y)
word: 123
sage: w.longest_common_prefix(w)
word: 12345
sage: y.longest_common_prefix(w)
word: 123
sage: y.longest_common_prefix(w)==w.longest_common_prefix(y)
True
sage: y.longest_common_prefix(y)==y
True
sage: W().longest_common_prefix(w)
word:
sage: w.longest_common_prefix(W()) == w
```

```
False
sage: w.longest_common_prefix(W()) == W()
True
sage: w.longest_common_prefix(w[:3]) == w[:3]
True
sage: w.longest_common_prefix(w[:3]) == w
False
sage: Words('12')("11").longest_common_prefix(Words('1')("1"))
word: 1
```

longest_common_suffix(*other*)

Returns the longest common suffix of self and other.

EXAMPLES:

```
sage: W = Words('0123456789')
sage: y = W('549332345')
sage: w = W('203945')
sage: w.longest_common_suffix(y)
word: 45
sage: w.longest_common_suffix(y.reversal())
word: 3945
sage: w.longest_common_suffix(W())
word:
sage: W().longest_common_suffix(w)
word:
sage: W().longest_common_suffix(W())
word:
sage: w.longest_common_suffix(w[3:]) == w[3:]
True
sage: w.longest_common_suffix(w[3:]) == w
False
```

lps(*f=None*)

Returns the longest palindromic (or f-palindromic) suffix of self.

INPUT:

- `f` - involution (default: None) on the alphabet of self. It must be something that WordMorphism's constructor understands (dict, str, ...).

OUTPUT:

- `word` - If f is None, the longest palindromic suffix of self; otherwise, the longest f-palindromic suffix of self.

EXAMPLES:

```
sage: Word('0111').lps()
word: 111
sage: Word('011101').lps()
word: 101
sage: Word('6667').lps()
word: 7
sage: Word('abbabaab').lps()
word: baab
sage: Word().lps()
word:
sage: Word('abbabaab').lps('a->b,b->a')
word: abbabaab
```

lyndon_factorization()

Returns the Lyndon factorization of self.

The *Lyndon factorization* of a finite word w is the unique factorization of w as a non-increasing product of Lyndon words, i.e., $w = l_1 \cdots l_n$ where each l_i is a Lyndon word and $l_1 \geq \cdots \geq l_n$. See for instance [1].

OUTPUT:

- `list` - the list of factors obtained

EXAMPLES:

```
sage: Words('01')('010010010001000').lyndon_factorization()
(01.001.001.0001.0.0.0)
sage: Words('10')('010010010001000').lyndon_factorization()
(0.10010010001000)
sage: Words('ab')('abbababbaababba').lyndon_factorization()
(abb.ababb.aababb.a)
sage: Words('ba')('abbababbaababba').lyndon_factorization()
(a.bbababbaaba.bba)
```

TESTS:

```
sage: Words('01')('01').lyndon_factorization()
(01)
sage: Words('10')('01').lyndon_factorization()
(0.1)
sage: lynfac = Words('ab')('abbababbaababba').lyndon_factorization()
sage: map(lambda x:x.is_lyndon(), lynfac)
[True, True, True, True]
sage: lynfac = Words('ba')('abbababbaababba').lyndon_factorization()
sage: map(lambda x:x.is_lyndon(), lynfac)
[True, True, True]
```

REFERENCES:

- [1] J.-P. Duval, Factorizing words over an ordered alphabet, J. Algorithms 4 (1983) 363-381.

minimal_period()

Returns the period of self.

Let A be an alphabet. An integer $p \geq 1$ is a *period* of a word $w = a_1 a_2 \cdots a_n$ where $a_i \in A$ if $a_i = a_{i+p}$ for $i = 1, \ldots, n-p$. The smallest period of w is called *the* period of w. See Chapter 1 of [1].

EXAMPLES:

```
sage: Word('aba').minimal_period()
2
sage: Word('abab').minimal_period()
2
sage: Word('ababa').minimal_period()
2
sage: Word('ababaa').minimal_period()
5
sage: Word('ababac').minimal_period()
6
sage: Word('aaaaaa').minimal_period()
1
sage: Word('a').minimal_period()
1
sage: Word().minimal_period()
1
```

REFERENCES:

- [1] M. Lothaire, Algebraic Combinatorics On Words, vol. 90 of Encyclopedia of Mathematics and its Applications, Cambridge University Press, U.K., 2002.

nb_factor_occurrences_in(*other*)

Returns the number of times self appears as a factor in other.

EXAMPLES:

```
sage: W = Words('123')
sage: W().nb_factor_occurrences_in(W('123'))
...
NotImplementedError: undefined value
sage: W('123').nb_factor_occurrences_in(W('112332312313112332121123'))
4
sage: W('321').nb_factor_occurrences_in(W('112332312313112332211123'))
0
```

nb_subword_occurrences_in(*other*)

Returns the number of times self appears in other as a subword.

EXAMPLES:

```
sage: W = Words('1234')
sage: W().nb_subword_occurrences_in(W('123'))
Traceback (most recent call last):
  ...
NotImplementedError: undefined value
sage: W('123').nb_subword_occurrences_in(W('1133432311132311112'))
11
sage: W('4321').nb_subword_occurrences_in(W('113223111223321234223111 2'))
0
sage: W('3').nb_subword_occurrences_in(W('122332112321213'))
4
```

number_of_factors(*n=None*)

Counts the number of distinct factors of self.

INPUT:

- n - an integer, or None.

OUTPUT: If n is an integer, returns the number of distinct factors of length n. If n is None, returns the total number of distinct factors.

EXAMPLES:

```
sage: w = Words([1,2,3])([1,2,1,2,3])
sage: w.number_of_factors()
13
sage: map(w.number_of_factors, range(6))
[1, 3, 3, 3, 2, 1]

sage: Words('123')('1213121').number_of_factors()
22
sage: Words('123')('1213121').number_of_factors(1)
3

sage: Words('a')('a'*100).number_of_factors()
101
sage: Words('a')('a'*100).number_of_factors(77)
1

sage: Words([])().number_of_factors()
1
sage: Words([])().number_of_factors(17)
0

sage: blueberry = Word("blueberry")
sage: blueberry.number_of_factors()
```

```
43
sage: map(blueberry.number_of_factors, range(10))
[1, 6, 8, 7, 6, 5, 4, 3, 2, 1]
```

order()

Returns the order of self.

Let $p(w)$ be the period of a word w. The positive rational number $|w|/p(w)$ is the *order* of w. See Chapter 8 of [1].

OUTPUT:

- `rational` - the order

EXAMPLES:

```
sage: Word('abaaba').order()
2
sage: Word('ababaaba').order()
8/5
sage: Word('a').order()
1
sage: Word('aa').order()
2
sage: Word().order()
0
```

REFERENCES:

- [1] M. Lothaire, Algebraic Combinatorics On Words, vol. 90 of Encyclopedia of Mathematics and its Applications, Cambridge University Press, U.K., 2002.

overlap_partition(*other, delay=0, p=None*)

Returns the partition of the alphabet induced by the equivalence relation defined below.

Let $u = u_0u_1\cdots u_{n-1}$, $v = v_0v_1\cdots v_{m-1}$ be two words on the alphabet A where u_i, v_j are letters and let d be an integer. We define a relation $R_{u,v,d} \subset AimesA$ by $R_{u,v,d} = \{(u_k, v_{k-d}) : 0 \leq k < n, 0 \leq k-d < m\}$. The equivalence relation returned is the symmetric, reflexive and transitive closure of $R_{self,other,delay} \cup p$ (inspired from [1]).

EXAMPLE ILLUSTRATING THE PRECEDENT DEFINITION: Let $A = \{a, b, c, d, e, f, h, l, v\}$, $u = cheval$, $v = abcdef$ and $d = 3$. Then $0 \leq k < 6$ and $0 \leq k - 3 < 6$ implies that $3 \leq k \leq 5$. Then,

$$R_{u,v,d} = \{(u_3, v_0), (u_4, v_1), (u_5, v_2)\} = \{(v, a), (a, b), (l, c)\}$$

These three couples correspond to the pairs of letters one above the other in the following overlap:

```
cheval
   abcdef
```

The symmetric, reflexive and transitive closure of $R_{u,v,d}$ defines the following partition of the alphabet A:

$$\{\{a, b, v\}, \{c, l\}, \{d\}, \{e\}, \{f\}, \{h\}\}.$$

INPUT:

- `other` - word on the same alphabet as self
- `delay` - integer
- `p` - Set (default: None), a partition of the alphabet

OUTPUT:

- `p` - Set, a set partition of the alphabet of self and other.

EXAMPLES:

```
sage: W = Words('abcdefhlv')
sage: cheval = W('cheval')
sage: abcdef = W('abcdef')
sage: p = cheval.overlap_partition(abcdef,3); p
{{'f'}, {'e'}, {'d'}, {'a', 'b', 'v'}, {'c', 'l'}, {'h'}}
sage: cheval.overlap_partition(abcdef,2,p)
{{'f'}, {'a', 'c', 'b', 'e', 'd', 'v', 'l'}, {'h'}}
sage: W = Words('abcdef')
sage: w = W('abc')
sage: y = W('def')
sage: w.overlap_partition(y, -3)
{{'f'}, {'e'}, {'d'}, {'b'}, {'a'}, {'c'}}
sage: w.overlap_partition(y, -2)
{{'a', 'f'}, {'e'}, {'d'}, {'c'}, {'b'}}
sage: w.overlap_partition(y, -1)
{{'a', 'e'}, {'d'}, {'c'}, {'b', 'f'}}
sage: w.overlap_partition(y, 0)
{{'b', 'e'}, {'a', 'd'}, {'c', 'f'}}
sage: w.overlap_partition(y, 1)
{{'c', 'e'}, {'f'}, {'b', 'd'}, {'a'}}
sage: w.overlap_partition(y, 2)
{{'f'}, {'e'}, {'b'}, {'a'}, {'c', 'd'}}
sage: w.overlap_partition(y, 3)
{{'f'}, {'e'}, {'d'}, {'b'}, {'a'}, {'c'}}
sage: w.overlap_partition(y, 4)
{{'f'}, {'e'}, {'d'}, {'b'}, {'a'}, {'c'}}
sage: W = Words(range(2))
sage: w = W([0,1,0,1,0,1]); w
word: 010101
sage: w.overlap_partition(w, 0)
{{0}, {1}}
sage: w.overlap_partition(w, 1)
{{0, 1}}
```

TESTS:

```
sage: Word().overlap_partition(Word(),'yo')
...
TypeError: delay (type given: <type 'str'>) must be an integer
sage: Word().overlap_partition(Word(),2,'yo')
...
TypeError: p(=yo) is not a Set
sage: Word('a').overlap_partition(Word('b'),0)
...
TypeError: no coercion rule between Ordered Alphabet ['a'] and Ordered Alphabet ['b']
```

REFERENCES:

•[1] S. Labbé, Propriétés combinatoires des f-palindromes, Mémoire de maîtrise en Mathématiques, Montréal, UQAM, 2008, 109 pages.

palindromes(*f=None*)

Returns the set of all palindromic (or f-palindromic) factors of self.

INPUT:

•`f` - involution (default: None) on the alphabet of self. It must be something that WordMorphism's constructor understands (dict, str, ...).

OUTPUT:

•`set` - If f is None, the set of all palindromic factors of self; otherwise, the set of all f-palindromic factors of self.

EXAMPLES:

```
sage: W = Words('01')
sage: sorted(W('01101001').palindromes())
[word: , word: 0, word: 00, word: 010, word: 0110, word: 1, word: 1001, word: 101, word: 11]
sage: sorted(W('00000').palindromes())
[word: , word: 0, word: 00, word: 000, word: 0000, word: 00000]
sage: sorted(W('0').palindromes())
[word: , word: 0]
sage: sorted(W('').palindromes())
[word: ]
sage: sorted(W().palindromes())
[word: ]
sage: sorted(Word('abbabaab').palindromes('a->b,b->a'))
[word: , word: ab, word: abbabaab, word: ba, word: baba, word: bbabaa]
```

palindromic_closure(*side='right', f=None*)

Returns the shortest palindrome having self as a prefix (or as a suffix if side=='left').

Retourne le plus petit palindrome ayant self comme prefixe (ou comme suffixe si side=='left').

INPUT:

- `side` - 'right' or 'left' (default: 'right') the direction of the closure
- `f` - involution (default: None) on the alphabet of self. It must be something that WordMorphism's constructor understands (dict, str, ...).

OUTPUT:

- `word` - If f is None, the right palindromic closure of self; otherwise, the right f-palindromic closure of self. If side is 'left', the left palindromic closure.

EXAMPLES:

```
sage: W = Words('1234567890')
sage: W('1233').palindromic_closure()
word: 123321
sage: W('12332').palindromic_closure()
word: 123321
sage: W('0110343').palindromic_closure()
word: 01103430110
sage: W('0110343').palindromic_closure(side='left')
word: 3430110343
sage: W('01105678').palindromic_closure(side='left')
word: 876501105678
sage: w = Word('abbaba')
sage: w.palindromic_closure()
word: abbababba
sage: w.palindromic_closure(f='a->b,b->a')
word: abbabaab
sage: w.palindromic_closure(f='a->b,b->a',side='left')
word: babaabbaba
sage: w.palindromic_closure(f='a->b,b->b',side='left')
...
ValueError: f must be an involution
sage: w.palindromic_closure(f='a->c,c->a',side='left')
...
ValueError: self must be in the domain of the given involution
```

palindromic_lacunas_study(*f=None*)

Returns interesting statistics about longest (f-)palindromic suffixes and lacunas of self (see [1] and [2]).

Note that a word w has at most $|w| + 1$ different palindromic factors (see [4]).

INPUT:

- `f` - involution (default: None) on the alphabet of self. It must be something that WordMorphism's constructor understand (dict, str, ...).

OUTPUT:

- `list` - list of the length of the longest palindromic suffix (lps) for each non-empty prefix of self;
- `list` - list of all the lacunas, i.e. positions where there is no unioccurrent lps;
- `set` - set of palindromic factors of self.

EXAMPLES:

```
sage: W=Words('ab')
sage: a,b,c = W('abbabaabbaab').palindromic_lacunas_study()
sage: a
[1, 1, 2, 4, 3, 3, 2, 4, 2, 4, 6, 8]
sage: b
[8, 9]
sage: c           # random order
set([word: , word: b, word: bab, word: abba, word: bb, word: aa, word: baabbaab, word: baab,
sage: a,b,c = W('abbabaab').palindromic_lacunas_study(f='a->b,b->a')
sage: a
[0, 2, 0, 2, 2, 4, 6, 8]
sage: b
[0, 2, 4]
sage: c            # random order
set([word: , word: ba, word: baba, word: ab, word: bbabaa, word: abbabaab])
sage: c == set([W(), W('ba'), W('baba'), W('ab'), W('bbabaa'), W('abbabaab')])
True
```

parikh_vector()

Returns the Parikh vector of self, i.e., the vector containing the number of occurrences of each letter, given in the order of the alphabet.

See also evaluation, which returns a list truncated after the last nonzero entry.

EXAMPLES:

```
sage: Word('aabaa').parikh_vector()
[4, 1]
sage: Word('aabaacaccab').parikh_vector()
[6, 2, 3]
sage: Words('abc')('aabaa').parikh_vector()
[4, 1, 0]
sage: Word().parikh_vector()
[]
```

```
sage: Word('a').parikh_vector()
[1]
sage: Words('abc')('a').parikh_vector()
[1, 0, 0]
sage: Words('ab')().parikh_vector()
[0, 0]
sage: Words('abc')().parikh_vector()
[0, 0, 0]
sage: Words('abcd')().parikh_vector()
[0, 0, 0, 0]
```

TESTS:

```
sage: P = Alphabet(name="positive integers")
sage: w = Words(P)(range(1,10))
sage: w.parikh_vector()
...
TypeError: the alphabet is infinite; use evaluation() instead
```

phi()

Applies the phi function to self and returns the result.

See for instance [1] and [2].

INPUT:

- `self` - must be a word over integers

OUTPUT:

- `word` - the result of the phi function

EXAMPLES:

```
sage: W = Words([1, 2])
sage: W([2, 2, 1, 1, 2, 1, 2, 2, 1, 2, 2, 1, 1, 2]).phi()
word: 222222
sage: W().phi()
word:
sage: W([2, 1, 2, 2, 1, 2, 2, 1, 2, 1]).phi()
word: 212113
```

- [2] S. Brlek, S. Dulucq, A. Ladouceur, L. Vuillon, Combinatorial properties of smooth infinite words, Theoret. Comput. Sci. 352 (2006) 306-317.

phi_inv(*W=None*)

Applied the inverse of the phi function and returns the result.

INPUT:

- `self` - must be a word over the integers
- `W` - the set of words of the result (must also be over the integers)

OUTPUT:

- `word` - the inverse of the phi function

EXAMPLES:

```
sage: W = Words([1, 2])
sage: W([2, 2, 2, 2, 1, 2]).phi_inv()
word: 22112122
sage: W([2, 2, 2]).phi_inv(Words([2, 3]))
word: 2233
```

prefix_function_table()

Returns a vector containing the length of the proper prefix-suffixes for all the non-empty prefixes of self.

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('121321').prefix_function_table()
[0, 0, 1, 0, 0, 1]
sage: W('1241245').prefix_function_table()
[0, 0, 0, 1, 2, 3, 0]
sage: W().prefix_function_table()
[]
```

primitive()

Returns the primitive of self.

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('12312').primitive()
word: 12312
sage: W('121212').primitive()
word: 12
```

primitive_length()

Returns the length of the primitive of self.

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('1231').primitive_length()
4
sage: W('121212').primitive_length()
2
```

quasiperiods()

Returns the set of quasiperiods of self.

Let w be a finite or infinite word. A *quasiperiod* of w is a proper factor u of w such that the occurrences of u in w entirely cover w, i.e., every position of w falls within some occurrence of u in w. See for instance [1], [2], and [3].

TESTS:

```
sage: W = Words('abc')
sage: W('abaababaabaababaaba').quasiperiods() == set([W('aba'), W('abaaba'), W('abaababaaba'
True
sage: W('abaaba').quasiperiods() == set([W('aba')])
True
sage: W('abacaba').quasiperiods() == set([])
True
```

return_words(*fact*)

Returns the set of return words of fact in self.

This is the set of all factors starting by the given factor and ending just before the next occurrence of this factor. See [1] and [2].

EXAMPLES:

```
sage: W = Words('123')
sage: W('21331233213231').return_words(W('2')) == set([W('21331'), W('233'), W('213')])
True
sage: W().return_words(W('213')) == set()
True
sage: W('121212').return_words(W('1212')) == set([W('12')])
True
```

REFERENCES:

- [1] F. Durand, A characterization of substitutive sequences using return words, Discrete Math. 179 (1998) 89-101.
- [2] C. Holton, L.Q. Zamboni, Descendants of primitive substitutions, Theory Comput. Syst. 32 (1999) 133-157.

return_words_derivate (*fact, W=None*)

Returns the word generated by mapping a letter to each occurrence of the return words for the given factor dropping any dangling prefix and suffix.

The optional set of words parameter must be over an alphabet that contains as much letters as there are different return words in self, otherwise there will be some breakage in the function. The default value for this parameter always respects this property. The letters are attributed to the words in the order they are discovered.

EXAMPLES:

```
sage: Words('123')('121312213123131122').return_words_derivate(Words('1')('1'))
word: 123242
```

REFERENCES:

- [1] F. Durand, A characterization of substitutive sequences using return words, Discrete Math. 179 (1998) 89-101.

rev_lex_less (*other*)

Returns True if the word self is reverse lexicographically less than other.

EXAMPLES:

```
sage: W = Words([1,2,3,4])
sage: W([1,2,4]).rev_lex_less(W([1,3,2]))
True
sage: W([3,2,1]).rev_lex_less(W([1,2,3]))
False
```

reversal ()

Returns the reversal of self.

EXAMPLES:

```
sage: W = Words('0123456789')
sage: W('124563').reversal()
word: 365421
```

shifted_shuffle (*other*)

Returns the combinatorial class representing the shifted shuffle product between words self and other. This is the same as the shuffle product of self with the word obtained from other by incrementing the values by len(self).

EXAMPLES:

```
sage: W = Words("abcd")
sage: ab = W("ab")
sage: cd = W("cd")
sage: sp = ab.shifted_shuffle(ab); sp
```

```
Shuffle product of word: ab and word: cd
sage: sp.cardinality()
6
sage: sp.list()
[word: abcd, word: acbd, word: acdb, word: cabd, word: cadb, word: cdab]
```

shuffle(*other, overlap=0*)

Returns the combinatorial class representing the shuffle product between words self and other. This consists of all words of length len(self)+len(other) that have both self and other as subwords.

If overlap is non-zero, then the combinatorial class representing the shuffle product with overlaps is returned. The calculation of the shift in each overlap is done relative to the order of the alphabet. For example, "a" shifted by "a" is "b" in the alphabet [a, b, c] and 0 shifted by 1 in [0, 1, 2, 3] is 2.

EXAMPLES:

```
sage: W = Words("abcd")
sage: ab = W("ab")
sage: cd = W("cd")
sage: sp = ab.shuffle(cd); sp
Shuffle product of word: ab and word: cd
sage: sp.cardinality()
6
sage: sp.list()
[word: abcd, word: acbd, word: acdb, word: cabd, word: cadb, word: cdab]
sage: W = Words(range(10))
sage: w = W([0,1])
sage: u = W([2,3])
sage: w.shuffle(w)
Shuffle product of word: 01 and word: 01
sage: u.shuffle(u)
Shuffle product of word: 23 and word: 23
sage: w.shuffle(u)
Shuffle product of word: 01 and word: 23
sage: w.shuffle(u,2)
Overlapping shuffle product of word: 01 and word: 23 with 2 overlaps
```

standard_factorization()

Returns the standard factorization of self.

The *standard factorization* of a word w is the unique factorization: $w = uv$ where v is the longest proper suffix of w that qualifies as a Lyndon word.

Note that if w is a Lyndon word with standard factorization $w = uv$, then u and v are also Lyndon words and $u < v$.

See for instance [1] and [2].

OUTPUT:

- `list` - the list of factors

EXAMPLES:

```
sage: Words('01')('0010110011').standard_factorization()
(001011.0011)
sage: Words('123')('1223312').standard_factorization()
(12233.12)
```

REFERENCES:

- [1] K.-T. Chen, R.H. Fox, R.C. Lyndon, Free differential calculus, IV. The quotient groups of the lower central series, Ann. of Math. 68 (1958) 81-95.
- [2] J.-P. Duval, Factorizing words over an ordered alphabet, J. Algorithms 4 (1983) 363-381.

standard_factorization_of_lyndon_factorization()

Returns the standard factorization of the Lyndon factorization of self.

OUTPUT:

- `list of lists` - the factorization

EXAMPLES:

```
sage: Words('123')('1221131122').standard_factorization_of_lyndon_factorization()
[(12.2), (1.13), (1.122)]
```

standard_permutation()

Returns the standard permutation of the word self on the ordered alphabet. It is defined as the permutation with exactly the same number of inversions as w. Equivalently, it is the permutation of minimal length whose inverse sorts self.

EXAMPLES:

```
sage: w = Word([1,2,3,2,2,1]); w
word: 123221
sage: p = w.standard_permutation(); p
[1, 3, 6, 4, 5, 2]
sage: v = Word(p.inverse().action(w)); v
word: 112223
sage: Permutations(len(w)).filter( \
...     lambda q: q.length() <= p.length() and \
...                 q.inverse().action(w) == list(v) ).list()
[[1, 3, 6, 4, 5, 2]]

sage: w = Words([1,2,3])([1,2,3,2,2,1,2,1]); w
word: 12322121
sage: p = w.standard_permutation(); p
[1, 4, 8, 5, 6, 2, 7, 3]
sage: Word(p.inverse().action(w))
word: 11122223

sage: w = Words([3,2,1])([1,2,3,2,2,1,2,1]); w
word: 12322121
sage: p = w.standard_permutation(); p
[6, 2, 1, 3, 4, 7, 5, 8]
sage: Word(p.inverse().action(w))
word: 32222111

sage: w = Words('ab')('abbaba'); w
word: abbaba
sage: p = w.standard_permutation(); p
[1, 4, 5, 2, 6, 3]
sage: Word(p.inverse().action(w))
word: aaabbb

sage: w = Words('ba')('abbaba'); w
word: abbaba
sage: p = w.standard_permutation(); p
[4, 1, 2, 5, 3, 6]
sage: Word(p.inverse().action(w))
word: bbbaaa
```

string_rep()

Returns the raw sequence of letters as a string.

EXAMPLES:

```
sage: Words('ab')('abbabaab').string_rep()
'abbabaab'
sage: Words(range(2))([0, 1, 0, 0, 1]).string_rep()
'01001'
sage: Words(range(1000))([0,1,10,101]).string_rep()
'0,1,10,101'
sage: WordOptions(letter_separator='-')
sage: Words(range(1000))([0,1,10,101]).string_rep()
'0-1-10-101'
```

suffix_tree()

Alias for implicit_suffix_tree().

EXAMPLES:

```
sage: Words('ab')('abbabaab').suffix_tree()
Implicit Suffix Tree of the word: abbabaab
```

suffix_trie()

Returns the suffix trie of self.

The *suffix trie* of a finite word w is a data structure representing the factors of w. It is a tree whose edges are labelled with letters of w, and whose leafs correspond to suffixes of w.

See sage.combinat.words.suffix_trees.SuffixTrie? for more information.

EXAMPLES:

```
sage: w = Words("cao")("cacao")
sage: w.suffix_trie()
Suffix Trie of the word: cacao

sage: w = Words([0,1])([0,1,0,1,1])
sage: w.suffix_trie()
Suffix Trie of the word: 01011
```

swap(*i*, *j=None*)

Returns the word w with entries at positions i and j swapped. By default, j = i+1.

EXAMPLES:

```
sage: Word([1,2,3]).swap(0,2)
word: 321
sage: Word([1,2,3]).swap(1)
word: 132
sage: Words("ba")("abba").swap(1,-1)
word: aabb
```

swap_decrease(*i*)

Returns the word with positions i and i+1 exchanged if self[i] < self[i+1]. Otherwise, it returns self.

EXAMPLES:

```
sage: w = Word([1,3,2])
sage: w.swap_decrease(0)
word: 312
sage: w.swap_decrease(1)
word: 132
sage: w.swap_decrease(1) is w
True
sage: Words("ab")("abba").swap_decrease(0)
word: baba
sage: Words("ba")("abba").swap_decrease(0)
word: abba
```

swap_increase(*i*)
Returns the word with positions i and i+1 exchanged if self[i] > self[i+1]. Otherwise, it returns self.

EXAMPLES:

```
sage: w = Word([1,3,2])
sage: w.swap_increase(1)
word: 123
sage: w.swap_increase(0)
word: 132
sage: w.swap_increase(0) is w
True
sage: Words("ab")("abba").swap_increase(0)
word: abba
sage: Words("ba")("abba").swap_increase(0)
word: baba
```

class InfiniteWord_over_Alphabet(*parent, *args, **kwds*)

class InfiniteWord_over_OrderedAlphabet(*parent, *args, **kwds*)

Word(*data=None, alphabet=None*)
Returns a word over the given alphabet.

INPUT:

- `data` - An iterable (list, string, iterator) or a function defined on nonnegative integers that yields the letters of the word.
- `alphabet` - An iterable yielding letters in their comparative order. If alphabet is None and data is a string or list, then the letters appearing in data, ordered by Python's builtin sorted function, is used as alphabet.

OUTPUT: A FiniteWord_over_OrderedAlphabet or InfiniteWord_over_OrderedAlphabet object.

NOTE: Essentially, this function just returns Words(alphabet)(data).

EXAMPLES: 0. The empty word.

```
sage: Word()
word:
```

1.Finite words from strings.

```
sage: Word("abbabaab")
word: abbabaab
```

```
sage: Word("abbabaab", alphabet="abc")
word: abbabaab
```

1.Finite words from lists.

```
sage: Word(["a", "b", "b", "a", "b", "a", "a", "b"])
word: abbabaab
```

```
sage: Word([0,1,1,0,1,0])
word: 011010
```

1.Finite words from functions.

```
sage: f = lambda n : n % 2
sage: Word(f, [0, 1])[:17]
word: 01010101010101010
```

1.Finite words from iterators.

```
sage: def tmword():
...     thuemorse = WordMorphism('a->ab,b->ba')
...     w = thuemorse('a')[:]
...     i = 0
...     while w:
...         for x in thuemorse(w[i]):
...             yield x
...         else:
...             w *= thuemorse(w[i+1])
...             i += 1
sage: Word(tmword(), alphabet="ab")[:32]
word: abbabaabbaababbabaababbaabbabaab
```

1.Infinite words from functions.

```
sage: f = lambda n : n % 2
sage: Word(f, alphabet=[0, 1])
Infinite word over [0, 1]
```

1.Infinite words from iterators.

```
sage: def tmword():
...     thuemorse = WordMorphism('a->ab,b->ba')
...     w = thuemorse('a')[:]
...     i = 0
...     while w:
...         for x in thuemorse(w[i]):
...             yield x
...         else:
...             w *= thuemorse(w[i+1])
...             i += 1
sage: Word(tmword(), alphabet="ab")
Infinite word over ['a', 'b']
```

TESTS:

```
sage: f = lambda n : n % 2
sage: Word(f)
Traceback (most recent call last):
  ...
TypeError: alphabet is required for words not defined by lists or strings
sage: Word(f, alphabet=[1])
Infinite word over [1]
```

WordOptions(***kwargs*)

Sets the global options for elements of the word class. The defaults are for words to be displayed in list notation.

INPUT:

- `display` - 'string' (default), or 'list', words are displayed in string or list notation.
- `truncate` - boolean (default: True), whether to truncate the string output of long words (see truncate_length below).
- `truncate_length` - integer (default: 40), if the length of the word is greater than this integer, then the word is truncated.
- `letter_separator` - (string, default: ",") if the string representation of letters have length greater than 1, then the letters are separated by this string in the string representation of the word.

If no parameters are set, then the function returns a copy of the options dictionary.

EXAMPLES:

```
sage: w = Word([2,1,3,12])
sage: u = Word("abba")
sage: WordOptions(display='list')
sage: w
word: [2, 1, 3, 12]
sage: u
word: ['a', 'b', 'b', 'a']
sage: WordOptions(display='string')
sage: w
word: 2,1,3,12
sage: u
word: abba
```

class **Word_over_Alphabet** (*parent, *args, **kwds*)

alphabet()

Returns the alphabet of the parent.

EXAMPLES:

```
sage: Words('abc')('abbabaab').alphabet()
Ordered Alphabet ['a', 'b', 'c']
```

class **Word_over_OrderedAlphabet** (*parent, *args, **kwds*)

is_FiniteWord(*obj*)

Returns True if obj is a finite word, and False otherwise.

EXAMPLES:

```
sage: from sage.combinat.words.word import is_FiniteWord
sage: is_FiniteWord(33)
False
sage: is_FiniteWord(Word('baab'))
True
```

is_Word(*obj*)

Returns True if obj is a word, and False otherwise.

EXAMPLES:

```
sage: from sage.combinat.words.word import is_Word
sage: is_Word(33)
False
sage: is_Word(Word('abba'))
True
```

17.40.6 Word contents

BuildWordContent(*obj, mapping=<function id_f at 0x2c83938>, format=None, part=slice(None, None, None)*)

Builds the content for a word.

INPUT:

- `obj` - a function, an iterator or a list, potentially with a length defined
- `mapping` - function, a map sending elements of the iterable to nonnegative integers.
- `format` - string (default None), the explicit type of obj. Can be either 'empty', 'list', 'function' or 'iterator'. If set to None (the default), the type will be guessed from the properties of obj.
- `part` - slice (default slice(None)), the portion of the object to use

OUTPUT:

- `word content` - an object respecting the word content protocol wrapping obj

TESTS:

```
sage: from sage.combinat.words.word_content import BuildWordContent
sage: from itertools import count, imap, repeat
sage: len(BuildWordContent(None))
0
sage: len(BuildWordContent(None, format='empty'))
0
sage: c = BuildWordContent(['a', 'b'], format='empty')
...
TypeError: trying to build an empty word with something other than None
sage: len(BuildWordContent(['0', '1', '1'], int))
3
sage: len(BuildWordContent(['0', '1', '1'], int, format='list'))
3
sage: BuildWordContent(10, format='list')
...
TypeError: trying to build a word backed by a list with a sequence not providing the required op
sage: c = BuildWordContent(lambda x: x%2)
sage: len(BuildWordContent(lambda x: x%3, part=slice(0,10)))
10
sage: c = BuildWordContent(repeat(1))
sage: len(BuildWordContent(count(), part=slice(10)))
10
sage: len(BuildWordContent(count(), part=slice(10, 0, -2)))
5
```

class ConcatenateContent(*l*)

Class that acts as a function to concatenate contents.

class WordContent()

concatenate(*other*)

Method to concatenate two contents together.

TESTS:

```
sage: from sage.combinat.words.word_content import BuildWordContent
sage: list(BuildWordContent([1]).concatenate(BuildWordContent([2, 3, 4])))
[1, 2, 3, 4]
```

class WordContentFromFunction(*func, trans=<function id_f at 0x2c83938>*)

class WordContentFromIterator(*it, trans=<function id_f at 0x2c83938>*)

class WordContentFromList(*l, trans=<function id_f at 0x2c83938>*)

is_WordContent(*obj*)

Returns True if obj is the content of a word.

EXAMPLES:

```
sage: from sage.combinat.words.word_content import BuildWordContent, is_WordContent
sage: is_WordContent(33)
False
sage: is_WordContent(BuildWordContent([0, 1, 0], sage.combinat.words.utils.id_f))
True
```

17.40.7 Word generators

class ChristoffelWord_Lower(*p, q, alphabet=(0, 1)*)

markoff_number()

Returns the Markoff number associated to the Christoffel word self.

The *Markoff number* of a Christoffel word w is $1/3traceM(w)$, where $M(w)$ is the 2×2 matrix obtained by applying the morphism: 0 - matrix(2,[2,1,1,1]) 1 - matrix(2,[5,2,2,1])

EXAMPLES:

```
sage: from sage.combinat.words.word_generators import ChristoffelWord_Lower
sage: w0 = ChristoffelWord_Lower(4,7)
sage: w1, w2 = w0.standard_factorization()
sage: (m0,m1,m2) = (w.markoff_number() for w in (w0,w1,w2))
sage: (m0,m1,m2)
(294685, 13, 7561)
sage: m0**2 + m1**2 + m2**2 == 3*m0*m1*m2
True
```

standard_factorization()

Returns the standard factorization of the Christoffel word self.

The *standard factorization* of a Christoffel word w is the unique factorization of w into two Christoffel words.

EXAMPLES:

```
sage: from sage.combinat.words.word_generators import ChristoffelWord_Lower
sage: w = ChristoffelWord_Lower(5,9)
sage: print w
word: 00100100100101
sage: w1, w2 = w.standard_factorization()
sage: print w1
word: 001
sage: print w2
word: 00100100101

sage: w = ChristoffelWord_Lower(51,37)
sage: w1, w2 = w.standard_factorization()
sage: w1
Lower Christoffel word of slope 11/8 over the alphabet [0, 1]
sage: w2
Lower Christoffel word of slope 40/29 over the alphabet [0, 1]
```

```
sage: w1 * w2 == w
True
```

class WordGenerator()

A class consisting of constructors for several famous words.

TESTS:

```
sage: type(loads(dumps(words)))
<class 'sage.combinat.words.word_generators.WordGenerator'>
```

CharacteristicSturmianWord(*cf, alphabet=(0, 1), repeat=True*)

Returns the characteristic Sturmian word over the given two-letter alphabet with slope given by the continued fraction [0, cf[1], cf[2], ...]. Here cf should be an iterator.

The *characteristic Sturmian word of slope* $\alpha = [0, d[1] + 1, d[2], d[3], \ldots]$ is the limit of the sequence: $s_0 = 1$, $s_1 = 0$, ..., $s_{n+1} = s_n^{d_n} s_{n-1}$ for $n > 0$.

Equivalently, the n-th term of the characteristic Sturmian word of slope α is $\lfloor \alpha(n+1) \rfloor - \lfloor \alpha n \rfloor + \lfloor \alpha \rfloor$.

INPUT:

- `alphabet` - any container of length two that is suitable to build an instance of OrderedAlphabet (list, tuple, str, ...)
- `cf` - an iterator outputting integers (thought of as a continued fraction)

EXAMPLES:

```
sage: def cf():
...     yield 0
...     while True: yield 1
...
sage: F = words.CharacteristicSturmianWord(cf()); F
Characteristic Sturmian word over [0, 1], defined recursively
sage: Fib = words.FibonacciWord(); Fib
Fibonacci word over [0, 1], defined recursively
sage: F[:10000] == Fib[:10000]
True

sage: def cf():
...     yield 0
...     while True: yield 1
...
sage: G = words.CharacteristicSturmianWord(cf(),'rs'); G
Characteristic Sturmian word over ['r', 's'], defined recursively
sage: print G[:50]
word: rsrrsrsrrsrrsrsrrsrsrrsrrsrsrrsrrsrsrrsrsrrsrrsrsr
```

TESTS:

```
sage: words.CharacteristicSturmianWord([1,1,1],'xyz')
...
TypeError: alphabet does not contain two distinct elements
```

ChristoffelWord(*p, q, alphabet=(0, 1)*)

Returns the lower Christoffel word of slope p/q, where p and q are relatively prime non-negative integers, over the given two-letter alphabet.

The *Christoffel word of slope 'p/q'* is obtained from the Cayley graph of $\mathbf{Z}/(p+q)\mathbf{Z}$ with generator q as follows. If $u \to v$ is an edge in the Cayley graph, then $v = u + p \mod p + q$. Label the edge $u \to v$ by alphabet[1] if $u < v$ and alphabet[0] otherwise. The Christoffel word is the word obtained by reading the edge labels along the cycle beginning from 0.

INPUT:

- `alphabet` - any container of length two that is suitable to build an instance of OrderedAlphabet (list, tuple, str, ...)

EXAMPLES:

```
sage: w = words.ChristoffelWord(1,0); w
Lower Christoffel word of slope 1/0 over the alphabet [0, 1]
sage: print w
word: 1

sage: w = words.ChristoffelWord(0,1); w
Lower Christoffel word of slope 0/1 over the alphabet [0, 1]
sage: print w
word: 0

sage: w = words.ChristoffelWord(1,1); w
Lower Christoffel word of slope 1/1 over the alphabet [0, 1]
sage: print w
word: 01

sage: w = words.ChristoffelWord(4,7); w
Lower Christoffel word of slope 4/7 over the alphabet [0, 1]
sage: print w
word: 00100100101
```

TESTS:

```
sage: words.ChristoffelWord(51,43,"abc")
...
TypeError: alphabet does not contain two distinct elements
```

CodingOfRotationWord(*alpha, beta, x=0, alphabet=(0, 1)*)

Returns the infinite word obtained from the coding of rotation of parameters (α, β, x) over the given two-letter alphabet.

The *coding of rotation* corresponding to the parameters (α, β, x) is the symbolic sequence $u = (u_n)_{n\geq 0}$ defined over the binary alphabet $\{0, 1\}$ by $u_n = 1$ if $x + n\alpha \in [0, \beta[$ and $u_n = 0$ otherwise. See [1].

EXAMPLES:

```
sage: alpha = 0.45
sage: beta = 0.48
sage: w = words.CodingOfRotationWord(0.45, 0.48); w
Coding of rotation with parameters (0.450000000000000, 0.480000000000000, 0)
sage: w[:100]
Finite word of length 100 over [0, 1]
sage: w[:30]
word: 110101010100101010101101010101

sage: u = words.CodingOfRotationWord(0.45, 0.48, alphabet='xy')
sage: u[:100]
Finite word of length 100 over ['x', 'y']
sage: u[:30]
word: yyxyxyxyxyxxyxyxyxyxyyxyxyxyxy
```

TESTS:

```
sage: words.CodingOfRotationWord(0.51,0.43,alphabet=[1,0,2])
...
TypeError: alphabet does not contain two distinct elements
```

Number Theory 103 (2003) 27-37.

FibonacciWord(*alphabet=(0, 1), construction_method='recursive'*)

Returns the Fibonacci word on the given two-letter alphabet.

INPUT:

- `alphabet` - any container of length two that is suitable to build an instance of OrderedAlphabet (list, tuple, str, ...)
- `construction_method` - can be any of the following: "recursive", "fixed point" (see below for definitions).

Recursive construction: the Fibonacci word is the limit of the following sequence of words: $S_0 = 0$, $S_1 = 01$, $S_n = S_{n-1}S_{n-2}$ for $n \geq 2$.

Fixed point construction: the Fibonacci word is the fixed point of the morphism: $0 \mapsto 01$ and $1 \mapsto 0$. Hence, it can be constructed by the following read-write process:

beginning at the first letter of 01, if the next letter is 0, append 01 to the word; if the next letter is 1, append 1 to the word; move to the next letter of the word.

EXAMPLES:

```
sage: w = words.FibonacciWord(construction_method="recursive"); w
Fibonacci word over [0, 1], defined recursively
sage: print w[:99]
word: 010010100100101001010010010100100101001010010010100101001010010010100101001010010010100101001
```

```
sage: v = words.FibonacciWord(construction_method="recursive", alphabet='ab'); v
Fibonacci word over ['a', 'b'], defined recursively
sage: print v[:99]
word: abaababaabaababaababaabaababaabaababaababaabaababaabaababaabaababaababaabaababaabaababaababaabaab
```

```
sage: u = words.FibonacciWord(construction_method="fixed_point"); u
Fibonacci word over [0, 1], defined as the fixed point of a morphism
sage: print u[:99]
word: 010010100100101001010010010100100101001010010010100101001010010010100101001010010010100101001
```

```
sage: x = words.FibonacciWord(construction_method="fixed_point", alphabet=[4, 1]); x
Fibonacci word over [1, 4], defined as the fixed point of a morphism
sage: print x[:99]
word: 414414144144144144144144144144144144144144144144144144144144144144144144144144144144144144144
```

TESTS:

```
sage: from math import floor, sqrt
sage: golden_ratio = (1 + sqrt(5))/2.0
sage: a = golden_ratio / (1  + 2*golden_ratio)
sage: wn = lambda n : int(floor(a*(n+2)) - floor(a*(n+1)))
sage: f = Words([0,1])(wn); f
Infinite word over [0, 1]
sage: f[:10000] == w[:10000]
True
sage: f[:10000] == u[:10000] #long time
True
sage: words.FibonacciWord("abc")
...
TypeError: alphabet does not contain two distinct elements
```

FixedPointOfMorphism(*morphism, first_letter*)

Returns the fixed point of the morphism beginning with first_letter.

A *fixed point* of a morphism φ is a word w such that $\varphi(w) = w$.

INPUT:

- `morphism` - endomorphism prolongable on first_letter. It must be something that WordMorphism's constructor understands (dict, str, ...).
- `first_letter` - the first letter of the fixed point

OUTPUT:

- `word` - the fixed point of the morphism beginning with first_letter

EXAMPLES:

```
sage: mu = {0:[0,1], 1:[1,0]}
sage: tm = words.FixedPointOfMorphism(mu,0); tm
Fixed point beginning with 0 of the morphism WordMorphism: 0->01, 1->10
sage: TM = words.ThueMorseWord()
sage: tm[:1000] == TM[:1000]
True

sage: mu = {0:[0,1], 1:[0]}
sage: f = words.FixedPointOfMorphism(mu,0); f
Fixed point beginning with 0 of the morphism WordMorphism: 0->01, 1->0
sage: F = words.FibonacciWord(); F
Fibonacci word over [0, 1], defined recursively
sage: f[:1000] == F[:1000]
True

sage: fp = words.FixedPointOfMorphism('a->abc,b->,c->','a'); fp
Fixed point beginning with 'a' of the morphism WordMorphism: a->abc, b->, c->
sage: fp[:10]
word: abc
```

LowerChristoffelWord(*p, q, alphabet=(0, 1)*)

Returns the lower Christoffel word of slope p/q, where p and q are relatively prime non-negative integers, over the given two-letter alphabet.

The *Christoffel word of slope 'p/q'* is obtained from the Cayley graph of $\mathbf{Z}/(p+q)\mathbf{Z}$ with generator q as follows. If $u \to v$ is an edge in the Cayley graph, then $v = u + p \mod p+q$. Label the edge $u \to v$ by alphabet[1] if $u < v$ and alphabet[0] otherwise. The Christoffel word is the word obtained by reading the edge labels along the cycle beginning from 0.

INPUT:

- `alphabet` - any container of length two that is suitable to build an instance of OrderedAlphabet (list, tuple, str, ...)

EXAMPLES:

```
sage: w = words.ChristoffelWord(1,0); w
Lower Christoffel word of slope 1/0 over the alphabet [0, 1]
sage: print w
word: 1

sage: w = words.ChristoffelWord(0,1); w
Lower Christoffel word of slope 0/1 over the alphabet [0, 1]
sage: print w
word: 0

sage: w = words.ChristoffelWord(1,1); w
Lower Christoffel word of slope 1/1 over the alphabet [0, 1]
sage: print w
word: 01

sage: w = words.ChristoffelWord(4,7); w
Lower Christoffel word of slope 4/7 over the alphabet [0, 1]
```

```
sage: print w
word: 00100100101
```

TESTS:

```
sage: words.ChristoffelWord(51,43,"abc")
...
TypeError: alphabet does not contain two distinct elements
```

MinimalSmoothPrefix(*n*)

This function finds and returns the minimal smooth prefix of length n.

See [1] for a definition.

INPUT:

- `n` - the desired length of the prefix

OUTPUT:

- `word` - the prefix

Be patient, this function can take a really long time if asked for a large prefix.

EXAMPLES:

```
sage: words.MinimalSmoothPrefix(10)
word: 1212212112
```

REFERENCES: [1] S. Brlek, G. Melançon, G. Paquin, Properties of the extremal infinite smooth words, Discrete Math. Theor. Comput. Sci. 9 (2007) 33-49.

RandomWord(*n, m=2, alphabet=None*)

Returns a random word of length n over the given m-letter alphabet (default alphabet is 0,1,...,m-1).

INPUT:

- `n` - integer, the length of the word
- `m` - integer (default 2), the size of the output alphabet
- `alphabet` - any container of length m that is suitable to build an instance of OrderedAlphabet (list, tuple, str, ...)

EXAMPLES:

```
sage: words.RandomWord(10)          # random results
word: 0110100101
sage: words.RandomWord(10, 4)       # random results
word: 0322313320
sage: words.RandomWord(100, 7)
Finite word of length 100 over [0, 1, 2, 3, 4, 5, 6]
sage: words.RandomWord(100, 7, range(-3,4))
Finite word of length 100 over [-3, -2, -1, 0, 1, 2, 3]
sage: words.RandomWord(100, 5, "abcde")
Finite word of length 100 over ['a', 'b', 'c', 'd', 'e']
sage: words.RandomWord(17, 5, "abcde")      # random results
word: dcacbbecbddebaadd
```

TESTS:

```
sage: words.RandomWord(2,3,"abcd")
...
TypeError: alphabet does not contain 3 distinct elements
```

StandardEpisturmianWord(*directive_word*)

Returns the standard episturmian word (or epistandard word) directed by directive_word. Over a 2-letter alphabet, this function gives characteristic Sturmian words.

An infinite word w over a finite alphabet A is said to be *standard episturmian* (or *epistandard*) iff there exists an infinite word $x_1x_2x_3\cdots$ over A (called the *directive word* of w) such that w is the limit as n goes to infinity of $Pal(x_1\cdots x_n)$, where Pal is the iterated palindromic closure function.

Note that an infinite word is *episturmian* if it has the same set of factors as some epistandard word.

See for instance [1], [2], and [3].

INPUT:

- `directive word` - an infinite word or a period of a periodic infinite word

EXAMPLES:

```
sage: Fibonacci = words.StandardEpisturmianWord(Word('ab')); Fibonacci
Standard episturmian word over ['a', 'b']
sage: Fibonacci[:25]
word: abaababaabaababaababaaba
sage: Tribonacci = words.StandardEpisturmianWord(Word('abc')); Tribonacci
Standard episturmian word over ['a', 'b', 'c']
sage: Tribonacci[:25]
word: abacabaabacababacabaabaca
sage: S = words.StandardEpisturmianWord(Word('aabcabada')); S
Standard episturmian word over ['a', 'b', 'c', 'd']
sage: print S[:75]
word: aabaacaabaaabaacaabaabaacaabaaabaacaabaaabaacaabaabaacaabaaabaacaabaadaabaa
sage: S = words.StandardEpisturmianWord(Fibonacci); S
Standard episturmian word over ['a', 'b']
sage: S[:25]
word: abaabaababaabaabaababaaba
sage: S = words.StandardEpisturmianWord(Tribonacci); S
Standard episturmian word over ['a', 'b', 'c']
sage: S[:25]
word: abaabacabaabaabacabaababa
sage: words.StandardEpisturmianWord(123)
...
TypeError: directive_word is not a word, so it cannot be used to build an episturmian word
sage: words.StandardEpisturmianWord(Words('ab'))
...
TypeError: directive_word is not a word, so it cannot be used to build an episturmian word
```

ThueMorseWord(*alphabet=(0, 1)*)

Returns the Thue-Morse word over the given two-letter alphabet.

There are several ways to define the Thue-Morse word t. We use the following definition: $t[n]$ is the sum modulo 2 of the digits in the binary expansion of n.

INPUT:

- `alphabet` - any container of length two that is suitable to build an instance of OrderedAlphabet (list, tuple, str, ...)

EXAMPLES:

```
sage: t = words.ThueMorseWord(); t
Thue-Morse word on the alphabet [0, 1]
sage: print t[:50]
word: 01101001100101101001011001101001100101100110100101
```

```
sage: t = words.ThueMorseWord('ab'); t
Thue-Morse word on the alphabet ['a', 'b']
sage: print t[:50]
word: abbabaabbaababbabaababbaabbabaabbaababbaabbabaabab

sage: t = words.ThueMorseWord(['L1', 'L2']); t
Thue-Morse word on the alphabet ['L1', 'L2']
sage: words.ThueMorseWord(['L1','L2'])[:8]
word: L1,L2,L2,L1,L2,L1,L1,L2
```

TESTS:

```
sage: words.ThueMorseWord("abc")
...
TypeError: alphabet does not contain two distinct elements
```

UpperChristoffelWord(*p, q, alphabet=(0, 1)*)

Returns the upper Christoffel word of slope p/q, where p and q are relatively prime non-negative integers, over the given alphabet.

The *upper Christoffel word of slope 'p/q'* is equal to the reversal of the lower Christoffel word of slope p/q. Equivalently, if xuy is the lower Christoffel word of slope p/q, where x and y are letters, then yux is the upper Christoffel word of slope p/q (because u is a palindrome).

INPUT:

- `alphabet` - any container of length two that is suitable to build an instance of OrderedAlphabet (list, tuple, str, ...)

EXAMPLES:

```
sage: w = words.UpperChristoffelWord(1,0); w
Upper Christoffel word of slope 1/0 over the alphabet [0, 1]
sage: print w
word: 1

sage: w = words.UpperChristoffelWord(0,1); w
Upper Christoffel word of slope 0/1 over the alphabet [0, 1]
sage: print w
word: 0

sage: w = words.UpperChristoffelWord(1,1); w
Upper Christoffel word of slope 1/1 over the alphabet [0, 1]
sage: print w
word: 10

sage: w = words.UpperChristoffelWord(4,7); w
Upper Christoffel word of slope 4/7 over the alphabet [0, 1]
sage: print w
word: 10100100100
```

TESTS:

```
sage: words.UpperChristoffelWord(51,43,"abc")
...
TypeError: alphabet does not contain two distinct elements
```

17.40.8 Words

class FiniteWords_length_k_over_OrderedAlphabet(*alphabet, length*)

cardinality()

Returns the number of words of length n from alphabet.

EXAMPLES:

```
sage: Words(['a','b','c'], 4).cardinality()
81
sage: Words(3, 4).cardinality()
81
sage: Words(0,0).cardinality()
1
sage: Words(5,0).cardinality()
1
sage: Words(['a','b','c'],0).cardinality()
1
sage: Words(0,1).cardinality()
0
sage: Words(5,1).cardinality()
5
sage: Words(['a','b','c'],1).cardinality()
3
sage: Words(7,13).cardinality()
96889010407
sage: Words(['a','b','c','d','e','f','g'],13).cardinality()
96889010407
```

iterate_by_length(*length*)

All words in this class are of the same length, so use iterator instead.

TESTS:

```
sage: W = Words(['a', 'b'], 2)
sage: list(W.iterate_by_length(2))
[word: aa, word: ab, word: ba, word: bb]
sage: list(W.iterate_by_length(1))
[]
```

class **FiniteWords_over_OrderedAlphabet**(*alphabet*)

class **InfiniteWords_over_OrderedAlphabet**(*alphabet*)

Words(*alphabet=None, length=None, finite=True, infinite=True*)

Returns the combinatorial class of words of length k over an ordered alphabet.

EXAMPLES:

```
sage: Words()
Words
sage: Words(length=7)
Finite Words of length 7
sage: Words(5)
Words over Ordered Alphabet [1, 2, 3, 4, 5]
sage: Words(5, 3)
Finite Words over Ordered Alphabet [1, 2, 3, 4, 5] of length 3
sage: Words(5, infinite=False)
Finite Words over Ordered Alphabet [1, 2, 3, 4, 5]
sage: Words(5, finite=False)
Infinite Words over Ordered Alphabet [1, 2, 3, 4, 5]
sage: Words('ab')
Words over Ordered Alphabet ['a', 'b']
sage: Words('ab', 2)
Finite Words over Ordered Alphabet ['a', 'b'] of length 2
```

```
sage: Words('ab', infinite=False)
Finite Words over Ordered Alphabet ['a', 'b']
sage: Words('ab', finite=False)
Infinite Words over Ordered Alphabet ['a', 'b']
sage: Words('positive integers', finite=False)
Infinite Words over Ordered Alphabet of Positive Integers
sage: Words('natural numbers')
Words over Ordered Alphabet of Natural Numbers
```

class Words_all()

TESTS:

```
sage: from sage.combinat.words.words import Words_all
sage: list(Words_all())
...
NotImplementedError
sage: Words_all().list()
...
NotImplementedError: infinite list
sage: Words_all().cardinality()
+Infinity
```

class Words_n(*n*)

class Words_over_Alphabet(*alphabet*)

alphabet()

EXAMPLES:

```
sage: from sage.combinat.words.words import Words_over_Alphabet
sage: W = Words_over_Alphabet([1,2,3])
sage: W.alphabet()
[1, 2, 3]
sage: from sage.combinat.words.words import OrderedAlphabet
sage: W = Words_over_Alphabet(OrderedAlphabet('ab'))
sage: W.alphabet()
Ordered Alphabet ['a', 'b']
```

size_of_alphabet()

Returns the size of the alphabet.

EXAMPLES:

```
sage: Words('abcdef').size_of_alphabet()
6
sage: Words('').size_of_alphabet()
0
```

class Words_over_OrderedAlphabet(*alphabet*)

iter_morphisms(*l*)

Iterate over all endomorphisms φ of self satisfying $|\varphi(a[i])| = l[i]$, where a[i] is the i-th letter of self.

INPUT:

- `l` - list of integers such that len(l) == self.size_of_alphabet()

OUTPUT:

- `iterator outputting WordMorphism` - outputs the endomorphisms

EXAMPLES:

```
sage: W = Words('ab')
sage: map(str, W.iter_morphisms([2, 1]))
['WordMorphism: a->aa, b->a',
 'WordMorphism: a->aa, b->b',
 'WordMorphism: a->ab, b->a',
 'WordMorphism: a->ab, b->b',
 'WordMorphism: a->ba, b->a',
 'WordMorphism: a->ba, b->b',
 'WordMorphism: a->bb, b->a',
 'WordMorphism: a->bb, b->b']
sage: map(str, W.iter_morphisms([2, 2]))
['WordMorphism: a->aa, b->aa',
 'WordMorphism: a->aa, b->ab',
 'WordMorphism: a->aa, b->ba',
 'WordMorphism: a->aa, b->bb',
 'WordMorphism: a->ab, b->aa',
 'WordMorphism: a->ab, b->ab',
 'WordMorphism: a->ab, b->ba',
 'WordMorphism: a->ab, b->bb',
 'WordMorphism: a->ba, b->aa',
 'WordMorphism: a->ba, b->ab',
 'WordMorphism: a->ba, b->ba',
 'WordMorphism: a->ba, b->bb',
 'WordMorphism: a->bb, b->aa',
 'WordMorphism: a->bb, b->ab',
 'WordMorphism: a->bb, b->ba',
 'WordMorphism: a->bb, b->bb']
sage: map(str, W.iter_morphisms([0, 0]))
['WordMorphism: a->, b->']
sage: map(str, W.iter_morphisms([0, 1]))
['WordMorphism: a->, b->a', 'WordMorphism: a->, b->b']
sage: list(W.iter_morphisms([1,0]))
[Morphism from Words over Ordered Alphabet ['a', 'b'] to Words over Ordered Alphabet ['a', '
```

TESTS:

```
sage: list(W.iter_morphisms([0, 1, 2]))
...
TypeError: l (=[0, 1, 2]) must be a list of 2 integers
sage: list(W.iter_morphisms([0, 'a']))
...
TypeError: l (=[0, 'a']) must be a list of 2 integers
```

iterate_by_length(*l=1*)

Returns an iterator over all the words of self of length l.

INPUT:

- `l` - integer (default: 1) the length of the desired words

EXAMPLES:

```
sage: W = Words('ab')
sage: list(W.iterate_by_length(1))
[word: a, word: b]
sage: list(W.iterate_by_length(2))
[word: aa, word: ab, word: ba, word: bb]
sage: list(W.iterate_by_length(3))
[word: aaa,
 word: aab,
 word: aba,
```

```
 word: abb,
 word: baa,
 word: bab,
 word: bba,
 word: bbb]
sage: list(W.iterate_by_length('a'))
...
TypeError: the parameter l ('a') must be an integer
```

is_Words(*obj*)

Returns True if obj is a word set and False otherwise.

EXAMPLES:

```
sage: from sage.combinat.words.words import is_Words
sage: is_Words(33)
False
sage: is_Words(Words('ab'))
True
```

17.40.9 Word utilities

class Factorization()

A list subclass having a nicer representation for factorization of words.

TESTS:

```
sage: f = sage.combinat.words.utils.Factorization()
sage: f == loads(dumps(f))
True
```

clamp(*x, min, max*)

Clamp a value between a maximum and a minimum.

EXAMPLES:

```
sage: from sage.combinat.words.utils import clamp
sage: clamp(0, -1, 1)
0
sage: clamp(-2, 0, 4)
0
sage: clamp(10, 0, 4)
4
```

copy_it(*it*)

Copy an iterator using its builtin __copy__ method if available, otherwise use itertools.tee(). Define __copy__ for your iterators. (See PEP 323)

TESTS:

```
sage: from sage.combinat.words.utils import copy_it
sage: it = iter([1, 2, 3, 4, 5])
sage: it, it2 = copy_it(it)
sage: list(it)
[1, 2, 3, 4, 5]
sage: it2.next()
1
sage: it2, it3 = copy_it(it2)
```

```
sage: list(it2)
[2, 3, 4, 5]
sage: it3.next()
2
```

haslen(*obj*)

Returns true if obj has a properly defined length

EXAMPLES:

```
sage: from sage.combinat.words.utils import haslen
sage: haslen([1, 2, 3])
True
sage: haslen(33)
False
```

TESTS:

```
sage: class test(object):
...       def __len__(self):
...           return -1
...
sage: haslen(test())
False
```

id_f(*x*)

Dummy identity function for when a function is required but none is desired.

TESTS:

```
sage: l = [1, 2, 3]
sage: l is sage.combinat.words.utils.id_f(l)
True
```

is_iterable(*obj*)

Returns true if the obj is iterable.

EXAMPLES:

```
sage: from sage.combinat.words.utils import is_iterable
sage: is_iterable('123')
True
sage: is_iterable([1, 2, 3])
True
sage: is_iterable(xrange(1, 4))
True
sage: is_iterable(33)
False
```

isint(*obj*)

Returns True if obj is an integer or a custom object representing an integer and False otherwise.

EXAMPLES:

```
sage: from sage.combinat.words.utils import isint
sage: isint(1)
True
sage: isint("2")
False
```

```
sage: isint(1.0)
False
```

len_it(*it*)

Returns the number of elements in it.

This function will modify the iterator, so if you want to access the elements later, make a copy of the iterator and pass it to this function.

EXAMPLES:

```
sage: from sage.combinat.words.utils import len_it
sage: len_it(iter([1, 2, 3]))
3
```

peek_it(*it*)

Returns the first element of an iterator and returns an iterator at the same position as the original iterator

EXAMPLES:

```
sage: from sage.combinat.words.utils import peek_it
sage: it = iter([1, 2, 3])
sage: it, n = peek_it(it); n
1
sage: it.next()
1
```

reverse_map(*d*)

Return a new dict with swapped keys and values

EXAMPLES:

```
sage: from sage.combinat.words.utils import reverse_map
sage: reverse_map({'a': 1, 'b': 2}) == {1: 'a', 2: 'b'}
True
```

slice_indices(*s, l*)

Implement slice.indices without bugs.

TESTS:

```
sage: from sage.combinat.words.utils import slice_indices
sage: slice_indices(slice(None), 8)
(0, 8, 1)
sage: slice_indices(slice(1), 8)
(0, 1, 1)
sage: slice_indices(slice(10), 8)
(0, 8, 1)
sage: slice_indices(slice(-4), 8)
(0, 4, 1)
sage: slice_indices(slice(-10), 8)
(0, 0, 1)
sage: slice_indices(slice(1, None), 8)
(1, 8, 1)
sage: slice_indices(slice(10, None), 8)
(8, 8, 1)
sage: slice_indices(slice(-4, None), 8)
(4, 8, 1)
sage: slice_indices(slice(-10, None), 8)
(0, 8, 1)
```

```
sage: slice_indices(slice(None, None, 2), 8)
(0, 8, 2)
sage: slice_indices(slice(None, None, -2), 8)
(7, -1, -2)
```

slice_it(*it, l, key*)

Slice an iterator, supporting negative step sizes by expliciting the elements if needed.

NOTE: The iterator returned depends on it. You must pass in a copy of your iterator if you intend to keep using the original iterator.

TESTS:

```
sage: from sage.combinat.words.utils import slice_it
sage: list(slice_it(iter(range(5)), 5, slice(None)))
[0, 1, 2, 3, 4]
sage: list(slice_it(iter(range(5)), 5, slice(3)))
[0, 1, 2]
sage: list(slice_it(iter(range(5)), 5, slice(-1)))
[0, 1, 2, 3]
sage: list(slice_it(iter(range(5)), 5, slice(2, 4)))
[2, 3]
sage: list(slice_it(iter(range(5)), 5, slice(3, 1, -1)))
[3, 2]
```

slice_ok(*part*)

Returns true if part is a slice and doesn't have funny values.

EXAMPLES:

```
sage: from sage.combinat.words.utils import slice_ok
sage: slice_ok(slice(None))
True
sage: slice_ok(slice(2))
True
sage: slice_ok(slice(1, 2, 3))
True
sage: slice_ok(slice(None, 2, 3))
True
sage: slice_ok(slice(1, None, 3))
True
sage: slice_ok(slice(1, 2, None))
True
sage: slice_ok(slice("a"))
False
sage: slice_ok(slice("a", 1))
False
sage: slice_ok(slice(1, 2, "a"))
False
sage: slice_ok(1)
False
```

sliceable(*obj*)

Returns true if obj is completely sliceable, including negative step sizes

EXAMPLES:

```
sage: from sage.combinat.words.utils import sliceable
sage: sliceable([1, 2, 3])
```

```
True
sage: sliceable(33)
False
```

TESTS:

```
sage: class test(object):
...       def __getitem__(self, key):
...           return islice(iter([1]), *key)
...
sage: sliceable(test())
False
```

17.41 Miscellaneous

class DoublyLinkedList(*l*)

A doubly linked list class that provides constant time hiding and unhiding of entries.

Note that this list's indexing is 1-based.

EXAMPLES:

```
sage: dll = sage.combinat.misc.DoublyLinkedList([1,2,3]); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
sage: dll.hide(1); dll
Doubly linked list of [1, 2, 3]: [2, 3]
sage: dll.unhide(1); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
sage: dll.hide(2); dll
Doubly linked list of [1, 2, 3]: [1, 3]
sage: dll.unhide(2); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
```

head()

TESTS:

```
sage: dll = sage.combinat.misc.DoublyLinkedList([1,2,3])
sage: dll.head()
1
sage: dll.hide(1)
sage: dll.head()
2
```

hide(*i*)

TESTS:

```
sage: dll = sage.combinat.misc.DoublyLinkedList([1,2,3])
sage: dll.hide(1)
sage: list(dll)
[2, 3]
```

next(*j*)

TESTS:

```
sage: dll = sage.combinat.misc.DoublyLinkedList([1,2,3])
sage: dll.next(1)
2
sage: dll.hide(2)
```

```
sage: dll.next(1)
3
```

prev(*j*)

TESTS:

```
sage: dll = sage.combinat.misc.DoublyLinkedList([1,2,3])
sage: dll.prev(3)
2
sage: dll.hide(2)
sage: dll.prev(3)
1
```

unhide(*i*)

TESTS:

```
sage: dll = sage.combinat.misc.DoublyLinkedList([1,2,3])
sage: dll.hide(1); dll.unhide(1)
sage: list(dll)
[1, 2, 3]
```

class **IterableFunctionCall**(*f, *args, **kwargs*)

This class wraps functions with a yield statement (generators) by an object that can be iterated over. For example,

EXAMPLES:

```
sage: def f(): yield 'a'; yield 'b'
```

This does not work:

```
sage: for z in f: print z
...
TypeError: 'function' object is not iterable
```

Use IterableFunctionCall if you want something like the above to work:

```
sage: from sage.combinat.misc import IterableFunctionCall
sage: g = IterableFunctionCall(f)
sage: for z in g: print z
a
b
```

If your function takes arguments, just put them after the function name. You needn't enclose them in a tuple or anything, just put them there:

```
sage: def f(n, m): yield 'a' * n; yield 'b' * m; yield 'foo'
sage: g = IterableFunctionCall(f, 2, 3)
sage: for z in g: print z
aa
bbb
foo
```

check_integer_list_constraints(*l, **kwargs*)

EXAMPLES:

```
sage: from sage.combinat.misc import check_integer_list_constraints
sage: cilc = check_integer_list_constraints
sage: l = [[2,1,3],[1,2],[3,3],[4,1,1]]
sage: cilc(l, min_part=2)
```

```
[[3, 3]]
sage: cilc(l, max_part=2)
[[1, 2]]
sage: cilc(l, length=2)
[[1, 2], [3, 3]]
sage: cilc(l, max_length=2)
[[1, 2], [3, 3]]
sage: cilc(l, min_length=3)
[[2, 1, 3], [4, 1, 1]]
sage: cilc(l, max_slope=0)
[[3, 3], [4, 1, 1]]
sage: cilc(l, min_slope=1)
[[1, 2]]
sage: cilc(l, outer=[2,2])
[[1, 2]]
sage: cilc(l, inner=[2,2])
[[3, 3]]

sage: cilc([1,2,3], length=3, singleton=True)
[1, 2, 3]
sage: cilc([1,2,3], length=2, singleton=True) is None
True
```

umbral_operation(*poly*)

Returns the umbral operation $\downarrow$ applied to poly.

The umbral operation replaces each instance of $x_i^{a_i}$ with $x_i * (x_i - 1) * \cdots * (x_i - a_i + 1)$.

EXAMPLES:

```
sage: P = PolynomialRing(QQ, 2, 'x')
sage: x = P.gens()
sage: from sage.combinat.misc import umbral_operation
sage: umbral_operation(x[0]^3) == x[0]*(x[0]-1)*(x[0]-2)
True
sage: umbral_operation(x[0]*x[1])
x0*x1
sage: umbral_operation(x[0]+x[1])
x0 + x1
sage: umbral_operation(x[0]^2*x[1]^2) == x[0]*(x[0]-1)*x[1]*(x[1]-1)
True
```

CHAPTER

EIGHTEEN

NUMERICAL OPTIMIZATION

18.1 Knapsack Problems

This module implements a number of solutions to various knapsack problems, otherwise known as linear integer programming problems. Solutions to the following knapsack problems are implemented:

- Solving the subset sum problem for super-increasing sequences.

AUTHORS:

- Minh Van Nguyen (2009-04): initial version

EXAMPLES:

We can test for whether or not a sequence is super-increasing:

```
sage: from sage.numerical.knapsack import Superincreasing
sage: L = [1, 2, 5, 21, 69, 189, 376, 919]
sage: seq = Superincreasing(L)
sage: seq
Super-increasing sequence of length 8
sage: seq.is_superincreasing()
True
sage: Superincreasing().is_superincreasing([1,3,5,7])
False
```

Solving the subset sum problem for a super-increasing sequence and target sum:

```
sage: L = [1, 2, 5, 21, 69, 189, 376, 919]
sage: Superincreasing(L).subset_sum(98)
[69, 21, 5, 2, 1]
```

class **Superincreasing**(*seq=None*)

A class for super-increasing sequences.

Let $L = (a_1, a_2, a_3, \ldots, a_n)$ be a non-empty sequence of non-negative integers. Then L is said to be super-increasing if each a_i is strictly greater than the sum of all previous values. That is, for each $a_i \in L$ the sequence L must satisfy the property

$$a_i > \sum_{k=1}^{i-1} a_k$$

in order to be called a super-increasing sequence, where $|L| \geq 2$. If L has only one element, it is also defined to be a super-increasing sequence.

If `seq` is `None`, then construct an empty sequence. By defintion, this empty sequence is not super-increasing.

INPUT:

- `seq` – (default: `None`) a non-empty sequence.

EXAMPLES:

```
sage: from sage.numerical.knapsack import Superincreasing
sage: L = [1, 2, 5, 21, 69, 189, 376, 919]
sage: Superincreasing(L).is_superincreasing()
True
sage: Superincreasing().is_superincreasing([1,3,5,7])
False
sage: seq = Superincreasing(); seq
An empty sequence.
sage: seq = Superincreasing([1, 3, 6]); seq
Super-increasing sequence of length 3
sage: seq = Superincreasing(list([1, 2, 5, 21, 69, 189, 376, 919])); seq
Super-increasing sequence of length 8
```

is_superincreasing(*seq=None*)

Determine whether or not `seq` is super-increasing.

If `seq=None` then determine whether or not `self` is super-increasing.

Let $L = (a_1, a_2, a_3, \ldots, a_n)$ be a non-empty sequence of non-negative integers. Then L is said to be super-increasing if each a_i is strictly greater than the sum of all previous values. That is, for each $a_i \in L$ the sequence L must satisfy the property

$$a_i > \sum_{k=1}^{i-1} a_k$$

in order to be called a super-increasing sequence, where $|L| \geq 2$. If L has exactly one element, then it is also defined to be a super-increasing sequence.

INPUT:

- `seq` – (default: `None`) a sequence to test

OUTPUT:

- If `seq` is `None`, then test `self` to determine whether or not it is super-increasing. In that case, return `True` if `self` is super-increasing; `False` otherwise.
- If `seq` is not `None`, then test `seq` to determine whether or not it is super-increasing. Return `True` if `seq` is super-increasing; `False` otherwise.

EXAMPLES:

By definition, an empty sequence is not super-increasing:

```
sage: from sage.numerical.knapsack import Superincreasing
sage: Superincreasing().is_superincreasing([])
False
sage: Superincreasing().is_superincreasing()
False
sage: Superincreasing().is_superincreasing(tuple())
False
sage: Superincreasing().is_superincreasing(())
False
```

But here is an example of a super-increasing sequence:

```
sage: L = [1, 2, 5, 21, 69, 189, 376, 919]
sage: Superincreasing(L).is_superincreasing()
True
sage: L = (1, 2, 5, 21, 69, 189, 376, 919)
sage: Superincreasing(L).is_superincreasing()
True
```

A super-increasing sequence can have zero as one of its elements:

```
sage: L = [0, 1, 2, 4]
sage: Superincreasing(L).is_superincreasing()
True
```

A super-increasing sequence can be of length 1:

```
sage: Superincreasing([randint(0, 100)]).is_superincreasing()
True
```

TESTS:

The sequence must contain only integers:

```
sage: from sage.numerical.knapsack import Superincreasing
sage: L = [1.0, 2.1, pi, 21, 69, 189, 376, 919]
sage: Superincreasing(L).is_superincreasing()
...
TypeError: Element e (= 1.00000000000000) of seq must be a non-negative integer.
sage: L = [1, 2.1, pi, 21, 69, 189, 376, 919]
sage: Superincreasing(L).is_superincreasing()
...
TypeError: Element e (= 2.10000000000000) of seq must be a non-negative integer.
```

largest_less_than(*N*)

Return the largest integer in the sequence `self` that is less than or equal to `N`.

This function narrows down the candidate solution using a binary trim, similar to the way binary search halves the sequence at each iteration.

INPUT:

- `N` – integer; the target value to search for.
- `seq` – the non-empty sequence in which to search.

OUTPUT:

The largest integer in `self` that is less than or equal to `N`. If no solution exists, then return `None`.

EXAMPLES:

When a solution is found, return it:

```
sage: from sage.numerical.knapsack import Superincreasing
sage: L = [2, 3, 7, 25, 67, 179, 356, 819]
sage: Superincreasing(L).largest_less_than(207)
179
sage: L = (2, 3, 7, 25, 67, 179, 356, 819)
sage: Superincreasing(L).largest_less_than(2)
2
```

But if no solution exists, return `None`:

```
sage: L = [2, 3, 7, 25, 67, 179, 356, 819]
sage: Superincreasing(L).largest_less_than(-1) == None
True
```

TESTS:

The target `N` must be an integer:

```
sage: from sage.numerical.knapsack import Superincreasing
sage: L = [2, 3, 7, 25, 67, 179, 356, 819]
sage: Superincreasing(L).largest_less_than(2.30)
...
TypeError: N (= 2.30000000000000) must be an integer.
```

The sequence that `self` represents must also be non-empty:

```
sage: Superincreasing([]).largest_less_than(2)
...
ValueError: seq must be a super-increasing sequence
sage: Superincreasing(list()).largest_less_than(2)
...
ValueError: seq must be a super-increasing sequence
```

subset_sum(*N*)

Solving the subset sum problem for a super-increasing sequence.

Let $S = (s_1, s_2, s_3, \ldots, s_n)$ be a non-empty sequence of non-negative integers, and let $N \in \mathbf{Z}$ be non-negative. The subset sum problem asks for a subset $A \subseteq S$ all of whose elements sum to N. This method specializes the subset sum problem to the case of super-increasing sequences. If a solution exists, then it is also a super-increasing sequence.

Note: This method only solves the subset sum problem for super-increasing sequences. In general, solving the subset sum problem for an arbitrary sequence is known to be computationally hard.

INPUT:

- `N` – a non-negative integer.

OUTPUT:

- A non-empty subset of `self` whose elements sum to `N`. This subset is also a super-increasing sequence. If no such subset exists, then return the empty list.

ALGORITHMS:

The algorithm used is adapted from page 355 of [HPS08].

EXAMPLES:

Solving the subset sum problem for a super-increasing sequence and target sum:

```
sage: from sage.numerical.knapsack import Superincreasing
sage: L = [1, 2, 5, 21, 69, 189, 376, 919]
sage: Superincreasing(L).subset_sum(98)
[69, 21, 5, 2, 1]
```

TESTS:

The target `N` must be a non-negative integer:

```
sage: from sage.numerical.knapsack import Superincreasing
sage: L = [0, 1, 2, 4]
sage: Superincreasing(L).subset_sum(-6)
...
TypeError: N (= -6) must be a non-negative integer.
sage: Superincreasing(L).subset_sum(-6.2)
...
TypeError: N (= -6.20000000000000) must be a non-negative integer.
```

The sequence that `self` represents must only contain non-negative integers:

```
sage: L = [-10, -9, -8, -7, -6, -5, -4, -3, -2, -1, 0, 1]
sage: Superincreasing(L).subset_sum(1)
...
TypeError: Element e (= -10) of seq must be a non-negative integer.
```

18.2 Numerical Root Finding and Optimization

AUTHOR:

- William Stein (2007): initial version

find_fit (*data, model, initial_guess=None, parameters=None, variables=None, solution_dict=False*)

Finds numerical estimates for the parameters of the function model to give a best fit to data.

INPUT:

- `data` – A two dimensional table of floating point numbers of the form $[[x_{1,1}, x_{1,2}, \ldots, x_{1,k}, f_1], [x_{2,1}, x_{2,2}, \ldots, x_{2,k}, f_2], \ldots, [x_{n,1}, x_{n,2}, \ldots, x_{n,k}, f_n]]$ given as either a list of lists, matrix, or numpy array.
- `model` – Either a symbolic expression, symbolic function, or a Python function. `model` has to be a function of the variables $(x_1, x_2, \ldots, x_k)$ and free parameters $(a_1, a_2, \ldots, a_l)$.
- `initial_guess` – (default: `None`) Initial estimate for the parameters $(a_1, a_2, \ldots, a_l)$, given as either a list, tuple, vector or numpy array. If `None`, the default estimate for each parameter is 1.
- `parameters` – (default: `None`) A list of the parameters $(a_1, a_2, \ldots, a_l)$. If model is a symbolic function it is ignored, and the free parameters of the symbolic function are used.
- `variables` – (default: `None`) A list of the variables $(x_1, x_2, \ldots, x_k)$. If model is a symbolic function it is ignored, and the variables of the symbolic function are used.
- `solution_dict` – (default: `False`) if `True`, return the solution as a dictionary rather than an equation.

EXAMPLES:

First we create some datapoints of a sine function with some random perturbations:

```
sage: data = [(i, 1.2 * sin(0.5*i-0.2) + 0.1 * normalvariate(0, 1)) for i in xsrange(0, 4*pi, 0.
sage: var('a, b, c, x')
(a, b, c, x)
```

We define a function with free parameters a, b and c:

```
sage: model(x) = a * sin(b * x - c)
```

We search for the parameters that give the best fit to the data:

```
sage: find_fit(data, model)
[a == 1.21..., b == 0.49..., c == 0.19...]
```

We can also use a Python function for the model:

```
sage: def f(x, a, b, c): return a * sin(b * x - c)
sage: fit = find_fit(data, f, parameters = [a, b, c], variables = [x], solution_dict = True)
sage: fit[a], fit[b], fit[c]
(1.21..., 0.49..., 0.19...)
```

We search for a formula for the n-th prime number:

```
sage: dataprime = [(i, nth_prime(i)) for i in xrange(1, 5000, 100)]
sage: find_fit(dataprime, a * x * log(b * x), parameters = [a, b], variables = [x])
[a == 1.11..., b == 1.24...]
```

ALGORITHM:

Uses `scipy.optimize.leastsq` which in turn uses MINPACK's lmdif and lmder algorithms.

find_maximum_on_interval (*f, a, b, tol=1.48e-08, maxfun=500*)

Numerically find the maximum of the expression f on the interval $[a, b]$ (or $[b, a]$) along with the point at which the maximum is attained.

See the documentation for `find_minimum_on_interval()` for more details.

EXAMPLES:

```
sage: f = lambda x: x*cos(x)
sage: find_maximum_on_interval(f, 0,5)
(0.561096338191..., 0.8603335890...)
sage: find_maximum_on_interval(f, 0,5, tol=0.1, maxfun=10)
(0.561090323458..., 0.857926501456...)
```

find_minimum_on_interval (*f, a, b, tol=1.48e-08, maxfun=500*)

Numerically find the minimum of the expression `self` on the interval $[a, b]$ (or $[b, a]$) and the point at which it attains that minimum. Note that `self` must be a function of (at most) one variable.

INPUT:

- `a`, `b` – endpoints of interval on which to minimize self.
- `tol` – the convergence tolerance
- `maxfun` – maximum function evaluations

OUTPUT:

- `minval` – (float) the minimum value that self takes on in the interval $[a, b]$
- `x` – (float) the point at which self takes on the minimum value

EXAMPLES:

```
sage: f = lambda x: x*cos(x)
sage: find_minimum_on_interval(f, 1, 5)
(-3.28837139559..., 3.4256184695...)
sage: find_minimum_on_interval(f, 1, 5, tol=1e-3)
(-3.28837136189098..., 3.42575079030572...)
sage: find_minimum_on_interval(f, 1, 5, tol=1e-2, maxfun=10)
(-3.28837084598..., 3.4250840220...)
sage: show(plot(f, 0, 20))
sage: find_minimum_on_interval(f, 1, 15)
(-9.4772942594..., 9.5293344109...)
```

ALGORITHM:

Uses scipy.optimize.fminbound which uses Brent's method.

AUTHOR:

- William Stein (2007-12-07)

find_root (*f, a, b, xtol=9.9999999999999998e-13, rtol=4.5000000000000002e-16, maxiter=100, full_output=False*)

Numerically find a root of `f` on the closed interval $[a, b]$ (or $[b, a]$) if possible, where `f` is a function in the one variable.

INPUT:

- `f` – a function of one variable or symbolic equality
- `a`, `b` – endpoints of the interval
- `xtol`, `rtol` – the routine converges when a root is known to lie within `xtol` of the value return. Should be ≥ 0. The routine modifies this to take into account the relative precision of doubles.

- `maxiter` – integer; if convergence is not achieved in `maxiter` iterations, an error is raised. Must be ≥ 0.
- `full_output` – bool (default: `False`), if `True`, also return object that contains information about convergence.

EXAMPLES:

An example involving an algebraic polynomial function:

```
sage: R.<x> = QQ[]
sage: f = (x+17)*(x-3)*(x-1/8)^3
sage: find_root(f, 0,4)
2.9999999999999951
sage: find_root(f, 0,1)  # note -- precision of answer isn't very good on some machines.
0.124999...
sage: find_root(f, -20,-10)
-17.0
```

In Pomerance book on primes he asserts that the famous Riemann Hypothesis is equivalent to the statement that the function $f(x)$ defined below is positive for all $x \geq 2.01$:

```
sage: def f(x):
...       return sqrt(x) * log(x) - abs(Li(x) - prime_pi(x))
```

We find where f equals, i.e., what value that is slightly smaller than 2.01 that could have been used in the formulation of the Riemann Hypothesis:

```
sage: find_root(f, 2, 4, rtol=0.0001)
2.0082590205656166
```

This agrees with the plot:

```
sage: plot(f,2,2.01)
```

linear_program(*c, G, h, A=None, b=None*)

Solves the dual linear programs:

- Minimize $c'x$ subject to $Gx + s = h$, $Ax = b$, and $s \geq 0$ where $'$ denotes transpose.
- Maximize $-h'z - b'y$ subject to $G'z + A'y + c = 0$ and $z \geq 0$.

INPUT:

- `c` – a vector
- `G` – a matrix
- `h` – a vector
- `A` – a matrix
- `b` — a vector

These can be over any field that can be turned into a floating point number.

OUTPUT:

A dictionary `sol` with keys `x`, `s`, `y`, `z` corresponding to the variables above:

- `sol['x']` – the solution to the linear program
- `sol['s']` – the slack variables for the solution
- `sol['z']`, `sol['y']` – solutions to the dual program

EXAMPLES:

First, we minimize $-4x_1 - 5x_2$ subject to $2x_1 + x_2 \leq 3$, $x_1 + 2x_2 \leq 3$, $x_1 \geq 0$, and $x_2 \geq 0$:

```
sage: c=vector(RDF,[-4,-5])
sage: G=matrix(RDF,[[2,1],[1,2],[-1,0],[0,-1]])
sage: h=vector(RDF,[3,3,0,0])
sage: sol=linear_program(c,G,h)
sage: sol['x']
(0.999..., 1.000...)
```

Next, we maximize $x + y - 50$ subject to $50x + 24y \leq 2400$, $30x + 33y \leq 2100$, $x \geq 45$, and $y \geq 5$:

```
sage: v=vector([-1.0,-1.0,-1.0])
sage: m=matrix([[50.0,24.0,0.0],[30.0,33.0,0.0],[-1.0,0.0,0.0],[0.0,-1.0,0.0],[0.0,0.0,1.0],[0.0
sage: h=vector([2400.0,2100.0,-45.0,-5.0,1.0,-1.0])
sage: sol=linear_program(v,m,h)
sage: sol['x']
(45.000000..., 6.2499999...3, 1.00000000...)
```

minimize (*func, x0, gradient=None, hessian=None, algorithm='default', **args*)

This function is an interface to a variety of algorithms for computing the minimum of a function of several variables.

INPUT:

- `func` – Either a symbolic function or a Python function whose argument is a tuple with n components
- `x0` – Initial point for finding minimum.
- `gradient` – Optional gradient function. This will be computed automatically for symbolic functions. For Python functions, it allows the use of algorithms requiring derivatives. It should accept a tuple of arguments and return a numpy array containing the partial derivatives at that point.
- `hessian` – Optional hessian function. This will be computed automatically for symbolic functions. For Python functions, it allows the use of algorithms requiring derivatives. It should accept a tuple of arguments and return a numpy array containing the second partial derivatives of the function.
- `algorithm` – String specifying algorithm to use. Options are `'default'` (for Python functions, the simplex method is the default) (for symbolic functions bfgs is the default):
  - `'simplex'`
  - `'powell'`
  - `'bfgs'` – (broyden-fletcher-goldfarb-shannon) requires `gradient`
  - `'cg'` – (conjugate-gradient) requires gradient
  - `'ncg'` – (newton-conjugate gradient) requires gradient and hessian

EXAMPLES:

```
sage: vars=var('x y z')
sage: f=100*(y-x^2)^2+(1-x)^2+100*(z-y^2)^2+(1-y)^2
sage: minimize(f,[.1,.3,.4],disp=0)
(1.00..., 1.00..., 1.00...)

sage: minimize(f,[.1,.3,.4],algorithm="ncg",disp=0)
(0.9999999..., 0.999999..., 0.999999...)
```

Same example with just Python functions:

```
sage: def rosen(x): # The Rosenbrock function
...       return sum(100.0r*(x[1r:]-x[:-1r]**2.0r)**2.0r + (1r-x[:-1r])**2.0r)
sage: minimize(rosen,[.1,.3,.4],disp=0)
(1.00..., 1.00..., 1.00...)
```

Same example with a pure Python function and a Python function to compute the gradient:

```
sage: def rosen(x): # The Rosenbrock function
...       return sum(100.0r*(x[1r:]-x[:-1r]**2.0r)**2.0r + (1r-x[:-1r])**2.0r)
sage: import numpy
sage: from numpy import zeros
sage: def rosen_der(x):
...       xm = x[1r:-1r]
...       xm_m1 = x[:-2r]
...       xm_p1 = x[2r:]
...       der = zeros(x.shape,dtype=float)
...       der[1r:-1r] = 200r*(xm-xm_m1**2r) - 400r*(xm_p1 - xm**2r)*xm - 2r*(1r-xm)
...       der[0] = -400r*x[0r]*(x[1r]-x[0r]**2r) - 2r*(1r-x[0])
...       der[-1] = 200r*(x[-1r]-x[-2r]**2r)
...       return der
sage: minimize(rosen,[.1,.3,.4],gradient=rosen_der,algorithm="bfgs",disp=0)
(1.00...,  1.00..., 1.00...)
```

minimize_constrained(*func, cons, x0, gradient=None, algorithm='default', **args*)

Minimize a function with constraints.

INPUT:

- `func` – Either a symbolic function, or a Python function whose argument is a tuple with n components
- `cons` – constraints. This should be either a function or list of functions that must be positive. Alternatively, the constraints can be specified as a list of intervals that define the region we are minimizing in. If the constraints are specified as functions, the functions should be functions of a tuple with n components (assuming n variables). If the constraints are specifed as a list of intervals and there are no constraints for a given variable, that component can be (`None`, `None`).
- `x0` – Initial point for finding minimum
- `algorithm` – Optional, specify the algorithm to use:
  - `'default'` – default choices
  - `'l-bfgs-b'` – only effective if you specify bound constraints. See [ZBN97].
- `gradient` – Optional gradient function. This will be computed automatically for symbolic functions. This is only used when the constraints are specified as a list of intervals.

EXAMPLES:

Let us maximize $x+y-50$ subject to the following constraints: $50x+24y \leq 2400$, $30x+33y \leq 2100$, $x \geq 45$, and $y \geq 5$:

```
sage: y = var('y')
sage: f = lambda p: -p[0]-p[1]+50
sage: c_1 = lambda p: p[0]-45
sage: c_2 = lambda p: p[1]-5
sage: c_3 = lambda p: -50*p[0]-24*p[1]+2400
sage: c_4 = lambda p: -30*p[0]-33*p[1]+2100
sage: a = minimize_constrained(f,[c_1,c_2,c_3,c_4],[2,3])
sage: a
(45.0, 6.25)
```

Let's find a minimum of $\sin(xy)$:

```
sage: x,y = var('x y')
sage: f = sin(x*y)
sage: minimize_constrained(f, [(None,None),(4,10)],[5,5])
(4.8..., 4.8...)
```

Check, if L-BFGS-B finds the same minimum:

```
sage: minimize_constrained(f, [(None,None),(4,10)],[5,5], algorithm='l-bfgs-b')
(4.7..., 4.9...)
```

Rosenbrock funcion, [http://en.wikipedia.org/wiki/Rosenbrock_function]:

```
sage: from scipy.optimize import rosen, rosen_der
sage: minimize_constrained(rosen, [(-50,-10),(5,10)],[1,1],gradient=rosen_der,algorithm='l-bfgs-
(-10.0, 10.0)
sage: minimize_constrained(rosen, [(-50,-10),(5,10)],[1,1],algorithm='l-bfgs-b')
(-10.0, 10.0)
```

NINETEEN

PROBABILITY

19.1 Random variables and probability spaces

This introduces a class of random variables, with the focus on discrete random variables (i.e. on a discrete probability space). This avoids the problem of defining a measure space and measurable functions.

class **DiscreteProbabilitySpace** (*X, P, codomain=None, check=False*)

The discrete probability space

entropy ()

The entropy of the probability space.

set ()

The set of values of the probability space taking possibly nonzero probability (a subset of the domain).

class **DiscreteRandomVariable** (*X, f, codomain=None, check=False*)

A random variable on a discrete probability space.

correlation (*other*)

The correlation of the probability space X = self with Y = other.

covariance (*other*)

The covariance of the discrete random variable X = self with Y = other.

Let S be the probability space of X = self, with probability function p, and $E(X)$ be the expectation of X. Then the variance of X is:

$$\text{cov}(X,Y) = E((X - E(X) * (Y - E(Y)) = \sum_{x \in S} p(x)(X(x) - E(X))(Y(x) - E(Y))$$

expectation ()

The expectation of the discrete random variable, namely $\sum_{x \in S} p(x)X[x]$, where X = self and S is the probability space of X.

function ()

The function defining the random variable.

standard_deviation ()

The standard deviation of the discrete random variable.

Let S be the probability space of X = self, with probability function p, and $E(X)$ be the expectation of X. Then the standard deviation of X is defined to be

$$\sigma(X) = \sqrt{\sum_{x \in S} p(x)(X(x) - E(x)) * *2}$$

translation_correlation (*other, map*)

The correlation of the probability space X = self with image of Y = other under map.

translation_covariance(*other, map*)

The covariance of the probability space X = self with image of Y = other under the given map of the probability space.

Let S be the probability space of X = self, with probability function p, and $E(X)$ be the expectation of X. Then the variance of X is:

$$\mathrm{cov}(X,Y) = E((X - E(X) * (Y - E(Y)) = \sum_{x \in S} p(x)(X(x) - E(X))(Y(x) - E(Y))$$

translation_expectation(*map*)

The expectation of the discrete random variable, namely $\sum_{x \in S} p(x)X[e(x)]$, where X = self, S is the probability space of X, and e = map.

translation_standard_deviation(*map*)

The standard deviation of the translated discrete random variable $X \circ e$, where X = self and e = map.

Let S be the probability space of X = self, with probability function p, and $E(X)$ be the expectation of X. Then the standard deviation of X is defined to be

$$\sigma(X) = \sqrt{\sum_{x \in S} p(x)(X(x) - E(x)) * *2}$$

translation_variance(*map*)

The variance of the discrete random variable $X \circ e$, where X = self, and e = map.

Let S be the probability space of X = self, with probability function p, and $E(X)$ be the expectation of X. Then the variance of X is:

$$\mathrm{var}(X) = E((X - E(x))^2) = \sum_{x \in S} p(x)(X(x) - E(x))^2$$

variance()

The variance of the discrete random variable.

Let S be the probability space of X = self, with probability function p, and $E(X)$ be the expectation of X. Then the variance of X is:

$$\mathrm{var}(X) = E((X - E(x))^2) = \sum_{x \in S} p(x)(X(x) - E(x))^2$$

class **ProbabilitySpace_generic**(*domain, RR*)

A probability space.

domain()

class **RandomVariable_generic**(*X, RR*)

A random variable.

codomain()

domain()

field()

probability_space()

CATEGORY THEORY

20.1 Categories

AUTHORS:

- David Kohel and William Stein

Every Sage object lies in a category. Categories in Sage are modeled on the mathematical idea of category, and are distinct from Python classes, which are a programming construct.

In most cases, typing `x.category()` returns the category to which x belongs. If C is a category and x is any object, $C(x)$ tries to make an object in C from x.

EXAMPLES: We create a couple of categories.

```
sage: Sets()
Category of sets
sage: GSets(AbelianGroup([2,4,9]))
Category of G-sets for Multiplicative Abelian Group isomorphic to C2 x C4 x C9
sage: Semigroups()
Category of semigroups
sage: VectorSpaces(FiniteField(11))
Category of vector spaces over Finite Field of size 11
sage: Ideals(IntegerRing())
Category of ring ideals in Integer Ring
```

The default category for elements x of an objects O is the category of all objects of O. For example,

```
sage: V = VectorSpace(RationalField(), 3)
sage: x = V.gen(1)
sage: x.category()
Category of elements of Vector space of dimension 3 over Rational Field
```

class **Category**(*s=None*)

The base class for all categories.

category()

is_abelian()

is_subcategory(*c*)

Returns True if self is naturally embedded as a subcategory of c.

EXAMPLES:

```
sage: Rings  = Rings()
sage: AbGrps = AbelianGroups()
sage: Rings.is_subcategory(AbGrps)
True
sage: AbGrps.is_subcategory(Rings)
False
```

The `is_subcategory` function takes into account the base.

```
sage: M3 = VectorSpaces(FiniteField(3))
sage: M9 = VectorSpaces(FiniteField(9, 'a'))
sage: M3.is_subcategory(M9)
False
```

short_name()

class Category_uniq(*s=None*)

class Sets(*s=None*)

The category of sets.

EXAMPLES: sage: Sets() Category of sets

is_Category(*x*)

Returns True if x is a category.

class uniq()

class uniq1()

20.2 Homsets

AUTHORS:

- David Kohel and William Stein
- David Joyner (2005-12-17): added examples
- William Stein (2006-01-14): Changed from Homspace to Homset.

End(*X*, *cat=None*)

Create the set of endomorphisms of X in the category cat.

INPUT:

- `X` - anything
- `cat` - (optional) category in which to coerce X

OUTPUT: a set of endomorphisms in cat

EXAMPLES:

```
sage: V = VectorSpace(QQ, 3)
sage: End(V)
Set of Morphisms from Vector space of dimension 3 over Rational
Field to Vector space of dimension 3 over Rational Field in
Category of vector spaces over Rational Field
```

```
sage: G = SymmetricGroup(3)
sage: S = End(G); S
Set of Morphisms from SymmetricGroup(3) to SymmetricGroup(3) in Category of groups
sage: from sage.categories.homset import is_Endset
sage: is_Endset(S)
True
sage: S.domain()
Symmetric group of order 3! as a permutation group
```

Homsets are *not* objects in their category. They are currently sets.

```
sage: S.category()
Category of sets
sage: S.domain().category()
Category of groups
```

Hom(*X, Y, cat=None*)

Create the space of homomorphisms from X to Y in the category cat.

INPUT:

- `X` - anything
- `Y` - anything
- `cat` - (optional) category in which the morphisms must be

OUTPUT: a homset in cat

EXAMPLES:

```
sage: V = VectorSpace(QQ,3)
sage: Hom(V, V)
Set of Morphisms from Vector space of dimension 3 over Rational
Field to Vector space of dimension 3 over Rational Field in
Category of vector spaces over Rational Field
sage: G = SymmetricGroup(3)
sage: Hom(G, G)
Set of Morphisms from SymmetricGroup(3) to SymmetricGroup(3) in Category of groups
sage: Hom(ZZ, QQ, Sets())
Set of Morphisms from Integer Ring to Rational Field in Category of sets
```

class **Homset**(*X, Y, cat=None, check=True*)

The class for collections of morphisms in a category.

EXAMPLES:

```
sage: H = Hom(QQ^2, QQ^3)
sage: loads(H.dumps()) == H
True
sage: E = End(AffineSpace(2, names='x,y'))
sage: loads(E.dumps()) == E
True
```

codomain()

coerce_map_from_c(*R*)

domain()

get_action_c(*R, op, self_on_left*)

homset_category()
Return the category that this is a Hom in, i.e., this is typically the category of the domain or codomain object.

EXAMPLES:

```
sage: H = Hom(SymmetricGroup(4), SymmetricGroup(7))
sage: H.homset_category()
Category of groups
```

identity()

is_endomorphism_set()
Return True if the domain and codomain of self are the same object.

natural_map()

reversed()
Return the corresponding homset, but with the domain and codomain reversed.

EXAMPLES:

```
sage: H = Hom(ZZ^2, ZZ^3); H
Set of Morphisms from Ambient free module of rank 2 over the principal ideal domain Integer
sage: type(H)
<class 'sage.modules.free_module_homspace.FreeModuleHomspace'>
sage: H.reversed()
Set of Morphisms from Ambient free module of rank 3 over the principal ideal domain Integer
sage: type(H.reversed())
<class 'sage.modules.free_module_homspace.FreeModuleHomspace'>
```

class HomsetWithBase(*X, Y, cat=None, check=True, base=None*)

end(*X, f*)
Return End(X)(f), where f is data that defines an element of End(X).

EXAMPLES:

```
sage: R, x = PolynomialRing(QQ,'x').objgen()
sage: phi = end(R, [x + 1])
sage: phi
Ring endomorphism of Univariate Polynomial Ring in x over Rational Field
  Defn: x |--> x + 1
sage: phi(x^2 + 5)
x^2 + 2*x + 6
```

hom(*X, Y, f*)
Return Hom(X,Y)(f), where f is data that defines an element of Hom(X,Y).

EXAMPLES:

```
sage: R, x = PolynomialRing(QQ,'x').objgen()
sage: phi = hom(R, QQ, [2])
sage: phi(x^2 + 3)
7
```

is_Endset(*x*)
Return True if x is a set of endomorphisms in a category.

is_Homset(*x*)
Return True if x is a set of homomorphisms in a category.

20.3 Morphisms

AUTHORS:

- William Stein: initial version

20.4 Functors

AUTHORS:

- David Kohel and William Stein
- David Joyner (2005-12-17): examples
- Robert Bradshaw (2007-06-23): Pyrexify

ForgetfulFunctor()
Construct the forgetful function from one category to another.

EXAMPLES:

```
sage: rings = Rings()
sage: abgrps = AbelianGroups()
sage: F = ForgetfulFunctor(rings, abgrps)
sage: F
The forgetful functor from Rings to AbelianGroups
```

class ForgetfulFunctor_generic()

class Functor()
EXAMPLES:

```
sage: rings  = Rings()
sage: abgrps = AbelianGroups()
sage: F = ForgetfulFunctor(rings, abgrps)
sage: F.domain()
Category of rings
sage: F.codomain()
Category of abelian groups
sage: from sage.categories.functor import is_Functor
sage: is_Functor(F)
True
sage: I = IdentityFunctor(abgrps)
sage: I
The identity functor on AbelianGroups
sage: I.domain()
Category of abelian groups
sage: is_Functor(I)
True
```

codomain()

domain()

IdentityFunctor()

class **IdentityFunctor_generic**()

is_Functor()

CHAPTER

TWENTYONE

MONOIDS

Sage supports free monoids and free abelian monoids in any finite number of indeterminates.

21.1 Free Monoids

AUTHORS:

- David Kohel (2005-09)

Sage supports free monoids on any prescribed finite number $n \geq 0$ of generators. Use the `FreeMonoid` function to create a free monoid, and the `gen` and `gens` functions to obtain the corresponding generators. You can print the generators as arbitrary strings using the optional `names` argument to the `FreeMonoid` function.

class FreeMonoidFactory()

Returns a free monoid on n generators.

INPUT:

- `n` - integer
- `names` - names of generators

OUTPUT: free abelian monoid

EXAMPLES:

```
sage: FreeMonoid(0,'')
Free monoid on 0 generators ()
sage: F.<a,b,c,d,e> = FreeMonoid(5); F
Free monoid on 5 generators (a, b, c, d, e)
sage: F(1)
1
sage: mul([ a, b, a, c, b, d, c, d ], F(1))
a*b*a*c*b*d*c*d
```

create_key(*n, names*)

create_object(*version, key*)

class FreeMonoid_class(*n, names=None*)

The free monoid on n generators.

gen(*i=0*)

The i-th generator of the monoid.

INPUT:

- i - integer (default: 0)

EXAMPLES:

```
sage: F = FreeMonoid(3, 'a')
sage: F.gen(1)
a1
sage: F.gen(2)
a2
sage: F.gen(5)
...
IndexError: Argument i (= 5) must be between 0 and 2.
```

ngens()

The number of free generators of the monoid.

EXAMPLES:

```
sage: F = FreeMonoid(2005, 'a')
sage: F.ngens()
2005
```

is_FreeMonoid(*x*)

Return True if *x* is a free monoid.

EXAMPLES:

```
sage: from sage.monoids.free_monoid import is_FreeMonoid
sage: is_FreeMonoid(5)
False
sage: is_FreeMonoid(FreeMonoid(7,'a'))
True
sage: is_FreeMonoid(FreeAbelianMonoid(7,'a'))
False
sage: is_FreeMonoid(FreeAbelianMonoid(0,''))
False
```

21.2 Monoid Elements

AUTHORS:

- David Kohel (2005-09-29)

Elements of free monoids are represented internally as lists of pairs of integers.

class **FreeMonoidElement**(*F, x, check=True*)

Element of a free monoid.

EXAMPLES:

```
sage: a = FreeMonoid(5, 'a').gens()
sage: x = a[0]*a[1]*a[4]**3
sage: x**3
a0*a1*a4^3*a0*a1*a4^3*a0*a1*a4^3
sage: x**0
1
sage: x**(-1)
...
TypeError: bad operand type for unary ~: 'FreeMonoidElement'
```

is_FreeMonoidElement(x)

21.3 Free abelian monoids

AUTHORS:

- David Kohel (2005-09)

Sage supports free abelian monoids on any prescribed finite number $n \geq 0$ of generators. Use the `FreeAbelianMonoid` function to create a free abelian monoid, and the `gen` and `gens` functions to obtain the corresponding generators. You can print the generators as arbitrary strings using the optional `names` argument to the `FreeAbelianMonoid` function.

EXAMPLE 1: It is possible to create an abelian monoid in zero or more variables; the syntax T(1) creates the monoid indentity element even in the rank zero case.

```
sage: T = FreeAbelianMonoid(0, '')
sage: T
Free abelian monoid on 0 generators ()
sage: T.gens()
()
sage: T(1)
1
```

EXAMPLE 2: A free abelian monoid uses a multiplicative representation of elements, but the underlying representation is lists of integer exponents.

```
sage: F = FreeAbelianMonoid(5,names='a,b,c,d,e')
sage: (a,b,c,d,e) = F.gens()
sage: a*b^2*e*d
a*b^2*d*e
sage: x = b^2*e*d*a^7
sage: x
a^7*b^2*d*e
sage: x.list()
[7, 2, 0, 1, 1]
```

class FreeAbelianMonoidFactory()

Create the free abelian monoid in n generators.

INPUT:

- `n` - integer
- `names` - names of generators

OUTPUT: free abelian monoid

EXAMPLES:

```
sage: FreeAbelianMonoid(0, '')
Free abelian monoid on 0 generators ()
sage: F = FreeAbelianMonoid(5,names = list("abcde"))
sage: F
Free abelian monoid on 5 generators (a, b, c, d, e)
sage: F(1)
1
```

```
sage: (a, b, c, d, e) = F.gens()
sage: mul([ a, b, a, c, b, d, c, d ], F(1))
a^2*b^2*c^2*d^2
sage: a**2 * b**3 * a**2 * b**4
a^4*b^7

sage: loads(dumps(F)) is F
True
```

create_key(*n, names*)

create_object(*version, key*)

class FreeAbelianMonoid_class(*n, names*)

Free abelian monoid on n generators.

gen(*i=0*)

The i-th generator of the abelian monoid.

EXAMPLES:

```
sage: F = FreeAbelianMonoid(5,'a')
sage: F.gen(0)
a0
sage: F.gen(2)
a2
```

ngens()

The number of free generators of the abelian monoid.

EXAMPLES:

```
sage: F = FreeAbelianMonoid(3000, 'a')
sage: F.ngens()
3000
```

is_FreeAbelianMonoid(*x*)

Return True if x is a free abelian monoid.

EXAMPLES:

```
sage: from sage.monoids.free_abelian_monoid import is_FreeAbelianMonoid
sage: is_FreeAbelianMonoid(5)
False
sage: is_FreeAbelianMonoid(FreeAbelianMonoid(7,'a'))
True
sage: is_FreeAbelianMonoid(FreeMonoid(7,'a'))
False
sage: is_FreeAbelianMonoid(FreeMonoid(0,''))
False
```

21.4 Abelian monoid elements

AUTHORS:

- David Kohel (2005-09)

EXAMPLES: Recall the example from abelian monoids.

```
sage: F = FreeAbelianMonoid(5,names = list("abcde"))
sage: (a,b,c,d,e) = F.gens()
sage: a*b^2*e*d
a*b^2*d*e
sage: x = b^2*e*d*a^7
sage: x
a^7*b^2*d*e
sage: x.list()
[7, 2, 0, 1, 1]
```

It is important to note that lists are mutable and the returned list is not a copy. As a result, reassignment of an element of the list changes the object.

```
sage: x.list()[0] = 0
sage: x
b^2*d*e
```

class FreeAbelianMonoidElement (*F*, *x*)

list ()

Return (a reference to) the underlying list used to represent this element. If this is a monoid in an abelian monoid on n generators, then this is a list of nonnegative integers of length n.

EXAMPLES:

```
sage: F = FreeAbelianMonoid(5, 'abcde')
sage: (a, b, c, d, e) = F.gens()
sage: a.list()
[1, 0, 0, 0, 0]
```

is_FreeAbelianMonoidElement (*x*)

CHAPTER

TWENTYTWO

GROUPS

22.1 Base class for groups

class AbelianGroup()
Generic abelian group.

is_abelian()
Return True.

class AlgebraicGroup()
Generic algebraic group.

class FiniteGroup()
Generic finite group.

cayley_graph()
Returns the cayley graph for this finite group, as a Sage DiGraph object. To plot the graph with with different colors

EXAMPLES:

```
sage: D4 = DihedralGroup(4); D4
Dihedral group of order 8 as a permutation group
sage: G = D4.cayley_graph()
sage: show(G, color_by_label=True, edge_labels=True)
sage: A5 = AlternatingGroup(5); A5
Alternating group of order 5!/2 as a permutation group
sage: G = A5.cayley_graph()
sage: G.show3d(color_by_label=True, edge_size=0.01, edge_size2=0.02, vertex_size=0.03)
sage: G.show3d(vertex_size=0.03, edge_size=0.01, edge_size2=0.02, vertex_colors={(1,1,1):G.v

sage: s1 = SymmetricGroup(1); s = s1.cayley_graph(); s.vertices()
[()]
```

AUTHORS:

- Bobby Moretti (2007-08-10)
- Robert Miller (2008-05-01): editing

is_finite()
Return True.

class Group()
Generic group class

category()
The category of all groups

is_abelian()
Return True if this group is abelian.

is_atomic_repr()
True if the elements of this group have atomic string representations. For example, integers are atomic but polynomials are not.

is_finite()
Returns True if this group is finite.

is_multiplicative()
Returns True if the group operation is given by * (rather than +).

Override for additive groups.

order()
Returns the number of elements of this group, which is either a positive integer or infinity.

quotient()
Return the quotient of this group by the normal subgroup H.

random_element()
Return a random element of this group.

22.2 Multiplicative Abelian Groups

AUTHORS:

- William Stein, David Joyner (2008-12): added (user requested) is_cyclic, fixed elementary_divisors.
- David Joyner (2006-03): (based on free abelian monoids by David Kohel)
- David Joyner (2006-05) several significant bug fixes
- David Joyner (2006-08) trivial changes to docs, added random, fixed bug in how invariants are recorded
- David Joyner (2006-10) added dual_group method
- David Joyner (2008-02) fixed serious bug in word_problem
- David Joyner (2008-03) fixed bug in trivial group case
- David Loeffler (2009-05) added subgroups method

TODO:

- additive abelian groups should also be supported

Background on invariant factors and the Smith normal form (according to section 4.1 of [C1]): An abelian group is a group A for which there exists an exact sequence $\mathbf{Z}^k \to \mathbf{Z}^\ell \to A \to 1$, for some positive integers k, ℓ with $k \leq \ell$. For example, a finite abelian group has a decomposition

$$A = \langle a_1 \rangle \times \cdots \times \langle a_\ell \rangle,$$

where $ord(a_i) = p_i^{c_i}$, for some primes p_i and some positive integers c_i, $i = 1, ..., \ell$. GAP calls the list (ordered by size) of the $p_i^{c_i}$ the *abelian invariants*. In Sage they will be called *invariants*. In this situation, $k = \ell$ and $\phi : \mathbf{Z}^\ell \to A$ is the map $\phi(x_1, ..., x_\ell) = a_1^{x_1} ... a_\ell^{x_\ell}$, for $(x_1, ..., x_\ell) \in \mathbf{Z}^\ell$. The matrix of relations $M : \mathbf{Z}^k \to \mathbf{Z}^\ell$ is the matrix whose rows generate the kernel of ϕ as a $\mathbf{Z}$-module. In other words, $M = (M_{ij})$ is a $\ell \times \ell$ diagonal matrix with $M_{ii} = p_i^{c_i}$.

Consider now the subgroup $B \subset A$ generated by $b_1 = a_1^{f_{1,1}}...a_\ell^{f_{\ell,1}}$, ..., $b_m = a_1^{f_{1,m}}...a_\ell^{f_{\ell,m}}$. The kernel of the map $\phi_B : \mathbf{Z}^m \to B$ defined by $\phi_B(y_1, ..., y_m) = b_1^{y_1}...b_m^{y_m}$, for $(y_1, ..., y_m) \in \mathbf{Z}^m$, is the kernel of the matrix

$$F = \begin{pmatrix} f_{11} & f_{12} & \cdots & f_{1m} \\ f_{21} & f_{22} & \cdots & f_{2m} \\ \vdots & & \ddots & \vdots \\ f_{\ell,1} & f_{\ell,2} & \cdots & f_{\ell,m} \end{pmatrix},$$

regarded as a map $\mathbf{Z}^m \to (\mathbf{Z}/p_1^{c_1}\mathbf{Z}) \times ... \times (\mathbf{Z}/p_\ell^{c_\ell}\mathbf{Z})$. In particular, $B \cong \mathbf{Z}^m/ker(F)$. If $B = A$ then the Smith normal form (SNF) of a generator matrix of $ker(F)$ and the SNF of M are the same. The diagonal entries s_i of the SNF $S = diag[s_1, s_2, s_3, ...s_r, 0, 0, ...0]$, are called *determinantal divisors* of F. where r is the rank. The {it invariant factors} of A are:

$$s_1, s_2/s_1, s_3/s_2, ...s_r/s_{r-1}.$$

Sage supports multiplicative abelian groups on any prescribed finite number $n \geq 0$ of generators. Use the `AbelianGroup` function to create an abelian group, and the `gen` and `gens` functions to obtain the corresponding generators. You can print the generators as arbitrary strings using the optional `names` argument to the `AbelianGroup` function.

EXAMPLE 1:

We create an abelian group in zero or more variables; the syntax T(1) creates the identity element even in the rank zero case.

```
sage: T = AbelianGroup(0,[])
sage: T
Trivial Abelian Group
sage: T.gens()
()
sage: T(1)
1
```

EXAMPLE 2: An abelian group uses a multiplicative representation of elements, but the underlying representation is lists of integer exponents.

```
sage: F = AbelianGroup(5,[3,4,5,5,7],names = list("abcde"))
sage: F
Multiplicative Abelian Group isomorphic to C3 x C4 x C5 x C5 x C7
sage: (a,b,c,d,e) = F.gens()
sage: a*b^2*e*d
a*b^2*d*e
sage: x = b^2*e*d*a^7
sage: x
a*b^2*d*e
sage: x.list()
[1, 2, 0, 1, 1]
```

- [R] J. Rotman, An introduction to the theory of groups, 4th ed, Springer, 1995.

Warning: Many basic properties for infinite abelian groups are not implemented.

AbelianGroup(*n, invfac=None, names='f'*)

Create the multiplicative abelian group in n generators with given invariants (which need not be prime powers).

INPUT:

- `n` - integer
- `invfac` - (the"invariant factors") a list of non-negative integers in the form [a0, a1,...,a(n-1)], typically written in increasing order. This list is padded with zeros if it has length less than n.
- `names` - (optional) names of generators

  Alternatively, you can also give input in the following form:

  `AbelianGroup(invfac, names="f"),`

  where names must be explicitly named.

OUTPUT: Abelian group with generators and invariant type. The default name for generator A.i is fi, as in GAP.

EXAMPLES:

```
sage: F = AbelianGroup(5, [5,5,7,8,9], names='abcde')
sage: F(1)
1
sage: (a, b, c, d, e) = F.gens()
sage: mul([ a, b, a, c, b, d, c, d ], F(1))
a^2*b^2*c^2*d^2
sage: d * b**2 * c**3
b^2*c^3*d
sage: F = AbelianGroup(3,[2]*3); F
Multiplicative Abelian Group isomorphic to C2 x C2 x C2
sage: H = AbelianGroup([2,3], names="xy"); H
Multiplicative Abelian Group isomorphic to C2 x C3
sage: AbelianGroup(5)
Multiplicative Abelian Group isomorphic to Z x Z x Z x Z x Z
sage: AbelianGroup(5).order()
+Infinity
```

Notice how 0's are padded on.

```
sage: AbelianGroup(5, [2,3,4])
Multiplicative Abelian Group isomorphic to Z x Z x C2 x C3 x C4
```

The invariant list can't be longer than the number of generators.

```
sage: AbelianGroup(2, [2,3,4])
...
ValueError: invfac (=[2, 3, 4]) must have length n (=2)
```

class **AbelianGroup_class**(*n, invfac, names='f'*)

Abelian group on n generators. The invariant factors $[a_1, a_2, ..., a_k]$ need not be prime powers. divisors will be).

EXAMPLES:

```
sage: F = AbelianGroup(5,[5,5,7,8,9],names = list("abcde")); F
Multiplicative Abelian Group isomorphic to C5 x C5 x C7 x C8 x C9
sage: F = AbelianGroup(5,[2, 4, 12, 24, 120],names = list("abcde")); F
Multiplicative Abelian Group isomorphic to C2 x C4 x C12 x C24 x C120
sage: F.elementary_divisors()
[2, 4, 12, 24, 120]
```

The entry 1 in the list of invariants is ignored:

```
sage: F = AbelianGroup(3,[1,2,3],names='a')
sage: F.invariants()
[2, 3]
sage: F.gens()
(a0, a1)
sage: F.ngens()
2
sage: (F.0).order()
2
sage: (F.1).order()
3
sage: AbelianGroup(1, [1], names='e')
Multiplicative Abelian Group isomorphic to C1
sage: AbelianGroup(1, [1], names='e').gens()
(e,)
sage: AbelianGroup(1, [1], names='e').list()
[1]
sage: AbelianGroup(3, [2, 1, 2], names=list('abc')).list()
[1, b, a, a*b]
```

dual_group()

Returns the dual group.

EXAMPLES:

elementary_divisors()

This returns the elementary divisors of the group, using Pari.

Note: Here is another algorithm for computing the elementary divisors $d_1, d_2, d_3, \ldots$, of a finite abelian group (where $d_1|d_2|d_3|\ldots$ are composed of prime powers dividing the invariants of the group in a way described below). Just factor the invariants a_i that define the abelian group. Then the biggest d_i is the product of the maximum prime powers dividing some a_j. In other words, the largest d_i is the product of p^v, where $v = max(ord_p(a_j)\text{forall}j)$. Now divide out all those p^v's into the list of invariants a_i, and get a new list of "smaller invariants"". Repeat the above procedure on these ""smaller invariants"" to compute d_{i-1}, and so on. (Thanks to Robert Miller for communicating this algorithm.)

TODO: When somebody wants to speed this code up, please implement he above algorithm.

EXAMPLES:

```
sage: G = AbelianGroup(2,[2,3])
sage: G.elementary_divisors()
[6]
sage: G = AbelianGroup(1, [6])
sage: G.elementary_divisors()
[6]
sage: G = AbelianGroup(2,[2,6])
sage: G
Multiplicative Abelian Group isomorphic to C2 x C6
sage: G.invariants()
[2, 6]
sage: G.elementary_divisors()
[2, 6]
sage: J = AbelianGroup([1,3,5,12])
sage: J.elementary_divisors()
[3, 60]
sage: G = AbelianGroup(2,[0,6])
sage: G.elementary_divisors()
[6, 0]
```

exponent()

Return the exponent of this abelian group.

EXAMPLES:

```
sage: G = AbelianGroup([2,3,7]); G
Multiplicative Abelian Group isomorphic to C2 x C3 x C7
sage: G.exponent()
42
```

gen(*i=0*)

The i-th generator of the abelian group.

EXAMPLES:

```
sage: F = AbelianGroup(5,[],names='a')
sage: F.0
a0
sage: F.2
a2
sage: F.invariants()
[0, 0, 0, 0, 0]
```

invariants()

Return a copy of the list of invariants of this group.

It is safe to modify the returned list.

EXAMPLES:

```
sage: J = AbelianGroup([2,3])
sage: J.invariants()
[2, 3]
sage: v = J.invariants(); v
[2, 3]
sage: v[0] = 5
sage: J.invariants()
[2, 3]
sage: J.invariants() is J.invariants()
False
```

is_commutative()

Return True since this group is commutative.

EXAMPLES:

```
sage: G = AbelianGroup([2,3,9, 0])
sage: G.is_commutative()
True
sage: G.is_abelian()
True
```

is_cyclic()

Return True if the group is a cyclic group.

EXAMPLES: sage: J = AbelianGroup([2,3]) sage: J.invariants() [2, 3] sage: J.elementary_divisors() [6] sage: J.is_cyclic() True sage: G = AbelianGroup([6]) sage: G.invariants() [6] sage: G.is_cyclic() True sage: H = AbelianGroup([2,2]) sage: H.invariants() [2, 2] sage: H.is_cyclic() False sage: H = AbelianGroup([2,4]) sage: H.elementary_divisors() [2, 4] sage: H.is_cyclic() False sage: H.permutation_group().is_cyclic() False sage: T = AbelianGroup([]) sage: T.is_cyclic() True sage: T = AbelianGroup(1,[0]); T Multiplicative Abelian Group isomorphic to Z sage: T.is_cyclic() True

list()

Return list of all elements of this group.

EXAMPLES:

```
sage: G = AbelianGroup([2,3], names = "ab")
sage: G.list()
[1, b, b^2, a, a*b, a*b^2]

sage: G = AbelianGroup([]); G
Trivial Abelian Group
sage: G.list()
[1]
```

ngens()

The number of free generators of the abelian group.

EXAMPLES:

```
sage: F = AbelianGroup(10000)
sage: F.ngens()
10000
```

order()

Return the order of this group.

EXAMPLES:

```
sage: G = AbelianGroup(2,[2,3])
sage: G.order()
6
sage: G = AbelianGroup(3,[2,3,0])
sage: G.order()
+Infinity
```

permutation_group()

Return the permutation group isomorphic to this abelian group.

If the invariants are $q_1, \ldots, q_n$ then the generators of the permutation will be of order $q_1, \ldots, q_n$, respectively.

EXAMPLES:

```
sage: G = AbelianGroup(2,[2,3]); G
Multiplicative Abelian Group isomorphic to C2 x C3
sage: G.permutation_group()
Permutation Group with generators [(1,4)(2,5)(3,6), (1,2,3)(4,5,6)]
```

random_element()

Return a random element of this group. (Renamed random to random_element.)

EXAMPLES:

```
sage: G = AbelianGroup([2,3,9])
sage: G.random_element()
f0*f1^2*f2
```

subgroup(*gensH*, *names='f'*)

Create a subgroup of this group. The "big" group must be defined using "named" generators.

INPUT:

- `gensH` - list of elements which are products of the generators of the ambient abelian group G = self

EXAMPLES:

```
sage: G.<a,b,c> = AbelianGroup(3, [2,3,4]); G
Multiplicative Abelian Group isomorphic to C2 x C3 x C4
sage: H = G.subgroup([a*b,a]); H
Multiplicative Abelian Group isomorphic to C2 x C3, which is the subgroup of
Multiplicative Abelian Group isomorphic to C2 x C3 x C4
```

```
generated by [a*b, a]
sage: H < G
True
sage: F = G.subgroup([a,b^2])
sage: F
Multiplicative Abelian Group isomorphic to C2 x C3, which is the subgroup of
Multiplicative Abelian Group isomorphic to C2 x C3 x C4
generated by [a, b^2]
sage: F.gens()
[a, b^2]
sage: F = AbelianGroup(5,[30,64,729],names = list("abcde"))
sage: a,b,c,d,e = F.gens()
sage: F.subgroup([a,b])
Multiplicative Abelian Group isomorphic to Z x Z, which is
the subgroup of Multiplicative Abelian Group isomorphic to
Z x Z x C30 x C64 x C729 generated by [a, b]
sage: F.subgroup([c,e])
Multiplicative Abelian Group isomorphic to C2 x C3 x C5 x
C729, which is the subgroup of Multiplicative Abelian
Group isomorphic to Z x Z x C30 x C64 x C729 generated by
[c, e]
```

subgroup_reduced(*elts, verbose=False*)

Given a list of lists of integers (corresponding to elements of self), find a set of independent generators for the subgroup generated by these elements, and return the subgroup with these as generators, forgetting the original generators.

This is used by the `subgroups` routine.

An error will be raised if the elements given are not linearly independent over QQ.

EXAMPLE:

```
sage: G = AbelianGroup([4,4])
sage: G.subgroup( [ G([1,0]), G([1,2]) ])
Multiplicative Abelian Group isomorphic to C2 x C4, which is the subgroup of
Multiplicative Abelian Group isomorphic to C4 x C4
generated by [f0, f0*f1^2]
sage: AbelianGroup([4,4]).subgroup_reduced( [ [1,0], [1,2] ])
Multiplicative Abelian Group isomorphic to C2 x C4, which is the subgroup of
Multiplicative Abelian Group isomorphic to C4 x C4
generated by [f1^2, f0]
```

subgroups(*check=False*)

Compute all the subgroups of this abelian group (which must be finite).

TODO: This is *many orders of magnitude* slower than Magma.

INPUT:

- check: if True, performs the same computation in GAP and checks that the number of subgroups generated is the same. (I don't know how to convert GAP's output back into Sage, so we don't actually compare the subgroups).

ALGORITHM:

If the group is cyclic, the problem is easy. Otherwise, write it as a direct product A x B, where B is cyclic. Compute the subgroups of A (by recursion).
Now, for every subgroup C of A x B, let G be its *projection onto* A and H its *intersection with* B. Then there is a well-defined homomorphism f: G -> B/H that sends a in G to the class mod H of b, where (a,b) is any element of C lifting a; and every subgroup C arises from a unique triple (G, H, f).

EXAMPLES:

```
sage: AbelianGroup([2,3]).subgroups()
[Multiplicative Abelian Group isomorphic to C2 x C3, which is the subgroup of
Multiplicative Abelian Group isomorphic to C2 x C3
generated by [f0*f1^2],
 Multiplicative Abelian Group isomorphic to C2, which is the subgroup of
Multiplicative Abelian Group isomorphic to C2 x C3
generated by [f0],
 Multiplicative Abelian Group isomorphic to C3, which is the subgroup of
Multiplicative Abelian Group isomorphic to C2 x C3
generated by [f1],
 Trivial Abelian Group, which is the subgroup of
Multiplicative Abelian Group isomorphic to C2 x C3
generated by []]

sage: len(AbelianGroup([2,4,8]).subgroups())
81
```

class AbelianGroup_subgroup(*ambient, gens, names='f'*)

Subgroup subclass of AbelianGroup_class, so instance methods are inherited.

TODO:

- There should be a way to coerce an element of a subgroup into the ambient group.

ambient_group()

Return the ambient group related to self.

gen(*n*)

Return the nth generator of this subgroup.

EXAMPLE:

```
sage: G.<a,b> = AbelianGroup(2)
sage: A = G.subgroup([a])
sage: A.gen(0)
a
```

gens()

Return the generators for this subgroup.

invs()

Return the invariants for this subgroup.

is_AbelianGroup(*x*)

Return True if x is an abelian group.

EXAMPLES:

```
sage: from sage.groups.abelian_gps.abelian_group import is_AbelianGroup
sage: F = AbelianGroup(5,[5,5,7,8,9],names = list("abcde")); F
Multiplicative Abelian Group isomorphic to C5 x C5 x C7 x C8 x C9
sage: is_AbelianGroup(F)
True
sage: is_AbelianGroup(AbelianGroup(7, [3]*7))
True
```

word_problem(*words, g, verbose=False*)

G and H are abelian, g in G, H is a subgroup of G generated by a list (words) of elements of G. If g is in H, return the expression for g as a word in the elements of (words).

The 'word problem' for a finite abelian group G boils down to the following matrix-vector analog of the Chinese remainder theorem.

Problem: Fix integers $1 < n_1 \leq n_2 \leq ... \leq n_k$ (indeed, these n_i will all be prime powers), fix a generating set $g_i = (a_{i1}, ..., a_{ik})$ (with $a_{ij} \in \mathrm{Z}/n_j\mathrm{Z}$), for $1 \leq i \leq \ell$, for the group G, and let $d = (d_1, ..., d_k)$ be an element of the direct product $\mathrm{Z}/n_1\mathrm{Z} \times ... \times \mathrm{Z}/n_k\mathrm{Z}$. Find, if they exist, integers $c_1, ..., c_\ell$ such that $c_1 g_1 + ... + c_\ell g_\ell = d$. In other words, solve the equation $cA = d$ for $c \in \mathrm{Z}^\ell$, where A is the matrix whose rows are the g_i's. Of course, it suffices to restrict the c_i's to the range $0 \leq c_i \leq N - 1$, where N denotes the least common multiple of the integers $n_1, ..., n_k$.

This function does not solve this directly, as perhaps it should. Rather (for both speed and as a model for a similar function valid for more general groups), it pushes it over to GAP, which has optimized (non-deterministic) algorithms for the word problem. Essentially, this function is a wrapper for the GAP function 'Factorization'.

EXAMPLE:

```
sage: G.<a,b,c> = AbelianGroup(3,[2,3,4]); G
Multiplicative Abelian Group isomorphic to C2 x C3 x C4
sage: word_problem([a*b,a*c], b*c)
[[a*b, 1], [a*c, 1]]
sage: word_problem([a*c,c],a)
[[a*c, 1], [c, -1]]
sage: word_problem([a*c,c],a,verbose=True)
a = (a*c)^1*(c)^-1
[[a*c, 1], [c, -1]]

sage: A.<a,b,c,d,e> = AbelianGroup(5,[4, 5, 5, 7, 8])
sage: b1 = a^3*b*c*d^2*e^5
sage: b2 = a^2*b*c^2*d^3*e^3
sage: b3 = a^7*b^3*c^5*d^4*e^4
sage: b4 = a^3*b^2*c^2*d^3*e^5
sage: b5 = a^2*b^4*c^2*d^4*e^5
sage: word_problem([b1,b2,b3,b4,b5],e)
[[a^3*b*c*d^2*e^5, 1], [a^2*b*c^2*d^3*e^3, 1], [a^3*b^3*d^4*e^4, 3], [a^2*b^4*c^2*d^4*e^5, 1]]
sage: word_problem([a,b,c,d,e],e)
[[e, 1]]
sage: word_problem([a,b,c,d,e],b)
[[b, 1]]
```

Warning:

1. Might have unpleasant effect when the word problem cannot be solved.

2. Uses permutation groups, so may be slow when group is large. The instance method word_problem of the class AbelianGroupElement is implemented differently (wrapping GAP's 'EpimorphismFromFreeGroup' and 'PreImagesRepresentative') and may be faster.

22.3 Abelian group elements

AUTHORS:

- David Joyner (2006-02); based on free_abelian_monoid_element.py, written by David Kohel.
- David Joyner (2006-05); bug fix in order
- David Joyner (2006-08); bug fix+new method in pow for negatives+fixed corresponding examples.
- David Joyner (2009-02): Fixed bug in order.

EXAMPLES: Recall an example from abelian groups.

```
sage: F = AbelianGroup(5,[4,5,5,7,8],names = list("abcde"))
sage: (a,b,c,d,e) = F.gens()
sage: x = a*b^2*e*d^20*e^12
sage: x
a*b^2*d^6*e^5
sage: x = a^10*b^12*c^13*d^20*e^12
sage: x
a^2*b^2*c^3*d^6*e^4
sage: y = a^13*b^19*c^23*d^27*e^72
sage: y
a*b^4*c^3*d^6
sage: x*y
a^3*b*c*d^5*e^4
sage: x.list()
[2, 2, 3, 6, 4]
```

It is important to note that lists are mutable and the returned list is not a copy. As a result, reassignment of an element of the list changes the object.

```
sage: x.list()[0] = 3
sage: x.list()
[3, 2, 3, 6, 4]
sage: x
a^3*b^2*c^3*d^6*e^4
```

class AbelianGroupElement(*F*, *x*)

as_permutation()

Return the element of the permutation group G (isomorphic to the abelian group A) associated to a in A.

EXAMPLES:

```
sage: G = AbelianGroup(3,[2,3,4],names="abc"); G
Multiplicative Abelian Group isomorphic to C2 x C3 x C4
sage: a,b,c=G.gens()
sage: Gp = G.permutation_group(); Gp
Permutation Group with generators [(1,13)(2,14)(3,15)(4,16)(5,17)(6,18)(7,19)(8,20)(9,21)(10
sage: a.as_permutation()
(1,13)(2,14)(3,15)(4,16)(5,17)(6,18)(7,19)(8,20)(9,21)(10,22)(11,23)(12,24)
sage: ap = a.as_permutation(); ap
(1,13)(2,14)(3,15)(4,16)(5,17)(6,18)(7,19)(8,20)(9,21)(10,22)(11,23)(12,24)
sage: ap in Gp
True
```

inverse()

Returns the inverse element.

EXAMPLE:

```
sage: G.<a,b> = AbelianGroup(2)
sage: a^-1
a^-1
sage: a.list()
[1, 0]
sage: a.inverse().list()
[-1, 0]
sage: a.inverse()
a^-1
```

list()

Return (a reference to) the underlying list used to represent this element. If this is a word in an abelian group on n generators, then this is a list of nonnegative integers of length n.

EXAMPLES:

```
sage: F = AbelianGroup(5, [3,4,5,8,7], 'abcde')
sage: (a, b, c, d, e) = F.gens()
sage: a.list()
[1, 0, 0, 0, 0]
```

order()

Returns the (finite) order of this element or Infinity if this element does not have finite order.

EXAMPLES:

```
sage: F = AbelianGroup(3,[7,8,9]); F
Multiplicative Abelian Group isomorphic to C7 x C8 x C9
sage: F.gens()[2].order()
9
sage: a,b,c = F.gens()
sage: (b*c).order()
72
sage: G = AbelianGroup(3,[7,8,9])
sage: type((G.0 * G.1).order())==Integer
True
```

random_element()

Return a random element of this dual group.

word_problem(*words*)

TODO - this needs a rewrite - see stuff in the matrix_grp directory.

G and H are abelian groups, g in G, H is a subgroup of G generated by a list (words) of elements of G. If self is in H, return the expression for self as a word in the elements of (words).

This function does not solve the word problem in Sage. Rather it pushes it over to GAP, which has optimized (non-deterministic) algorithms for the word problem.

Warning: Don't use E (or other GAP-reserved letters) as a generator name.

EXAMPLE:

```
sage: G = AbelianGroup(2,[2,3], names="xy")
sage: x,y = G.gens()
sage: x.word_problem([x,y])
[[x, 1]]
sage: y.word_problem([x,y])
[[y, 1]]
sage: (y*x).word_problem([x,y])
[[x, 1], [y, 1]]
```

is_AbelianGroupElement(*x*)

Return true if x is an abelian group element, i.e., an element of type AbelianGroupElement.

EXAMPLES: Though the integer 3 is in the integers, and the integers have an abelian group structure, 3 is not an AbelianGroupElement:

```
sage: from sage.groups.abelian_gps.abelian_group_element import is_AbelianGroupElement
sage: is_AbelianGroupElement(3)
False
sage: F = AbelianGroup(5, [3,4,5,8,7], 'abcde')
sage: is_AbelianGroupElement(F.0)
True
```

22.4 Homomorphisms of abelian groups

TODO:

- there must be a homspace first
- there should be hom and Hom methods in abelian group

AUTHORS:

- David Joyner (2006-03-03): initial version

class AbelianGroupMap (*parent*)
A set-theoretic map between AbelianGroups.

class AbelianGroupMorphism (*G, H, genss, imgss*)
Some python code for wrapping GAP's GroupHomomorphismByImages function for abelian groups. Returns "fail" if gens does not generate self or if the map does not extend to a group homomorphism, self - other.

EXAMPLES:

```
sage: G = AbelianGroup(3,[2,3,4],names="abc"); G
Multiplicative Abelian Group isomorphic to C2 x C3 x C4
sage: a,b,c = G.gens()
sage: H = AbelianGroup(2,[2,3],names="xy"); H
Multiplicative Abelian Group isomorphic to C2 x C3
sage: x,y = H.gens()

sage: from sage.groups.abelian_gps.abelian_group_morphism import AbelianGroupMorphism
sage: phi = AbelianGroupMorphism(H,G,[x,y],[a,b])
```

AUTHORS:

•David Joyner (2006-02)

codomain ()

domain ()

image (*J*)
Only works for finite groups.

J must be a subgroup of G. Computes the subgroup of H which is the image of J.

EXAMPLES:

```
sage: G = AbelianGroup(2,[2,3],names="xy")
sage: x,y = G.gens()
sage: H = AbelianGroup(3,[2,3,4],names="abc")
sage: a,b,c = H.gens()
sage: phi = AbelianGroupMorphism(G,H,[x,y],[a,b])
```

kernel ()
Only works for finite groups.

TODO: not done yet; returns a gap object but should return a Sage group.

EXAMPLES:

```
sage: H = AbelianGroup(3,[2,3,4],names="abc"); H
Multiplicative Abelian Group isomorphic to C2 x C3 x C4
sage: a,b,c = H.gens()
sage: G = AbelianGroup(2,[2,3],names="xy"); G
Multiplicative Abelian Group isomorphic to C2 x C3
sage: x,y = G.gens()
sage: phi = AbelianGroupMorphism(G,H,[x,y],[a,b])
sage: phi.kernel()
'Group([  ])'
```

range()

class **AbelianGroupMorphism_id**(*X*)

Return the identity homomorphism from X to itself.

EXAMPLES:

is_AbelianGroupMorphism(*f*)

22.5 Basic functionality for dual groups of finite multiplicative Abelian groups

AUTHORS:

- David Joyner (2006-08) (based on abelian_groups)
- David Joyner (2006-10) modifications suggested by William Stein

TODO:

- additive abelian groups should also be supported.

The basic idea is very simple. Let G be an abelian group and G^* its dual (i.e., the group of homomorphisms from G to $\mathbf{C}^\times$). Let g_j, $j = 1,..,n$, denote generators of G - say g_j is of order $m_j > 1$. There are generators X_j, $j = 1,..,n$, of G^* for which $X_j(g_j) = \exp(2\pi i/m_j)$ and $X_i(g_j) = 1$ if $i \neq j$. These are used to construct G^* in the DualAbelianGroup class below.

Sage supports multiplicative abelian groups on any prescribed finite number $n > 0$ of generators. Use the `AbelianGroup` function to create an abelian group, the `DualAbelianGroup` function to create its dual, and then the `gen` and `gens` functions to obtain the corresponding generators. You can print the generators as arbitrary strings using the optional `names` argument to the `DualAbelianGroup` function.

DualAbelianGroup(*G, names='X', base_ring=Complex Field with 53 bits of precision*)

Create the dual group of the multiplicative abelian group G.

INPUT:

- `G` - a finite abelian group
- `names` - (optional) names of generators

OUTPUT: The dual group of G.

EXAMPLES:

```
sage: F = AbelianGroup(5, [2,5,7,8,9], names='abcde')
sage: (a, b, c, d, e) = F.gens()
sage: Fd = DualAbelianGroup(F,names='ABCDE')
```

```
sage: A,B,C,D,E = Fd.gens()
sage: A(a)     ## random
-1.0000000000000000 + 0.00000000000000013834419720915037*I
sage: A(b); A(c); A(d); A(e)
1.00000000000000
1.00000000000000
1.00000000000000
1.00000000000000
```

class **DualAbelianGroup_class**(*G, names='X', bse_ring=None*)

Dual of abelian group.

EXAMPLES:

```
sage: F = AbelianGroup(5,[3,5,7,8,9],names = list("abcde"))
sage: DualAbelianGroup(F)
Dual of Abelian Group isomorphic to Z/3Z x Z/5Z x Z/7Z x Z/8Z x Z/9Z  over Complex Field with 53
sage: F = AbelianGroup(4,[15,7,8,9],names = list("abcd"))
sage: DualAbelianGroup(F)
Dual of Abelian Group isomorphic to Z/15Z x Z/7Z x Z/8Z x Z/9Z  over Complex Field with 53 bits
```

base_ring()

gen(*i=0*)

The i-th generator of the abelian group.

EXAMPLES:

```
sage: F = AbelianGroup(3,[1,2,3],names='a')
sage: Fd = DualAbelianGroup(F, names="A")
sage: Fd.0
A0
sage: Fd.1
A1
sage: Fd.invariants()
[2, 3]
```

group()

invariants()

The invariants of the dual group.

EXAMPLES:

```
sage: F = AbelianGroup(1000)
sage: Fd = DualAbelianGroup(F)
sage: invs = Fd.invariants(); len(invs)
1000
```

This can be slow for 10000 or more generators.

is_commutative()

Return True since this group is commutative.

EXAMPLES:

```
sage: G = AbelianGroup([2,3,9])
sage: Gd = DualAbelianGroup(G)
sage: Gd.is_commutative()
True
sage: Gd.is_abelian()
True
```

list()
Return list of all elements of this group.
EXAMPLES:

```
sage: G = AbelianGroup([2,3], names = "ab")
sage: Gd = DualAbelianGroup(G, names = "AB")
sage: Gd.list()
[1, B, B^2, A, A*B, A*B^2]
```

ngens()
The number of generators of the dual group.
EXAMPLES:

```
sage: F = AbelianGroup(1000)
sage: Fd = DualAbelianGroup(F)
sage: Fd.ngens()
1000
```

This can be slow for 10000 or more generators.

order()
Return the order of this group.
EXAMPLES:

```
sage: G = AbelianGroup([2,3,9])
sage: Gd = DualAbelianGroup(G)
sage: Gd.order()
54
```

random()
Deprecated. Use self.random_element() instead.

random_element()
Return a random element of this dual group.
EXAMPLES:

```
sage: G = AbelianGroup([2,3,9])
sage: Gd = DualAbelianGroup(G)
sage: Gd.random_element()
X0*X1^2*X2
sage: N = 43^2-1
sage: G = AbelianGroup([N],names="a")
sage: Gd = DualAbelianGroup(G,names="A")
sage: a, = G.gens()
sage: A, = Gd.gens()
sage: x = a^(N/4); y = a^(N/3); z = a^(N/14)
sage: X = Gd.random_element(); X
A^615
sage: len([a for a in [x,y,z] if abs(X(a)-1)>10^(-8)])
2
```

is_DualAbelianGroup(x)
Return True if x is the dual group of an abelian group.
EXAMPLES:

```
sage: from sage.groups.abelian_gps.dual_abelian_group import is_DualAbelianGroup
sage: F = AbelianGroup(5,[3,5,7,8,9],names = list("abcde"))
sage: Fd = DualAbelianGroup(F)
sage: is_DualAbelianGroup(Fd)
True
```

```
sage: F = AbelianGroup(3,[1,2,3],names='a')
sage: Fd = DualAbelianGroup(F)
sage: Fd.gens()
(X0, X1)
sage: F.gens()
(a0, a1)
```

22.6 Permutation groups

A permutation group is a finite group G whose elements are permutations of a given finite set X (i.e., bijections $X \longrightarrow X$) and whose group operation is the composition of permutations. The number of elements of X is called the degree of G.

In Sage, a permutation is represented as either a string that defines a permutation using disjoint cycle notation, or a list of tuples, which represent disjoint cycles. That is:

```
(a,...,b)(c,...,d)...(e,...,f)  <--> [(a,...,b), (c,...,d),..., (e,...,f)]
                    () = identity <--> []
```

You can make the "named" permutation groups (see `permgp_named.py`) and use the following constructions:

- permutation group generated by elements,
- `direct_product_permgroups`, which takes a list of permutation groups and returns their direct product.

JOKE: Q: What's hot, chunky, and acts on a polygon? A: Dihedral soup. Renteln, P. and Dundes, A. "Foolproof: A Sampling of Mathematical Folk Humor." Notices Amer. Math. Soc. 52, 24-34, 2005.

AUTHORS:

- David Joyner (2005-10-14): first version
- David Joyner (2005-11-17)
- William Stein (2005-11-26): rewrite to better wrap Gap
- David Joyner (2005-12-21)
- William Stein and David Joyner (2006-01-04): added conjugacy_class_representatives
- David Joyner (2006-03): reorganization into subdirectory perm_gps; added __contains__, has_element; fixed _cmp_; added subgroup class+methods, PGL,PSL,PSp, PSU classes,
- David Joyner (2006-06): added PGU, functionality to SymmetricGroup, AlternatingGroup, direct_product_permgroups
- David Joyner (2006-08): added degree, ramification_module_decomposition_modular_curve and ramification_module_decomposition_hurwitz_curve methods to PSL(2,q), MathieuGroup, is_isomorphic
- Bobby Moretti (2006)-10): Added KleinFourGroup, fixed bug in DihedralGroup
- David Joyner (2006-10): added is_subgroup (fixing a bug found by Kiran Kedlaya), is_solvable, normalizer, is_normal_subgroup, Suzuki
- David Kohel (2007-02): fixed __contains__ to not enumerate group elements, following the convention for __call__

- David Harvey, Mike Hansen, Nick Alexander, William Stein (2007-02,03,04,05): Various patches
- Nathan Dunfield (2007-05): added orbits
- David Joyner (2007-06): added subgroup method (suggested by David Kohel), composition_series, lower_central_series, upper_central_series, cayley_table, quotient_group, sylow_subgroup, is_cyclic, homology, homology_part, cohomology, cohomology_part, poincare_series, molien_series, is_simple, is_monomial, is_supersolvable, is_nilpotent, is_perfect, is_polycyclic, is_elementary_abelian, is_pgroup, gens_small, isomorphism_type_info_simple_group. moved all the"named" groups to a new file.
- Nick Alexander (2007-07): move is_isomorphic to isomorphism_to, add from_gap_list
- William Stein (2007-07): put is_isomorphic back (and make it better)
- David Joyner (2007-08): fixed bugs in composition_series, upper/lower_central_series, derived_series,
- David Joyner (2008-06): modified is_normal (reported by W. J. Palenstijn), and added normalizes
- David Joyner (2008-08): Added example to docstring of cohomology.
- Simon King (2009-04): __cmp__ methods for PermutationGroup_generic and PermutationGroup_subgroup

REFERENCES:

- Dixon, J. and Mortimer, B., Permutation Groups, Springer-Verlag, Berlin/New York, 1996.

Note: Though Suzuki groups are okay, Ree groups should *not* be wrapped as permutation groups - the construction is too slow - unless (for small values or the parameter) they are made using explicit generators.

PermutationGroup(*gens=None, gap_group=None, canonicalize=True*)

Return the permutation group associated to x (typically a list of generators).

INPUT:

- `gens` - list of generators (default: `None`)
- `gap_group` - a gap permutation group (default: `None`)
- `canonicalize` - bool (default: `True`); if `True`, sort generators and remove duplicates

OUTPUT:

- A permutation group.

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2,3),(4,5)],[(3,4)]])
sage: G
Permutation Group with generators [(3,4), (1,2,3)(4,5)]
```

We can also make permutation groups from PARI groups:

```
sage: H = pari('x^4 - 2*x^3 - 2*x + 1').polgalois()
sage: G = PariGroup(H, 4); G
PARI group [8, -1, 3, "D(4)"] of degree 4
sage: H = PermutationGroup(G); H          # optional - database_gap
Transitive group number 3 of degree 4
sage: H.gens()                            # optional - database_gap
[(1,2,3,4), (1,3)]
```

We can also create permutation groups whose generators are Gap permutation objects:

```
sage: p = gap('(1,2)(3,7)(4,6)(5,8)'); p
(1,2)(3,7)(4,6)(5,8)
sage: PermutationGroup([p])
Permutation Group with generators [(1,2)(3,7)(4,6)(5,8)]
```

There is an underlying gap object that implements each permutation group:

```
sage: G = PermutationGroup([[(1,2,3,4)]])
sage: G._gap_()
Group( [ (1,2,3,4) ] )
sage: gap(G)
Group( [ (1,2,3,4) ] )
sage: gap(G) is G._gap_()
True
sage: G = PermutationGroup([[(1,2,3),(4,5)],[(3,4)]])
sage: current_randstate().set_seed_gap()
sage: G._gap_().DerivedSeries()
[ Group( [ (3,4), (1,2,3)(4,5) ] ), Group( [ (1,5)(3,4), (1,5)(2,4), (1,5,3) ] ) ]
```

TESTS:

```
sage: PermutationGroup(SymmetricGroup(5))
...
TypeError: gens must be a tuple, list, or GapElement
```

class **PermutationGroup_generic**(*gens=None, gap_group=None, canonicalize=True*)

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2,3),(4,5)],[(3,4)]])
sage: G
Permutation Group with generators [(3,4), (1,2,3)(4,5)]
sage: G.center()
Permutation Group with generators [()]
sage: G.group_id()          # optional - database_gap
[120, 34]
sage: n = G.order(); n
120
sage: G = PermutationGroup([[(1,2,3),(4,5)],[(3,4)]])
sage: loads(G.dumps()) == G
True
```

cayley_table(*names='x'*)

Returns the multiplication table, or Cayley table, of the finite group G in the form of a matrix with symbolic coefficients. This function is useful for learning, teaching, and exploring elementary group theory. Of course, G must be a group of low order.

EXAMPLES:

As the last line below illustrates, the ordering used here in the first row is the same as in `G.list()`:

```
sage: G = PermutationGroup(['(1,2,3)', '(2,3)'])
sage: G.cayley_table()
[x0 x1 x2 x3 x4 x5]
[x1 x0 x3 x2 x5 x4]
[x2 x4 x0 x5 x1 x3]
[x3 x5 x1 x4 x0 x2]
[x4 x2 x5 x0 x3 x1]
[x5 x3 x4 x1 x2 x0]
```

```
sage: G.list()[3]*G.list()[3] == G.list()[4]
True
sage: G.cayley_table("y")
[y0 y1 y2 y3 y4 y5]
[y1 y0 y3 y2 y5 y4]
[y2 y4 y0 y5 y1 y3]
[y3 y5 y1 y4 y0 y2]
[y4 y2 y5 y0 y3 y1]
[y5 y3 y4 y1 y2 y0]
sage: G.cayley_table(names="abcdef")
[a b c d e f]
[b a d c f e]
[c e a f b d]
[d f b e a c]
[e c f a d b]
[f d e b c a]
```

center()

Return the subgroup of elements that commute with every element of this group.

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2,3,4)]])
sage: G.center()
Permutation Group with generators [(1,2,3,4)]
sage: G = PermutationGroup([[(1,2,3,4)], [(1,2)]])
sage: G.center()
Permutation Group with generators [()]
```

centralizer(*g*)

Returns the centralizer of `g` in `self`.

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2),(3,4)], [(1,2,3,4)]])
sage: g = G([(1,3)])
sage: G.centralizer(g)
Permutation Group with generators [(2,4), (1,3)]
sage: g = G([(1,2,3,4)])
sage: G.centralizer(g)
Permutation Group with generators [(1,2,3,4)]
sage: H = G.subgroup([G([(1,2,3,4)])])
sage: G.centralizer(H)
Permutation Group with generators [(1,2,3,4)]
```

character(*values*)

Returns a group character from `values`, where `values` is a list of the values of the character evaluated on the conjugacy classes.

EXAMPLES:

```
sage: G = AlternatingGroup(4)
sage: n = len(G.conjugacy_classes_representatives())
sage: G.character([1]*n)
Character of Alternating group of order 4!/2 as a permutation group
```

character_table()

Returns the matrix of values of the irreducible characters of a permutation group G at the conjugacy classes of G. The columns represent the conjugacy classes of G and the rows represent the different irreducible characters in the ordering given by GAP.

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2),(3,4)], [(1,2,3)]])
sage: G.order()
12
sage: G.character_table()
[          1           1           1           1]
[          1           1 -zeta3 - 1      zeta3]
[          1           1      zeta3 -zeta3 - 1]
[          3          -1           0           0]
sage: G = PermutationGroup([[(1,2),(3,4)], [(1,2,3)]])
sage: CT = gap(G).CharacterTable()
```

Type `print gap.eval("Display(%s)"%CT.name())` to display this nicely.

```
sage: G = PermutationGroup([[(1,2),(3,4)], [(1,2,3,4)]])
sage: G.order()
8
sage: G.character_table()
[ 1  1  1  1  1]
[ 1 -1 -1  1  1]
[ 1 -1  1 -1  1]
[ 1  1 -1 -1  1]
[ 2  0  0  0 -2]
sage: CT = gap(G).CharacterTable()
```

Again, type `print gap.eval("Display(%s)"%CT.name())` to display this nicely.

```
sage: SymmetricGroup(2).character_table()
[ 1 -1]
[ 1  1]
sage: SymmetricGroup(3).character_table()
[ 1 -1  1]
[ 2  0 -1]
[ 1  1  1]
sage: SymmetricGroup(5).character_table()
[ 1 -1  1  1 -1 -1  1]
[ 4 -2  0  1  1  0 -1]
[ 5 -1  1 -1 -1  1  0]
[ 6  0 -2  0  0  0  1]
[ 5  1  1 -1  1 -1  0]
[ 4  2  0  1 -1  0 -1]
[ 1  1  1  1  1  1  1]
sage: list(AlternatingGroup(6).character_table())
[(1, 1, 1, 1, 1, 1, 1), (5, 1, 2, -1, -1, 0, 0), (5, 1, -1, 2, -1, 0, 0), (8, 0, -1, -1, 0,
```

Suppose that you have a class function $f(g)$ on G and you know the values $v_1, \ldots, v_n$ on the conjugacy class elements in `conjugacy_classes_representatives(G)` = $[g_1, \ldots, g_n]$. Since the irreducible characters $\rho_1, \ldots, \rho_n$ of G form an E-basis of the space of all class functions (E a "sufficiently large" cyclotomic field), such a class function is a linear combination of these basis elements, $f = c_1\rho_1 + \cdots + c_n\rho_n$. To find the coefficients c_i, you simply solve the linear system `character_table_values(G)` $[v_1, ..., v_n] = [c_1, ..., c_n]$, where $[v_1, \ldots, v_n]$ = `character_table_values(G)` $^{(-1)}[c_1, ..., c_n]$.

AUTHORS:

- David Joyner and William Stein (2006-01-04)

cohomology (*n, p=0*)

Computes the group cohomology $H^n(G, F)$, where $F = \mathbf{Z}$ if $p = 0$ and $F = \mathbf{Z}/p\mathbf{Z}$ if $p > 0$ is a prime. Wraps HAP's `GroupHomology` function, written by Graham Ellis.

REQUIRES: GAP package HAP (in gap_packages-*.spkg).

EXAMPLES:

```
sage: G = SymmetricGroup(4)
sage: G.cohomology(1,2)                                  # optional - gap_packages
Multiplicative Abelian Group isomorphic to C2
sage: G = SymmetricGroup(3)
sage: G.cohomology(5)                                    # optional - gap_packages
Trivial Abelian Group
sage: G.cohomology(5,2)                                  # optional - gap_packages
Multiplicative Abelian Group isomorphic to C2
sage: G.homology(5,3)                                    # optional - gap_packages
Trivial Abelian Group
sage: G.homology(5,4)                                    # optional - gap_packages
...
ValueError: p must be 0 or prime
```

This computes $H^4(S_3, \mathbf{Z})$ and $H^4(S_3, \mathbf{Z}/2\mathbf{Z})$, respectively.

cohomology_part(*n, p=0*)

Computes the p-part of the group cohomology $H^n(G, F)$, where $F = \mathbf{Z}$ if $p = 0$ and $F = \mathbf{Z}/p\mathbf{Z}$ if $p > 0$ is a prime. Wraps HAP's Homology function, written by Graham Ellis, applied to the p-Sylow subgroup of G.

REQUIRES: GAP package HAP (in gap_packages-*.spkg).

EXAMPLES:

```
sage: G = SymmetricGroup(5)
sage: G.cohomology_part(7,2)                      # optional - gap_packages
Multiplicative Abelian Group isomorphic to C2 x C2 x C2
sage: G = SymmetricGroup(3)
sage: G.cohomology_part(2,3)                      # optional - gap_packages
Multiplicative Abelian Group isomorphic to C3
```

AUTHORS:

- David Joyner and Graham Ellis

composition_series()

Return the composition series of this group as a list of permutation groups.

EXAMPLES:

These computations use pseudo-random numbers, so we set the seed for reproducible testing.

```
sage: set_random_seed(0)
sage: G = PermutationGroup([[(1,2,3),(4,5)],[(3,4)]])
sage: G.composition_series()  # random output
[Permutation Group with generators [(1,2,3)(4,5), (3,4)], Permutation Group with generators
sage: G = PermutationGroup([[(1,2,3),(4,5)], [(1,2)]])
sage: CS = G.composition_series()
sage: CS[3]
Permutation Group with generators [()]
```

conjugacy_classes_representatives()

Returns a complete list of representatives of conjugacy classes in a permutation group G. The ordering is that given by GAP.

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2),(3,4)], [(1,2,3,4)]])
sage: cl = G.conjugacy_classes_representatives(); cl
[(), (2,4), (1,2)(3,4), (1,2,3,4), (1,3)(2,4)]
sage: cl[3] in G
True

sage: G = SymmetricGroup(5)
sage: G.conjugacy_classes_representatives ()
[(), (1,2), (1,2)(3,4), (1,2,3), (1,2,3)(4,5), (1,2,3,4), (1,2,3,4,5)]
```

AUTHORS:

- David Joyner and William Stein (2006-01-04)

conjugacy_classes_subgroups()

Returns a complete list of representatives of conjugacy classes of subgroups in a permutation group G. The ordering is that given by GAP.

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2),(3,4)], [(1,2,3,4)]])
sage: cl = G.conjugacy_classes_subgroups()
sage: cl
[Permutation Group with generators [()],
 Permutation Group with generators [(1,2)(3,4)],
 Permutation Group with generators [(1,3)(2,4)],
 Permutation Group with generators [(2,4)],
 Permutation Group with generators [(1,4)(2,3), (1,2)(3,4)],
 Permutation Group with generators [(1,3)(2,4), (2,4)],
 Permutation Group with generators [(1,3)(2,4), (1,2,3,4)],
 Permutation Group with generators [(1,3)(2,4), (1,2)(3,4), (1,2,3,4)]]

sage: G = SymmetricGroup(3)
sage: G.conjugacy_classes_subgroups()
[Permutation Group with generators [()],
 Permutation Group with generators [(2,3)],
 Permutation Group with generators [(1,2,3)],
 Permutation Group with generators [(1,3,2), (1,2)]]
```

AUTHORS:

- David Joyner (2006-10)

degree()

Return the largest point moved by a permutation in this group.

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2),(3,4)], [(1,2,3,4)]])
sage: G.largest_moved_point()
4
sage: G = PermutationGroup([[(1,2),(3,4)], [(1,2,3,4,10)]])
sage: G.largest_moved_point()
10

sage: G = PermutationGroup([[(1,2,3),(4,5)],[(3,4)]])
sage: G.degree()
5
```

derived_series()

Return the derived series of this group as a list of permutation groups.

EXAMPLES:

These computations use pseudo-random numbers, so we set the seed for reproducible testing.

```
sage: set_random_seed(0)
sage: G = PermutationGroup([[(1,2,3),(4,5)],[(3,4)]])
sage: G.derived_series()  # random output
[Permutation Group with generators [(1,2,3)(4,5), (3,4)], Permutation Group with generators
```

direct_product (*other, maps=True*)

Wraps GAP's `DirectProduct`, `Embedding`, and `Projection`.

Sage calls GAP's `DirectProduct`, which chooses an efficient representation for the direct product. The direct product of permutation groups will be a permutation group again. For a direct product `D`, the GAP operation `Embedding(D,i)` returns the homomorphism embedding the i-th factor into `D`. The GAP operation `Projection(D,i)` gives the projection of `D` onto the i-th factor. This method returns a 5-tuple: a permutation group and 4 morphisms.

INPUT:

- `self, other` - permutation groups

OUTPUT:

- `D` - a direct product of the inputs, returned as a permutation group as well
- `iota1` - an embedding of `self` into `D`
- `iota2` - an embedding of `other` into `D`
- `pr1` - the projection of `D` onto `self` (giving a splitting 1 - other - D - self - 1)
- `pr2` - the projection of `D` onto `other` (giving a splitting 1 - self - D - other - 1)

EXAMPLES:

```
sage: G = CyclicPermutationGroup(4)
sage: D = G.direct_product(G,False)
sage: D
Permutation Group with generators [(1,2,3,4), (5,6,7,8)]
sage: D,iota1,iota2,pr1,pr2 = G.direct_product(G)
sage: D; iota1; iota2; pr1; pr2
Permutation Group with generators [(1,2,3,4), (5,6,7,8)]
Homomorphism : Cyclic group of order 4 as a permutation group --> Permutation Group with gen
Homomorphism : Cyclic group of order 4 as a permutation group --> Permutation Group with gen
Homomorphism : Permutation Group with generators [(1,2,3,4), (5,6,7,8)] --> Cyclic group of
Homomorphism : Permutation Group with generators [(1,2,3,4), (5,6,7,8)] --> Cyclic group of

sage: g=D([(1,3),(2,4)]); g
(1,3)(2,4)
sage: d=D([(1,4,3,2),(5,7),(6,8)]); d
(1,4,3,2)(5,7)(6,8)
sage: iota1(g); iota2(g); pr1(d); pr2(d)
(1,3)(2,4)
(5,7)(6,8)
(1,4,3,2)
(1,3)(2,4)
```

exponent ()

Computes the exponent of the group. The exponent e of a group G is the LCM of the orders of its elements, that is, e is the smallest integer such that $g^e = 1$ for all $g \in G$.

EXAMPLES:

```
sage: G = AlternatingGroup(4)
sage: G.exponent()
6
```

gen (*i*)

Returns the i-th generator of `self`; that is, the i-th element of the list `self.gens()`.

EXAMPLES:

We explicitly construct the alternating group on four elements:

```
sage: A4 = PermutationGroup([[(1,2,3)],[(2,3,4)]]); A4
Permutation Group with generators [(2,3,4), (1,2,3)]
sage: A4.gens()
[(2,3,4), (1,2,3)]
sage: A4.gen(0)
(2,3,4)
sage: A4.gen(1)
(1,2,3)
sage: A4.gens()[0]; A4.gens()[1]
(2,3,4)
(1,2,3)
```

gens()

Return tuple of generators of this group. These need not be minimal, as they are the generators used in defining this group.

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2,3)], [(1,2)]])
sage: G.gens()
[(1,2), (1,2,3)]
```

Note that the generators need not be minimal, though duplicates are removed:

```
sage: G = PermutationGroup([[(1,2)], [(1,3)], [(2,3)], [(1,2)]])
sage: G.gens()
[(2,3), (1,2), (1,3)]
```

We can use index notation to access the generators returned by `self.gens`:

```
sage: G = PermutationGroup([[(1,2,3,4), (5,6)], [(1,2)]])
sage: g = G.gens()
sage: g[0]
(1,2)
sage: g[1]
(1,2,3,4)(5,6)
```

TESTS:

We make sure that the trivial group gets handled correctly:

```
sage: SymmetricGroup(1).gens()
[()]
```

gens_small()

For this group, returns a generating set which has few elements. As neither irredundancy nor minimal length is proven, it is fast.

EXAMPLES:

```
sage: R = "(25,27,32,30)(26,29,31,28)( 3,38,43,19)( 5,36,45,21)( 8,33,48,24)" ## R = right
sage: U = "( 1, 3, 8, 6)( 2, 5, 7, 4)( 9,33,25,17)(10,34,26,18)(11,35,27,19)" ## U = top
sage: L = "( 9,11,16,14)(10,13,15,12)( 1,17,41,40)( 4,20,44,37)( 6,22,46,35)" ## L = left
sage: F = "(17,19,24,22)(18,21,23,20)( 6,25,43,16)( 7,28,42,13)( 8,30,41,11)" ## F = front
sage: B = "(33,35,40,38)(34,37,39,36)( 3, 9,46,32)( 2,12,47,29)( 1,14,48,27)" ## B = back or
sage: D = "(41,43,48,46)(42,45,47,44)(14,22,30,38)(15,23,31,39)(16,24,32,40)" ## D = down or
sage: G = PermutationGroup([R,L,U,F,B,D])
sage: len(G.gens_small())
2
```

group_id()

Return the ID code of this group, which is a list of two integers. Requires "optional" database_gap-4.4.x package.

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2,3),(4,5)], [(1,2)]])
sage: G.group_id()    # optional - database_gap
[12, 4]
```

has_element (*item*)

Returns boolean value of `item in self` - however *ignores* parentage.

EXAMPLES:

```
sage: G = CyclicPermutationGroup(4)
sage: gens = G.gens()
sage: H = DihedralGroup(4)
sage: g = G([(1,2,3,4)]); g
(1,2,3,4)
sage: G.has_element(g)
True
sage: h = H([(1,2),(3,4)]); h
(1,2)(3,4)
sage: G.has_element(h)
False
```

homology (*n, p=0*)

Computes the group homology $H_n(G, F)$, where $F = \mathbf{Z}$ if $p = 0$ and $F = \mathbf{Z}/p\mathbf{Z}$ if $p > 0$ is a prime. Wraps HAP's `GroupHomology` function, written by Graham Ellis.

REQUIRES: GAP package HAP (in gap_packages-*.spkg).

AUTHORS:

- David Joyner and Graham Ellis

The example below computes $H_7(S_5, \mathbf{Z})$, $H_7(S_5, \mathbf{Z}/2\mathbf{Z})$, $H_7(S_5, \mathbf{Z}/3\mathbf{Z})$, and $H_7(S_5, \mathbf{Z}/5\mathbf{Z})$, respectively. To compute the 2-part of $H_7(S_5, \mathbf{Z})$, use the `homology_part` function.

EXAMPLES:

```
sage: G = SymmetricGroup(5)
sage: G.homology(7)                                  # optional - gap_packages
Multiplicative Abelian Group isomorphic to C2 x C2 x C4 x C3 x C5
sage: G.homology(7,2)                                # optional - gap_packages
Multiplicative Abelian Group isomorphic to C2 x C2 x C2 x C2 x C2
sage: G.homology(7,3)                                # optional - gap_packages
Multiplicative Abelian Group isomorphic to C3
sage: G.homology(7,5)                                # optional - gap_packages
Multiplicative Abelian Group isomorphic to C5
```

- D. Joyner, "A primer on computational group homology and cohomology", http://front.math.ucdavis.edu/0706.0549

homology_part (*n, p=0*)

Computes the p-part of the group homology $H_n(G, F)$, where $F = \mathbf{Z}$ if $p = 0$ and $F = \mathbf{Z}/p\mathbf{Z}$ if $p > 0$ is a prime. Wraps HAP's `Homology` function, written by Graham Ellis, applied to the p-Sylow subgroup of G.

REQUIRES: GAP package HAP (in gap_packages-*.spkg).

EXAMPLES:

```
sage: G = SymmetricGroup(5)
sage: G.homology_part(7,2)                              # optional - gap_packages
Multiplicative Abelian Group isomorphic to C2 x C2 x C2 x C2 x C4
```

AUTHORS:

- David Joyner and Graham Ellis

id()

(Same as `self.group_id()`.) Return the ID code of this group, which is a list of two integers. Requires "optional" database_gap-4.4.x package.

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2,3),(4,5)], [(1,2)]])
sage: G.group_id()     # optional - database_gap
[12, 4]
```

identity()

Return the identity element of this group.

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2,3),(4,5)]])
sage: e = G.identity()
sage: e
()
sage: g = G.gen(0)
sage: g*e
(1,2,3)(4,5)
sage: e*g
(1,2,3)(4,5)
```

irreducible_characters()

Returns a list of the irreducible characters of `self`.

EXAMPLES:

```
sage: irr = SymmetricGroup(3).irreducible_characters()
sage: [x.values() for x in irr]
[[1, -1, 1], [2, 0, -1], [1, 1, 1]]
```

is_abelian()

Return `True` if this group is abelian.

EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5)', '(1,2,3,4,5)'])
sage: G.is_abelian()
False
sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: G.is_abelian()
True
```

is_commutative()

Return `True` if this group is commutative.

EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5)', '(1,2,3,4,5)'])
sage: G.is_commutative()
False
sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: G.is_commutative()
True
```

is_cyclic()
Return True if this group is cyclic.
EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5)', '(1,2,3,4,5)'])
sage: G.is_cyclic()
False
sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: G.is_cyclic()
True
```

is_elementary_abelian()
Return True if this group is elementary abelian. An elementary abelian group is a finite abelian group, where every nontrivial element has order p, where p is a prime.
EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5)', '(1,2,3,4,5)'])
sage: G.is_elementary_abelian()
False
sage: G = PermutationGroup(['(1,2,3)','(4,5,6)'])
sage: G.is_elementary_abelian()
True
```

is_isomorphic(*right*)
Return True if the groups are isomorphic. If mode="verbose" then an isomorphism is printed.
INPUT:

- self - this group
- right - a permutation group

OUTPUT:

- boolean; True if self and right are isomorphic groups; False otherwise.

EXAMPLES:

```
sage: v = ['(1,2,3)(4,5)', '(1,2,3,4,5)']
sage: G = PermutationGroup(v)
sage: H = PermutationGroup(['(1,2,3)(4,5)'])
sage: G.is_isomorphic(H)
False
sage: G.is_isomorphic(G)
True
sage: G.is_isomorphic(PermutationGroup(list(reversed(v))))
True
```

is_monomial()
Returns True if the group is monomial. A finite group is monomial if every irreducible complex character is induced from a linear character of a subgroup.
EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: G.is_monomial()
True
```

is_nilpotent()
Return True if this group is nilpotent.
EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5)', '(1,2,3,4,5)'])
sage: G.is_nilpotent()
```

```
False
sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: G.is_nilpotent()
True
```

is_normal(*other*)

Return `True` if this group is a normal subgroup of `other`.

EXAMPLES:

```
sage: AlternatingGroup(4).is_normal(SymmetricGroup(4))
True
sage: H = PermutationGroup(['(1,2,3)(4,5)'])
sage: G = PermutationGroup(['(1,2,3)(4,5)', '(1,2,3,4,5)'])
sage: H.is_normal(G)
False
```

is_perfect()

Return `True` if this group is perfect. A group is perfect if it equals its derived subgroup.

EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5)', '(1,2,3,4,5)'])
sage: G.is_perfect()
False
sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: G.is_perfect()
False
```

is_pgroup()

Returns `True` if this group is a p-group. A finite group is a p-group if its order is of the form p^n for a prime integer p and a nonnegative integer n.

EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3,4,5)'])
sage: G.is_pgroup()
True
```

is_polycyclic()

Return `True` if this group is polycyclic. A group is polycyclic if it has a subnormal series with cyclic factors. (For finite groups, this is the same as if the group is solvable - see `is_solvable`.)

EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5)', '(1,2,3,4,5)'])
sage: G.is_polycyclic()
False
sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: G.is_polycyclic()
True
```

is_simple()

Returns `True` if the group is simple. A group is simple if it has no proper normal subgroups.

EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: G.is_simple()
False
```

is_solvable()

Returns `True` if the group is solvable.

EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: G.is_solvable()
True
```

is_subgroup(*other*)

Returns `True` if `self` is a subgroup of `other`.

EXAMPLES:

```
sage: G = AlternatingGroup(5)
sage: H = SymmetricGroup(5)
sage: G.is_subgroup(H)
True
```

is_supersolvable()

Returns `True` if the group is supersolvable. A finite group is supersolvable if it has a normal series with cyclic factors.

EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: G.is_supersolvable()
True
```

is_transitive()

Return `True` if `self` is a transitive group, i.e., if the action of self on [1..n] is transitive.

EXAMPLES:

```
sage: G = SymmetricGroup(5)
sage: G.is_transitive()
True
sage: G = PermutationGroup(['(1,2)(3,4)(5,6)'])
sage: G.is_transitive()
False
```

Note that this differs from the definition in GAP, where `IsTransitive` returns whether the group is transitive on the set of points moved by the group.

```
sage: G = PermutationGroup([(2,3)])
sage: G.is_transitive()
False
sage: gap(G).IsTransitive()
true
```

isomorphism_to(*right*)

Return an isomorphism from `self` to `right` if the groups are isomorphic, otherwise `None`.

INPUT:

- `self` - this group
- `right` - a permutation group

OUTPUT:

- `None` or a morphism of permutation groups.

EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5)', '(1,2,3,4,5)'])
sage: H = PermutationGroup(['(1,2,3)(4,5)'])
sage: G.isomorphism_to(H) is None
True
sage: G = PermutationGroup([(1,2,3), (2,3)])
sage: H = PermutationGroup([(1,2,4), (1,4)])
```

```
sage: G.isomorphism_to(H)
Homomorphism : Permutation Group with generators [(2,3), (1,2,3)] --> Permutation Group with
```

isomorphism_type_info_simple_group()

If the group is simple, then this returns the name of the group.

EXAMPLES:

```
sage: G = CyclicPermutationGroup(5)
sage: G.isomorphism_type_info_simple_group()
rec( series := "Z", parameter := 5, name := "Z(5)" )
```

largest_moved_point()

Return the largest point moved by a permutation in this group.

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2),(3,4)], [(1,2,3,4)]])
sage: G.largest_moved_point()
4
sage: G = PermutationGroup([[(1,2),(3,4)], [(1,2,3,4,10)]])
sage: G.largest_moved_point()
10

sage: G = PermutationGroup([[(1,2,3),(4,5)],[(3,4)]])
sage: G.degree()
5
```

list()

Return list of all elements of this group.

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2,3,4)], [(1,2)]])
sage: G.list()
[(), (3,4), (2,3), (2,3,4), (2,4,3), (2,4), (1,2), (1,2)(3,4), (1,2,3), (1,2,3,4), (1,2,4,3)
```

lower_central_series()

Return the lower central series of this group as a list of permutation groups.

EXAMPLES:

These computations use pseudo-random numbers, so we set the seed for reproducible testing.

```
sage: set_random_seed(0)
sage: G = PermutationGroup([[(1,2,3),(4,5)],[(3,4)]])
sage: G.lower_central_series()  # random output
[Permutation Group with generators [(1,2,3)(4,5), (3,4)], Permutation Group with generators
```

molien_series()

Returns the Molien series of a transitive permutation group. The function

$$M(x) = (1/|G|) \sum_{g \in G} \det(1 - x * g)^{-1}$$

is sometimes called the "Molien series" of G. GAP's `MolienSeries` is associated to a character of a group G. How are these related? A group G, given as a permutation group on n points, has a "natural" representation of dimension n, given by permutation matrices. The Molien series of G is the one associated to that permutation representation of G using the above formula. Character values then count fixed points of the corresponding permutations.

EXAMPLES:

```
sage: G = SymmetricGroup(5)
sage: G.molien_series()
1/(-x^15 + x^14 + x^13 - x^10 - x^9 - x^8 + x^7 + x^6 + x^5 - x^2 - x + 1)
sage: G = SymmetricGroup(3)
sage: G.molien_series()
1/(-x^6 + x^5 + x^4 - x^2 - x + 1)
```

multiplication_table(*names='x'*)

Returns the multiplication table, or Cayley table, of the finite group G in the form of a matrix with symbolic coefficients. This function is useful for learning, teaching, and exploring elementary group theory. Of course, G must be a group of low order.

EXAMPLES:

As the last line below illustrates, the ordering used here in the first row is the same as in `G.list()`:

```
sage: G = PermutationGroup(['(1,2,3)', '(2,3)'])
sage: G.cayley_table()
[x0 x1 x2 x3 x4 x5]
[x1 x0 x3 x2 x5 x4]
[x2 x4 x0 x5 x1 x3]
[x3 x5 x1 x4 x0 x2]
[x4 x2 x5 x0 x3 x1]
[x5 x3 x4 x1 x2 x0]
sage: G.list()[3]*G.list()[3] == G.list()[4]
True
sage: G.cayley_table("y")
[y0 y1 y2 y3 y4 y5]
[y1 y0 y3 y2 y5 y4]
[y2 y4 y0 y5 y1 y3]
[y3 y5 y1 y4 y0 y2]
[y4 y2 y5 y0 y3 y1]
[y5 y3 y4 y1 y2 y0]
sage: G.cayley_table(names="abcdef")
[a b c d e f]
[b a d c f e]
[c e a f b d]
[d f b e a c]
[e c f a d b]
[f d e b c a]
```

normal_subgroups()

Return the normal subgroups of this group as a (sorted in increasing order) list of permutation groups.

The normal subgroups of $H = PSL(2,7) \times PSL(2,7)$ are 1, two copies of $PSL(2,7)$ and H itself, as the following example shows.

EXAMPLES:

```
sage: G = PSL(2,7)
sage: D = G.direct_product(G)
sage: H = D[0]
sage: NH = H.normal_subgroups()
sage: len(NH)
4
sage: NH[1].is_isomorphic(G)
True
sage: NH[2].is_isomorphic(G)
True
```

normalizer(*g*)

Returns the normalizer of `g` in `self`.

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2),(3,4)], [(1,2,3,4)]])
sage: g = G([(1,3)])
sage: G.normalizer(g)
Permutation Group with generators [(2,4), (1,3)]
sage: g = G([(1,2,3,4)])
sage: G.normalizer(g)
Permutation Group with generators [(2,4), (1,2,3,4), (1,3)(2,4)]
sage: H = G.subgroup([G([(1,2,3,4)])])
sage: G.normalizer(H)
Permutation Group with generators [(2,4), (1,2,3,4), (1,3)(2,4)]
```

normalizes(*other*)

Returns `True` if the group `other` is normalized by `self`. Wraps GAP's `IsNormal` function.

A group G normalizes a group U if and only if for every $g \in G$ and $u \in U$ the element u^g is a member of U. Note that U need not be a subgroup of G.

EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: H = PermutationGroup(['(1,2,3)(4,5)', '(1,2,3,4,5)'])
sage: H.normalizes(G)
False
sage: G = SymmetricGroup(3)
sage: H = PermutationGroup( [ (4,5,6) ] )
sage: G.normalizes(H)
True
sage: H.normalizes(G)
True
```

In the last example, G and H are disjoint, so each normalizes the other.

orbits()

Returns the orbits of [1,2,...,degree] under the group action.

EXAMPLES:

```
sage: G = PermutationGroup([ [(3,4)], [(1,3)] ])
sage: G.orbits()
[[1, 3, 4], [2]]
sage: G = PermutationGroup([[(1,2),(3,4)], [(1,2,3,4,10)]])
sage: G.orbits()
[[1, 2, 3, 4, 10], [5], [6], [7], [8], [9]]
```

The answer is cached:

```
sage: G.orbits() is G.orbits()
True
```

AUTHORS:

- Nathan Dunfield

order()

Return the number of elements of this group.

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2,3),(4,5)], [(1,2)]])
sage: G.order()
12
sage: G = PermutationGroup([()])
sage: G.order()
1
```

```
sage: G = PermutationGroup([])
sage: G.order()
1
```

poincare_series (*p=2, n=10*)

Returns the Poincare series of $G \mod p$ ($p \geq 2$ must be a prime), for n large. In other words, if you input a finite group G, a prime p, and a positive integer n, it returns a quotient of polynomials $f(x) = P(x)/Q(x)$ whose coefficient of x^k equals the rank of the vector space $H_k(G, \mathbf{Z}/p\mathbf{Z})$, for all k in the range $1 \leq k \leq n$.

REQUIRES: GAP package HAP (in gap_packages-*.spkg).

EXAMPLES:

```
sage: G = SymmetricGroup(5)
sage: G.poincare_series(2,10)                                   # optional - gap_packages
(x^2 + 1)/(x^4 - x^3 - x + 1)
sage: G = SymmetricGroup(3)
sage: G.poincare_series(2,10)                                   # optional - gap_packages
1/(-x + 1)
```

AUTHORS:

- David Joyner and Graham Ellis

quotient_group (*N*)

Returns the quotient group permgp/N, where N is a normal subgroup. Wraps the GAP operator "/".

EXAMPLES:

```
sage: G = PermutationGroup([(1,2,3), (2,3)])
sage: N = PermutationGroup([(1,2,3)])
sage: G.quotient_group(N)
Permutation Group with generators [(1,2)]
```

random_element ()

Return a random element of this group.

EXAMPLES:

```
sage: G = PermutationGroup([[(1,2,3),(4,5)], [(1,2)]])
sage: G.random_element()
(1,2)(4,5)
```

smallest_moved_point ()

Return the smallest point moved by a permutation in this group.

EXAMPLES:

```
sage: G = PermutationGroup([[(3,4)], [(2,3,4)]])
sage: G.smallest_moved_point()
2
sage: G = PermutationGroup([[(1,2),(3,4)], [(1,2,3,4,10)]])
sage: G.smallest_moved_point()
1
```

subgroup (*gens*)

Wraps the `PermutationGroup_subgroup` constructor. The argument `gens` is a list of elements of `self`.

EXAMPLES:

```
sage: G = PermutationGroup([(1,2,3),(3,4,5)])
sage: g = G((1,2,3))
sage: G.subgroup([g])
Subgroup of Permutation Group with generators [(3,4,5), (1,2,3)] generated by [(1,2,3)]
```

sylow_subgroup(*p*)
Returns a Sylow p-subgroup of the finite group G, where p is a prime. This is a p-subgroup of G whose index in G is coprime to p. Wraps the GAP function `SylowSubgroup`.

EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)', '(2,3)'])
sage: G.sylow_subgroup(2)
Permutation Group with generators [(2,3)]
sage: G.sylow_subgroup(5)
Permutation Group with generators [()]
```

trivial_character()
Returns the trivial character of `self`.

EXAMPLES:

```
sage: SymmetricGroup(3).trivial_character()
Character of Symmetric group of order 3! as a permutation group
```

upper_central_series()
Return the upper central series of this group as a list of permutation groups.

EXAMPLES:

These computations use pseudo-random numbers, so we set the seed for reproducible testing.

```
sage: G = PermutationGroup([[(1,2,3),(4,5)],[(3,4)]])
sage: G.upper_central_series()
[Permutation Group with generators [()]]
```

class PermutationGroup_subgroup(*ambient, gens, from_group=False, check=True, canonicalize=True*)
Subgroup subclass of `PermutationGroup_generic`, so instance methods are inherited.

EXAMPLES:

```
sage: G = CyclicPermutationGroup(4)
sage: gens = G.gens()
sage: H = DihedralGroup(4)
sage: PermutationGroup_subgroup(H,list(gens))
Subgroup of Dihedral group of order 8 as a permutation group generated by [(1,2,3,4)]
sage: K=PermutationGroup_subgroup(H,list(gens))
sage: K.list()
[(), (1,2,3,4), (1,3)(2,4), (1,4,3,2)]
sage: K.ambient_group()
Dihedral group of order 8 as a permutation group
sage: K.gens()
[(1,2,3,4)]
```

ambient_group()
Return the ambient group related to `self`.

EXAMPLES:

An example involving the dihedral group on four elements, D_8:

```
sage: G = DihedralGroup(4)
sage: H = CyclicPermutationGroup(4)
sage: gens = H.gens()
sage: S = PermutationGroup_subgroup(G, list(gens))
sage: S.ambient_group()
Dihedral group of order 8 as a permutation group
sage: S.ambient_group() == G
True
```

gens()

Return the generators for this subgroup.

EXAMPLES:

An example involving the dihedral group on four elements, D_8:

```
sage: G = DihedralGroup(4)
sage: H = CyclicPermutationGroup(4)
sage: gens = H.gens()
sage: S = PermutationGroup_subgroup(G, list(gens))
sage: S.gens()
[(1,2,3,4)]
sage: S.gens() == list(H.gens())
True
```

direct_product_permgroups(*P*)

Takes the direct product of the permutation groups listed in `P`.

EXAMPLES:

```
sage: G1 = AlternatingGroup([1,2,4,5])
sage: G2 = AlternatingGroup([3,4,6,7])
sage: D = direct_product_permgroups([G1,G2,G1])
sage: D.order()
1728
sage: D = direct_product_permgroups([G1])
sage: D==G1
True
sage: direct_product_permgroups([])
Symmetric group of order 1! as a permutation group
```

from_gap_list(*G*, *src*)

Convert a string giving a list of GAP permutations into a list of elements of `G`.

EXAMPLES:

```
sage: from sage.groups.perm_gps.permgroup import from_gap_list
sage: G = PermutationGroup([[(1,2,3),(4,5)],[(3,4)]])
sage: L = from_gap_list(G, "[(1,2,3)(4,5), (3,4)]"); L
[(1,2,3)(4,5), (3,4)]
sage: L[0].parent() is G
True
sage: L[1].parent() is G
True
```

load_hap()

Load the GAP hap package into the default GAP interpreter interface. If this fails, try one more time to load it.

EXAMPLES:

```
sage: sage.groups.perm_gps.permgroup.load_hap()
```

22.7 Permutation group elements

AUTHORS:

- David Joyner (2006-02)

- David Joyner (2006-03): word problem method and reorganization
- Robert Bradshaw (2007-11): convert to Cython

EXAMPLES: The Rubik's cube group:

```
sage: f= [(17,19,24,22),(18,21,23,20),(6,25,43,16),(7,28,42,13),(8,30,41,11)]
sage: b=[(33,35,40,38),(34,37,39,36),( 3, 9,46,32),( 2,12,47,29),( 1,14,48,27)]
sage: l=[( 9,11,16,14),(10,13,15,12),( 1,17,41,40),( 4,20,44,37),( 6,22,46,35)]
sage: r=[(25,27,32,30),(26,29,31,28),( 3,38,43,19),( 5,36,45,21),( 8,33,48,24)]
sage: u=[( 1, 3, 8, 6),( 2, 5, 7, 4),( 9,33,25,17),(10,34,26,18),(11,35,27,19)]
sage: d=[(41,43,48,46),(42,45,47,44),(14,22,30,38),(15,23,31,39),(16,24,32,40)]
sage: cube = PermutationGroup([f,b,l,r,u,d])
sage: F=cube.gens()[0]
sage: B=cube.gens()[1]
sage: L=cube.gens()[2]
sage: R=cube.gens()[3]
sage: U=cube.gens()[4]
sage: D=cube.gens()[5]
sage: cube.order()
43252003274489856000
sage: F.order()
4
```

The interested user may wish to explore the following commands: move = cube.random_element() and time word_problem([F,B,L,R,U,D], move, False). This typically takes about 5 minutes (on a 2 Ghz machine) and outputs a word ('solving' the cube in the position move) with about 60 terms or so.

OTHER EXAMPLES: We create element of a permutation group of large degree.

```
sage: G = SymmetricGroup(30)
sage: s = G(srange(30,0,-1)); s
(1,30)(2,29)(3,28)(4,27)(5,26)(6,25)(7,24)(8,23)(9,22)(10,21)(11,20)(12,19)(13,18)(14,17)(15,16)
```

class PermutationGroupElement()

An element of a permutation group.

EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: G
Permutation Group with generators [(1,2,3)(4,5)]
sage: g = G.random_element()
sage: g in G
True
sage: g = G.gen(0); g
(1,2,3)(4,5)
sage: print g
(1,2,3)(4,5)
sage: g*g
(1,3,2)
sage: g**(-1)
(1,3,2)(4,5)
sage: g**2
(1,3,2)
sage: G = PermutationGroup([(1,2,3)])
sage: g = G.gen(0); g
(1,2,3)
```

```
sage: g.order()
3
```

This example illustrates how permutations act on multivariate polynomials.

```
sage: R = PolynomialRing(RationalField(), 5, ["x","y","z","u","v"])
sage: x, y, z, u, v = R.gens()
sage: f = x**2 - y**2 + 3*z**2
sage: G = PermutationGroup(['(1,2,3)(4,5)', '(1,2,3,4,5)'])
sage: sigma = G.gen(0)
sage: f * sigma
3*x^2 + y^2 - z^2
```

cycle_tuples()
Return self as a list of disjoint cycles, represented as tuples rather than permutation group elements.

cycles()
Return self as a list of disjoint cycles.
EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5,6,7)'])
sage: g = G.0
sage: g.cycles()
[(1,2,3), (4,5,6,7)]
sage: a, b = g.cycles()
sage: a(1), b(1)
(2, 1)
```

dict()
Returns list of the images of the integers from 1 to n under this permutation as a list of Python ints.
Note: `list()` returns a zero-indexed list. `dict()` return the actual mapping of the permutation, which will be indexed starting with 1.
EXAMPLES:

```
sage: G = SymmetricGroup(4)
sage: g = G((1,2,3,4)); g
(1,2,3,4)
sage: v = g.dict(); v
{1: 2, 2: 3, 3: 4, 4: 1}
sage: type(v[1])
<type 'int'>
sage: x = G([2,1]); x
(1,2)
sage: x.dict()
{1: 2, 2: 1, 3: 3, 4: 4}
```

list()
Returns list of the images of the integers from 1 to n under this permutation as a list of Python ints.
EXAMPLES:

```
sage: G = SymmetricGroup(4)
sage: x = G([2,1,4,3]); x
(1,2)(3,4)
sage: v = x.list(); v
[2, 1, 4, 3]
sage: type(v[0])
<type 'int'>
sage: x = G([2,1]); x
```

```
(1,2)
sage: x.list()
[2, 1, 3, 4]
```

matrix()

Returns deg x deg permutation matrix associated to the permutation self

EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: g = G.gen(0)
sage: g.matrix()
[0 1 0 0 0]
[0 0 1 0 0]
[1 0 0 0 0]
[0 0 0 0 1]
[0 0 0 1 0]
```

orbit()

Returns the orbit of the integer n under this group element, as a sorted list of integers.

EXAMPLES:

```
sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: g = G.gen(0)
sage: g.orbit(4)
[4, 5]
sage: g.orbit(3)
[1, 2, 3]
sage: g.orbit(10)
[10]
```

order()

Return the order of this group element, which is the smallest positive integer n for which $g^n = 1$.

EXAMPLES:

```
sage: s = PermutationGroupElement('(1,2)(3,5,6)')
sage: s.order()
6
```

TESTS:

```
sage: prod(primes(150))
149218235093927932005887573661584106854758386332686453041O
sage: L = [tuple(range(sum(primes(p))+1, sum(primes(p))+1+p)) for p in primes(150)]
sage: PermutationGroupElement(L).order()
149218235093927932005887573661584106854758386332686453041O
```

sign()

Returns the sign of self, which is $(-1)^s$, where s is the number of swaps.

EXAMPLES:

```
sage: s = PermutationGroupElement('(1,2)(3,5,6)')
sage: s.sign()
-1
```

ALGORITHM: Only even cycles contribute to the sign, thus

$$sign(sigma) = (-1)^{\sum_c len(c)-1}$$

where the sum is over cycles in self.

tuple()
Return tuple of images of integers under self.
EXAMPLES:

```
sage: G = SymmetricGroup(5)
sage: s = G([2,1,5,3,4])
sage: s.tuple()
(2, 1, 5, 3, 4)
```

word_problem()
G and H are permutation groups, g in G, H is a subgroup of G generated by a list (words) of elements of G. If g is in H, return the expression for g as a word in the elements of (words).
This function does not solve the word problem in Sage. Rather it pushes it over to GAP, which has optimized algorithms for the word problem. Essentially, this function is a wrapper for the GAP functions "EpimorphismFromFreeGroup" and "PreImagesRepresentative".
EXAMPLE:

```
sage: G = PermutationGroup([[(1,2,3),(4,5)],[(3,4)]], canonicalize=False)
sage: g1 = G.gens()[0]
sage: g2 = G.gens()[1]
sage: h = g1^2*g2*g1
sage: h.word_problem([g1,g2], False)
('x1^2*x2^-1*x1', '(1,2,3)(4,5)^2*(3,4)^-1*(1,2,3)(4,5)')
sage: h.word_problem([g1,g2])
   x1^2*x2^-1*x1
   [['(1,2,3)(4,5)', 2], ['(3,4)', -1], ['(1,2,3)(4,5)', 1]]
('x1^2*x2^-1*x1', '(1,2,3)(4,5)^2*(3,4)^-1*(1,2,3)(4,5)')
```

gap_format()
Put a permutation in Gap format, as a string.

is_PermutationGroupElement()

make_permgroup_element()

string_to_tuples()
EXAMPLES:

```
sage: from sage.groups.perm_gps.permgroup_element import string_to_tuples
sage: string_to_tuples('(1,2,3)')
[(1, 2, 3)]
sage: string_to_tuples('(1,2,3)(4,5)')
[(1, 2, 3), (4, 5)]
sage: string_to_tuples(' (1,2, 3) (4,5)')
[(1, 2, 3), (4, 5)]
sage: string_to_tuples('(1,2)(3)')
[(1, 2), (3,)]
```

22.8 Permutation group homomorphisms

AUTHORS:

- David Joyner (2006-03-21): first version
- David Joyner (2008-06): fixed kernel and image to return a group, instead of a string.

EXAMPLES:

```
sage: G = CyclicPermutationGroup(4)
sage: gens = G.gens()
sage: H = DihedralGroup(4)
sage: g = G([(1,2,3,4)])
sage: phi = PermutationGroupMorphism_im_gens( G, H, gens, gens)
sage: phi.image(G)
Permutation Group with generators [(1,2,3,4)]
sage: phi.kernel()
Permutation Group with generators [()]
sage: phi.image(g)
(1,2,3,4)
sage: phi(g)
(1,2,3,4)
sage: phi.range()
Dihedral group of order 8 as a permutation group
sage: phi.codomain()
Dihedral group of order 8 as a permutation group
sage: phi.domain()
Cyclic group of order 4 as a permutation group
```

class PermutationGroupMap(*parent*)

A set-theoretic map between PermutationGroups.

class PermutationGroupMorphism(*G, H, gensG, imgsH*)

Some python code for wrapping GAP's GroupHomomorphismByImages function but only for permutation groups. Can be expensive if G is large. Returns "fail" if gens does not generate self or if the map does not extend to a group homomorphism, self - other.

EXAMPLES:

```
sage: G = CyclicPermutationGroup(4)
sage: gens = G.gens()
sage: H = DihedralGroup(4)
sage: g = G([(1,3),(2,4)]); g
(1,3)(2,4)
sage: phi = PermutationGroupMorphism_im_gens( G, H, gens, gens)
sage: phi
Homomorphism : Cyclic group of order 4 as a permutation group --> Dihedral group of order 8 as a
sage: phi(g)
(1,3)(2,4)
sage: gens1 = G.gens()
sage: gens2 = ((4,3,2,1),)
sage: phi = PermutationGroupMorphism_im_gens( G, G, gens1, gens2)
sage: g = G([(1,2,3,4)]); g
(1,2,3,4)
sage: phi(g)
(1,4,3,2)
```

AUTHORS:

- David Joyner (2006-02)

codomain()

domain()

image(*J*)

J must be a subgroup of G. Computes the subgroup of H which is the image of J.

EXAMPLES:

```
sage: G = CyclicPermutationGroup(4)
sage: gens = G.gens()
sage: H = DihedralGroup(4)
sage: g = G([(1,2,3,4)])
sage: phi = PermutationGroupMorphism_im_gens( G, H, gens, gens)
sage: phi.image(G)
Permutation Group with generators [(1,2,3,4)]
sage: phi.image(g)
(1,2,3,4)
```

kernel()

range()

class PermutationGroupMorphism_from_gap(*G, H, gap_hom_str, name='phi'*)

This is a Python trick to allow Sage programmers to create a group homomorphism using GAP using very general constructions. An example of its usage is in the direct_product instance method of the PermutationGroup_generic class in permgroup.py.

Basic syntax:

PermutationGroupMorphism_from_gap(domain_group, range_group,'phi:=gap_hom_command;','phi') And don't forget the line: from sage.groups.perm_gps.permgroup_morphism import PermutationGroupMorphism_from_gap in your program.

EXAMPLES:

```
sage: from sage.groups.perm_gps.permgroup_morphism import PermutationGroupMorphism_from_gap
sage: G = PermutationGroup([[(1,2),(3,4)], [(1,2,3,4)]])
sage: H = G.subgroup([G([(1,2,3,4)])])
sage: PermutationGroupMorphism_from_gap(H, G, 'phi:=Identity','phi')
Homomorphism : Subgroup of Permutation Group with generators [(1,2)(3,4), (1,2,3,4)] generated b
```

codomain()

domain()

image(*J*)

J must be an element or a subgroup of G. Computes the subgroup of H which is the image of J.

EXAMPLES:

```
sage: G = PSL(2,7)
sage: D = G.direct_product(G)
sage: H = D[0]
sage: pr1 = D[3]
sage: pr1.image(G)
Permutation Group with generators [(3,7,5)(4,8,6), (1,2,6)(3,4,8)]
sage: G.is_isomorphic(pr1.image(G))
True
```

kernel()

Computes the subgroup of the domain group which is the kernel of self.

EXAMPLES:

```
sage: G = PSL(2,7)
sage: D = G.direct_product(G)
sage: H = D[0]
sage: pr1 = D[3]
sage: G.is_isomorphic(pr1.kernel())
True
```

range()

class PermutationGroupMorphism_id(*X*)

TODO: NOT FINISHED YET!! Return the identity homomorphism from X to itself.

EXAMPLES:

class PermutationGroupMorphism_im_gens(*G, H, gensG, imgsH*)

Some python code for wrapping GAP's GroupHomomorphismByImages function but only for permutation groups. Can be expensive if G is large. Returns "fail" if gens does not generate self or if the map does not extend to a group homomorphism, self - other.

EXAMPLES:

```
sage: G = CyclicPermutationGroup(4)
sage: gens = G.gens()
sage: H = DihedralGroup(4)
sage: g = G([(1,3),(2,4)]); g
(1,3)(2,4)
sage: phi = PermutationGroupMorphism_im_gens( G, H, gens, gens)
sage: phi
Homomorphism : Cyclic group of order 4 as a permutation group --> Dihedral group of order 8 as a
sage: phi(g)
(1,3)(2,4)
sage: gens1 = G.gens()
sage: gens2 = ((4,3,2,1),)
sage: phi = PermutationGroupMorphism_im_gens( G, G, gens1, gens2)
sage: g = G([(1,2,3,4)]); g
(1,2,3,4)
sage: phi(g)
(1,4,3,2)
```

AUTHORS:

- David Joyner (2006-02)

codomain()

domain()

image(*J*)

J must be a subgroup of G. Computes the subgroup of H which is the image of J.

EXAMPLES:

```
sage: G = CyclicPermutationGroup(4)
sage: gens = G.gens()
sage: H = DihedralGroup(4)
sage: g = G([(1,2,3,4)])
sage: phi = PermutationGroupMorphism_im_gens( G, H, gens, gens)
sage: phi.image(G)
Permutation Group with generators [(1,2,3,4)]
sage: phi.image(g)
(1,2,3,4)
```

kernel()

range()

gap_format(*x*)

Put a permutation in Gap format, as a string.

is_PermutationGroupMorphism(*f*)

22.9 Rubik's cube group functions

Note: "Rubik's cube" is trademarked. We shall omit the trademark symbol below for simplcity.

NOTATION: B denotes a clockwise quarter turn of the back face D denotes a clockwise quarter turn of the down face and similarly for F (front), L (left), R (right), U (up) Products of moves are read right to left, so for example, R*U means move U first and then R.

See `CubeGroup.parse()` for all possible input notations.

The "Singmaster notation":

- moves: U, D, R, L, F, B as in the diagram below,
- corners: xyz means the facet is on face x (in R,F,L,U,D,B) and the clockwise rotation of the corner sends x-y-z
- edges: xy means the facet is on face x and a flip of the edge sends x-y.

```
sage: rubik = CubeGroup()
sage: rubik.display2d("")
              +--------------+
              |  1    2    3 |
              |  4   top   5 |
              |  6    7    8 |
+-------------+--------------+-------------+------------+
|  9  10  11 | 17   18   19 | 25   26  27 | 33  34  35 |
| 12 left 13 | 20  front 21 | 28 right 29 | 36 rear 37 |
| 14  15  16 | 22   23   24 | 30   31  32 | 38  39  40 |
+-------------+--------------+-------------+------------+
              | 41   42   43 |
              | 44 bottom 45 |
              | 46   47   48 |
              +--------------+
```

AUTHORS:

- David Joyner (2006-10-21): first version
- David Joyner (2007-05): changed faces, added legal and solve
- David Joyner(2007-06): added plotting functions
- David Joyner (2007, 2008): colors corrected, "solve" rewritten (again),typos fixed.
- Robert Miller (2007, 2008): editing, cleaned up display2d
- Robert Bradshaw (2007, 2008): RubiksCube object, 3d plotting.
- David Joyner (2007-09): rewrote docstring for CubeGroup's "solve".
- Robert Bradshaw (2007-09): Versatile parse function for all input types.
- Robert Bradshaw (2007-11): Cleanup.

class CubeGroup()

A python class to help compute Rubik's cube group actions.

EXAMPLES: If G denotes the cube group then it may be regarded as a subgroup of SymmetricGroup(48), where the 48 facets are labeled as follows.

```
sage: rubik = CubeGroup()
sage: rubik.display2d("")
             +--------------+
             |  1    2    3 |
             |  4   top   5 |
             |  6    7    8 |
+------------+--------------+-------------+------------+
|  9  10  11 | 17   18   19 | 25   26  27 | 33  34  35 |
| 12 left 13 | 20  front 21 | 28 right 29 | 36 rear 37 |
| 14  15  16 | 22   23   24 | 30   31  32 | 38  39  40 |
+------------+--------------+-------------+------------+
             | 41   42   43 |
             | 44 bottom 45 |
             | 46   47   48 |
             +--------------+

sage: rubik
The PermutationGroup of all legal moves of the Rubik's cube.
sage: print rubik
The Rubik's cube group with genrators R,L,F,B,U,D in SymmetricGroup(48).
```

B()

D()

F()

L()

R()

U()

display2d(*mv*)

faces(*mv*)

Returns the dictionary of faces created by the effect of the move mv, which is a string of the form $X^a * Y^b * ...$, where X, Y, ... are in $\{R, L, F, B, U, D\}$ and $a, b, ...$ are integers. We call this ordering of the faces the "BDFLRU, L2R, T2B ordering".

EXAMPLES:

```
sage: rubik = CubeGroup()
```

Now type `rubik.faces("")` for the dictionary of the solved state and `rubik.faces("R*L")` for the dictionary of the state obtained after making the move R followed by L.

facets(*g=None*)

Returns the set of facets on which the group acts. This function is a "constant".

EXAMPLES:

```
sage: rubik = CubeGroup()
sage: rubik.facets()==range(1,49)
True
```

gen_names()

gens()

group()

legal(*state, mode='quiet'*)

Returns 1 (true) if the dictionary `state` (in the same format as returned by the faces method) represents a legal position (or state) of the Rubik's cube. Returns 0 (false) otherwise.

EXAMPLES:

```
sage: rubik = CubeGroup()
sage: G = rubik.group()
sage: r0 = rubik.faces("")
sage: r1 = {'back': [[33, 34, 35], [36, 0, 37], [38, 39, 40]], 'down': [[41, 42, 43], [44, 0
sage: rubik.legal(r0)
1
sage: rubik.legal(r0,"verbose")
(1, ())
sage: rubik.legal(r1)
0
```

move(*mv*)

Returns the group element and the reordered list of facets, as moved by the list mv (read left-to-right)

INPUT: mv is a string of the form `Xa*Yb*...`, where X, Y, ... are in R,L,F,B,U,D and a,b, ... are integers.

EXAMPLES:

```
  sage: rubik = CubeGroup()
sage: rubik.move("")[0]
()
sage: rubik.move("R")[0]
(3,38,43,19)(5,36,45,21)(8,33,48,24)(25,27,32,30)(26,29,31,28)
sage: rubik.R()
(3,38,43,19)(5,36,45,21)(8,33,48,24)(25,27,32,30)(26,29,31,28)
```

parse(*mv*)

This function allows one to create the permutation group element from a variety of formats.

INPUT: one of the following

- `list` - list of facets (as returned by self.facets())
- `dict` - list of faces (as returned by self.faces())
- `str` - either cycle notation (passed to GAP) or a product of generators or Singmaster notation
- `perm_group element` - returned as an element of self.group()

EXAMPLES:

```
sage: C = CubeGroup()
sage: C.parse(range(1,49))
()
sage: g = C.parse("L"); g
(1,17,41,40)(4,20,44,37)(6,22,46,35)(9,11,16,14)(10,13,15,12)
sage: C.parse(str(g)) == g
True
sage: facets = C.facets(g); facets
[17, 2, 3, 20, 5, 22, 7, 8, 11, 13, 16, 10, 15, 9, 12, 14, 41, 18, 19, 44, 21, 46, 23, 24, 2
sage: C.parse(facets)
(1,17,41,40)(4,20,44,37)(6,22,46,35)(9,11,16,14)(10,13,15,12)
sage: C.parse(facets) == g
True
sage: faces = C.faces("L"); faces
{'right': [[25, 26, 27], [28, 0, 29], [30, 31, 32]], 'up': [[17, 2, 3], [20, 0, 5], [22, 7,
```

```
sage: C.parse(faces) == C.parse("L")
True
sage: C.parse("L' R2") == C.parse("L^(-1)*R^2")
True
sage: C.parse("L' R2")
(1,40,41,17)(3,43)(4,37,44,20)(5,45)(6,35,46,22)(8,48)(9,14,16,11)(10,12,15,13)(19,38)(21,36
sage: C.parse("L^4")
()
sage: C.parse("L^(-1)*R")
(1,40,41,17)(3,38,43,19)(4,37,44,20)(5,36,45,21)(6,35,46,22)(8,33,48,24)(9,14,16,11)(10,12,1
```

plot3d_cube(*mv, title=True*)

Displays F,U,R faces of the cube after the given move mv, where mv is a string in the Singmaster notation. Mostly included for the purpose of drawing pictures and checking moves.

The first one below is "superflip+4 spot" (in 26q* moves) and the second one is the superflip (in 20f* moves). Type show(P) to view them.

EXAMPLES:

```
sage: rubik = CubeGroup()
sage: P = rubik.plot3d_cube("U^2*F*U^2*L*R^(-1)*F^2*U*F^3*B^3*R*L*U^2*R*D^3*U*L^3*R*D*R^3*L^
sage: P = rubik.plot3d_cube("R*L*D^2*B^3*L^2*F^2*R^2*U^3*D*R^3*D^2*F^3*B^3*D^3*F^2*D^3*R^2*U
```

plot_cube(*mv, title=True, colors=, [(1, 0.63, 1), (1, 1, 0), (1, 0, 0), (0, 1, 0), (1, 0.59999999999999998, 0.29999999999999999), (0, 0, 1)]*)

Input the move mv, as a string in the Singmaster notation, and output the 2-d plot of the cube in that state.

Type P.show() to display any of the plots below.

EXAMPLES:

```
sage: rubik = CubeGroup()
sage: P = rubik.plot_cube("R^2*U^2*R^2*U^2*R^2*U^2", title = False)
sage: # (R^2U^2)^3  permutes 2 pairs of edges (uf,ub)(fr,br)
sage: P = rubik.plot_cube("R*L*D^2*B^3*L^2*F^2*R^2*U^3*D*R^3*D^2*F^3*B^3*D^3*F^2*D^3*R^2*U^3
sage: # the superflip (in 20f* moves)
sage: P = rubik.plot_cube("U^2*F*U^2*L*R^(-1)*F^2*U*F^3*B^3*R*L*U^2*R*D^3*U*L^3*R*D*R^3*L^3*
sage: # "superflip+4 spot" (in 26q* moves)
```

repr2d(*mv*)

Displays a 2d map of the Rubik's cube after the move mv has been made. Nothing is returned.

EXAMPLES:

```
sage: rubik = CubeGroup()
sage: rubik.display2d("")
             +-------------+
             |  1    2    3 |
             |  4   top   5 |
             |  6    7    8 |
+------------+-------------+-------------+------------+
|  9  10  11 | 17   18   19 | 25   26  27 | 33  34  35 |
| 12 left 13 | 20  front 21 | 28 right 29 | 36 rear 37 |
| 14  15  16 | 22   23   24 | 30   31  32 | 38  39  40 |
+------------+-------------+-------------+------------+
             | 41   42   43 |
             | 44 bottom 45 |
             | 46   47   48 |
             +-------------+

sage: rubik.display2d("R")
             +-------------+
```

```
                |  1    2   38 |
                |  4   top  36 |
                |  6    7   33 |
    +-----------+--------------+-------------+-----------+
    |  9  10  11 | 17   18    3 | 27   29  32 | 48  34  35 |
    | 12 left 13 | 20  front  5 | 26 right 31 | 45 rear 37 |
    | 14  15  16 | 22   23    8 | 25   28  30 | 43  39  40 |
    +-----------+--------------+-------------+-----------+
                | 41   42   19 |
                | 44 bottom 21 |
                | 46   47   24 |
                +--------------+
```

You can see the right face has been rotated but not the left face.

solve (*state, algorithm='default'*)

Solves the cube in the `state`, given as a dictionary as in `legal`. See the `solve` method of the RubiksCube class for more details.

This may use GAP's `EpimorphismFromFreeGroup` and `PreImagesRepresentative` as explained below, if 'gap' is passed in as the algorithm.

This algorithm

1. constructs the free group on 6 generators then computes a reasonable set of relations which they satisfy
2. computes a homomorphism from the cube group to this free group quotient
3. takes the cube position, regarded as a group element, and maps it over to the free group quotient
4. using those relations and tricks from combinatorial group theory (stabilizer chains), solves the "word problem" for that element.
5. uses python string parsing to rewrite that in cube notation.

The Rubik's cube group has about 4.3×10^{19} elements, so this process is time-consuming. See http://www.gap-system.org/Doc/Examples/rubik.html for an interesting discussion of some GAP code analyzing the Rubik's cube.

EXAMPLES:

```
sage: rubik = CubeGroup()
sage: state = rubik.faces("R")
sage: rubik.solve(state)
'R'
sage: state = rubik.faces("R*U")
sage: rubik.solve(state, algorithm='gap')        # long time
'R*U'
```

You can also check this another (but similar) way using the `word_problem` method (eg, G = rubik.group(); g = G("(3,38,43,19)(5,36,45,21)(8,33,48,24)(25,27,32,30)(26,29,31,28)"); g.word_problem([b,d,f,l,r,u]), though the output will be less intuitive).

class RubiksCube (*state=None, history=, [], colors=, [(1, 0.63, 1), (1, 1, 0), (1, 0, 0), (0, 1, 0), (1, 0.5999999999999998, 0.2999999999999999), (0, 0, 1)]*)

```
sage: C = RubiksCube().move("R U R'")
sage: C.show3d()
```

```
sage: C = RubiksCube("R*L"); C
                +--------------+
                | 17    2   38 |
                | 20   top  36 |
                | 22    7   33 |
    +-----------+--------------+-------------+-----------+
```

```
| 11  13  16 | 41   18    3 | 27   29  32 | 48  34   6 |
| 10 left 15 | 44  front  5 | 26 right 31 | 45 rear  4 |
|  9  12  14 | 46   23    8 | 25   28  30 | 43  39   1 |
+------------+--------------+-------------+------------+
             | 40   42   19 |
             | 37 bottom 21 |
             | 35   47   24 |
             +--------------+
sage: C.show()
sage: C.solve(algorithm='gap')  # long time
'L R'
sage: C == RubiksCube("L*R")
True
```

cubie(*size, gap, x, y, z, colors, stickers=True*)

facets()

move(*g*)

plot()

plot3d(*stickers=True*)

```
sage: C = RubiksCube().move("R*U")
sage: C.plot3d()
sage: C.plot()
```

scramble(*moves=30*)

show()

show3d()

solve(*algorithm='hybrid', timeout=15*)

Algorithm must be one of : hybrid - try kociemba for timeout seconds, then dietz kociemba - Use Dik T. Winter's program (reasonable speed, few moves) dietz - Use Eric Dietz's cubex program (fast but lots of moves) optimal - Use Michael Reid's optimal program (may take a long time) gap - Use GAP word solution (can be slow)

EXAMPLE:

```
sage: C = RubiksCube("R U F L B D")
sage: C.solve()
'R U F L B D'
```

Dietz's program is much faster, but may give highly non-optimal solutions.

```
sage: s = C.solve('dietz'); s
"U' L' L' U L U' L U D L L D' L' D L' D' L D L' U' L D' L' U L' B' U' L' U B L D L D' U' L'
sage: C2 = RubiksCube(s)
sage: C == C2
True
```

undo()

color_of_square(*facet, colors=, ['lpurple', 'yellow', 'red', 'green', 'orange', 'blue']*)

Returns the color the facet has in the solved state.

EXAMPLES:

```
sage: from sage.groups.perm_gps.cubegroup import *
sage: color_of_square(41)
'blue'
```

create_poly(*face, color*)

cubie_centers(*label*)

cubie_colors(*label, state0*)

cubie_faces()

This provides a map from the 6 faces of the 27 cubies to the 48 facets of the larger cube.

-1,-1,-1 is left, top, front

index2singmaster(*facet*)

Translates index used (eg, 43) to Singmaster facet notation (eg, fdr).

EXAMPLES:

```
sage: from sage.groups.perm_gps.cubegroup import *
sage: index2singmaster(41)
'dlf'
```

inv_list(*lst*)

Input a list of ints 1, ..., m (in any order), outputs inverse perm.

EXAMPLES:

```
sage: from sage.groups.perm_gps.cubegroup import *
sage: L = [2,3,1]
sage: inv_list(L)
[3, 1, 2]
```

plot3d_cubie(*cnt, clrs*)

Plots the front, up and right face of a cubie centered at cnt and rgbcolors given by clrs (in the order FUR).

Type P.show() to view.

EXAMPLES:

```
sage: from sage.groups.perm_gps.cubegroup import *
sage: clrF = blue; clrU = red; clrR = green
sage: P = plot3d_cubie([1/2,1/2,1/2],[clrF,clrU,clrR])
```

polygon_plot3d(*points, tilt=30, turn=30, **kwargs*)

Plots a polygon viewed from an angle determined by tilt, turn, and vertices points.

> **Warning:** The ordering of the points is important to get "correct" and if you add several of these plots together, the one added first is also drawn first (ie, addition of Graphics objects is not commutative).

The following example produced a green-colored square with vertices at the points indicated.

EXAMPLES:

```
sage: from sage.groups.perm_gps.cubegroup import *
sage: P = polygon_plot3d([[1,3,1],[2,3,1],[2,3,2],[1,3,2],[1,3,1]],rgbcolor=green)
```

rotation_list(*tilt, turn*)

xproj(*x, y, z, r*)

yproj(*x, y, z, r*)

22.10 Matrix Groups

AUTHORS:

- William Stein: initial version
- David Joyner (2006-03-15): degree, base_ring, _contains_, list, random, order methods; examples
- William Stein (2006-12): rewrite
- David Joyner (2007-12): Added invariant_generators (with Martin Albrecht and Simon King)
- David Joyner (2008-08): Added module_composition_factors (interface to GAP's MeatAxe implementation) and as_permutation_group (returns isomorphic PermutationGroup).

This class is designed for computing with matrix groups defined by a (relatively small) finite set of generating matrices.

EXAMPLES:

```
sage: F = GF(3)
sage: gens = [matrix(F,2, [1,0, -1,1]), matrix(F, 2, [1,1,0,1])]
sage: G = MatrixGroup(gens)
sage: G.conjugacy_class_representatives()
[
[1 0]
[0 1],
[0 1]
[2 1],
[0 1]
[2 2],
[0 2]
[1 1],
[0 2]
[1 2],
[0 1]
[2 0],
[2 0]
[0 2]
]
```

Loading and saving work:

```
sage: G = GL(2,5); G
General Linear Group of degree 2 over Finite Field of size 5
sage: loads(dumps(G)) == G
True
sage: g = G.1; g
[4 1]
[4 0]
sage: loads(dumps(g)) == g
True
```

MatrixGroup(*gens*)

Return the matrix group with given generators.

INPUT:

•`gens` - list of matrices in a matrix space or matrix group

EXAMPLES:

```
sage: F = GF(5)
sage: gens = [matrix(F,2,[1,2, -1, 1]), matrix(F,2, [1,1, 0,1])]
sage: G = MatrixGroup(gens); G
Matrix group over Finite Field of size 5 with 2 generators:
[[[1, 2], [4, 1]], [[1, 1], [0, 1]]]
```

In the second example, the generators are a matrix over $\mathbf{Z}$, a matrix over a finite field, and the integer 2. Sage determines that they both canonically map to matrices over the finite field, so creates that matrix group there.

```
sage: gens = [matrix(2,[1,2, -1, 1]), matrix(GF(7), 2, [1,1, 0,1]), 2]
sage: G = MatrixGroup(gens); G
Matrix group over Finite Field of size 7 with 3 generators:
[[[1, 2], [6, 1]], [[1, 1], [0, 1]], [[2, 0], [0, 2]]]
```

Each generator must be invertible:

```
sage: G = MatrixGroup([matrix(ZZ,2,[1,2,3,4])])
...
ValueError: each generator must be an invertible matrix but one is not:
[1 2]
[3 4]
```

Some groups aren't supported:

```
sage: SL(2, CC).gens()
...
NotImplementedError: Matrix group over Complex Field with 53 bits of precision not implemented.
sage: G = SL(0, QQ)
...
ValueError: The degree must be at least 1
```

class MatrixGroup_gap(*n, R, var='a'*)

as_matrix_group()

Return this group, but as a general matrix group, i.e., throw away the extra structure of general unitary group.

EXAMPLES:

```
sage: G = SU(4,GF(5))
sage: G.as_matrix_group()
Matrix group over Finite Field in a of size 5^2 with 2 generators:
[[[a, 0, 0, 0], [0, 2*a + 3, 0, 0], [0, 0, 4*a + 1, 0], [0, 0, 0, 3*a]], [[1, 0, 4*a + 3, 0]

sage: G = GO(3,GF(5))
sage: G.as_matrix_group()
Matrix group over Finite Field of size 5 with 2 generators:
[[[2, 0, 0], [0, 3, 0], [0, 0, 1]], [[0, 1, 0], [1, 4, 4], [0, 2, 1]]]
```

base_field()

Return the base ring of this matrix group.

EXAMPLES:

```
sage: GL(2,GF(3)).base_ring()
Finite Field of size 3
sage: G = SU(3,GF(5))
sage: G.base_ring()
```

```
Finite Field of size 5
sage: G.field_of_definition()
Finite Field in a of size 5^2
```

base_ring()
Return the base ring of this matrix group.
EXAMPLES:

```
sage: GL(2,GF(3)).base_ring()
Finite Field of size 3
sage: G = SU(3,GF(5))
sage: G.base_ring()
Finite Field of size 5
sage: G.field_of_definition()
Finite Field in a of size 5^2
```

degree()
Return the degree of this matrix group.
EXAMPLES:

```
sage: SU(5,5).degree()
5
```

field_of_definition(*var='a'*)
Return a field that contains all the matrices in this matrix group.
EXAMPLES:

```
sage: G = SU(3,GF(5))
sage: G.base_ring()
Finite Field of size 5
sage: G.field_of_definition()
Finite Field in a of size 5^2
sage: G = GO(4,GF(7),1)
sage: G.field_of_definition()
Finite Field of size 7
sage: G.base_ring()
Finite Field of size 7
```

gen(*n*)
Return the n-th generator.
EXAMPLES:

```
sage: G = GU(4,GF(5), var='beta')
sage: G.gen(0)
[  beta      0      0      0]
[     0      1      0      0]
[     0      0      1      0]
[     0      0      0 3*beta]
```

gens()
Return generators for this matrix group.
EXAMPLES:

```
sage: G = GO(3,GF(5))
sage: G.gens()
[
[2 0 0]
[0 3 0]
[0 0 1],
```

```
[0 1 0]
[1 4 4]
[0 2 1]
]
```

hom(*x*)

irreducible_characters()

Returns the list of irreducible characters of the group.

EXAMPLES:

```
sage: G = GL(2,2)
sage: G.irreducible_characters()
[Character of General Linear Group of degree 2 over Finite Field of size 2,
 Character of General Linear Group of degree 2 over Finite Field of size 2,
 Character of General Linear Group of degree 2 over Finite Field of size 2]
```

is_finite()

Return True if this matrix group is finite.

EXAMPLES:

```
sage: G = GL(2,GF(3))
sage: G.is_finite()
True
sage: SL(2,ZZ).is_finite()
False
```

list()

Return list of all elements of this group.

Always returns a new list, so it is safe to change the returned list.

EXAMPLES:

```
sage: F = GF(3)
sage: gens = [matrix(F,2, [1,0, -1,1]), matrix(F, 2, [1,1,0,1])]
sage: G = MatrixGroup(gens)
sage: G.order()
24
sage: v = G.list()
sage: len(v)
24
sage: v[:2]
[[0 1]
[2 0], [0 1]
[2 1]]
sage: G.list()[0] in G
True
```

An example over a ring (see trac 5241):

```
sage: M1 = matrix(ZZ,2,[[-1,0],[0,1]])
sage: M2 = matrix(ZZ,2,[[1,0],[0,-1]])
sage: M3 = matrix(ZZ,2,[[-1,0],[0,-1]])
sage: MG = MatrixGroup([M1, M2, M3])
sage: MG.list()
[[-1  0]
[ 0 -1], [-1  0]
[ 0  1], [ 1  0]
[ 0 -1], [1 0]
[0 1]]
sage: MG.list()[1]
```

```
[-1  0]
[ 0  1]
sage: MG.list()[1].parent()
Matrix group over Integer Ring with 3 generators:
[[[-1, 0], [0, 1]], [[1, 0], [0, -1]], [[-1, 0], [0, -1]]]

sage: GL(2,ZZ).list()
...
ValueError: group must be finite
```

matrix_space()

Return the matrix space corresponding to this matrix group.

This is a matrix space over the field of definition of this matrix group.

EXAMPLES:

```
sage: F = GF(5); MS = MatrixSpace(F,2,2)
sage: G = MatrixGroup([MS(1), MS([1,2,3,4])])
sage: G.matrix_space()
Full MatrixSpace of 2 by 2 dense matrices over Finite Field of size 5
```

ngens()

Return the number of generators of this linear group.

EXAMPLES:

```
sage: G = GO(3,GF(5))
sage: G.ngens()
2
```

order()

EXAMPLES:

```
sage: G = Sp(4,GF(3))
sage: G.order()
51840
sage: G = SL(4,GF(3))
sage: G.order()
12130560
sage: F = GF(5); MS = MatrixSpace(F,2,2)
sage: gens = [MS([[1,2],[-1,1]]),MS([[1,1],[0,1]])]
sage: G = MatrixGroup(gens)
sage: G.order()
480
sage: G = MatrixGroup([matrix(ZZ,2,[1,1,0,1])])
sage: G.order()
+Infinity
```

class **MatrixGroup_gap_finite_field**(*n, R, var='a'*)

Python class for matrix groups over a finite field.

center()

Return the center of this linear group as a matrix group.

EXAMPLES:

```
sage: G = SU(3,GF(2))
sage: G.center()
Matrix group over Finite Field in a of size 2^2 with 1 generators:
 [[[a, 0, 0], [0, a, 0], [0, 0, a]]]
sage: GL(2,GF(3)).center()
Matrix group over Finite Field of size 3 with 1 generators:
```

```
 [[[2, 0], [0, 2]]]
sage: GL(3,GF(3)).center()
Matrix group over Finite Field of size 3 with 1 generators:
 [[[2, 0, 0], [0, 2, 0], [0, 0, 2]]]
sage: GU(3,GF(2)).center()
Matrix group over Finite Field in a of size 2^2 with 1 generators:
 [[[a + 1, 0, 0], [0, a + 1, 0], [0, 0, a + 1]]]
```

conjugacy_class_representatives()

Return a set of representatives for each of the conjugacy classes of the group.

EXAMPLES:

```
sage: G = SU(3,GF(2))
sage: len(G.conjugacy_class_representatives())
16
sage: len(GL(2,GF(3)).conjugacy_class_representatives())
8
sage: len(GU(2,GF(5)).conjugacy_class_representatives())
36
```

order()

EXAMPLES:

```
sage: G = Sp(4,GF(3))
sage: G.order()
51840
sage: G = SL(4,GF(3))
sage: G.order()
12130560
sage: F = GF(5); MS = MatrixSpace(F,2,2)
sage: gens = [MS([[1,2],[-1,1]]),MS([[1,1],[0,1]])]
sage: G = MatrixGroup(gens)
sage: G.order()
480
sage: G = MatrixGroup([matrix(ZZ,2,[1,1,0,1])])
sage: G.order()
+Infinity
```

random()

Deprecated. Use self.random_element() instead.

random_element()

Return a random element of this group.

EXAMPLES:

```
sage: G = Sp(4,GF(3))
sage: G.random_element()
[2 1 1 1]
[1 0 2 1]
[0 1 1 0]
[1 0 0 1]

sage: F = GF(5); MS = MatrixSpace(F,2,2)
sage: gens = [MS([[1,2],[-1,1]]),MS([[1,1],[0,1]])]
sage: G = MatrixGroup(gens)
sage: G.random_element()
[1 3]
[0 3]
sage: G.random_element()
```

```
[2 2]
[1 0]
sage: G.random_element()
[4 0]
[1 4]
```

class MatrixGroup_generic()

class MatrixGroup_gens(*gensG*)

EXAMPLES:

A ValueError is raised if one of the generators is not invertible.

```
sage: F = GF(5); MS = MatrixSpace(F,2,2)
sage: G = MatrixGroup([MS.0])
...
ValueError: each generator must be an invertible matrix but one is not:
[1 0]
[0 0]
```

as_permutation_group(*method=None*)

This returns a permutation group representation for the group. In most cases occurring in practice, this is a permutation group of minimal degree (the degree begin determined from orbits under the group action). When these orbits are hard to compute, the procedure can be time-consuming and the degree may not be minimal. The "method=smaller" option tries return an isomorphic group of lower degree.

EXAMPLES:

```
sage: MS = MatrixSpace( GF(2), 5, 5)
sage: A = MS([[0,0,0,0,1],[0,0,0,1,0],[0,0,1,0,0],[0,1,0,0,0],[1,0,0,0,0]])
sage: G = MatrixGroup([A])
sage: G.as_permutation_group()
Permutation Group with generators [(1,2)]
sage: MS = MatrixSpace( GF(7), 12, 12)
sage: GG = gap("ImfMatrixGroup( 12, 3 )")
sage: GG.GeneratorsOfGroup().Length()
3
sage: g1 = MS(eval(str(GG.GeneratorsOfGroup()[1]).replace("\n","")))
sage: g2 = MS(eval(str(GG.GeneratorsOfGroup()[2]).replace("\n","")))
sage: g3 = MS(eval(str(GG.GeneratorsOfGroup()[3]).replace("\n","")))
sage: G = MatrixGroup([g1, g2, g3])
sage: G.order()
21499084800
sage: set_random_seed(0); current_randstate().set_seed_gap()
sage: G.as_permutation_group()
Permutation Group with generators [(2,3,5,11,20,38,14,26,43,66)(4,8,16,29,47,63,48,74,56,86)
sage: set_random_seed(3); current_randstate().set_seed_gap()
sage: G.as_permutation_group(method="smaller")
Permutation Group with generators [(1,2)(3,7,13,25,45,5,10,19,35,60)(8,16,30,41,69,11,22,40,
```

In this case, the "smaller" option returned an isomorphic group of lower degree. The above example used GAP's library of irreducible maximal finite ("imf") integer matrix groups to construct the MatrixGroup G over GF(7). The section "Irreducible Maximal Finite Integral Matrix Groups" in the GAP reference manual has more details.

gens()

EXAMPLES:

```
sage: F = GF(3); MS = MatrixSpace(F,2,2)
sage: gens = [MS([[1,0],[0,1]]),MS([[1,1],[0,1]])]
```

```
sage: G = MatrixGroup(gens)
sage: gens[0] in G
True
sage: gens = G.gens()
sage: gens[0] in G
True
sage: gens = [MS([[1,0],[0,1]]),MS([[1,1],[0,1]])]

sage: F = GF(5); MS = MatrixSpace(F,2,2)
sage: G = MatrixGroup([MS(1), MS([1,2,3,4])])
sage: G
Matrix group over Finite Field of size 5 with 2 generators:
 [[[1, 0], [0, 1]], [[1, 2], [3, 4]]]
sage: G.gens()
[[1 0]
[0 1], [1 2]
[3 4]]
```

invariant_generators()

Wraps Singular's invariant_algebra_reynolds and invariant_ring in finvar.lib, with help from Simon King and Martin Albrecht. Computes generators for the polynomial ring $F[x_1, \ldots, x_n]^G$, where G in GL(n,F) is a finite matrix group.

In the "good characteristic" case the polynomials returned form a minimal generating set for the algebra of G-invariant polynomials. In the "bad" case, the polynomials returned are primary and secondary invariants, forming a not necessarily minimal generating set for the algebra of G-invariant polynomials.

EXAMPLES:

```
sage: F = GF(7); MS = MatrixSpace(F,2,2)
sage: gens = [MS([[0,1],[-1,0]]),MS([[1,1],[2,3]])]
sage: G = MatrixGroup(gens)
sage: G.invariant_generators()
[x1^7*x2 - x1*x2^7, x1^12 - 2*x1^9*x2^3 - x1^6*x2^6 + 2*x1^3*x2^9 + x2^12, x1^18 + 2*x1^15*x
sage: q = 4; a = 2
sage: MS = MatrixSpace(QQ, 2, 2)
sage: gen1 = [[1/a,(q-1)/a],[1/a, -1/a]]; gen2 = [[1,0],[0,-1]]; gen3 = [[-1,0],[0,1]]
sage: G = MatrixGroup([MS(gen1),MS(gen2),MS(gen3)])
sage: G.order()
12
sage: G.invariant_generators()
[x1^2 + 3*x2^2, x1^6 + 15*x1^4*x2^2 + 15*x1^2*x2^4 + 33*x2^6]
sage: F = GF(5); MS = MatrixSpace(F,2,2)
sage: gens = [MS([[1,2],[-1,1]]),MS([[1,1],[-1,1]])]
sage: G = MatrixGroup(gens)
sage: G.invariant_generators()  ## takes a long time (several mins)
[x1^20 + x1^16*x2^4 + x1^12*x2^8 + x1^8*x2^12 + x1^4*x2^16 + x2^20, x1^20*x2^4 + x1^16*x2^8
sage: F=CyclotomicField(8)
sage: z=F.gen()
sage: a=z+1/z
sage: b=z^2
sage: MS=MatrixSpace(F,2,2)
sage: g1=MS([[1/a,1/a],[1/a,-1/a]])
sage: g2=MS([[1,0],[0,b]])
sage: g3=MS([[b,0],[0,1]])
sage: G=MatrixGroup([g1,g2,g3])
sage: G.invariant_generators()
[x1^8 + 14*x1^4*x2^4 + x2^8,
 x1^24 + 10626/1025*x1^20*x2^4 + 735471/1025*x1^16*x2^8 + 2704156/1025*x1^12*x2^12 + 735471/
```

module_composition_factors(*method=None*)

Returns a list of triples consisting of [base field, dimension, irreducibility], for each of the Meataxe composition factors modules. The method="verbose" option returns more information, but in Meataxe notation.

EXAMPLES:

```
sage: F=GF(3);MS=MatrixSpace(F,4,4)
sage: M=MS(0)
sage: M[0,1]=1;M[1,2]=1;M[2,3]=1;M[3,0]=1
sage: G = MatrixGroup([M])
sage: G.module_composition_factors()
[[Finite Field of size 3, 1, True],
 [Finite Field of size 3, 1, True],
 [Finite Field of size 3, 2, True]]
sage: F = GF(7); MS = MatrixSpace(F,2,2)
sage: gens = [MS([[0,1],[-1,0]]),MS([[1,1],[2,3]])]
sage: G = MatrixGroup(gens)
sage: G.module_composition_factors()
[[Finite Field of size 7, 2, True]]
```

Type "G.module_composition_factors(method='verbose')" to get a more verbose version.

For more on MeatAxe notation, see http://www.gap-system.org/Manuals/doc/htm/ref/CHAP067.htm

class MatrixGroup_gens_finite_field(*gensG*)

is_MatrixGroup(*x*)

EXAMPLES:

```
sage: from sage.groups.matrix_gps.matrix_group import is_MatrixGroup
sage: is_MatrixGroup(MatrixSpace(QQ,3))
False
sage: is_MatrixGroup(Mat(QQ,3))
False
sage: is_MatrixGroup(GL(2,ZZ))
True
sage: is_MatrixGroup(MatrixGroup([matrix(2,[1,1,0,1])]))
True
```

22.11 Matrix Group Elements

AUTHORS:

- David Joyner (2006-05): initial version David Joyner
- David Joyner (2006-05): various modifications to address William Stein's TODO's.
- William Stein (2006-12-09): many revisions.

EXAMPLES:

```
sage: F = GF(3); MS = MatrixSpace(F,2,2)
sage: gens = [MS([[1,0],[0,1]]),MS([[1,1],[0,1]])]
sage: G = MatrixGroup(gens); G
Matrix group over Finite Field of size 3 with 2 generators:
 [[[1, 0], [0, 1]], [[1, 1], [0, 1]]]
sage: g = G([[1,1],[0,1]])
sage: h = G([[1,2],[0,1]])
sage: g*h
[1 0]
[0 1]
```

You cannot add two matrices, since this is not a group operation. You can coerce matrices back to the matrix space and add them there:

```
sage: g + h
...
TypeError: unsupported operand type(s) for +: 'MatrixGroupElement' and 'MatrixGroupElement'

sage: g.matrix() + h.matrix()
[2 0]
[0 2]

sage: 2*g
...
TypeError: unsupported operand parent(s) for '*': 'Integer Ring' and 'Matrix group over Finite Field
 [[[1, 0], [0, 1]], [[1, 1], [0, 1]]]'
sage: 2*g.matrix()
[2 2]
[0 2]
```

class **MatrixGroupElement** (*g, parent, check=True*)

An element of a matrix group.

EXAMPLES:

```
sage: F = GF(3); MS = MatrixSpace(F,2,2)
       sage: gens = [MS([[1,0],[0,1]]),MS([[1,1],[0,1]])]
sage: G = MatrixGroup(gens)
sage: g = G.random_element()
sage: type(g)
<class 'sage.groups.matrix_gps.matrix_group_element.MatrixGroupElement'>
```

list ()

Return list representation of this matrix.

EXAMPLES:

```
sage: F = GF(3); MS = MatrixSpace(F,2,2)
sage: gens = [MS([[1,0],[0,1]]),MS([[1,1],[0,1]])]
sage: G = MatrixGroup(gens)
sage: g = G.0
sage: g.list()
[[1, 0], [0, 1]]
```

matrix ()

Obtain the usual matrix (as an element of a matrix space) associated to this matrix group element.

One reason to compute the associated matrix is that matrices support a huge range of functionality.

EXAMPLES:

```
sage: k = GF(7); G = MatrixGroup([matrix(k,2,[1,1,0,1]), matrix(k,2,[1,0,0,2])])
sage: g = G.0
sage: g.matrix()
[1 1]
[0 1]
sage: parent(g.matrix())
Full MatrixSpace of 2 by 2 dense matrices over Finite Field of size 7
```

Matrices have extra functionality that matrix group elements do not have.

```
sage: g.matrix().charpoly('t')
t^2 + 5*t + 1
```

order()

Return the order of this group element, which is the smallest positive integer n such that $g^n = 1$, or +Infinity if no such integer exists.

EXAMPLES:

```
sage: k = GF(7); G = MatrixGroup([matrix(k,2,[1,1,0,1]), matrix(k,2,[1,0,0,2])])
sage: G
Matrix group over Finite Field of size 7 with 2 generators:
 [[[1, 1], [0, 1]], [[1, 0], [0, 2]]]
sage: G.order()
21
```

See trac #1170

```
sage: gl=GL(2,ZZ); gl
General Linear Group of degree 2 over Integer Ring
sage: g=gl.gens()[2]; g
[1 1]
[0 1]
sage: g.order()
+Infinity
```

word_problem(*words=None*)

Right this group element in terms of the elements of the list `words`.

If G and H are permutation groups (with G the parent of self), H is a subgroup of G generated by a list `words` of elements of G. If g is in H, return the expression for g as a word in the elements of `words`.

ALGORITHM: Use GAP, which has optimized algorithms for solving the word problem (the GAP functions EpimorphismFromFreeGroup and PreImagesRepresentative).

INPUT:

- `words` - list (default: None) a list of elements of the parent group; if words is empty, uses the gens of the parent group.

EXAMPLE:

```
sage: G = GL(2,5); G
General Linear Group of degree 2 over Finite Field of size 5
sage: G.gens()
[
[2 0]
[0 1],
[4 1]
[4 0]
]
sage: G(1).word_problem([G.1, G.0])
1
```

Next we construct a more complicated element of the group from the generators:

```
sage: (G.0).order(), (G.1).order()
(4, 3)
sage: g = G.0^3 * G.1^2
```

We then ask to solve the word problem, with the generators reversed (just to make it trickier):

```
sage: s = g.word_problem([G.1, G.0]); s
([2 0]
[0 1])^-1 *
([4 1]
[4 0])^-1
```

It worked!

```
sage: s.prod() == g
True
```

is_MatrixGroupElement(*x*)

22.12 Homomorphisms Between Matrix Groups

AUTHORS:

- David Joyner and William Stein (2006-03): initial version
- David Joyner (2006-05): examples

class MatrixGroupMap(*parent*)
A set-theoretic map between matrix groups.

class MatrixGroupMorphism(*parent*)

class MatrixGroupMorphism_im_gens(*homset, imgsH, check=True*)
Some python code for wrapping GAP's GroupHomomorphismByImages function but only for matrix groups. Can be expensive if G is large. Returns "fail" if gens does not generate self or if the map does not extend to a group homomorphism, self - other.

TODO: what does it mean to return fail? It's a constructor for a class.

EXAMPLES:

```
sage: F = GF(5); MS = MatrixSpace(F,2,2)
sage: G = MatrixGroup([MS([1,1,0,1])])
sage: H = MatrixGroup([MS([1,0,1,1])])
sage: phi = G.hom(H.gens())
sage: phi
Homomorphism : Matrix group over Finite Field of size 5 with 1 generators:
 [[[1, 1], [0, 1]]] --> Matrix group over Finite Field of size 5 with 1 generators:
 [[[1, 0], [1, 1]]]
sage: phi(MS([1,1,0,1]))
[1 0]
[1 1]
sage: F = GF(7); MS = MatrixSpace(F,2,2)
sage: F.multiplicative_generator()
3
```

```
sage: G = MatrixGroup([MS([3,0,0,1])])
sage: a = G.gens()[0]^2
sage: phi = G.hom([a])
```

image(*J*)

J must be a subgroup of G. Computes the subgroup of H which is the image of J.

EXAMPLES:

```
sage: F = GF(7); MS = MatrixSpace(F,2,2)
sage: F.multiplicative_generator()
3
sage: G = MatrixGroup([MS([3,0,0,1])])
sage: a = G.gens()[0]^2
sage: phi = G.hom([a])
sage: phi.image(G.gens()[0])
'[ [ Z(7)^2, 0*Z(7) ], [ 0*Z(7), Z(7)^0 ] ]'
sage: H = MatrixGroup([MS(a.list())])
sage: H
Matrix group over Finite Field of size 7 with 1 generators:
[[[2, 0], [0, 1]]]
sage: phi.image(H)
'Group([ [ [ Z(7)^4, 0*Z(7) ], [ 0*Z(7), Z(7)^0 ] ] ])'
```

kernel()

EXAMPLES:

```
sage: F = GF(7); MS = MatrixSpace(F,2,2)
sage: F.multiplicative_generator()
3
sage: G = MatrixGroup([MS([3,0,0,1])])
sage: a = G.gens()[0]^2
sage: phi = G.hom([a])
sage: phi.kernel()
'Group([ [ [ Z(7)^3, 0*Z(7) ], [ 0*Z(7), Z(7)^0 ] ] ])'
sage: phi.image(G.gens()[0])
'[ [ Z(7)^2, 0*Z(7) ], [ 0*Z(7), Z(7)^0 ] ]'
```

22.13 Matrix Group Homsets

AUTHORS:

- William Stein (2006-05-07): initial version

class MatrixGroupHomset(*G, H*)

is_MatrixGroupHomset(*x*)

22.14 Linear Groups

AUTHORS:

- William Stein: initial version
- David Joyner: degree, base_ring, random, order methods; examples

- David Joyner (2006-05): added center, more examples, renamed random attributes, bug fixes.
- William Stein (2006-12): total rewrite

EXAMPLES:

22.15 General Linear Groups

EXAMPLES:

```
sage: GL(4,QQ)
General Linear Group of degree 4 over Rational Field
sage: GL(1,ZZ)
General Linear Group of degree 1 over Integer Ring
sage: GL(100,RR)
General Linear Group of degree 100 over Real Field with 53 bits of precision
sage: GL(3,GF(49,'a'))
General Linear Group of degree 3 over Finite Field in a of size 7^2
```

AUTHORS:

- David Joyner (2006-01)
- William Stein (2006-01)
- David Joyner (2006-05): added _latex_, __str__, examples
- William Stein (2006-12-09): rewrite

GL(*n, R, var='a'*)

Return the general linear group of degree n over the ring R.

EXAMPLES:

```
sage: G = GL(6,GF(5))
sage: G.order()
11064475422000000000000000
sage: G.base_ring()
Finite Field of size 5
```

```
sage: F = GF(3); MS = MatrixSpace(F,2,2)
sage: gens = [MS([[0,1],[1,0]]),MS([[1,1],[0,1]])]
sage: G = MatrixGroup(gens)
sage: G.order()
48
sage: H = GL(2,F)
sage: H.order()
48
```

```
sage: H == G
True
sage: H.as_matrix_group() == G
True
sage: H.gens()
[
[2 0]
[0 1],
[2 1]
[2 0]
]
```

class GeneralLinearGroup_finite_field(*n, R, var='a'*)

class GeneralLinearGroup_generic(*n, R, var='a'*)

22.16 Special Linear Groups

AUTHORS:

- William Stein: initial version
- David Joyner (2006-05): added examples, _latex_, __str__, gens, as_matrix_group
- William Stein (2006-12-09): rewrite

EXAMPLES:

```
sage: SL(2, ZZ)
Special Linear Group of degree 2 over Integer Ring
sage: G = SL(2,GF(3)); G
Special Linear Group of degree 2 over Finite Field of size 3
sage: G.is_finite()
True
sage: G.conjugacy_class_representatives()
[
[1 0]
[0 1],
[0 2]
[1 1],
[0 1]
[2 1],
[2 0]
[0 2],
[0 2]
[1 2],
[0 1]
[2 2],
[0 2]
[1 0]
]
sage: G = SL(6,GF(5))
sage: G.gens()
[
[2 0 0 0 0 0]
[0 3 0 0 0 0]
```

```
[0 0 1 0 0 0]
[0 0 0 1 0 0]
[0 0 0 0 1 0]
[0 0 0 0 0 1],
[4 0 0 0 0 1]
[4 0 0 0 0 0]
[0 4 0 0 0 0]
[0 0 4 0 0 0]
[0 0 0 4 0 0]
[0 0 0 0 4 0]
]
```

SL(*n, R, var='a'*)

Return the special linear group of degree n over the ring R.

EXAMPLES:

```
sage: SL(3,GF(2))
Special Linear Group of degree 3 over Finite Field of size 2
sage: G = SL(15,GF(7)); G
Special Linear Group of degree 15 over Finite Field of size 7
sage: G.order()
19567125956981469620152190624295863411240180071820494789160673696387130667378823633935199663436
sage: len(G.gens())
2
sage: G = SL(2,ZZ); G
Special Linear Group of degree 2 over Integer Ring
sage: G.gens()
[
[ 0  1]
[-1  0],
[1 1]
[0 1]
]
```

Next we compute generators for $\mathrm{SL}_3(\mathbf{Z})$.

```
sage: G = SL(3,ZZ); G
Special Linear Group of degree 3 over Integer Ring
sage: G.gens()
[
[0 1 0]
[0 0 1]
[1 0 0],
[ 0  1  0]
[-1  0  0]
[ 0  0  1],
[1 1 0]
[0 1 0]
[0 0 1]
]
```

class SpecialLinearGroup_finite_field(*n, R, var='a'*)

class SpecialLinearGroup_generic(*n, R, var='a'*)

22.17 Orthogonal Linear Groups

Paraphrased from the GAP manual: The general orthogonal group $GO(e, d, q)$ consists of those $d \times d$ matrices over the field $GF(q)$ that respect a non-singular quadratic form specified by e. (Use the GAP command InvariantQuadraticForm to determine this form explicitly.) The value of e must be 0 for odd d (and can optionally be omitted in this case), respectively one of 1 or -1 for even d.

SpecialOrthogonalGroup returns a group isomorphic to the special orthogonal group $SO(e, d, q)$, which is the subgroup of all those matrices in the general orthogonal group that have determinant one. (The index of $SO(e, d, q)$ in $GO(e, d, q)$ is 2 if q is odd, but $SO(e, d, q) = GO(e, d, q)$ if q is even.)

Warning: GAP notation: GO([e,] d, q), SO([e,] d, q) ([...] denotes and optional value)

Sage notation: GO(d, GF(q), e=0), SO(d, GF(q), e=0)

There is no Python trick I know of to allow the first argument to have the default value e=0 and leave the other two arguments as non-default. This forces us into non-standard notation.

AUTHORS:

- David Joyner (2006-03): initial version
- David Joyner (2006-05): added examples, _latex_, __str__, gens, as_matrix_group
- William Stein (2006-12-09): rewrite

GO(*n, R, e=0*)

Return the general orthogonal group.

EXAMPLES:

class GeneralOrthogonalGroup_finite_field(*n, R, e=0, var='a'*)

class GeneralOrthogonalGroup_generic(*n, R, e=0, var='a'*)

EXAMPLES:

```
sage: GO( 3, GF(7), 0)
General Orthogonal Group of degree 3, form parameter 0, over the Finite Field of size 7
sage: GO( 3, GF(7), 0).order()
672
sage: GO( 3, GF(7), 0).random_element()
[5 1 4]
[1 0 0]
[6 0 1]
```

invariant_quadratic_form()

This wraps GAP's command "InvariantQuadraticForm". From the GAP documentation:

INPUT:

- `self` - a matrix group G

OUTPUT:

- `Q` - the matrix satisfying the property: The quadratic form q on the natural vector space V on which G acts is given by $q(v) = vQv^t$, and the invariance under G is given by the equation $q(v) = q(vM)$ for all $v \in V$ and $M \in G$.

EXAMPLES:

```
sage: G = GO( 4, GF(7), 1)
sage: G.invariant_quadratic_form()
[0 1 0 0]
[0 0 0 0]
[0 0 3 0]
[0 0 0 1]
```

class **OrthogonalGroup**(*n, R, e=0, var='a'*)

invariant_form()

Return the invariant form of this orthogonal group.

TODO: What is the point of this? What does it do? How does it work?

EXAMPLES:

```
sage: G = SO( 4, GF(7), 1)
sage: G.invariant_form()
1
```

SO(*n, R, e=0, var='a'*)

Return the special orthogonal group of degree n over the ring R.

INPUT:

- n - the degree
- R - ring
- e - a parameter for orthogonal groups only depending on the invariant form

EXAMPLES:

```
sage: G = SO(3,GF(5))
sage: G.gens()
[
[2 0 0]
[0 3 0]
[0 0 1],
[3 2 3]
[0 2 0]
[0 3 1],
[1 4 4]
[4 0 0]
[2 0 4]
]
sage: G = SO(3,GF(5))
sage: G.as_matrix_group()
Matrix group over Finite Field of size 5 with 3 generators:
[[[2, 0, 0], [0, 3, 0], [0, 0, 1]], [[3, 2, 3], [0, 2, 0], [0, 3, 1]], [[1, 4, 4], [4, 0, 0], [2
```

class **SpecialOrthogonalGroup_finite_field**(*n, R, e=0, var='a'*)

class **SpecialOrthogonalGroup_generic**(*n, R, e=0, var='a'*)

EXAMPLES:

```
sage: G = SO( 4, GF(7), 1); G
Special Orthogonal Group of degree 4, form parameter 1, over the Finite Field of size 7
sage: G._gap_init_()
'SO(1, 4, 7)'
sage: G.random_element()
[1 2 5 0]
```

```
[2 2 1 0]
[1 3 1 5]
[1 3 1 3]
```

invariant_quadratic_form()

Return the quadratic form $q(v) = vQv^t$ on the space on which this group G that satisfies the equation $q(v) = q(vM)$ for all $v \in V$ and $M \in G$.

Note: Uses GAP's command InvariantQuadraticForm.

OUTPUT:

- Q - matrix that defines the invariant quadratic form.

EXAMPLES:

```
sage: G = SO( 4, GF(7), 1)
sage: G.invariant_quadratic_form()
[0 1 0 0]
[0 0 0 0]
[0 0 3 0]
[0 0 0 1]
```

22.18 Symplectic Linear Groups

AUTHORS:

- David Joyner (2006-03): initial version, modified from special_linear (by W. Stein)

EXAMPLES:

```
sage: G = Sp(4,GF(7))
sage: G._gap_init_()
'Sp(4, 7)'
sage: G
Symplectic Group of rank 2 over Finite Field of size 7
sage: G.random_element()
[1 6 5 5]
[2 1 4 5]
[1 2 4 5]
[4 0 2 2]
sage: G.order()
276595200
```

Sp(*n, R, var='a'*)

Return the symplectic group of degree n over R.

EXAMPLES:

```
sage: Sp(4,5)
Symplectic Group of rank 2 over Finite Field of size 5
sage: Sp(3,GF(7))
...
ValueError: the degree n (=3) must be even
```

class SymplecticGroup_finite_field(*n, R, var='a'*)

class SymplecticGroup_generic(*n, R, var='a'*)

22.19 Unitary Groups $GU(n, q)$ and $SU(n, q)$

These are $n \times n$ unitary matrices with entries in $GF(q^2)$.

AUTHORS:

- David Joyner (2006-03): initial version, modified from special_linear (by W. Stein)
- David Joyner (2006-05): minor additions (examples, _latex_, __str__, gens)
- William Stein (2006-12): rewrite

EXAMPLES:

```
sage: G = SU(3,GF(5))
sage: G.order()
378000
sage: G
Special Unitary Group of degree 3 over Finite Field of size 5
sage: G._gap_init_()
'SU(3, 5)'
sage: G.random_element()
[      1 4*a + 4 4*a + 1]
[2*a + 4 2*a + 1       0]
[      4     3*a 4*a + 2]
sage: G.base_ring()
Finite Field of size 5
sage: G.field_of_definition()
Finite Field in a of size 5^2
```

GU(*n, F, var='a'*)

Return the general unitary group of degree n over the finite field F.

INPUT:

- `n` - a positive integer
- `F` - finite field
- `var` - variable used to represent generator of quadratic extension of F, if needed.

EXAMPLES:

```
sage: G = GU(3,GF(7)); G
General Unitary Group of degree 3 over Finite Field of size 7
sage: G.gens()
[
[  a   0   0]
[  0   1   0]
[  0   0 5*a],
[6*a   6   1]
[  6   6   0]
[  1   0   0]
]
sage: G = GU(2,QQ)
...
NotImplementedError: general unitary group only implemented over finite fields
```

```
sage: G = GU(3,GF(5), var='beta')
sage: G.gens()
[
[  beta       0       0]
[     0       1       0]
[     0       0 3*beta],
[4*beta       4       1]
[     4       4       0]
[     1       0       0]
]
```

class GeneralUnitaryGroup_finite_field(*n, R, var='a'*)

SU(*n, F, var='a'*)

Return the special unitary group of degree n over F.

EXAMPLES:

```
sage: SU(3,5)
Special Unitary Group of degree 3 over Finite Field of size 5
sage: SU(3,QQ)
...
NotImplementedError: special unitary group only implemented over finite fields
```

class SpecialUnitaryGroup_finite_field(*n, R, var='a'*)

class UnitaryGroup_finite_field(*n, R, var='a'*)

field_of_definition()

Return the field of definition of this general unity group.

EXAMPLES:

```
sage: G = GU(3,GF(5))
sage: G.field_of_definition()
Finite Field in a of size 5^2
sage: G.base_field()
Finite Field of size 5
```

CHAPTER

TWENTYTHREE

GENERAL RINGS, IDEALS, AND MORPHISMS

23.1 Ideals

Sage provides functionality for computing with ideals. One can create an ideal in any commutative ring R by giving a list of generators, using the notation `R.ideal([a,b,...])`.

Cyclic(*R, n=None, homog=False, singular=Singular*)

Ideal of cyclic n-roots from 1-st n variables of R if R is coercable to Singular. If n==None n is set to R.ngens()

INPUT:

- `R` - base ring to construct ideal for
- `n` - number of cyclic roots (default: None)
- `homog` - if True a homogenous ideal is returned using the last variable in the ideal (default: False)
- `singular` - singular instance to use

Note: R will be set as the active ring in Singular

EXAMPLES:

An example from a multivariate polynomial ring over the rationals:

```
sage: P.<x,y,z> = PolynomialRing(QQ,3,order='lex')
sage: I = sage.rings.ideal.Cyclic(P)
sage: I
Ideal (x + y + z, x*y + x*z + y*z, x*y*z - 1) of Multivariate Polynomial
Ring in x, y, z over Rational Field
sage: I.groebner_basis()
[x + y + z, y^2 + y*z + z^2, z^3 - 1]
```

We compute a Groebner basis for cyclic 6, which is a standard benchmark and test ideal:

```
sage: R.<x,y,z,t,u,v> = QQ['x,y,z,t,u,v']
sage: I = sage.rings.ideal.Cyclic(R,6)
sage: B = I.groebner_basis()
sage: len(B)
45
```

FieldIdeal(*R*)

Let q = R.base_ring().order() and (x0,...,x_n) = R.gens() then if q is finite this constructor returns $< x_0^q - x_0, ..., x_n^q - x_n >$.

We call this ideal the field ideal and the generators the field equations.

EXAMPLES:

The Field Ideal generated from the polynomial ring over two variables in the finite field of size 2:

```
sage: P.<x,y> = PolynomialRing(GF(2),2)
sage: I = sage.rings.ideal.FieldIdeal(P); I
Ideal (x^2 + x, y^2 + y) of Multivariate Polynomial Ring in x, y over
Finite Field of size 2
```

Another, similar example:

```
sage: Q.<x1,x2,x3,x4> = PolynomialRing(GF(2^4,name='alpha'), 4)
sage: J = sage.rings.ideal.FieldIdeal(Q); J
Ideal (x1^16 + x1, x2^16 + x2, x3^16 + x3, x4^16 + x4) of
Multivariate Polynomial Ring in x1, x2, x3, x4 over Finite
Field in alpha of size 2^4
```

Ideal (**args, **kwds*)

Create the ideal in ring with given generators.

There are some shorthand notations for creating an ideal, in addition to using the Ideal function:

```
--  R.ideal(gens, coerce=True)
--  gens*R
--  R*gens
```

INPUT:

- `R (optional)` - a ring (if not given, will try to infer it from gens)
- `gens` - list of elements generating the ideal
- `coerce (optional)` - bool (default: True); whether gens need to be coerced into ring.

OUTPUT: The ideal of ring generated by gens.

EXAMPLES:

```
sage: R, x = PolynomialRing(ZZ, 'x').objgen()
sage: I = R.ideal([4 + 3*x + x^2, 1 + x^2])
sage: I
Ideal (x^2 + 3*x + 4, x^2 + 1) of Univariate Polynomial Ring in x over Integer Ring
sage: Ideal(R, [4 + 3*x + x^2, 1 + x^2])
Ideal (x^2 + 3*x + 4, x^2 + 1) of Univariate Polynomial Ring in x over Integer Ring
sage: Ideal((4 + 3*x + x^2, 1 + x^2))
Ideal (x^2 + 3*x + 4, x^2 + 1) of Univariate Polynomial Ring in x over Integer Ring

sage: ideal(x^2-2*x+1, x^2-1)
Ideal (x^2 - 2*x + 1, x^2 - 1) of Univariate Polynomial Ring in x over Integer Ring
sage: ideal([x^2-2*x+1, x^2-1])
Ideal (x^2 - 2*x + 1, x^2 - 1) of Univariate Polynomial Ring in x over Integer Ring
sage: l = [x^2-2*x+1, x^2-1]
sage: ideal(f^2 for f in l)
Ideal (x^4 - 4*x^3 + 6*x^2 - 4*x + 1, x^4 - 2*x^2 + 1) of
Univariate Polynomial Ring in x over Integer Ring
```

This example illustrates how Sage finds a common ambient ring for the ideal, even though 1 is in the integers (in this case).

```
sage: R.<t> = ZZ['t']
sage: i = ideal(1,t,t^2)
sage: i
Ideal (1, t, t^2) of Univariate Polynomial Ring in t over Integer Ring
sage: ideal(1/2,t,t^2)
Principal ideal (1) of Univariate Polynomial Ring in t over Rational Field
```

This shows that the issues at trac #1104 are resolved:

```
sage: Ideal(3, 5)
Principal ideal (1) of Integer Ring
sage: Ideal(ZZ, 3, 5)
Principal ideal (1) of Integer Ring
sage: Ideal(2, 4, 6)
Principal ideal (2) of Integer Ring
```

TESTS:

```
sage: R, x = PolynomialRing(ZZ, 'x').objgen()
sage: I = R.ideal([4 + 3*x + x^2, 1 + x^2])
sage: I == loads(dumps(I))
True

sage: I = Ideal(R, [4 + 3*x + x^2, 1 + x^2])
sage: I == loads(dumps(I))
True

sage: I = Ideal((4 + 3*x + x^2, 1 + x^2))
sage: I == loads(dumps(I))
True
```

class **Ideal_fractional**(*ring, gens, coerce=True*)

class **Ideal_generic**(*ring, gens, coerce=True*)

An ideal.

apply_morphism(*phi*)

Apply the morphism phi to every element of this ideal. Returns an ideal in the domain of phi.

EXAMPLES: sage: psi = CC['x'].hom([-CC['x'].0]) sage: J = ideal([CC['x'].0 + 1]); J Principal ideal (1.00000000000000*x + 1.00000000000000) of Univariate Polynomial Ring in x over Complex Field with 53 bits of precision sage: psi(J) Principal ideal (-1.00000000000000*x + 1.00000000000000) of Univariate Polynomial Ring in x over Complex Field with 53 bits of precision sage: J.apply_morphism(psi) Principal ideal (-1.00000000000000*x + 1.00000000000000) of Univariate Polynomial Ring in x over Complex Field with 53 bits of precision
sage: psi = ZZ['x'].hom([-ZZ['x'].0]) sage: J = ideal([ZZ['x'].0, 2]); J Ideal (x, 2) of Univariate Polynomial Ring in x over Integer Ring sage: psi(J) Ideal (-x, 2) of Univariate Polynomial Ring in x over Integer Ring sage: J.apply_morphism(psi) Ideal (-x, 2) of Univariate Polynomial Ring in x over Integer Ring

TESTS: sage: K.<a> = NumberField(x^2 + 1) sage: A = K.ideal(a) sage: taus = K.embeddings(K) sage: A.apply_morphism(taus[0]) # identity Fractional ideal (a) sage: A.apply_morphism(taus[1]) # complex conjugation Fractional ideal (-a) sage: A.apply_morphism(taus[0]) == A.apply_morphism(taus[1]) True
sage: K.<a> = NumberField(x^2 + 5) sage: B = K.ideal([2, a + 1]); B Fractional ideal (2, a + 1) sage: taus = K.embeddings(K) sage: B.apply_morphism(taus[0]) # identity Fractional ideal (2, a + 1)
Since 2 is totally ramified, complex conjugation fixes it:
sage: B.apply_morphism(taus[1]) # complex conjugation Fractional ideal (2, a + 1)

sage: taus[1](B) Fractional ideal (2, a + 1)

base_ring()

Returns the base ring of this ideal.

EXAMPLES:

```
sage: R = ZZ
sage: I = 3*R; I
Principal ideal (3) of Integer Ring
sage: J = 2*I; J
Principal ideal (6) of Integer Ring
sage: I.base_ring(); J.base_ring()
Integer Ring
Integer Ring
```

We construct an example of an ideal of a quotient ring:

```
sage: R = PolynomialRing(QQ, 'x'); x = R.gen()
sage: I = R.ideal(x^2 - 2)
sage: I.base_ring()
Rational Field
```

And p-adic numbers:

```
sage: R = Zp(7, prec=10); R
7-adic Ring with capped relative precision 10
sage: I = 7*R; I
Principal ideal (7 + O(7^11)) of 7-adic Ring with capped relative precision 10
sage: I.base_ring()
7-adic Ring with capped relative precision 10
```

category()

Return the category of this ideal.

EXAMPLES:

Note that category is dependent on the ring of the ideal.

```
sage: I = ZZ.ideal(7)
sage: J = ZZ[x].ideal(7,x)
sage: K = ZZ[x].ideal(7)
sage: I.category()
Category of ring ideals in Integer Ring
sage: J.category()
Category of ring ideals in Univariate Polynomial Ring in x
over Integer Ring
sage: K.category()
Category of ring ideals in Univariate Polynomial Ring in x
over Integer Ring
```

gens()

Return a set of generators / a basis of self. This is usually the set of generators provided during object creation.

EXAMPLE:

```
sage: P.<x,y> = PolynomialRing(QQ,2)
sage: I = Ideal([x,y+1]); I
Ideal (x, y + 1) of Multivariate Polynomial Ring in x, y over Rational Field
sage: I.gens()
(x, y + 1)
```

```
sage: ZZ.ideal(5,10).gens()
(5,)
```

gens_reduced()

Same as gens() for this ideal, since there is currently no special gens_reduced algorithm implemented for this ring.

This method is provided so that ideals in ZZ have the method gens_reduced(), just like ideals of number fields.

EXAMPLES:

```
sage: ZZ.ideal(5).gens_reduced()
(5,)
```

is_maximal()

Returns True if the ideal is maximal in the ring containing the ideal.

TODO: Make self.is_maximal() work! Write this code!

EXAMPLES:

```
sage: R = ZZ
sage: I = R.ideal(7)
sage: I.is_maximal()
...
NotImplementedError
```

is_prime()

Returns True if the ideal is prime in the ring containing the ideal.

TODO: Make self.is_prime() work! Write this code!

EXAMPLES:

```
sage: R = ZZ[x]
sage: I = R.ideal(7)
sage: I.is_prime()
...
NotImplementedError
```

is_principal()

Returns True if the ideal is principal in the ring containing the ideal.

TODO: Code is naive. Only keeps track of ideal generators as set during intiialization of the ideal. (Can the base ring change? See example below.)

EXAMPLES:

```
sage: R = ZZ[x]
sage: I = R.ideal(2,x)
sage: I.is_principal()
...
NotImplementedError
sage: J = R.base_extend(QQ).ideal(2,x)
sage: J.is_principal()
True
```

is_trivial()

Return True if this ideal is (0) or (1).

TESTS:

```
sage: I = ZZ.ideal(5)
sage: I.is_trivial()
False
```

```
sage: I = ZZ['x'].ideal(-1)
sage: I.is_trivial()
True

sage: I = ZZ['x'].ideal(ZZ['x'].gen()^2)
sage: I.is_trivial()
False

sage: I = QQ['x', 'y'].ideal(-5)
sage: I.is_trivial()
True

sage: I = CC['x'].ideal(0)
sage: I.is_trivial()
True
```

reduce(*f*)

Return the reduction of the element of f modulo the ideal I (=self). This is an element of R that is equivalent modulo I to f.

EXAMPLES:

```
sage: ZZ.ideal(5).reduce(17)
2
sage: parent(ZZ.ideal(5).reduce(17))
Integer Ring
```

ring()

Returns the ring containing this ideal.

EXAMPLES:

```
sage: R = ZZ
sage: I = 3*R; I
Principal ideal (3) of Integer Ring
sage: J = 2*I; J
Principal ideal (6) of Integer Ring
sage: I.ring(); J.ring()
Integer Ring
Integer Ring
```

Note that `self.ring()` is different from `self.base_ring()`

```
sage: R = PolynomialRing(QQ, 'x'); x = R.gen()
sage: I = R.ideal(x^2 - 2)
sage: I.base_ring()
Rational Field
sage: I.ring()
Univariate Polynomial Ring in x over Rational Field
```

Another example using polynomial rings:

```
sage: R = PolynomialRing(QQ, 'x'); x = R.gen()
sage: I = R.ideal(x^2 - 3)
sage: I.ring()
Univariate Polynomial Ring in x over Rational Field
sage: Rbar = R.quotient(I, names='a')
sage: S = PolynomialRing(Rbar, 'y'); y = Rbar.gen(); S
Univariate Polynomial Ring in y over Univariate Quotient Polynomial Ring in a over Rational
sage: J = S.ideal(y^2 + 1)
sage: J.ring()
Univariate Polynomial Ring in y over Univariate Quotient Polynomial Ring in a over Rational
```

class **Ideal_pid**(*ring, gen*)

An ideal of a principal ideal domain.

gcd(*other*)

Returns the greatest common divisor of the principal ideal with the ideal `other`; that is, the largest principal ideal contained in both the ideal and `other`

TODO: This is not implemented in the case when `other` is neither principal nor when the generator of `self` is contained in `other`. Also, it seems that this class is used only in PIDs–is this redundant? Note: second example is broken.

EXAMPLES:

An example in the principal ideal domain ZZ:

```
sage: R = ZZ
sage: I = R.ideal(42)
sage: J = R.ideal(70)
sage: I.gcd(J)
Principal ideal (14) of Integer Ring
sage: J.gcd(I)
Principal ideal (14) of Integer Ring
```

TESTS:

We cannot take the gcd of a principal ideal with a non-principal ideal as well: (gcd(I,J) should be (7))

```
sage: I = ZZ.ideal(7)
sage: J = ZZ[x].ideal(7,x)
sage: I.gcd(J)
...
NotImplementedError
sage: J.gcd(I)
...
AttributeError: 'Ideal_generic' object has no attribute 'gcd'
```

Note:

```
sage: type(I)
<class 'sage.rings.ideal.Ideal_pid'>
sage: type(J)
<class 'sage.rings.ideal.Ideal_generic'>
```

is_prime()

Returns True if the ideal is prime. This relies on the ring elements having a method is_irreducible() implemented, since an ideal (a) is prime iff a is irreducible (or 0)

EXAMPLES:

```
sage: ZZ.ideal(2).is_prime()
True
sage: ZZ.ideal(-2).is_prime()
True
sage: ZZ.ideal(4).is_prime()
False
sage: ZZ.ideal(0).is_prime()
True
sage: R.<x>=QQ[]
sage: P=R.ideal(x^2+1); P
Principal ideal (x^2 + 1) of Univariate Polynomial Ring in x over Rational Field
sage: P.is_prime()
True
```

reduce(*f*)

Return the reduction of f modulo self.

EXAMPLES:

```
sage: I = 8*ZZ
sage: I.reduce(10)
2
sage: n = 10; n.mod(I)
2
```

residue_field()

Return the residue class field of this ideal, which must be prime.

TODO: Implement this for more general rings. Currently only defined for ZZ and for number field orders.

EXAMPLES:

```
sage: P = ZZ.ideal(61); P
Principal ideal (61) of Integer Ring
sage: F = P.residue_field(); F
Residue field of Integers modulo 61
sage: pi = F.reduction_map(); pi
Partially defined reduction map from Rational Field to Residue field of Integers modulo 61
sage: pi(123/234)
6
sage: pi(1/61)
...
ZeroDivisionError: Cannot reduce rational 1/61 modulo 61: it has negative valuation
sage: lift = F.lift_map(); lift
Lifting map from Residue field of Integers modulo 61 to Rational Field
sage: lift(F(12345/67890))
33
sage: (12345/67890) % 61
33
```

TESTS:

```
sage: ZZ.ideal(96).residue_field()
...
ValueError: The ideal (Principal ideal (96) of Integer Ring) is not prime

sage: R.<x>=QQ[]
sage: I=R.ideal(x^2+1)
sage: I.is_prime()
True
sage: I.residue_field()
Traceback (most recent call last):
NotImplementedError: residue_field() is only implemented for ZZ and rings of integers of num
```

class **Ideal_principal**(*ring, gen*)

A principal ideal.

divides(*other*)

Returns True if self divides other.

EXAMPLES:

```
sage: P.<x> = PolynomialRing(QQ)
sage: I = P.ideal(x)
sage: J = P.ideal(x^2)
sage: I.divides(J)
True
sage: J.divides(I)
False
```

gen()

Returns the generator of the principal ideal. The generators are elements of the ring containing the ideal.

EXAMPLES:

A simple example in the integers:

```
sage: R = ZZ
sage: I = R.ideal(7)
sage: J = R.ideal(7, 14)
sage: I.gen(); J.gen()
7
7
```

Note that the generator belongs to the ring from which the ideal was initialized:

```
sage: R = ZZ[x]
sage: I = R.ideal(x)
sage: J = R.base_extend(QQ).ideal(2,x)
sage: a = I.gen(); a
x
sage: b = J.gen(); b
1
sage: a.base_ring()
Integer Ring
sage: b.base_ring()
Rational Field
```

is_principal()

Returns True if the ideal is principal in the ring containing the ideal. When the ideal construction is explicitly principal (i.e. when we define an ideal with one element) this is always the case.

EXAMPLES:

Note that Sage automatically coerces ideals into principal ideals during initialization:

```
sage: R = ZZ[x]
sage: I = R.ideal(x)
sage: J = R.ideal(2,x)
sage: K = R.base_extend(QQ).ideal(2,x)
sage: I
Principal ideal (x) of Univariate Polynomial Ring in x
over Integer Ring
sage: J
Ideal (2, x) of Univariate Polynomial Ring in x over Integer Ring
sage: K
Principal ideal (1) of Univariate Polynomial Ring in x
over Rational Field
sage: I.is_principal()
True
sage: K.is_principal()
True
```

Katsura(*R, n=None, homog=False, singular=Singular*)

n-th katsura ideal of R if R is coercable to Singular. If n==None n is set to R.ngens()

INPUT:

- `R` - base ring to construct ideal for
- `n` - which katsura ideal of R
- `homog` - if True a homogenous ideal is returned using the last variable in the ideal (default: False)
- `singular` - singular instance to use

EXAMPLES:

```
sage: P.<x,y,z> = PolynomialRing(QQ,3)
sage: I = sage.rings.ideal.Katsura(P,3); I
Ideal (x + 2*y + 2*z - 1, x^2 + 2*y^2 + 2*z^2 - x, 2*x*y + 2*y*z - y)
of Multivariate Polynomial Ring in x, y, z over Rational Field

sage: Q.<x> = PolynomialRing(QQ,1)
sage: J = sage.rings.ideal.Katsura(Q,1); J
Ideal (x - 1) of Multivariate Polynomial Ring in x over Rational Field
```

is_Ideal(*x*)

Returns True if object is an ideal of a ring.

EXAMPLES:

A simple example involving the ring of integers. Note that Sage does not interpret rings objects themselves as ideals. However, one can still explicitly construct these ideals:

```
sage: from sage.rings.ideal import is_Ideal
sage: R = ZZ
sage: is_Ideal(R)
False
sage: 1*R; is_Ideal(1*R)
Principal ideal (1) of Integer Ring
True
sage: 0*R; is_Ideal(0*R)
Principal ideal (0) of Integer Ring
True
```

Sage recognizes ideals of polynomial rings as well:

```
sage: R = PolynomialRing(QQ, 'x'); x = R.gen()
sage: I = R.ideal(x^2 + 1); I
Principal ideal (x^2 + 1) of Univariate Polynomial Ring in x over Rational Field
sage: is_Ideal(I)
True
sage: is_Ideal((x^2 + 1)*R)
True
```

23.2 Monoid of Ring Ideals

IdealMonoid(*R*)

class IdealMonoid_c(*R*)

ring()

23.3 Homomorphisms of rings

We give a large number of examples of ring homomorphisms.

EXAMPLE: Natural inclusion $\mathbf{Z} \hookrightarrow \mathbf{Q}$.

```
sage: H = Hom(ZZ, QQ)
sage: phi = H([1])
sage: phi(10)
10
sage: phi(3/1)
3
sage: phi(2/3)
...
TypeError: 2/3 must be coercible into Integer Ring
```

There is no homomorphism in the other direction:

```
sage: H = Hom(QQ, ZZ)
sage: H([1])
...
TypeError: images do not define a valid homomorphism
```

EXAMPLE: Reduction to finite field.

```
sage: H = Hom(ZZ, GF(9, 'a'))
sage: phi = H([1])
sage: phi(5)
2
sage: psi = H([4])
sage: psi(5)
2
```

EXAMPLE: Map from single variable polynomial ring.

```
sage: R, x = PolynomialRing(ZZ, 'x').objgen()
sage: phi = R.hom([2], GF(5))
sage: phi
Ring morphism:
  From: Univariate Polynomial Ring in x over Integer Ring
  To:   Finite Field of size 5
  Defn: x |--> 2
sage: phi(x + 12)
4
```

EXAMPLE: Identity map on the real numbers.

```
sage: f = RR.hom([RR(1)]); f
Ring endomorphism of Real Field with 53 bits of precision
  Defn: 1.00000000000000 |--> 1.00000000000000
sage: f(2.5)
2.50000000000000
sage: f = RR.hom( [2.0] )
...
TypeError: images do not define a valid homomorphism
```

EXAMPLE: Homomorphism from one precision of field to another.

From smaller to bigger doesn't make sense:

```
sage: R200 = RealField(200)
sage: f = RR.hom( R200 )
```

```
...
TypeError: Natural coercion morphism from Real Field with 53 bits of precision to Real Field with 200
```

From bigger to small does:

```
sage: f = RR.hom( RealField(15) )
sage: f(2.5)
2.500
sage: f(RR.pi())
3.142
```

EXAMPLE: Inclusion map from the reals to the complexes:

```
sage: i = RR.hom([CC(1)]); i
Ring morphism:
  From: Real Field with 53 bits of precision
  To:   Complex Field with 53 bits of precision
  Defn: 1.00000000000000 |--> 1.00000000000000
sage: i(RR('3.1'))
3.10000000000000
```

EXAMPLE: A map from a multivariate polynomial ring to itself:

```
sage: R.<x,y,z> = PolynomialRing(QQ,3)
sage: phi = R.hom([y,z,x^2]); phi
Ring endomorphism of Multivariate Polynomial Ring in x, y, z over Rational Field
  Defn: x |--> y
        y |--> z
        z |--> x^2
sage: phi(x+y+z)
x^2 + y + z
```

EXAMPLE: An endomorphism of a quotient of a multi-variate polynomial ring:

```
sage: R.<x,y> = PolynomialRing(QQ)
sage: S.<a,b> = quo(R, ideal(1 + y^2))
sage: phi = S.hom([a^2, -b])
sage: phi
Ring endomorphism of Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the idea
  Defn: a |--> a^2
        b |--> -b
sage: phi(b)
-b
sage: phi(a^2 + b^2)
a^4 - 1
```

EXAMPLE: The reduction map from the integers to the integers modulo 8, viewed as a quotient ring:

```
sage: R = ZZ.quo(8*ZZ)
sage: pi = R.cover()
sage: pi
Ring morphism:
  From: Integer Ring
  To:   Ring of integers modulo 8
  Defn: Natural quotient map
sage: pi.domain()
Integer Ring
```

```
sage: pi.codomain()
Ring of integers modulo 8
sage: pi(10)
2
sage: pi.lift()
Set-theoretic ring morphism:
  From: Ring of integers modulo 8
  To:   Integer Ring
  Defn: Choice of lifting map
sage: pi.lift(13)
5
```

EXAMPLE: Inclusion of GF(2) into GF(4,'a').

```
sage: k = GF(2)
sage: i = k.hom(GF(4, 'a'))
sage: i
Ring Coercion morphism:
  From: Finite Field of size 2
  To:   Finite Field in a of size 2^2
sage: i(0)
0
sage: a = i(1); a.parent()
Finite Field in a of size 2^2
```

We next compose the inclusion with reduction from the integers to GF(2).

```
sage: pi = ZZ.hom(k)
sage: pi
Ring Coercion morphism:
  From: Integer Ring
  To:   Finite Field of size 2
sage: f = i * pi
sage: f
Composite map:
  From: Integer Ring
  To:   Finite Field in a of size 2^2
  Defn:   Ring Coercion morphism:
          From: Integer Ring
          To:   Finite Field of size 2
        then
          Ring Coercion morphism:
          From: Finite Field of size 2
          To:   Finite Field in a of size 2^2
sage: a = f(5); a
1
sage: a.parent()
Finite Field in a of size 2^2
```

EXAMPLE: Inclusion from $\mathbf{Q}$ to the 3-adic field.

```
sage: phi = QQ.hom(Qp(3, print_mode = 'series'))
sage: phi
Ring Coercion morphism:
  From: Rational Field
  To:   3-adic Field with capped relative precision 20
sage: phi.codomain()
```

```
3-adic Field with capped relative precision 20
sage: phi(394)
1 + 2*3 + 3^2 + 2*3^3 + 3^4 + 3^5 + O(3^20)
```

EXAMPLE: An automorphism of a quotient of a univariate polynomial ring.

```
sage: R.<x> = PolynomialRing(QQ)
sage: S.<sqrt2> = R.quo(x^2-2)
sage: sqrt2^2
2
sage: (3+sqrt2)^10
993054*sqrt2 + 1404491
sage: c = S.hom([-sqrt2])
sage: c(1+sqrt2)
-sqrt2 + 1
```

Note that Sage verifies that the morphism is valid:

```
sage: (1 - sqrt2)^2
-2*sqrt2 + 3
sage: c = S.hom([1-sqrt2])    # this is not valid
...
TypeError: images do not define a valid homomorphism
```

EXAMPLE: Endomorphism of power series ring.

```
sage: R.<t> = PowerSeriesRing(QQ); R
Power Series Ring in t over Rational Field
sage: f = R.hom([t^2]); f
Ring endomorphism of Power Series Ring in t over Rational Field
  Defn: t |--> t^2
sage: R.set_default_prec(10)
sage: s = 1/(1 + t); s
1 - t + t^2 - t^3 + t^4 - t^5 + t^6 - t^7 + t^8 - t^9 + O(t^10)
sage: f(s)
1 - t^2 + t^4 - t^6 + t^8 - t^10 + t^12 - t^14 + t^16 - t^18 + O(t^20)
```

EXAMPLE: Frobenious on a power series ring over a finite field.

```
sage: R.<t> = PowerSeriesRing(GF(5))
sage: f = R.hom([t^5]); f
Ring endomorphism of Power Series Ring in t over Finite Field of size 5
  Defn: t |--> t^5
sage: a = 2 + t + 3*t^2 + 4*t^3 + O(t^4)
sage: b = 1 + t + 2*t^2 + t^3 + O(t^5)
sage: f(a)
2 + t^5 + 3*t^10 + 4*t^15 + O(t^20)
sage: f(b)
1 + t^5 + 2*t^10 + t^15 + O(t^25)
sage: f(a*b)
2 + 3*t^5 + 3*t^10 + t^15 + O(t^20)
sage: f(a)*f(b)
2 + 3*t^5 + 3*t^10 + t^15 + O(t^20)
```

EXAMPLE: Homomorphism of Laurent series ring.

```
sage: R.<t> = LaurentSeriesRing(QQ)
sage: f = R.hom([t^3 + t]); f
Ring endomorphism of Laurent Series Ring in t over Rational Field
  Defn: t |--> t + t^3
sage: R.set_default_prec(10)
sage: s = 2/t^2 + 1/(1 + t); s
2*t^-2 + 1 - t + t^2 - t^3 + t^4 - t^5 + t^6 - t^7 + t^8 - t^9 + O(t^10)
sage: f(s)
2*t^-2 - 3 - t + 7*t^2 - 2*t^3 - 5*t^4 - 4*t^5 + 16*t^6 - 9*t^7 + O(t^8)
sage: f = R.hom([t^3]); f
Ring endomorphism of Laurent Series Ring in t over Rational Field
  Defn: t |--> t^3
sage: f(s)
2*t^-6 + 1 - t^3 + t^6 - t^9 + t^12 - t^15 + t^18 - t^21 + t^24 - t^27
sage: s = 2/t^2 + 1/(1 + t); s
2*t^-2 + 1 - t + t^2 - t^3 + t^4 - t^5 + t^6 - t^7 + t^8 - t^9 + O(t^10)
sage: f(s)
2*t^-6 + 1 - t^3 + t^6 - t^9 + t^12 - t^15 + t^18 - t^21 + t^24 - t^27
```

Note that the homomorphism must result in a converging Laurent series, so the valuation of the image of the generator must be positive:

```
sage: R.hom([1/t])
...
TypeError: images do not define a valid homomorphism
sage: R.hom([1])
...
TypeError: images do not define a valid homomorphism
```

EXAMPLE: Complex conjugation on cyclotomic fields.

```
sage: K.<zeta7> = CyclotomicField(7)
sage: c = K.hom([1/zeta7]); c
Ring endomorphism of Cyclotomic Field of order 7 and degree 6
  Defn: zeta7 |--> -zeta7^5 - zeta7^4 - zeta7^3 - zeta7^2 - zeta7 - 1
sage: a = (1+zeta7)^5; a
zeta7^5 + 5*zeta7^4 + 10*zeta7^3 + 10*zeta7^2 + 5*zeta7 + 1
sage: c(a)
5*zeta7^5 + 5*zeta7^4 - 4*zeta7^2 - 5*zeta7 - 4
sage: c(zeta7 + 1/zeta7)       # this element is obviously fixed by inversion
-zeta7^5 - zeta7^4 - zeta7^3 - zeta7^2 - 1
sage: zeta7 + 1/zeta7
-zeta7^5 - zeta7^4 - zeta7^3 - zeta7^2 - 1
```

EXAMPLE: Embedding a number field into the reals.

```
sage: R.<x> = PolynomialRing(QQ)
sage: K.<beta> = NumberField(x^3 - 2)
sage: alpha = RR(2)^(1/3); alpha
1.25992104989487
sage: i = K.hom([alpha],check=False); i
Ring morphism:
  From: Number Field in beta with defining polynomial x^3 - 2
  To:   Real Field with 53 bits of precision
  Defn: beta |--> 1.25992104989487
sage: i(beta)
```

```
1.25992104989487
sage: i(beta^3)
2.00000000000000
sage: i(beta^2 + 1)
2.58740105196820
```

An example from Jim Carlson:

```
sage: K = QQ # by the way :-)
sage: R.<a,b,c,d> = K[]; R
Multivariate Polynomial Ring in a, b, c, d over Rational Field
sage: S.<u> = K[]; S
Univariate Polynomial Ring in u over Rational Field
sage: f = R.hom([0,0,0,u], S); f
Ring morphism:
  From: Multivariate Polynomial Ring in a, b, c, d over Rational Field
  To:   Univariate Polynomial Ring in u over Rational Field
  Defn: a |--> 0
        b |--> 0
        c |--> 0
        d |--> u
sage: f(a+b+c+d)
u
sage: f( (a+b+c+d)^2 )
u^2
```

TESTS:

```
sage: H = Hom(ZZ, QQ)
sage: H == loads(dumps(H))
True

sage: K.<zeta7> = CyclotomicField(7)
sage: c = K.hom([1/zeta7])
sage: c == loads(dumps(c))
True

sage: R.<t> = PowerSeriesRing(GF(5))
sage: f = R.hom([t^5])
sage: f == loads(dumps(f))
True
```

class RingHomomorphism()

Homomorphism of rings.

inverse_image()

Return the inverse image of the ideal I under this ring homomorphism.

EXAMPLES:

This is not implemented in any generality yet:

```
sage: f = ZZ.hom(ZZ)
sage: f.inverse_image(ZZ.ideal(2))
...
NotImplementedError
```

is_injective()

Return whether or not this morphism is injective, or raise a NotImplementedError.

EXAMPLES:

Note that currently this is not implemented in most interesting cases:

```
sage: f = ZZ.hom(QQ)
sage: f.is_injective()
...
NotImplementedError
```

is_zero()

Return True if this is the zero map and False otherwise.

A *ring* homomorphism is considered to be 0 if and only if it sends the 1 element of the domain to the 0 element of the codomain. Since rings in Sage all have a 1 element, the zero homomorphism is only to a ring of order 1, where 1==0, e.g., the ring `Integers(1)`.

EXAMPLES:

First an example of a map that is obviously nonzero.

```
sage: h = Hom(ZZ, QQ)
sage: f = h.natural_map()
sage: f.is_zero()
False
```

Next we make the zero ring as $\mathbf{Z}/1\mathbf{Z}$.

```
sage: R = Integers(1)
sage: R
Ring of integers modulo 1
sage: h = Hom(ZZ, R)
sage: f = h.natural_map()
sage: f.is_zero()
True
```

Finally we check an example in characteristic 2.

```
sage: h = Hom(ZZ, GF(2))
sage: f = h.natural_map()
sage: f.is_zero()
False
```

lift()

Return a lifting homomorphism associated to this homomorphism, if it has been defined.

If x is not None, return the value of the lift morphism on x.

EXAMPLES:

```
sage: R.<x,y> = QQ[]
sage: f = R.hom([x,x])
sage: f(x+y)
2*x
sage: f.lift()
...
ValueError: no lift map defined
sage: g = R.hom(R)
sage: f._set_lift(g)
sage: f.lift() == g
True
sage: f.lift(x)
x
```

pushforward()

Returns the pushforward of the ideal I under this ring homomorphism.

EXAMPLES:

```
sage: R.<x,y> = QQ[]; S.<xx,yy> = R.quo([x^2,y^2]);  f = S.cover()
sage: f.pushforward(R.ideal([x,3*x+x*y+y^2]))
Ideal (xx, xx*yy + 3*xx) of Quotient of Multivariate Polynomial Ring in x, y over Rational F
```

class RingHomomorphism_coercion()

class RingHomomorphism_cover()

A homomorphism induced by quotienting a ring out by an ideal.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ, 2)
sage: S.<a,b> = R.quo(x^2 + y^2)
sage: phi = S.cover(); phi
Ring morphism:
  From: Multivariate Polynomial Ring in x, y over Rational Field
  To:   Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the ideal (x^2 +
  Defn: Natural quotient map
sage: phi(x+y)
a + b
```

kernel()

Return the kernel of this covering morphism, which is the ideal that was quotiented out by.

EXAMPLES:

```
sage: f = Zmod(6).cover()
sage: f.kernel()
Principal ideal (6) of Integer Ring
```

class RingHomomorphism_from_quotient()

A ring homomorphism with domain a generic quotient ring.

INPUT:

- `parent` - a ring homset Hom(R,S)
- `phi` - a ring homomorphism C –> S, where C is the domain of R.cover()

OUTPUT: a ring homomorphism

The domain R is a quotient object $C \to R$, and `R.cover()` is the ring homomorphism $\varphi : C \to R$. The condition on the elements `im_gens` of S is that they define a homomorphism $C \to S$ such that each generator of the kernel of φ maps to 0.

EXAMPLES:

```
sage: R.<x, y, z> = PolynomialRing(QQ, 3)
sage: S.<a, b, c> = R.quo(x^3 + y^3 + z^3)
sage: phi = S.hom([b, c, a]); phi
Ring endomorphism of Quotient of Multivariate Polynomial Ring in x, y, z over Rational Field by
  Defn: a |--> b
        b |--> c
        c |--> a
sage: phi(a+b+c)
a + b + c
sage: loads(dumps(phi)) == phi
True
```

Validity of the homomorphism is determined, when possible, and a TypeError is raised if there is no homomorphism sending the generators to the given images.

```
sage: S.hom([b^2, c^2, a^2])
...
TypeError: images do not define a valid homomorphism
```

morphism_from_cover()

Underlying morphism used to define this quotient map, i.e., the morphism from the cover of the domain.

EXAMPLES:

```
sage: R.<x,y> = QQ[]; S.<xx,yy> = R.quo([x^2,y^2])
sage: S.hom([yy,xx]).morphism_from_cover()
Ring morphism:
  From: Multivariate Polynomial Ring in x, y over Rational Field
  To:   Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the ideal (x
  Defn: x |--> yy
        y |--> xx
```

class RingHomomorphism_im_gens()

A ring homomorphism determined by the images of generators.

im_gens()

Return the images of the generators of the domain.

OUTPUT: • `list` – a copy of the list of gens (it is safe to change this)

EXAMPLES:

```
sage: R.<x,y> = QQ[]
sage: f = R.hom([x,x+y])
sage: f.im_gens()
[x, x + y]
```

We verify that the returned list of images of gens is a copy, so changing it doesn't change f:

```
sage: f.im_gens()[0] = 5
sage: f.im_gens()
[x, x + y]
```

class RingMap()

Set-theoretic map between rings.

class RingMap_lift()

Given rings R and S such that for any $x \in R$ the function `x.lift()` is an element that naturally coerces to S, this returns the set-theoretic ring map $R \to S$ sending x to `x.lift()`.

EXAMPLES:

```
sage: R, (x,y) = PolynomialRing(QQ, 2, 'xy').objgens()
sage: S.<xbar,ybar> = R.quo( (x^2 + y^2, y) )
sage: S.lift()
Set-theoretic ring morphism:
  From: Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the ideal (x^2 +
  To:   Multivariate Polynomial Ring in x, y over Rational Field
  Defn: Choice of lifting map
sage: S.lift() == 0
False
```

is_RingHomomorphism()

Return True if phi is of type RingHomomorphism.

EXAMPLES:

```
sage: f = Zmod(8).cover()
sage: sage.rings.morphism.is_RingHomomorphism(f)
True
sage: sage.rings.morphism.is_RingHomomorphism(2/3)
False
```

23.4 Space of homomorphisms between two rings.

RingHomset(*R*, *S*)

class RingHomset_generic(*R*, *S*)

has_coerce_map_from(*x*)
The default for coercion maps between ring homomorphism spaces is very restrictive (until more implementation work is done).

natural_map()

class RingHomset_quo_ring(*R*, *S*)
Space of ring homomorphism where the domain is a (formal) quotient ring.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ, 2)
sage: S.<a,b> = R.quotient(x^2 + y^2)
sage: phi = S.hom([b,a]); phi
Ring endomorphism of Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the
  Defn: a |--> b
        b |--> a
sage: phi(a)
b
sage: phi(b)
a
```

TESTS:

We test pickling of a homset from a quotient.

```
sage: R.<x,y> = PolynomialRing(QQ, 2)
sage: S.<a,b> = R.quotient(x^2 + y^2)
sage: H = S.Hom(R)
sage: H == loads(dumps(H))
True
```

We test pickling of actual homomorphisms in a quotient:

```
sage: phi = S.hom([b,a])
sage: phi == loads(dumps(phi))
True
```

is_RingHomset(*H*)

23.5 Infinity Rings

The unsigned infinity "ring" is the set of two elements

1. infinity
2. A number less than infinity

The rules for arithmetic are that the unsigned infinity ring does not canonically coerce to any other ring, and all other rings canonically coerce to the unsigned infinity ring, sending all elements to the single element "a number less than infinity" of the unsigned infinity ring. Arithmetic and comparisons then take place in the unsigned infinity ring, where all arithmetic operations that are well-defined are defined.

The infinity "ring" is the set of five elements

1. plus infinity
2. a positive finite element
3. zero
4. a negative finite element
5. negative infinity

The infinity ring coerces to the unsigned infinity ring, sending the infinite elements to infinity and the non-infinite elements to "a number less than infinity." Any ordered ring coerces to the infinity ring in the obvious way.

Note: the shorthand oo is predefined in Sage to be the same as +Infinity in the infinity ring. It is considered equal to, but not the same as Infinity in the UnsignedInfinityRing:

```
sage: oo
+Infinity
sage: oo is InfinityRing.0
True
sage: oo is UnsignedInfinityRing.0
False
sage: oo == UnsignedInfinityRing.0
True
```

EXAMPLES:

We fetch the unsigned infinity ring and create some elements:

```
sage: P = UnsignedInfinityRing; P
The Unsigned Infinity Ring
sage: P(5)
A number less than infinity
sage: P.ngens()
1
sage: unsigned_oo = P.0; unsigned_oo
Infinity
```

We compare finite numbers with infinity:

```
sage: 5 < unsigned_oo
True
sage: 5 > unsigned_oo
False
sage: unsigned_oo < 5
False
sage: unsigned_oo > 5
True
```

We do arithmetic:

```
sage: unsigned_oo + 5
Infinity
```

We make 1 / unsigned_oo return the integer 0 so that arithmetic of the following type works:

```
sage: (1/unsigned_oo) + 2
2
sage: 32/5 - (2.439/unsigned_oo)
32/5
```

Note that many operations are not defined, since the result is not well-defined:

```
sage: unsigned_oo/0
...
ValueError: unsigned oo times smaller number not defined
```

What happened above is that 0 is canonically coerced to "a number less than infinity" in the unsigned infinity ring, and the quotient is then not well-defined.

```
sage: 0/unsigned_oo
0
sage: unsigned_oo * 0
...
ValueError: unsigned oo times smaller number not defined
sage: unsigned_oo/unsigned_oo
...
ValueError: unsigned oo times smaller number not defined
```

In the infinity ring, we can negate infinity, multiply positive numbers by infinity, etc.

```
sage: P = InfinityRing; P
The Infinity Ring
sage: P(5)
A positive finite number
```

The symbol oo is predefined as a shorthand for +Infinity:

```
sage: oo
+Infinity
```

We compare finite and infinite elements:

```
sage: 5 < oo
True
sage: P(-5) < P(5)
True
sage: P(2) < P(3)
False
sage: -oo < oo
True
```

We can do more arithmetic than in the unsigned infinity ring:

```
sage: 2 * oo
+Infinity
sage: -2 * oo
-Infinity
sage: 1 - oo
-Infinity
sage: 1 / oo
0
sage: -1 / oo
0
```

We make 1 / oo and 1 / -oo return the integer 0 instead of the infinity ring Zero so that arithmetic of the following type works:

```
sage: (1/oo) + 2
2
sage: 32/5 - (2.439/-oo)
32/5
```

If we try to subtract infinities or multiply infinity by zero we still get an error:

```
sage: oo - oo
...
SignError: cannot add infinity to minus infinity
sage: 0 * oo
...
SignError: cannot multiply infinity by zero
sage: P(2) + P(-3)
...
SignError: cannot add positive finite value to negative finite value
```

TESTS:

```
sage: P = InfinityRing
sage: P == loads(dumps(P))
True
```

```
sage: P(2) == loads(dumps(P(2)))
True
```

The following is assumed in a lot of code (i.e., "is" is used for testing whether something is infinity), so make sure it is satisfied:

```
sage: loads(dumps(infinity)) is infinity
True
```

class AnInfinity()

lcm(*x*)

Return the least common multiple of oo and x, which is by definition oo unless x is 0.

EXAMPLES:

```
sage: oo.lcm(0)
0
sage: oo.lcm(oo)
```

```
+Infinity
sage: oo.lcm(-oo)
+Infinity
sage: oo.lcm(10)
+Infinity
sage: (-oo).lcm(10)
+Infinity
```

class **FiniteNumber**(*parent, x*)

sqrt()

EXAMPLES:

```
sage: InfinityRing(7).sqrt()
A positive finite number
sage: InfinityRing(0).sqrt()
Zero
sage: InfinityRing(-.001).sqrt()
...
SignError: cannot take square root of a negative number
```

class **InfinityRing_class**()

fraction_field()

This isn't really a ring, let alone an integral domain.

TEST:

```
sage: InfinityRing.fraction_field()
...
TypeError: infinity 'ring' has no fraction field
```

gen(*n=0*)

The two generators are plus and minus infinity.

EXAMPLES:

```
sage: InfinityRing.gen(0)
+Infinity
sage: InfinityRing.gen(1)
-Infinity
sage: InfinityRing.gen(2)
...
IndexError: n must be 0 or 1
```

gens()

The two generators are plus and minus infinity.

EXAMPLES:

```
sage: InfinityRing.gens()
[+Infinity, -Infinity]
```

ngens()

The two generators are plus and minus infinity.

EXAMPLES:

```
sage: InfinityRing.ngens()
2
sage: len(InfinityRing.gens())
2
```

class LessThanInfinity(*parent=The Unsigned Infinity Ring*)

class MinusInfinity()

sqrt()
EXAMPLES:

```
sage: (-oo).sqrt()
...
SignError: cannot take square root of negative infinity
```

class PlusInfinity()

sqrt()
EXAMPLES:

```
sage: oo.sqrt()
+Infinity
```

exception SignError

class UnsignedInfinity()

class UnsignedInfinityRing_class()

fraction_field()
The unsigned infinity ring isn't an integral domain.
EXAMPLES:

```
sage: UnsignedInfinityRing.fraction_field()
...
TypeError: infinity 'ring' has no fraction field
```

gen(*n=0*)
The "generator" of self is the infinity object.
EXAMPLES:

```
sage: UnsignedInfinityRing.gen()
Infinity
sage: UnsignedInfinityRing.gen(1)
...
IndexError: UnsignedInfinityRing only has one generator
```

gens()
The "generator" of self is the infinity object.
EXAMPLES:

```
sage: UnsignedInfinityRing.gens()
[Infinity]
```

less_than_infinity()
This is the element that represents a finite value.
EXAMPLES:

```
sage: UnsignedInfinityRing.less_than_infinity()
A number less than infinity
sage: UnsignedInfinityRing(5) is UnsignedInfinityRing.less_than_infinity()
True
```

ngens()
The unsigned infinity ring has one "generator."
EXAMPLES:

```
sage: UnsignedInfinityRing.ngens()
1
sage: len(UnsignedInfinityRing.gens())
1
```

is_Infinite(*x*)
This is a type check for infinity elements.
EXAMPLES:

```
sage: sage.rings.infinity.is_Infinite(oo)
True
sage: sage.rings.infinity.is_Infinite(-oo)
True
sage: sage.rings.infinity.is_Infinite(unsigned_infinity)
True
sage: sage.rings.infinity.is_Infinite(3)
False
sage: sage.rings.infinity.is_Infinite(RR(infinity))
False
sage: sage.rings.infinity.is_Infinite(ZZ)
False
```

23.6 Fraction Field of Integral Domains

AUTHORS:

- William Stein (with input from David Joyner, David Kohel, and Joe Wetherell)
- Burcin Erocal

EXAMPLES:

Quotienting is a constructor for an element of the fraction field:

```
sage: R.<x> = QQ[]
sage: (x^2-1)/(x+1)
x - 1
sage: parent((x^2-1)/(x+1))
Fraction Field of Univariate Polynomial Ring in x over Rational Field
```

The GCD is not taken (since it doesn't converge sometimes) in the inexact case.

```
sage: Z.<z> = CC[]
sage: I = CC.gen()
sage: (1+I+z)/(z+0.1*I)
(1.00000000000000*z + 1.00000000000000 + 1.00000000000000*I)/(1.00000000000000*z + 0.100000000000000
sage: (1+I*z)/(z+1.1)
(1.00000000000000*I*z + 1.00000000000000)/(1.00000000000000*z + 1.10000000000000)
```

TESTS:

```
sage: F = FractionField(IntegerRing())
sage: F == loads(dumps(F))
True

sage: F = FractionField(PolynomialRing(RationalField(),'x'))
sage: F == loads(dumps(F))
True

sage: F = FractionField(PolynomialRing(IntegerRing(),'x'))
sage: F == loads(dumps(F))
True

sage: F = FractionField(PolynomialRing(RationalField(),2,'x'))
sage: F == loads(dumps(F))
True
```

FractionField(*R, names=None*)

Create the fraction field of the integral domain R.

INPUT:

- R - an integral domain
- names - ignored

EXAMPLES: We create some example fraction fields.

```
sage: FractionField(IntegerRing())
Rational Field
sage: FractionField(PolynomialRing(RationalField(),'x'))
Fraction Field of Univariate Polynomial Ring in x over Rational Field
sage: FractionField(PolynomialRing(IntegerRing(),'x'))
Fraction Field of Univariate Polynomial Ring in x over Integer Ring
sage: FractionField(PolynomialRing(RationalField(),2,'x'))
Fraction Field of Multivariate Polynomial Ring in x0, x1 over Rational Field
```

Dividing elements often implicitly creates elements of the fraction field.

```
sage: x = PolynomialRing(RationalField(), 'x').gen()
sage: f = x/(x+1)
sage: g = x**3/(x+1)
sage: f/g
1/x^2
sage: g/f
x^2
```

The input must be an integral domain.

```
sage: Frac(Integers(4))
...
TypeError: R must be an integral domain.
```

class FractionField_generic(*R, element_class=<type 'sage.rings.fraction_field_element.FractionFieldElement'>*)

The fraction field of an integral domain.

base_ring()
Return the base ring of self; this is the base ring of the ring which this fraction field is the fraction field of.
EXAMPLES:

```
sage: R = Frac(ZZ['t'])
sage: R.base_ring()
Integer Ring
```

characteristic()
Return the characteristic of this fraction field.
EXAMPLES:

```
sage: R = Frac(ZZ['t'])
sage: R.base_ring()
Integer Ring
sage: R = Frac(ZZ['t']); R.characteristic()
0
sage: R = Frac(GF(5)['w']); R.characteristic()
5
```

construction()
EXAMPLES:

```
sage: Frac(ZZ['x']).construction()
(FractionField, Univariate Polynomial Ring in x over Integer Ring)
sage: K = Frac(GF(3)['t'])
sage: f, R = K.construction()
sage: f(R)
Fraction Field of Univariate Polynomial Ring in t over Finite Field of size 3
sage: f(R) == K
True
```

gen(*i=0*)
Return the ith generator of self.
EXAMPLES:

```
sage: R = Frac(PolynomialRing(QQ,'z',10)); R
Fraction Field of Multivariate Polynomial Ring in z0, z1, z2, z3, z4, z5, z6, z7, z8, z9 ove
sage: R.0
z0
sage: R.gen(3)
z3
sage: R.3
z3
```

is_exact()
EXAMPLES:

```
sage: Frac(ZZ['x']).is_exact()
True
sage: Frac(CDF['x']).is_exact()
False
```

is_field()
Returns True, since the fraction field is a field.
EXAMPLES:

```
sage: Frac(ZZ).is_field()
True
```

ngens()
This is the same as for the parent object.
EXAMPLES:

```
sage: R = Frac(PolynomialRing(QQ,'z',10)); R
Fraction Field of Multivariate Polynomial Ring in z0, z1, z2, z3, z4, z5, z6, z7, z8, z9 ove
sage: R.ngens()
10
```

random_element(**args, **kwds*)
Returns a random element in this fraction field.
EXAMPLES:

```
sage: F = ZZ['x'].fraction_field()
sage: F.random_element()
(2*x - 8)/(-x^2 + x)

sage: F.random_element(degree=5)
(-12*x^5 - 2*x^4 - x^3 - 95*x^2 + x + 2)/(-x^5 + x^4 - x^3 + x^2)
```

ring()
Return the ring that this is the fraction field of.
EXAMPLES:

```
sage: R = Frac(QQ['x,y'])
sage: R
Fraction Field of Multivariate Polynomial Ring in x, y over Rational Field
sage: R.ring()
Multivariate Polynomial Ring in x, y over Rational Field
```

is_FractionField(*x*)
Tests whether or not x inherits from FractionField_generic.
EXAMPLES:

```
sage: from sage.rings.fraction_field import is_FractionField
sage: is_FractionField(Frac(ZZ['x']))
True
sage: is_FractionField(QQ)
False
```

23.7 Fraction Field Elements

AUTHORS:

- William Stein (input from David Joyner, David Kohel, and Joe Wetherell)

class **FractionFieldElement**()
EXAMPLES:

```
sage: K, x = FractionField(PolynomialRing(QQ, 'x')).objgen()
sage: K
Fraction Field of Univariate Polynomial Ring in x over Rational Field
sage: loads(K.dumps()) == K
True
sage: f = (x^3 + x)/(17 - x^19); f
```

```
(x^3 + x)/(-x^19 + 17)
sage: loads(f.dumps()) == f
True
```

TESTS:

Test if #5451 is fixed:

```
sage: A = FiniteField(9,'theta')['t']
sage: K.<t> = FractionField(A)
sage: f= 2/(t^2+2*t); g =t^9/(t^18 + t^10 + t^2);f+g
(2*t^15 + 2*t^14 + 2*t^13 + 2*t^12 + 2*t^11 + 2*t^10 + 2*t^9 + t^7 + t^6 + t^5 + t^4 + t^3 + t^2
```

copy()

EXAMPLES:

```
sage: R.<x,y> = ZZ[]
sage: f = x/y+1; f
(x + y)/y
sage: f.copy()
(x + y)/y
```

denominator()

EXAMPLES:

```
sage: R.<x,y> = ZZ[]
sage: f = x/y+1; f
(x + y)/y
sage: f.denominator()
y
```

derivative()

The derivative of this rational function, with respect to variables supplied in args.

Multiple variables and iteration counts may be supplied; see documentation for the global derivative() function for more details.

See Also:

_derivative()

EXAMPLES:

```
sage: F = FractionField(PolynomialRing(RationalField(),'x'))
sage: x = F.gen()
sage: (1/x).derivative()
-1/x^2

sage: (x+1/x).derivative(x, 2)
2/x^3

sage: F = FractionField(PolynomialRing(RationalField(),'x,y'))
sage: x,y = F.gens()
sage: (1/(x+y)).derivative(x,y)
2/(x^3 + 3*x^2*y + 3*x*y^2 + y^3)
```

factor()

Return the factorization of self over the base ring

EXAMPLES:

```
sage: K.<x> = QQ[]
sage: f = (x^3+x)/(x-3)
```

```
sage: f.factor()
(x - 3)^-1 * x * (x^2 + 1)
```

is_one()

Returns True if this element is equal to one.

EXAMPLES:

```
sage: F = ZZ['x,y'].fraction_field()
sage: x,y = F.gens()
sage: (x/x).is_one()
True
sage: (x/y).is_one()
False
```

is_zero()

Returns True if this element is equal to zero.

EXAMPLES:

```
sage: F = ZZ['x,y'].fraction_field()
sage: x,y = F.gens()
sage: t = F(0)/x
sage: t.is_zero()
True
sage: u = 1/x - 1/x
sage: u.is_zero()
True
sage: u.parent() is F
True
```

numerator()

EXAMPLES:

```
sage: R.<x,y> = ZZ[]
sage: f = x/y+1; f
(x + y)/y
sage: f.numerator()
x + y
```

partial_fraction_decomposition()

Decomposes fraction field element into a whole part and a list of fraction field elements over prime power denominators.

The sum will be equal to the original fraction.

AUTHORS:

- Robert Bradshaw (2007-05-31)

EXAMPLES:

```
sage: S.<t> = QQ[]
sage: q = 1/(t+1) + 2/(t+2) + 3/(t-3); q
(6*t^2 + 4*t - 6)/(t^3 - 7*t - 6)
sage: whole, parts = q.partial_fraction_decomposition(); parts
[3/(t - 3), 1/(t + 1), 2/(t + 2)]
sage: sum(parts) == q
True
sage: q = 1/(t^3+1) + 2/(t^2+2) + 3/(t-3)^5
sage: whole, parts = q.partial_fraction_decomposition(); parts
[1/3/(t + 1), 3/(t^5 - 15*t^4 + 90*t^3 - 270*t^2 + 405*t - 243), (-1/3*t + 2/3)/(t^2 - t + 1
sage: sum(parts) == q
True
```

We do the best we can over in-exact fields:

```
sage: R.<x> = RealField(20)[]
sage: q = 1/(x^2 + 2)^2 + 1/(x-1); q
(1.0000*x^4 + 4.0000*x^2 + 1.0000*x + 3.0000)/(1.0000*x^5 - 1.0000*x^4 + 4.0000*x^3 - 4.0000
sage: whole, parts = q.partial_fraction_decomposition(); parts
[1.0000/(1.0000*x - 1.0000), 1.0000/(1.0000*x^4 + 4.0000*x^2 + 4.0000)]
sage: sum(parts)
(1.0000*x^4 + 4.0000*x^2 + 1.0000*x + 3.0000)/(1.0000*x^5 - 1.0000*x^4 + 4.0000*x^3 - 4.0000
```

TESTS:

We test partial fraction for irreducible denominators:

```
sage: R.<x> = ZZ[]
sage: q = x^2/(x-1)
sage: q.partial_fraction_decomposition()
(x + 1, [1/(x - 1)])
sage: q = x^10/(x-1)^5
sage: whole, parts = q.partial_fraction_decomposition()
sage: whole + sum(parts) == q
True
```

And also over finite fields (see trac #6052):

```
sage: R.<x> = GF(2)[]
sage: q = (x+1)/(x^3+x+1)
sage: q.partial_fraction_decomposition()
(0, [(x + 1)/(x^3 + x + 1)])
```

reduce()

Divides out the gcd of the numerator and denominator.

Automatically called for exact rings, but because it may be numerically unstable for inexact rings it must be called manually in that case.

EXAMPLES:

```
sage: R.<x> = RealField(10)[]
sage: f = (x^2+2*x+1)/(x+1); f
(1.0*x^2 + 2.0*x + 1.0)/(1.0*x + 1.0)
sage: f.reduce(); f
1.0*x + 1.0
```

valuation()

Return the valuation of self, assuming that the numerator and denominator have valuation functions defined on them.

EXAMPLES:

```
sage: x = PolynomialRing(RationalField(),'x').gen()
sage: f = (x**3 + x)/(x**2 - 2*x**3)
sage: f
(x^2 + 1)/(-2*x^2 + x)
sage: f.valuation()
-1
```

is_FractionFieldElement()

Returns whether or not x is of type FractionFieldElement

EXAMPLES:

```
sage: from sage.rings.fraction_field_element import is_FractionFieldElement
sage: R.<x> = ZZ[]
sage: is_FractionFieldElement(x/2)
```

```
False
sage: is_FractionFieldElement(2/x)
True
sage: is_FractionFieldElement(1/3)
False
```

make_element()
Used for unpickling FractionFieldElement objects (and subclasses).

EXAMPLES:

```
sage: from sage.rings.fraction_field_element import make_element
sage: R = ZZ['x,y']
sage: x,y = R.gens()
sage: F = R.fraction_field()
sage: make_element(F, 1+x, 1+y)
(x + 1)/(y + 1)
```

make_element_old()
Used for unpickling old FractionFieldElement pickles.

EXAMPLES:

```
sage: from sage.rings.fraction_field_element import make_element_old
sage: R.<x,y> = ZZ[]
sage: F = R.fraction_field()
sage: make_element_old(F, {'_FractionFieldElement__numerator':x+y,'_FractionFieldElement__denomi
(x + y)/(x - y)
```

23.8 Quotient Rings

AUTHORS:

- William Stein

TESTS:

```
sage: R.<x> = PolynomialRing(ZZ)
sage: I = R.ideal([4 + 3*x + x^2, 1 + x^2])
sage: S = R.quotient_ring(I);
sage: S == loads(dumps(S))
True
```

QuotientRing(*R, I, names=None*)
Creates a quotient ring of the ring R by the ideal I. Variables are labeled by names. (If the quotient ring is a quotient of a polynomial ring.). If names isn't given, 'bar' will be appended to the variable names in R.

INPUTS:

- R - a commutative ring
- I - an ideal of R
- names - a list of strings to be used as names for the variables in the quotient ring R/I

OUTPUTS: R/I - the quotient ring R mod the ideal I

EXAMPLES:

Some simple quotient rings with the integers:

```
sage: R = QuotientRing(ZZ,7*ZZ); R
Quotient of Integer Ring by the ideal (7)
sage: R.gens()
(1,)
sage: 1*R(3); 6*R(3); 7*R(3)
3
4
0

sage: S = QuotientRing(ZZ,ZZ.ideal(8)); S
Quotient of Integer Ring by the ideal (8)
sage: 2*S(4)
0
```

With polynomial rings: (note that the variable name of the quotient ring can be specified as shown below)

```
sage: R.<xx> = QuotientRing(QQ[x], QQ[x].ideal(x^2 + 1)); R
Univariate Quotient Polynomial Ring in xx over Rational Field with modulus x^2 + 1
sage: R.gens(); R.gen()
(xx,)
xx
sage: for n in range(4): xx^n
1
xx
-1
-xx

sage: S = QuotientRing(QQ[x], QQ[x].ideal(x^2 - 2)); S
Univariate Quotient Polynomial Ring in xbar over Rational Field with
modulus x^2 - 2
sage: xbar = S.gen(); S.gen()
xbar
sage: for n in range(3): xbar^n
1
xbar
2
```

Sage coerces objects into ideals when possible:

```
sage: R = QuotientRing(QQ[x], x^2 + 1); R
Univariate Quotient Polynomial Ring in xbar over Rational Field with
modulus x^2 + 1
```

By Noether's homomorphism theorems, the quotient of a quotient ring in R is just the quotient of R by the sum of the ideals. In this example, we end up modding out the ideal (x) from the ring QQ[x,y]:

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: S.<a,b> = QuotientRing(R,R.ideal(1 + y^2))
sage: T.<c,d> = QuotientRing(S,S.ideal(a))
sage: T
Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the ideal (x, y^2 + 1)
sage: R.gens(); S.gens(); T.gens()
(x, y)
```

```
(a, b)
(0, d)
sage: for n in range(4): d^n
1
d
-1
-d
```

class **QuotientRing_generic**(*R, I, names*)

The quotient ring of R by the ideal I.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(ZZ,'x')
sage: I = R.ideal([4 + 3*x + x^2, 1 + x^2])
sage: S = R.quotient_ring(I); S
Quotient of Univariate Polynomial Ring in x over Integer Ring by the ideal (x^2 + 3*x + 4, x^2 +
```

```
sage: R.<x,y> = PolynomialRing(QQ)
sage: S.<a,b> = R.quo(x^2 + y^2)
sage: a^2 + b^2 == 0
True
sage: S(0) == a^2 + b^2
True
```

EXAMPLE: Quotient of quotient

A quotient of a quotient is just the quotient of the original top ring by the sum of two ideals.

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: S.<a,b> = R.quo(1 + y^2)
sage: T.<c,d> = S.quo(a)
sage: T
Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the ideal (x, y^2 + 1)
sage: T.gens()
(0, d)
```

characteristic()

Return the characteristic of the quotient ring.

TODO: Not yet implemented!

EXAMPLES:

```
sage: Q = QuotientRing(ZZ,7*ZZ)
sage: Q.characteristic()
...
NotImplementedError
```

construction()

EXAMPLES:

```
sage: R.<x> = PolynomialRing(ZZ,'x')
sage: I = R.ideal([4 + 3*x + x^2, 1 + x^2])
sage: R.quotient_ring(I).construction()
(QuotientFunctor, Univariate Polynomial Ring in x over Integer Ring)
```

TESTS:

```
sage: F, R = Integers(5).construction()
sage: F(R)
Ring of integers modulo 5
sage: F, R = GF(5).construction()
sage: F(R)
Finite Field of size 5
```

cover()

The covering ring homomorphism $R \to R/I$, equipped with a section.

EXAMPLES:

```
sage: R = ZZ.quo(3*ZZ)
sage: pi = R.cover()
sage: pi
Ring morphism:
  From: Integer Ring
  To:   Ring of integers modulo 3
  Defn: Natural quotient map
sage: pi(5)
2
sage: l = pi.lift()
```

EXAMPLES:

```
sage: R.<x,y>  = PolynomialRing(QQ)
sage: Q = R.quo( (x^2,y^2) )
sage: pi = Q.cover()
sage: pi(x^3+y)
ybar
sage: l = pi.lift(x+y^3)
sage: l
x
sage: l = pi.lift(); l
Set-theoretic ring morphism:
  From: Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the ideal (x
  To:   Multivariate Polynomial Ring in x, y over Rational Field
  Defn: Choice of lifting map
sage: l(x+y^3)
x
```

cover_ring()

Returns the cover ring of the quotient ring: that is, the original ring R from which we modded out an ideal, I.

TODO: PolynomialQuotientRings_field objects don't have a `cover_ring` function.

EXAMPLES:

```
sage: Q = QuotientRing(ZZ,7*ZZ)
sage: Q.cover_ring()
Integer Ring

sage: Q = QuotientRing(QQ[x], x^2 + 1)
sage: Q.cover_ring()
...
AttributeError: 'PolynomialQuotientRing_field' object has no attribute 'cover_ring'
```

defining_ideal()

Returns the ideal generating this quotient ring.

EXAMPLES:

In the integers:

```
sage: Q = QuotientRing(ZZ,7*ZZ)
sage: Q.defining_ideal()
Principal ideal (7) of Integer Ring
```

An example involving a quotient of a quotient. By Noether's homomorphism theorems, this is actually a quotient by a sum of two ideals:

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: S.<a,b> = QuotientRing(R,R.ideal(1 + y^2))
sage: T.<c,d> = QuotientRing(S,S.ideal(a))
sage: S.defining_ideal()
Ideal (y^2 + 1) of Multivariate Polynomial Ring in x, y over Rational Field
sage: T.defining_ideal()
Ideal (x, y^2 + 1) of Multivariate Polynomial Ring in x, y over Rational Field
```

gen(*i=0*)

Returns the ith generator for this quotient ring.

EXAMPLES:

```
sage: R = QuotientRing(ZZ,7*ZZ)
sage: R.gen(0)
1
```

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: S.<a,b> = QuotientRing(R,R.ideal(1 + y^2))
sage: T.<c,d> = QuotientRing(S,S.ideal(a))
sage: T
Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the ideal (x, y^2 +
sage: R.gen(0); R.gen(1)
x
y
sage: S.gen(0); S.gen(1)
a
b
sage: T.gen(0); T.gen(1)
0
d
```

ideal(**gens, **kwds*)

Return the ideal of self with the given generators.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ)
sage: S = R.quotient_ring(x^2+y^2)
sage: S.ideal()
Ideal (0) of Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the ide
sage: S.ideal(x+y+1)
Ideal (xbar + ybar + 1) of Quotient of Multivariate Polynomial Ring in x, y over Rational Fi
```

is_field()

Returns True if the quotient ring is a field. Checks to see if the defining ideal is maximal.

TESTS:

Requires the `is_maximal` function to be implemented:

```
sage: Q = QuotientRing(ZZ,7*ZZ)
sage: Q.is_field()
...
NotImplementedError
```

is_integral_domain()

If this function returns True then self is definitely an integral domain. If it returns False, then either self is definitely not an integral domain or this function was unable to determine whether or not self is an integral domain.

Use `self.defining_ideal().is_prime()` to find out for sure whether this quotient ring is really not an integral domain, of if Sage is unable to determine the answer.

EXAMPLES:

```
sage: R = Integers(8)
sage: R.is_integral_domain()
False
sage: R.<a,b,c> = ZZ['a','b','c']
sage: I = R.ideal(a,b)
sage: Q = R.quotient_ring(I)
sage: Q.is_integral_domain()
...
NotImplementedError
```

lift()

Return the lifting map to the cover.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ, 2)
sage: S = R.quotient(x^2 + y^2)
sage: pi = S.cover(); pi
Ring morphism:
  From: Multivariate Polynomial Ring in x, y over Rational Field
  To:   Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the ideal (x
  Defn: Natural quotient map
sage: L = S.lift(); L
Set-theoretic ring morphism:
  From: Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the ideal (x
  To:   Multivariate Polynomial Ring in x, y over Rational Field
  Defn: Choice of lifting map
sage: L(S.0)
x
sage: L(S.1)
y
```

Note that some reduction may be applied so that the lift of a reduction need not equal the original element.

```
sage: z = pi(x^3 + 2*y^2); z
-xbar*ybar^2 + 2*ybar^2
sage: L(z)
-x*y^2 + 2*y^2
sage: L(z) == x^3 + 2*y^2
False
```

ngens()

Returns the number of generators for this quotient ring.

TODO: Note that `ngens` counts 0 as a generator. Does this make sense? That is, since 0 only generates itself and the fact that this is true for all rings, is there a way to "knock it off" of the generators list if a generator of some original ring is modded out?

EXAMPLES:

```
sage: R = QuotientRing(ZZ,7*ZZ)
sage: R.gens(); R.ngens()
(1,)
1
```

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: S.<a,b> = QuotientRing(R,R.ideal(1 + y^2))
sage: T.<c,d> = QuotientRing(S,S.ideal(a))
sage: T
Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the ideal (x, y^2 +
sage: R.gens(); S.gens(); T.gens()
(x, y)
(a, b)
(0, d)
sage: R.ngens(); S.ngens(); T.ngens()
2
2
2
```

is_QuotientRing(*x*)

Tests whether or not x inherits from QuotientRing_generic.

EXAMPLES:

```
sage: from sage.rings.quotient_ring import is_QuotientRing
sage: R.<x> = PolynomialRing(ZZ,'x')
sage: I = R.ideal([4 + 3*x + x^2, 1 + x^2])
sage: S = R.quotient_ring(I)
sage: is_QuotientRing(S)
True
sage: is_QuotientRing(R)
False
```

23.9 Quotient Ring Elements

AUTHORS:

- William Stein

class QuotientRingElement(*parent, rep, reduce=True*)

An element of a quotient ring R/I.

INPUT:

- `parent` - the ring R/I
- `rep` - a representative of the element in R; this is used as the internal representation of the element
- `reduce` - bool (optional, default: True) - if True, then the internal representation of the element is `rep` reduced modulo the ideal I

EXAMPLES:

```
sage: R.<x> = PolynomialRing(ZZ)
sage: S.<xbar> = R.quo((4 + 3*x + x^2, 1 + x^2)); S
Quotient of Univariate Polynomial Ring in x over Integer Ring by the ideal (x^2 + 3*x + 4, x^2 +
sage: v = S.gens(); v
(xbar,)
```

```
sage: loads(v[0].dumps()) == v[0]
True
```

```
sage: R.<x,y> = PolynomialRing(QQ, 2)
sage: S = R.quo(x^2 + y^2); S
Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the ideal (x^2 + y^2)
sage: S.gens()
(xbar, ybar)
```

We name each of the generators.

```
sage: S.<a,b> = R.quotient(x^2 + y^2)
sage: a
a
sage: b
b
sage: a^2 + b^2 == 0
True
sage: b.lift()
y
sage: (a^3 + b^2).lift()
-x*y^2 + y^2
```

is_unit()

Return True if self is a unit in the quotient ring.

TODO: This is not fully implemented, as illustrated in the example below. So far, self is determined to be unit only if its representation in the cover ring R is also a unit.

EXAMPLES:

```
sage: R.<x,y> = QQ[]; S.<a,b> = R.quo(1 - x*y); type(a)
<class 'sage.rings.quotient_ring_element.QuotientRingElement'>
sage: a*b
1
sage: a.is_unit()
...
NotImplementedError
sage: S(1).is_unit()
True
```

lc()

Return the leading coefficent of this quotient ring element.

EXAMPLE:

```
sage: R.<x,y,z>=PolynomialRing(GF(7),3,order='lex')
sage: I = sage.rings.ideal.FieldIdeal(R)
sage: Q = R.quo( I )
sage: f = Q( z*y + 2*x )
sage: f.lc()
2
```

TESTS:

```
sage: R.<x,y> = QQ[]; S.<a,b> = R.quo(x^2 + y^2); type(a)
<class 'sage.rings.quotient_ring_element.QuotientRingElement'>
sage: (a+3*a*b+b).lc()
3
```

lift()

If self is an element of R/I, then return self as an element of R.

EXAMPLES:

```
sage: R.<x,y> = QQ[]; S.<a,b> = R.quo(x^2 + y^2); type(a)
<class 'sage.rings.quotient_ring_element.QuotientRingElement'>
sage: a.lift()
x
sage: (3/5*(a + a^2 + b^2)).lift()
3/5*x
```

lm()

Return the leading monomial of this quotient ring element.

EXAMPLE:

```
sage: R.<x,y,z>=PolynomialRing(GF(7),3,order='lex')
sage: I = sage.rings.ideal.FieldIdeal(R)
sage: Q = R.quo( I )
sage: f = Q( z*y + 2*x )
sage: f.lm()
xbar
```

TESTS:

```
sage: R.<x,y> = QQ[]; S.<a,b> = R.quo(x^2 + y^2); type(a)
<class 'sage.rings.quotient_ring_element.QuotientRingElement'>
sage: (a+3*a*b+b).lm()
a*b
```

lt()

Return the leading term of this quotient ring element.

EXAMPLE:

```
sage: R.<x,y,z>=PolynomialRing(GF(7),3,order='lex')
sage: I = sage.rings.ideal.FieldIdeal(R)
sage: Q = R.quo( I )
sage: f = Q( z*y + 2*x )
sage: f.lt()
2*xbar
```

TESTS:

```
sage: R.<x,y> = QQ[]; S.<a,b> = R.quo(x^2 + y^2); type(a)
<class 'sage.rings.quotient_ring_element.QuotientRingElement'>
sage: (a+3*a*b+b).lt()
3*a*b
```

monomials()

EXAMPLES:

```
sage: R.<x,y> = QQ[]; S.<a,b> = R.quo(x^2 + y^2); type(a)
<class 'sage.rings.quotient_ring_element.QuotientRingElement'>
sage: a.monomials()
[a]
sage: (a+a*b).monomials()
[a*b, a]
```

reduce(G)

Reduce this quotient ring element by a set of quotient ring elements G.

INPUT:

- G - a list of quotient ring elements

EXAMPLE:

```
sage: P.<a,b,c,d,e> = PolynomialRing(GF(2), 5, order='lex')
sage: I1 = ideal([a*b + c*d + 1, a*c*e + d*e, a*b*e + c*e, b*c + c*d*e + 1])
sage: Q = P.quotient( sage.rings.ideal.FieldIdeal(P) )
sage: I2 = ideal([Q(f) for f in I1.gens()])
sage: f = Q((a*b + c*d + 1)^2  + e)
sage: f.reduce(I2.gens())
ebar
```

variables()

EXAMPLES:

```
sage: R.<x,y> = QQ[]; S.<a,b> = R.quo(x^2 + y^2); type(a)
<class 'sage.rings.quotient_ring_element.QuotientRingElement'>
sage: a.variables()
[a]
sage: b.variables()
[b]
sage: s = a^2 + b^2 + 1; s
1
sage: s.variables()
[]
sage: (a+b).variables()
[a, b]
```

CHAPTER

TWENTYFOUR

STANDARD COMMUTATIVE RINGS

24.1 Ring $\mathbb{Z}$ of Integers

The class `IntegerRing` represents the ring $\mathbf{Z}$ of (arbitrary precision) integers. Each integer is an instance of the class `Integer`, which is defined in a Pyrex extension module that wraps GMP integers (the `mpz_t` type in GMP).

```
sage: Z = IntegerRing(); Z
Integer Ring
sage: Z.characteristic()
0
sage: Z.is_field()
False
```

There is a unique instances of class `IntegerRing`. To create an `Integer`, coerce either a Python int, long, or a string. Various other types will also coerce to the integers, when it makes sense.

```
sage: a = Z(1234); b = Z(5678); print a, b
1234 5678
sage: type(a)
<type 'sage.rings.integer.Integer'>
sage: a + b
6912
sage: Z('9480384908398593485983458394 5394')
948038490839859348598345839453 94
```

IntegerRing()
Return the integer ring

EXAMPLE:

```
sage: IntegerRing()
Integer Ring
sage: ZZ==IntegerRing()
True
```

class **IntegerRing_class**()
The ring of integers.

In order to introduce the ring $\mathbf{Z}$ of integers, we illustrate creation, calling a few functions, and working with its elements.

```
sage: Z = IntegerRing(); Z
Integer Ring
```

```
sage: Z.characteristic()
0
sage: Z.is_field()
False
```

We next illustrate basic arithmetic in $\mathbf{Z}$:

```
sage: a = Z(1234); b = Z(5678); print a, b
1234 5678
sage: type(a)
<type 'sage.rings.integer.Integer'>
sage: a + b
6912
sage: b + a
6912
sage: a * b
7006652
sage: b * a
7006652
sage: a - b
-4444
sage: b - a
4444
```

When we divide to integers using /, the result is automatically coerced to the field of rational numbers, even if the result is an integer.

```
sage: a / b
617/2839
sage: type(a/b)
<type 'sage.rings.rational.Rational'>
sage: a/a
1
sage: type(a/a)
<type 'sage.rings.rational.Rational'>
```

For floor division, instead using the // operator:

```
sage: a // b
0
sage: type(a//b)
<type 'sage.rings.integer.Integer'>
```

Next we illustrate arithmetic with automatic coercion. The types that coerce are: str, int, long, Integer.

```
sage: a + 17
1251
sage: a * 374
461516
sage: 374 * a
461516
sage: a/19
1234/19
sage: 0 + Z(-64)
-64
```

Integers can be coerced:

```
sage: a = Z(-64)
sage: int(a)
-64
```

We can create integers from several types of objects.

```
sage: ZZ(17/1)
17
sage: ZZ(Mod(19,23))
19
sage: ZZ(2 + 3*5 + O(5^3))
17
```

absolute_degree()
Return the absolute degree of the integers, which is 1
EXAMPLE:

```
sage: ZZ.absolute_degree()
1
```

characteristic()
Return the characteristic of the integers, which is 0
EXAMPLE:

```
sage: ZZ.characteristic()
0
```

completion()
Returns the completion of Z at p.
EXAMPLES:

```
sage: ZZ.completion(infinity, 53)
Real Field with 53 bits of precision
sage: ZZ.completion(5, 15, {'print_mode': 'bars'})
5-adic Ring with capped relative precision 15
```

degree()
Return the degree of the integers, which is 1
EXAMPLE:

```
sage: ZZ.degree()
1
```

extension()
Returns the order in the number field defined by poly generated (as a ring) by a root of poly.
EXAMPLES:

```
sage: ZZ.extension(x^2-5, 'a')
Order in Number Field in a with defining polynomial x^2 - 5
sage: ZZ.extension([x^2 + 1, x^2 + 2], 'a,b')
Relative Order in Number Field in a with defining polynomial x^2 + 1 over its base field
```

fraction_field()
Returns the field of rational numbers - the fraction field of the integers.
EXAMPLES:

```
sage: ZZ.fraction_field()
Rational Field
sage: ZZ.fraction_field() == QQ
True
```

gen()
Returns the additive generator of the integers, which is 1.
EXAMPLES:

```
sage: ZZ.gen()
1
sage: type(ZZ.gen())
<type 'sage.rings.integer.Integer'>
```

gens()
Returns the tuple (1,) containing a single element, the additive generator of the integers, which is 1.
EXAMPLES:

```
sage: ZZ.gens(); ZZ.gens()[0]
(1,)
1
sage: type(ZZ.gens()[0])
<type 'sage.rings.integer.Integer'>
```

is_atomic_repr()
Return True, since elements of the integers do not have to be printed with parentheses around them, when they are coefficients, e.g., in a polynomial.
EXAMPLE:

```
sage: ZZ.is_atomic_repr()
True
```

is_field()
Return False - the integers are not a field.
EXAMPLES:

```
sage: ZZ.is_field()
False
```

is_finite()
Return False - the integers are an infinite ring.
EXAMPLES:

```
sage: ZZ.is_finite()
False
```

is_noetherian()
Return True - the integers are a Noetherian ring.
EXAMPLES:

```
sage: ZZ.is_noetherian()
True
```

is_subring()
Return True if ZZ is a subring of other in a natural way.
Every ring of characteristic 0 contains ZZ as a subring.
EXAMPLES:

```
sage: ZZ.is_subring(QQ)
True
```

krull_dimension()
Return the Krull dimension of the integers, which is 1.
EXAMPLE:

```
sage: ZZ.krull_dimension()
1
```

ngens()

Returns the number of additive generators of the ring, which is 1.

EXAMPLES:

```
sage: ZZ.ngens()
1
sage: len(ZZ.gens())
1
```

order()

Return the order (cardinality) of the integers, which is +Infinity.

EXAMPLE:

```
sage: ZZ.order()
+Infinity
```

parameter()

Returns an integer of degree 1 for the Euclidean property of ZZ, namely 1.

EXAMPLES:

```
sage: ZZ.parameter()
1
```

quotient()

Return the quotient of $\mathbf{Z}$ by the ideal I or integer I.

EXAMPLES:

```
sage: ZZ.quo(6*ZZ)
Ring of integers modulo 6
sage: ZZ.quo(0*ZZ)
Integer Ring
sage: ZZ.quo(3)
Ring of integers modulo 3
sage: ZZ.quo(3*QQ)
...
TypeError: I must be an ideal of ZZ
```

random_element()

Return a random integer.

ZZ.random_element() return an integer using the default distribution described below

ZZ.random_element(n) return an integer uniformly distributed between 0 and n-1, inclusive.

ZZ.random_element(min, max) return an integer uniformly destributed between min and max-1, inclusive.

The default distribution for ZZ.random_element() is based on $X = \text{trunc}(4/(5R))$, where R is a random variable uniformly distributed between -1 and 1. This gives $\Pr(X = 0) = 1/5$, and $\Pr(X = n) = 2/(5|n|(|n| + 1))$ for $n \neq 0$. Most of the samples will be small; -1, 0, and 1 occur with probability 1/5 each. But we also have a small but non-negligible proportion of "outliers"; $\Pr(|X| \geq n) = 4/(5n)$, so for instance, we expect that $|X| \geq 1000$ on one in 1250 samples.

We actually use an easy-to-compute truncation of the above distribution; the probabilities given above hold fairly well up to about $|n| = 10000$, but around $|n| = 30000$ some values will never be returned at all, and we will never return anything greater than 2^{30}.

EXAMPLES:

The default distribution is on average 50% ± 1

```
sage: [ZZ.random_element() for _ in range(10)]
[-8, 2, 0, 0, 1, -1, 2, 1, -95, -1]
```

The default uniform distribution is integers between -2 and 2 inclusive:

```
sage: [ZZ.random_element(distribution="uniform") \
        for _ in range(10)]
[2, -2, 2, -2, -1, 1, -1, 2, 1, 0]
```

If a range is given, the distribution is uniform in that range:

```
sage: ZZ.random_element(-10,10)
-5
sage: ZZ.random_element(10)
7
sage: ZZ.random_element(10^50)
624989715467826655980230365229312342668011858916 99
sage: [ZZ.random_element(5) for _ in range(10)]
[1, 3, 4, 0, 3, 4, 0, 3, 0, 1]
```

Notice that the right endpoint is not included:

```
sage: [ZZ.random_element(-2,2) for _ in range(10)]
[-1, -2, 0, -2, 1, -1, -1, -2, -2, 1]
```

We compute a histogram over 1000 samples of the default distribution:

```
sage: from collections import defaultdict
sage: d = defaultdict(lambda: 0)
sage: for _ in range(1000):
...       samp = ZZ.random_element()
...       d[samp] = d[samp] + 1
sage: sorted(d.items())
[(-1026, 1), (-248, 1), (-145, 1), (-81, 1), (-80, 1), (-79, 1), (-75, 1), (-69, 1), (-68, 1
```

range()

Optimized range function for Sage integer.

AUTHORS:

- Robert Bradshaw (2007-09-20)

EXAMPLES:

```
sage: ZZ.range(10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
sage: ZZ.range(-5,5)
[-5, -4, -3, -2, -1, 0, 1, 2, 3, 4]
sage: ZZ.range(0,50,5)
[0, 5, 10, 15, 20, 25, 30, 35, 40, 45]
sage: ZZ.range(0,50,-5)
[]
sage: ZZ.range(50,0,-5)
[50, 45, 40, 35, 30, 25, 20, 15, 10, 5]
sage: ZZ.range(50,0,5)
[]
sage: ZZ.range(50,-1,-5)
[50, 45, 40, 35, 30, 25, 20, 15, 10, 5, 0]
```

It uses different code if the step doesn't fit in a long:

```
sage: ZZ.range(0,2^83,2^80)
[0, 1208925819614629174706176, 2417851639229258349412352, 3626777458843887524118528, 4835703
```

residue_field()

Return the residue field of the integers modulo the given prime, ie $\mathbf{Z}/p\mathbf{Z}$.

INPUT:

- `prime` - a prime number
- `check` - (boolean, default True) whether or not to check the primality of prime.

OUTPUT: The residue field at this prime.

EXAMPLES:

```
sage: F = ZZ.residue_field(61); F
Residue field of Integers modulo 61
sage: pi = F.reduction_map(); pi
Partially defined reduction map from Rational Field to Residue field of Integers modulo 61
sage: pi(123/234)
6
sage: pi(1/61)
...
ZeroDivisionError: Cannot reduce rational 1/61 modulo 61: it has negative valuation
sage: lift = F.lift_map(); lift
Lifting map from Residue field of Integers modulo 61 to Rational Field
sage: lift(F(12345/67890))
33
sage: (12345/67890) % 61
33
```

Construction can be from a prime ideal instead of a prime:

```
sage: ZZ.residue_field(ZZ.ideal(97))
Residue field of Integers modulo 97
```

TESTS:

```
sage: ZZ.residue_field(ZZ.ideal(96))
...
TypeError: Principal ideal (96) of Integer Ring is not prime
sage: ZZ.residue_field(96)
...
TypeError: 96 is not prime
```

zeta()

Return a primitive n'th root of unity in the integers, or raise an error if none exists

INPUT:

- `n` - a positive integer (default 2)

OUTPUT: an n'th root of unity in ZZ

EXAMPLE:

```
sage: ZZ.zeta()
-1
sage: ZZ.zeta(1)
1
sage: ZZ.zeta(3)
...
ValueError: no nth root of unity in integer ring
sage: ZZ.zeta(0)
...
ValueError: n must be positive in zeta()
```

clear_mpz_globals()

crt_basis()

Compute and return a Chinese Remainder Theorem basis for the list X of coprime integers.

INPUT:

- X - a list of Integers that are coprime in pairs

OUTPUT:

- E - a list of Integers such that E[i] = 1 (mod X[i]) and E[i] = 0 (mod X[j]) for all j!=i.

The E[i] have the property that if A is a list of objects, e.g., integers, vectors, matrices, etc., where A[i] is moduli X[i], then a CRT lift of A is simply

sum E[i] * A[i].

ALGORITHM: To compute E[i], compute integers s and t such that

s * X[i] + t * (prod over i!=j of X[j]) = 1. (*)

Then E[i] = t * (prod over i!=j of X[j]). Notice that equation (*) implies that E[i] is congruent to 1 modulo X[i] and to 0 modulo the other X[j] for j!=i.

COMPLEXITY: We compute len(X) extended GCD's.

EXAMPLES:

```
sage: X = [11,20,31,51]
sage: E = crt_basis([11,20,31,51])
sage: E[0]%X[0]; E[1]%X[0]; E[2]%X[0]; E[3]%X[0]
1
0
0
0
sage: E[0]%X[1]; E[1]%X[1]; E[2]%X[1]; E[3]%X[1]
0
1
0
0
sage: E[0]%X[2]; E[1]%X[2]; E[2]%X[2]; E[3]%X[2]
0
0
1
0
sage: E[0]%X[3]; E[1]%X[3]; E[2]%X[3]; E[3]%X[3]
0
0
0
1
```

factor()

Return the factorization of the positive integer n as a sorted list of tuples (p_i, e_i) such that $n = \prod p_i^{e_i}$.

For further documentation see sage.rings.arith.factor()

EXAMPLE:

```
sage: sage.rings.integer_ring.factor(420)
2^2 * 3 * 5 * 7
```

gmp_randrange()

init_mpz_globals()

is_IntegerRing()
Internal funtion: returns true iff x is the ring ZZ of integers

EXAMPLES:

```
sage: from sage.rings.integer_ring import  is_IntegerRing
sage: is_IntegerRing(ZZ)
True
sage: is_IntegerRing(QQ)
False
sage: is_IntegerRing(parent(3))
True
sage: is_IntegerRing(parent(1/3))
False
```

24.2 Elements of the ring $\mathbb{Z}$ of integers

AUTHORS:

- William Stein (2005): initial version
- Gonzalo Tornaria (2006-03-02): vastly improved python/GMP conversion; hashing
- Didier Deshommes (2006-03-06): numerous examples and docstrings
- William Stein (2006-03-31): changes to reflect GMP bug fixes
- William Stein (2006-04-14): added GMP factorial method (since it's now very fast).
- David Harvey (2006-09-15): added nth_root, exact_log
- David Harvey (2006-09-16): attempt to optimise Integer constructor
- Rishikesh (2007-02-25): changed quo_rem so that the rem is positive
- David Harvey, Martin Albrecht, Robert Bradshaw (2007-03-01): optimized Integer constructor and pool
- Pablo De Napoli (2007-04-01): multiplicative_order should return +infinity for non zero numbers
- Robert Bradshaw (2007-04-12): is_perfect_power, Jacobi symbol (with Kronecker extension). Convert some methods to use GMP directly rather than pari, Integer(), PY_NEW(Integer)
- David Roe (2007-03-21): sped up valuation and is_square, added val_unit, is_power, is_power_of and divide_knowing_divisible_by
- Robert Bradshaw (2008-03-26): gamma function, multifactorials
- Robert Bradshaw (2008-10-02): bounded squarefree part

EXAMPLES:

Add 2 integers:

```
sage: a = Integer(3) ; b = Integer(4)
sage: a + b == 7
True
```

Add an integer and a real number:

```
sage: a + 4.0
7.00000000000000
```

Add an integer and a rational number:

```
sage: a + Rational(2)/5
17/5
```

Add an integer and a complex number:

```
sage: b = ComplexField().0 + 1.5
sage: loads((a+b).dumps()) == a+b
True
```

```
sage: z = 32
sage: -z
-32
sage: z = 0; -z
0
sage: z = -0; -z
0
sage: z = -1; -z
1
```

Multiplication:

```
sage: a = Integer(3) ; b = Integer(4)
sage: a * b == 12
True
sage: loads((a * 4.0).dumps()) == a*b
True
sage: a * Rational(2)/5
6/5
```

```
sage: list([2,3]) * 4
[2, 3, 2, 3, 2, 3, 2, 3]
```

```
sage: 'sage'*Integer(3)
'sagesagesage'
```

COERCIONS: Returns version of this integer in the multi-precision floating real field R.

```
sage: n = 9390823
sage: RR = RealField(200)
sage: RR(n)
9.3908230000000000000000000000000000000000000000000000000000e6
```

GCD_list()

Return the GCD of a list v of integers. Elements of v are converted to Sage integers if they aren't already.

This function is used, e.g., by rings/arith.py

INPUT:

- v - list or tuple

OUTPUT: integer

EXAMPLES:

```
sage: from sage.rings.integer import GCD_list
sage: w = GCD_list([3,9,30]); w
3
sage: type(w)
<type 'sage.rings.integer.Integer'>
```

Check that the bug reported in trac #3118 has been fixed:

```
sage: sage.rings.integer.GCD_list([2,2,3])
1
```

The inputs are converted to Sage integers.

```
sage: w = GCD_list([int(3), int(9), '30']); w
3
sage: type(w)
<type 'sage.rings.integer.Integer'>
```

class Integer()

The `Integer` class represents arbitrary precision integers. It derives from the `Element` class, so integers can be used as ring elements anywhere in Sage.

Integer() interprets numbers and strings that begin with 0 as octal numbers, and numbers and strings that begin with 0x as hexadecimal numbers.

The class `Integer` is implemented in Pyrex, as a wrapper of the GMP `mpz_t` integer type.

EXAMPLES:

```
sage: Integer(010)
8
sage: Integer(0x10)
16
sage: Integer(10)
10
sage: Integer('0x12')
18
sage: Integer('012')
10
```

additive_order()

Return the additive order of self.

EXAMPLES:

```
sage: ZZ(0).additive_order()
1
sage: ZZ(1).additive_order()
+Infinity
```

binary()

Return the binary digits of self as a string.

EXAMPLES:

```
sage: print Integer(15).binary()
1111
sage: print Integer(16).binary()
10000
sage: print Integer(169384023840928430928430982 43).binary()
1101101011101100011110001110010010100111010001101010001111111000101000000000101111000010000
```

bits()

Return the bits in self as a list, least significant first.

EXAMPLES:

```
sage: 500.bits()
[0, 0, 1, 0, 1, 1, 1, 1, 1]
sage: 11.bits()
[1, 1, 0, 1]
```

ceil()

Return the ceiling of self, which is self since self is an integer.

EXAMPLES:

```
sage: n = 6
sage: n.ceil()
6
```

conjugate()

Return the complex conjugate of this integer, which is the integer itself.

EXAMPLES: sage: n = 205 sage: n.conjugate() 205

coprime_integers()

Return the positive integers $< m$ that are coprime to self.

EXAMPLES:

```
sage: n = 8
sage: n.coprime_integers(8)
[1, 3, 5, 7]
sage: n.coprime_integers(11)
[1, 3, 5, 7, 9]
sage: n = 5; n.coprime_integers(10)
[1, 2, 3, 4, 6, 7, 8, 9]
sage: n.coprime_integers(5)
[1, 2, 3, 4]
sage: n = 99; n.coprime_integers(99)
[1, 2, 4, 5, 7, 8, 10, 13, 14, 16, 17, 19, 20, 23, 25, 26, 28, 29, 31, 32, 34, 35, 37, 38, 4
```

AUTHORS:

- Naqi Jaffery (2006-01-24): examples

ALGORITHM: Naive - compute lots of GCD's. If this isn't good enough for you, please code something better and submit a patch.

crt()

Return the unique integer between 0 and mn that is congruent to the integer modulo m and to y modulo n. We assume that m and n are coprime.

EXAMPLES:

```
sage: n = 17
sage: m = n.crt(5, 23, 11); m
247
sage: m%23
17
```

```
sage: m%11
5
```

denominator()

Return the denominator of this integer.

EXAMPLES:

```
sage: x = 5
sage: x.denominator()
1
sage: x = 0
sage: x.denominator()
1
```

digits()

Return a list of digits for self in the given base in little endian order.

The return is unspecified if self is a negative number and the digits are given.

INPUT:

- `base` - integer (default: 2)
- `digits` - optional indexable object as source for the digits
- `padto` - the minimal length of the returned list, sufficient number of zeros are added to make the list minimum that length (default: 0)

EXAMPLE:

```
sage: 17.digits()
[7, 1]
sage: 5.digits(base=2, digits=["zero","one"])
['one', 'zero', 'one']
sage: 5.digits(3)
[2, 1]
sage: 0.digits(base=10)  # 0 has 0 digits
[]
sage: 0.digits(base=2)  # 0 has 0 digits
[]
sage: 10.digits(16,'0123456789abcdef')
['a']
sage: 0.digits(16,'0123456789abcdef')
[]
sage: 0.digits(16,'0123456789abcdef',padto=1)
['0']
sage: 123.digits(base=10,padto=5)
[3, 2, 1, 0, 0]
sage: 123.digits(base=2,padto=3)       # padto is the minimal length
[1, 1, 0, 1, 1, 1, 1]
sage: 123.digits(base=2,padto=10,digits=(1,-1))
[-1, -1, 1, -1, -1, -1, -1, 1, 1, 1]
sage: a=9939082340; a.digits(10)
[0, 4, 3, 2, 8, 0, 9, 3, 9, 9]
sage: a.digits(512)
[100, 302, 26, 74]
sage: (-12).digits(10)
[-2, -1]
sage: (-12).digits(2)
[0, 0, -1, -1]
```

We support large bases

```
sage: n=2^6000
sage: n.digits(2^3000)
[0, 0, 1]

sage: base=3; n=25
sage: l=n.digits(base)
sage: # the next relationship should hold for all n,base
sage: sum(base^i*l[i] for i in range(len(l)))==n
True
sage: base=3; n=-30; l=n.digits(base); sum(base^i*l[i] for i in range(len(l)))==n
True
```

Note: In some cases it is faster to give a digits collection. This would be particularly true for computing the digits of a series of small numbers. In these cases, the code is careful to allocate as few python objects as reasonably possible.

```
sage: digits = range(15)
sage: l=[ZZ(i).digits(15,digits) for i in range(100)]
sage: l[16]
[1, 1]
```

This function is comparable to `str` for speed.

```
sage: n=3^100000
sage: n.digits(base=10)[-1]  # slightly slower than str
1
sage: n=10^10000
sage: n.digits(base=10)[-1]  # slightly faster than str
1
```

AUTHORS:

- Joel B. Mohler (2008-03-02): significantly rewrote this entire function

divide_knowing_divisible_by()

Returns the integer self / right when self is divisible by right.

If self is not divisible by right, the return value is undefined, and may not even be close to self/right for multi-word integers.

EXAMPLES:

```
sage: a = 8; b = 4
sage: a.divide_knowing_divisible_by(b)
2
sage: (100000).divide_knowing_divisible_by(25)
4000
sage: (100000).divide_knowing_divisible_by(26) # close (random)
3846
```

However, often it's way off.

```
sage: a = 2^70; a
1180591620717411303424
sage: a // 11  # floor divide
107326510974310118493
sage: a.divide_knowing_divisible_by(11) # way off and possibly random
432153614787434223889704550 40
```

divides()

Return True if self divides n.

EXAMPLES:

```
sage: Z = IntegerRing()
sage: Z(5).divides(Z(10))
True
sage: Z(0).divides(Z(5))
False
sage: Z(10).divides(Z(5))
False
```

divisors()

Returns a list of all positive integer divisors of the integer self.

EXAMPLES:

```
sage: a = -3; a.divisors()
[1, 3]
sage: a = 6; a.divisors()
[1, 2, 3, 6]
sage: a = 28; a.divisors()
[1, 2, 4, 7, 14, 28]
sage: a = 2^5; a.divisors()
[1, 2, 4, 8, 16, 32]
sage: a = 100; a.divisors()
[1, 2, 4, 5, 10, 20, 25, 50, 100]
sage: a = 1; a.divisors()
[1]
sage: a = 0; a.divisors()
...
ValueError: n must be nonzero
sage: a = 2^3 * 3^2 * 17; a.divisors()
[1, 2, 3, 4, 6, 8, 9, 12, 17, 18, 24, 34, 36, 51, 68, 72, 102, 136, 153, 204, 306, 408, 612,
sage: a = odd_part(factorial(31))
sage: v = a.divisors(); len(v)
172800
sage: prod(e+1 for p,e in factor(a))
172800
sage: all([t.divides(a) for t in v])
True
```

Note: If one first computes all the divisors and then sorts it, the sorting step can easily dominate the runtime. Note, however, that (non-negative) multiplication on the left preserves relative order. One can leverage this fact to keep the list in order as one computes it using a process similar to that of the merge sort when adding new elements.

exact_log()

Returns the largest integer k such that $m^k \leq$ self, i.e., the floor of $\log_m(\text{self})$.

This is guaranteed to return the correct answer even when the usual log function doesn't have sufficient precision.

INPUT:

- m - integer >= 2

AUTHORS:

- David Harvey (2006-09-15)
- **Joel B. Mohler (2009-04-08) – rewrote this to handle small cases** and/or easy cases up to 100x faster..

EXAMPLES:

```
sage: Integer(125).exact_log(5)
3
sage: Integer(124).exact_log(5)
```

```
2
sage: Integer(126).exact_log(5)
3
sage: Integer(3).exact_log(5)
0
sage: Integer(1).exact_log(5)
0
sage: Integer(178^1700).exact_log(178)
1700
sage: Integer(178^1700-1).exact_log(178)
1699
sage: Integer(178^1700+1).exact_log(178)
1700
sage: # we need to exercise the large base code path too
sage: Integer(1780^1700-1).exact_log(1780)
1699

sage: # The following are very very fast.
sage: # Note that for base m a perfect power of 2, we get the exact log by counting bits.
sage: n=29835798237501857013751098 35; m=32
sage: n.exact_log(m)
18
sage: # The next is a favorite of mine.  The log2 approximate is exact and immediately prova
sage: n=901537105709127095179025790107932517092579012709417092479012097421 24;m=2135097213095
sage: n.exact_log(m)
4

sage: x = 3^100000
sage: RR(log(RR(x), 3))
100000.000000000
sage: RR(log(RR(x + 100000), 3))
100000.000000000

sage: x.exact_log(3)
100000
sage: (x+1).exact_log(3)
100000
sage: (x-1).exact_log(3)
99999

sage: x.exact_log(2.5)
...
TypeError: Attempt to coerce non-integral RealNumber to Integer
```

exp()

Returns the exponential function of self as a real number.

This function is provided only so that Sage integers may be treated in the same manner as real numbers when convenient.

INPUT:

- `prec` - integer (default: None): if None, returns symbolic, else to given bits of precision as in RealField

EXAMPLES:

```
sage: Integer(8).exp()
e^8
sage: Integer(8).exp(prec=100)
2980.9579870417282747435920995
```

```
sage: exp(Integer(8))
e^8
```

For even fairly large numbers, this may not be useful.

```
sage: y=Integer(145^145)
sage: y.exp()
e^25024207011349079210459585279553675697932183658421565260323592409432707306554163224876110
sage: y.exp(prec=53) # default RealField precision
+infinity
```

factor()

Return the prime factorization of the integer as a list of pairs (p, e), where p is prime and e is a positive integer.

INPUT:

- `algorithm` - string
  - `'pari'` - (default) use the PARI c library
  - `'kash'` - use KASH computer algebra system (requires the optional kash package be installed)
- `proof` - bool (default: True) whether or not to prove primality of each factor (only applicable for PARI).
- `limit` - int or None (default: None) if limit is given it must fit in a signed int, and the factorization is done using trial division and primes up to limit.

EXAMPLES:

```
sage: n = 2^100 - 1; n.factor()
3 * 5^3 * 11 * 31 * 41 * 101 * 251 * 601 * 1801 * 4051 * 8101 * 268501
```

We use proof=False, which doesn't prove correctness of the primes that appear in the factorization:

```
sage: n = 92038409284239042384829034820394809238408234908 2
sage: n.factor(proof=False)
2 * 11 * 1531 * 4402903 * 10023679 * 619162955472170540533894518173
sage: n.factor(proof=True)
2 * 11 * 1531 * 4402903 * 10023679 * 619162955472170540533894518173
```

We factor using trial division only:

```
sage: n.factor(limit=1000)
2 * 11 * 41835640583745019265831379463815822381094652231
```

factorial()

Return the factorial $n! = 1 \cdot 2 \cdot 3 \cdots n$. Self must fit in an `unsigned long int`.

EXAMPLES:

```
sage: for n in srange(7):
...       print n, n.factorial()
0 1
1 1
2 2
3 6
4 24
5 120
6 720
```

floor()

Return the floor of self, which is just self since self is an integer.

EXAMPLES:

```
sage: n = 6
sage: n.floor()
6
```

gamma()

The gamma function on integers is the factorial function (shifted by one) on positive integers, and $\pm\infty$ on non-positive integers.

EXAMPLES:

```
sage: gamma(5)
24
sage: gamma(0)
Infinity
sage: gamma(-1)
Infinity
sage: gamma(-2^150)
Infinity
```

gcd()

Return the greatest common divisor of self and n.

EXAMPLE:

```
sage: gcd(-1,1)
1
sage: gcd(0,1)
1
sage: gcd(0,0)
0
sage: gcd(2,2^6)
2
sage: gcd(21,2^6)
1
```

inverse_mod()

Returns the inverse of self modulo n, if this inverse exists. Otherwise, raises a `ZeroDivisionError` exception.

INPUT:

- `self` - Integer
- `n` - Integer

OUTPUT:

- `x` - Integer such that x*self = 1 (mod m), or raises ZeroDivisionError.

IMPLEMENTATION:

Call the mpz_invert GMP library function.

EXAMPLES:

```
sage: a = Integer(189)
sage: a.inverse_mod(10000)
4709
sage: a.inverse_mod(-10000)
4709
sage: a.inverse_mod(1890)
...
ZeroDivisionError: Inverse does not exist.
sage: a = Integer(19)**100000
sage: b = a*a
sage: c = a.inverse_mod(b)
```

```
...
ZeroDivisionError: Inverse does not exist.
```

inverse_of_unit()

Return inverse of self if self is a unit in the integers, i.e., self is -1 or 1. Otherwise, raise a ZeroDivisionError.

EXAMPLES:

```
sage: (1).inverse_of_unit()
1
sage: (-1).inverse_of_unit()
-1
sage: 5.inverse_of_unit()
...
ZeroDivisionError: Inverse does not exist.
sage: 0.inverse_of_unit()
...
ZeroDivisionError: Inverse does not exist.
```

is_integral()

Return `True` since integers are integral, i.e., satisfy a monic polynomial with integer coefficients.

EXAMPLES:

```
sage: Integer(3).is_integral()
True
```

is_irreducible()

Returns `True` if self is irreducible, i.e. +/- prime

EXAMPLES:

```
sage: z = 2^31 - 1
sage: z.is_irreducible()
True
sage: z = 2^31
sage: z.is_irreducible()
False
sage: z = 7
sage: z.is_irreducible()
True
sage: z = -7
sage: z.is_irreducible()
True
```

is_one()

Returns `True` if the integer is 1, otherwise `False`.

EXAMPLES:

```
sage: Integer(1).is_one()
True
sage: Integer(0).is_one()
False
```

is_perfect_power()

Returns `True` if self is a perfect power.

EXAMPLES:

```
sage: z = 8
sage: z.is_perfect_power()
True
sage: 144.is_perfect_power()
```

```
True
sage: 10.is_perfect_power()
False
sage: (-8).is_perfect_power()
True
sage: (-4).is_perfect_power()
False
```

This is a test to make sure we workaround a bug in GMP. (See trac #4612.)

```
sage: [ -a for a in srange(100) if not (-a^3).is_perfect_power() ]
[]
```

is_power()

Returns `True` if self is a perfect power, ie if there exist integers a and b, $b > 1$ with $self = a^b$.

EXAMPLES:

```
sage: Integer(-27).is_power()
True
sage: Integer(12).is_power()
False
```

is_power_of()

Returns `True` if there is an integer b with `self` $= n^b$.

EXAMPLES:

```
sage: Integer(64).is_power_of(4)
True
sage: Integer(64).is_power_of(16)
False
```

TESTS:

```
sage: Integer(-64).is_power_of(-4)
True
sage: Integer(-32).is_power_of(-2)
True
sage: Integer(1).is_power_of(1)
True
sage: Integer(-1).is_power_of(-1)
True
sage: Integer(0).is_power_of(1)
False
sage: Integer(0).is_power_of(0)
True
sage: Integer(1).is_power_of(0)
True
sage: Integer(1).is_power_of(8)
True
sage: Integer(-8).is_power_of(2)
False
```

Note: For large integers self, is_power_of() is faster than is_power(). The following examples gives some indication of how much faster.

```
sage: b = lcm(range(1,10000))
sage: b.exact_log(2)
14446
sage: t=cputime()
sage: for a in range(2, 1000): k = b.is_power()
sage: cputime(t)      # random
```

```
0.53203299999999976
sage: t=cputime()
sage: for a in range(2, 1000): k = b.is_power_of(2)
sage: cputime(t)      # random
0.0
sage: t=cputime()
sage: for a in range(2, 1000): k = b.is_power_of(3)
sage: cputime(t)      # random
0.032002000000000308

sage: b = lcm(range(1, 1000))
sage: b.exact_log(2)
1437
sage: t=cputime()
sage: for a in range(2, 10000): k = b.is_power() # note that we change the range from the ex
sage: cputime(t)      # random
0.17201100000000036
sage: t=cputime(); TWO=int(2)
sage: for a in range(2, 10000): k = b.is_power_of(TWO)
sage: cputime(t)      # random
0.0040000000000000036
sage: t=cputime()
sage: for a in range(2, 10000): k = b.is_power_of(3)
sage: cputime(t)      # random
0.040003000000000011
sage: t=cputime()
sage: for a in range(2, 10000): k = b.is_power_of(a)
sage: cputime(t)      # random
0.02800199999999986
```

is_prime()

Returns `True` if self is prime.

Note: Integer primes are by definition *positive*! This is different than Magma, but the same as in Pari. See also the `is_irreducible`() method.

EXAMPLES:

```
sage: z = 2^31 - 1
sage: z.is_prime()
True
sage: z = 2^31
sage: z.is_prime()
False
sage: z = 7
sage: z.is_prime()
True
sage: z = -7
sage: z.is_prime()
False
sage: z.is_irreducible()
True
```

is_prime_power()

Returns True if x is a prime power, and False otherwise.

INPUT:

- `flag` (for primality testing) - int
  - `0` (default): use a combination of algorithms.
  - `1`: certify primality using the Pocklington-Lehmer Test.

-2: certify primality using the APRCL test.

EXAMPLES:

```
sage: (-10).is_prime_power()
False
sage: (10).is_prime_power()
False
sage: (64).is_prime_power()
True
sage: (3^10000).is_prime_power()
True
sage: (10000).is_prime_power(flag=1)
False
```

Note: Currently in the case when self is a perfect power, we call self.factor, due to a bug in Pari's ispower function. See Trac #4777. We illustrate that this is fixed below.

```
sage: n = 150607571^14
sage: n.is_prime_power()
True
```

is_pseudoprime()

Returns True if self is a pseudoprime

EXAMPLES:

```
sage: z = 2^31 - 1
sage: z.is_pseudoprime()
True
sage: z = 2^31
sage: z.is_pseudoprime()
False
```

is_square()

Returns True if self is a perfect square

EXAMPLES:

```
sage: Integer(4).is_square()
True
sage: Integer(41).is_square()
False
```

is_squarefree()

Returns True if this integer is not divisible by the square of any prime and False otherwise.

EXAMPLES:

```
sage: Integer(100).is_squarefree()
False
sage: Integer(102).is_squarefree()
True
```

is_unit()

Returns true if this integer is a unit, i.e., 1 or -1.

EXAMPLES:

```
sage: for n in srange(-2,3):
...       print n, n.is_unit()
-2 False
-1 True
0 False
1 True
2 False
```

isqrt()

Returns the integer floor of the square root of self, or raises an `ValueError` if self is negative.

EXAMPLE:

```
sage: a = Integer(5)
sage: a.isqrt()
2

sage: Integer(-102).isqrt()
...
ValueError: square root of negative integer not defined.
```

jacobi()

Calculate the Jacobi symbol $\left(\frac{self}{b}\right)$.

EXAMPLES:

```
sage: z = -1
sage: z.jacobi(17)
1
sage: z.jacobi(19)
-1
sage: z.jacobi(17*19)
-1
sage: (2).jacobi(17)
1
sage: (3).jacobi(19)
-1
sage: (6).jacobi(17*19)
-1
sage: (6).jacobi(33)
0
sage: a = 3; b = 7
sage: a.jacobi(b) == -b.jacobi(a)
True
```

kronecker()

Calculate the Kronecker symbol $\left(\frac{self}{b}\right)$ with the Kronecker extension $(self/2) = (2/self)$ when self odd, or $(self/2) = 0$ when $self$ even.

EXAMPLES:

```
sage: z = 5
sage: z.kronecker(41)
1
sage: z.kronecker(43)
-1
sage: z.kronecker(8)
-1
sage: z.kronecker(15)
0
sage: a = 2; b = 5
sage: a.kronecker(b) == b.kronecker(a)
True
```

list()

Return a list with this integer in it, to be compatible with the method for number fields.

EXAMPLES:

```
sage: m = 5
sage: m.list()
[5]
```

log()

Returns symbolic log by default, unless the logarithm is exact (for an integer base). When precision is given, the RealField approximation to that bit precision is used.

This function is provided primarily so that Sage integers may be treated in the same manner as real numbers when convenient. Direct use of exact_log is probably best for arithmetic log computation.

INPUT:

- `m` - default: natural log base e
- `prec` - integer (default: None): if None, returns symbolic, else to given bits of precision as in RealField

EXAMPLES:

```
sage: Integer(124).log(5)
log(124)/log(5)
sage: Integer(124).log(5,100)
2.9950093311241087454822446806
sage: Integer(125).log(5)
3
sage: Integer(125).log(5,prec=53)
3.00000000000000
sage: log(Integer(125))
log(125)
```

For extremely large numbers, this works:

```
sage: x = 3^100000
sage: log(x,3)
100000
```

Do NOT try log(x) here, at least not with current Maxima symbolic backend; it may take a very, very long time. But approximations work well - up to the given precision, of course.

```
sage: x.log(3,53) # default precision for RealField
100000.000000000
sage: (x+1).log(3,53)
100000.000000000
sage: (x+1).log(3,1000)
100000.00000000000000000000000000000000000000000000000000000000000000000000000000000000000000000
```

We can use non-integer bases, with default e:

```
sage: x.log(2.5,prec=53)
119897.784671579
```

multifactorial()

Computes the k-th factorial $n!^{(k)}$ of self. For k=1 this is the standard factorial, and for k greater than one it is the product of every k-th terms down from self to k. The recursive definition is used to extend this function to the negative integers.

EXAMPLES:

```
sage: 5.multifactorial(1)
120
sage: 5.multifactorial(2)
15
sage: 23.multifactorial(2)
316234143225
```

```
sage: prod([1..23, step=2])
316234143225
sage: (-29).multifactorial(7)
1/2640
```

multiplicative_order()

Return the multiplicative order of self.

EXAMPLES:

```
sage: ZZ(1).multiplicative_order()
1
sage: ZZ(-1).multiplicative_order()
2
sage: ZZ(0).multiplicative_order()
+Infinity
sage: ZZ(2).multiplicative_order()
+Infinity
```

nbits()

Return the number of bits in self.

EXAMPLES:

```
sage: 500.nbits()
9
sage: 5.nbits()
3
sage: 12345.nbits() == len(12345.binary())
True
```

ndigits()

Return the number of digits of self expressed in the given base.

INPUT:

- `base` - integer (default: 10)

EXAMPLES:

```
sage: n = 52
sage: n.ndigits()
2
sage: n = -10003
sage: n.ndigits()
5
sage: n = 15
sage: n.ndigits(2)
4
sage: n=1000**1000000+1
sage: n.ndigits()
3000001
sage: n=1000**1000000-1
sage: n.ndigits()
3000000
sage: n=10**10000000-10**9999990
sage: n.ndigits()
10000000
```

next_prime()

Returns the next prime after self.

INPUT:

- `proof` - bool or None (default: None, see proof.arithmetic or sage.structure.proof) Note that the global Sage default is proof=True

EXAMPLES:

```
sage: Integer(100).next_prime()
101
```

Use Proof = False, which is way faster:

```
sage: b = (2^1024).next_prime(proof=False)

sage: Integer(0).next_prime()
2
sage: Integer(1001).next_prime()
1009
```

next_probable_prime()

Returns the next probable prime after self, as determined by PARI.

EXAMPLES:

```
sage: (-37).next_probable_prime()
2
sage: (100).next_probable_prime()
101
sage: (2^512).next_probable_prime()
13407807929942597099574024998205846127479365820592393377723561443721764030073546976801874298
sage: 0.next_probable_prime()
2
sage: 126.next_probable_prime()
127
sage: 144168.next_probable_prime()
144169
```

nth_root()

Returns the (possibly truncated) n'th root of self.

INPUT:

- `n` - integer >= 1 (must fit in C int type).
- `truncate_mode` - boolean, whether to allow truncation if self is not an n'th power.

OUTPUT: If truncate_mode is 0 (default), then returns the exact n'th root if self is an n'th power, or raises a ValueError if it is not.

If truncate_mode is 1, then if either n is odd or self is positive, returns a pair (root, exact_flag) where root is the truncated nth root (rounded towards zero) and exact_flag is a boolean indicating whether the root extraction was exact; otherwise raises a ValueError.

AUTHORS:

- David Harvey (2006-09-15)
- Interface changed by John Cremona (2009-04-04)

EXAMPLES:

```
sage: Integer(125).nth_root(3)
5
sage: Integer(124).nth_root(3)
...
ValueError: 124 is not a 3rd power
sage: Integer(124).nth_root(3, truncate_mode=1)
(4, False)
sage: Integer(125).nth_root(3, truncate_mode=1)
(5, True)
```

```
sage: Integer(126).nth_root(3, truncate_mode=1)
(5, False)

sage: Integer(-125).nth_root(3)
-5
sage: Integer(-125).nth_root(3,truncate_mode=1)
(-5, True)
sage: Integer(-124).nth_root(3,truncate_mode=1)
(-4, False)
sage: Integer(-126).nth_root(3,truncate_mode=1)
(-5, False)

sage: Integer(125).nth_root(2, True)
(11, False)
sage: Integer(125).nth_root(3, True)
(5, True)

sage: Integer(125).nth_root(-5)
...
ValueError: n (=-5) must be positive

sage: Integer(-25).nth_root(2)
...
ValueError: cannot take even root of negative number

sage: a=9
sage: a.nth_root(3)
...
ValueError: 9 is not a 3rd power

sage: a.nth_root(22)
...
ValueError: 9 is not a 22nd power

sage: ZZ(2^20).nth_root(21)
...
ValueError: 1048576 is not a 21st power

sage: ZZ(2^20).nth_root(21, truncate_mode=1)
(1, False)
```

numerator()

Return the numerator of this integer.

EXAMPLE:

```
sage: x = 5
sage: x.numerator()
5

sage: x = 0
sage: x.numerator()
0
```

ord()

Synonym for valuation

EXAMPLES:

```
sage: n=12
sage: n.ord(3)
1
```

ordinal_str()

Returns a string representation of the ordinal associated to self.

EXAMPLES:

```
sage: [ZZ(n).ordinal_str() for n in range(25)]
['0th',
'1st',
'2nd',
'3rd',
'4th',
...
'10th',
'11th',
'12th',
'13th',
'14th',
...
'20th',
'21st',
'22nd',
'23rd',
'24th']

sage: ZZ(1001).ordinal_str()
'1001st'
```

powermod()

Compute self**exp modulo mod.

EXAMPLES:

```
sage: z = 2
sage: z.powermod(31,31)
2
sage: z.powermod(0,31)
1
sage: z.powermod(-31,31) == 2^-31 % 31
True
```

As expected, the following is invalid:

```
sage: z.powermod(31,0)
...
ZeroDivisionError: cannot raise to a power modulo 0
```

powermodm_ui()

Computes self**exp modulo mod, where exp is an unsigned long integer.

EXAMPLES:

```
sage: z = 32
sage: z.powermodm_ui(2, 4)
0
sage: z.powermodm_ui(2, 14)
2
sage: z.powermodm_ui(2^32-2, 14)
2
```

```
sage: z.powermodm_ui(2^32-1, 14)
...                                                                 # 32-bit
OverflowError: exp (=4294967295) must be <= 4294967294              # 32-bit
8               # 64-bit
sage: z.powermodm_ui(2^65, 14)
...
OverflowError: exp (=36893488147419103232) must be <= 4294967294  # 32-bit
OverflowError: exp (=36893488147419103232) must be <= 18446744073709551614     # 64-bit
```

prime_divisors()

The prime divisors of self, sorted in increasing order. If n is negative, we do *not* include -1 among the prime divisors, since -1 is not a prime number.

EXAMPLES:

```
sage: a = 1; a.prime_divisors()
[]
sage: a = 100; a.prime_divisors()
[2, 5]
sage: a = -100; a.prime_divisors()
[2, 5]
sage: a = 2004; a.prime_divisors()
[2, 3, 167]
```

prime_factors()

The prime divisors of self, sorted in increasing order. If n is negative, we do *not* include -1 among the prime divisors, since -1 is not a prime number.

EXAMPLES:

```
sage: a = 1; a.prime_divisors()
[]
sage: a = 100; a.prime_divisors()
[2, 5]
sage: a = -100; a.prime_divisors()
[2, 5]
sage: a = 2004; a.prime_divisors()
[2, 3, 167]
```

prime_to_m_part()

Returns the prime-to-m part of self, i.e., the largest divisor of self that is coprime to m.

INPUT:

- `m` - Integer

OUTPUT: Integer

EXAMPLES:

```
sage: z = 43434
sage: z.prime_to_m_part(20)
21717
```

quo_rem()

Returns the quotient and the remainder of self divided by other. Note that the remainder returned is always either zero or of the same sign as other.

INPUT:

- `other` - the integer the divisor

OUTPUT:

- `q` - the quotient of self/other
- `r` - the remainder of self/other

EXAMPLES:

```
sage: z = Integer(231)
sage: z.quo_rem(2)
(115, 1)
sage: z.quo_rem(-2)
(-116, -1)
sage: z.quo_rem(0)
...
ZeroDivisionError: other (=0) must be nonzero
```

radical()

Return the product of the prime divisors of self.

If self is 0, returns 1.

EXAMPLES:

```
sage: Integer(10).radical()
10
sage: Integer(20).radical()
10
sage: Integer(-20).radical()
-10
sage: Integer(0).radical()
1
sage: Integer(36).radical()
6
```

rational_reconstruction()

Return the rational reconstruction of this integer modulo m, i.e., the unique (if it exists) rational number that reduces to self modulo m and whose numerator and denominator is bounded by sqrt(m/2).

EXAMPLES:

```
sage: (3/7)%100
29
sage: (29).rational_reconstruction(100)
3/7
```

sqrt()

The square root function.

INPUT:

- `prec` - integer (default: None): if None, returns an exact square root; otherwise returns a numerical square root if necessary, to the given bits of precision.
- `extend` - bool (default: True); if True, return a square root in an extension ring, if necessary. Otherwise, raise a ValueError if the square is not in the base ring. Ignored if prec is not None.
- `all` - bool (default: False); if True, return all square roots of self, instead of just one.

EXAMPLES:

```
sage: Integer(144).sqrt()
12
sage: sqrt(Integer(144))
12
sage: Integer(102).sqrt()
sqrt(102)

sage: n = 2
sage: n.sqrt(all=True)
[sqrt(2), -sqrt(2)]
sage: n.sqrt(prec=10)
```

```
1.4
sage: n.sqrt(prec=100)
1.4142135623730950488016887242
sage: n.sqrt(prec=100,all=True)
[1.4142135623730950488016887242, -1.4142135623730950488016887242]
sage: n.sqrt(extend=False)
...
ValueError: square root of 2 not an integer
sage: Integer(144).sqrt(all=True)
[12, -12]
sage: Integer(0).sqrt(all=True)
[0]
sage: type(Integer(5).sqrt())
<type 'sage.symbolic.expression.Expression'>
sage: type(Integer(5).sqrt(prec=53))
<type 'sage.rings.real_mpfr.RealNumber'>
sage: type(Integer(-5).sqrt(prec=53))
<type 'sage.rings.complex_number.ComplexNumber'>
```

sqrt_approx()

EXAMPLES:

```
sage: 5.sqrt_approx(prec=200)
doctest:1172: DeprecationWarning: This function is deprecated.  Use sqrt with a given number
2.2360679774997896964091736687312762354406183596115257242709
sage: 5.sqrt_approx()
2.23606797749979
sage: 4.sqrt_approx()
2
```

sqrtrem()

Return (s, r) where s is the integer square root of self and r is the remainder such that self $= s^2 + r$. Raises `ValueError` if self is negative.

EXAMPLES:

```
sage: 25.sqrtrem()
(5, 0)
sage: 27.sqrtrem()
(5, 2)
sage: 0.sqrtrem()
(0, 0)

sage: Integer(-102).sqrtrem()
...
ValueError: square root of negative integer not defined.
```

squarefree_part()

Return the square free part of x (=self), i.e., the unique integer z that $x = zy^2$, with y^2 a perfect square and z square-free.

Use `self.radical()` for the product of the primes that divide self.

If self is 0, just returns 0.

EXAMPLES:

```
sage: squarefree_part(100)
1
sage: squarefree_part(12)
3
sage: squarefree_part(17*37*37)
```

```
17
sage: squarefree_part(-17*32)
-34
sage: squarefree_part(1)
1
sage: squarefree_part(-1)
-1
sage: squarefree_part(-2)
-2
sage: squarefree_part(-4)
-1

sage: a = 8 * 5^6 * 101^2
sage: a.squarefree_part(bound=2).factor()
2 * 5^6 * 101^2
sage: a.squarefree_part(bound=5).factor()
2 * 101^2
sage: a.squarefree_part(bound=1000)
2
sage: a = 7^3 * next_prime(2^100)^2 * next_prime(2^200)
sage: a / a.squarefree_part(bound=1000)
49
```

str()

Return the string representation of `self` in the given base.

EXAMPLES:

```
sage: Integer(2^10).str(2)
'10000000000'
sage: Integer(2^10).str(17)
'394'

sage: two=Integer(2)
sage: two.str(1)
...
ValueError: base (=1) must be between 2 and 36

sage: two.str(37)
...
ValueError: base (=37) must be between 2 and 36

sage: big = 10^5000000
sage: s = big.str()                    # long time (> 20 seconds)
sage: len(s)                           # long time (depends on above defn of s)
5000001
sage: s[:10]                           # long time (depends on above defn of s)
'1000000000'
```

support()

Return a sorted list of the primes dividing this integer.

OUTPUT: The sorted list of primes appearing in the factorization of this rational with positive exponent.

EXAMPLES:

```
sage: factorial(10).support()
[2, 3, 5, 7]
sage: (-999).support()
[3, 37]
```

Trying to find the support of 0 gives an arithmetic error:

```
sage: 0.support()
...
ArithmeticError: Support of 0 not defined.
```

test_bit()

Return the bit at index.

EXAMPLES:

```
sage: w = 6
sage: w.str(2)
'110'
sage: w.test_bit(2)
1
sage: w.test_bit(-1)
0
```

trailing_zero_bits()

Return the number of trailing zero bits in self, i.e. the exponent of the largest power of 2 dividing self.

EXAMPLES:

```
sage: 11.trailing_zero_bits()
0
sage: (-11).trailing_zero_bits()
0
sage: (11<<5).trailing_zero_bits()
5
sage: (-11<<5).trailing_zero_bits()
5
sage: 0.trailing_zero_bits()
0
```

val_unit()

Returns a pair: the p-adic valuation of self, and the p-adic unit of self.

INPUT:

- p - an integer at least 2.

OUTPUT:

- v_p(self) - the p-adic valuation of self
- u_p(self) - self / $p^{v_p(\text{self})}$

EXAMPLE:

```
sage: n = 60
sage: n.val_unit(2)
(2, 15)
sage: n.val_unit(3)
(1, 20)
sage: n.val_unit(7)
(0, 60)
sage: (2^11).val_unit(4)
(5, 2)
sage: 0.val_unit(2)
(+Infinity, 1)
```

valuation()

Return the p-adic valuation of self.

INPUT:

- p - an integer at least 2.

EXAMPLE:

```
sage: n = 60
sage: n.valuation(2)
2
sage: n.valuation(3)
1
sage: n.valuation(7)
0
sage: n.valuation(1)
...
ValueError: You can only compute the valuation with respect to a integer larger than 1.
```

We do not require that p is a prime:

```
sage: (2^11).valuation(4)
5
```

class IntegerWrapper()

Python classes have problems inheriting from Integer directly, but they don't have issues with inheriting from IntegerWrapper.

LCM_list()

Return the LCM of a list v of integers. Elements of v are converted to Sage integers if they aren't already.

This function is used, e.g., by rings/arith.py

INPUT:

- v - list or tuple

OUTPUT: integer

EXAMPLES:

```
sage: from sage.rings.integer import LCM_list
sage: w = LCM_list([3,9,30]); w
90
sage: type(w)
<type 'sage.rings.integer.Integer'>
```

The inputs are converted to Sage integers.

```
sage: w = LCM_list([int(3), int(9), '30']); w
90
sage: type(w)
<type 'sage.rings.integer.Integer'>
```

clear_mpz_globals()

free_integer_pool()

gmp_randrange()

init_mpz_globals()

class int_to_Z()

is_Integer()

Return true if x is of the Sage integer type.

EXAMPLES:

```
sage: from sage.rings.integer import is_Integer
sage: is_Integer(2)
True
sage: is_Integer(2/1)
False
sage: is_Integer(int(2))
False
sage: is_Integer(long(2))
False
sage: is_Integer('5')
False
```

class long_to_Z()

EXAMPLES:

```
sage: f = ZZ.coerce_map_from(long); f
Native morphism:
  From: Set of Python objects of type 'long'
  To:   Integer Ring
sage: f(1rL)
1
sage: f(-100000000000000000000001r)
-100000000000000000000001
```

make_integer()

Create a Sage integer from the base-32 Python *string* s. This is used in unpickling integers.

EXAMPLES:

```
sage: from sage.rings.integer import make_integer
sage: make_integer('-29')
-73
sage: make_integer(29)
...
TypeError: expected string or Unicode object, sage.rings.integer.Integer found
```

parent()

24.3 Ring $\mathbf{Z}/n\mathbf{Z}$ of integers modulo n

EXAMPLES:

```
sage: R = Integers(97)
sage: a = R(5)
sage: a**1000000000000000000000000000000000000000000000000000000000000000000000000000000
61
```

This example illustrates the relation between $\mathbf{Z}/p\mathbf{Z}$ and $\mathbf{F}_p$. In particular, there is a canonical map to $\mathbf{F}_p$, but not in the other direction.

```
sage: r = Integers(7)
sage: s = GF(7)
sage: r.has_coerce_map_from(s)
False
sage: s.has_coerce_map_from(r)
```

```
True
sage: s(1) + r(1)
2
sage: parent(s(1) + r(1))
Finite Field of size 7
sage: parent(r(1) + s(1))
Finite Field of size 7
```

We list the elements of $\mathbf{Z}/3\mathbf{Z}$

```
sage: R = Integers(3)
sage: list(R)
[0, 1, 2]
```

AUTHORS:

- William Stein (initial code)
- David Joyner (2005-12-22): most examples
- Robert Bradshaw (2006-08-24): convert to SageX (Cython)
- William Stein (2007-04-29): square_roots_of_one

class **IntegerModFactory**()

Return the quotient ring $\mathbf{Z}/n\mathbf{Z}$.

INPUT:

•`order` - integer (default: 0), positive or negative

EXAMPLES:

```
sage: IntegerModRing(15)
Ring of integers modulo 15
sage: IntegerModRing(7)
Ring of integers modulo 7
sage: IntegerModRing(-100)
Ring of integers modulo 100
```

Note that you can also use `Integers`, which is a synonym for `IntegerModRing`.

```
sage: Integers(18)
Ring of integers modulo 18
sage: Integers() is Integers(0) is ZZ
True
```

create_key(*order=0*)

create_object(*version, order*)

EXAMPLES:

```
sage: R = Integers(10)
sage: loads(dumps(R)) is R
True
```

class **IntegerModRing_generic**(*order, cache=None*)

The ring of integers modulo N, with N composite.

EXAMPLES:

```
sage: R = IntegerModRing(97)
sage: a = R(5)
sage: a**(10^62)
61
```

cardinality()

characteristic()

EXAMPLES:

```
sage: R = IntegerModRing(18)
sage: FF = IntegerModRing(17)
sage: FF.characteristic()
17
sage: R.characteristic()
18
```

coerce_map_from_impl(S)

EXAMPLES:

```
sage: R = Integers(15)
sage: f = R.coerce_map_from(Integers(450)); f
Natural morphism:
  From: Ring of integers modulo 450
  To:   Ring of integers modulo 15
sage: f(-1)
14
sage: f = R.coerce_map_from(int); f
Native morphism:
  From: Set of Python objects of type 'int'
  To:   Ring of integers modulo 15
sage: f(-1r)
14
sage: f = R.coerce_map_from(ZZ); f
Natural morphism:
  From: Integer Ring
  To:   Ring of integers modulo 15
sage: f(-1)
14
sage: f = R.coerce_map_from(Integers(10)); print f
None
sage: f = R.coerce_map_from(QQ); print f
None
```

factored_order()

EXAMPLES:

```
sage: R = IntegerModRing(18)
sage: FF = IntegerModRing(17)
sage: R.factored_order()
2 * 3^2
sage: FF.factored_order()
17
```

field()

If this ring is a field, return the corresponding field as a finite field, which may have extra functionality and structure. Otherwise, raise a ValueError.

EXAMPLES:

```
sage: R = Integers(7); R
Ring of integers modulo 7
sage: R.field()
Finite Field of size 7
sage: R = Integers(9)
sage: R.field()
...
ValueError: self must be a field
```

is_field()

Return True precisely if the order is prime.

EXAMPLES:

```
sage: R = IntegerModRing(18)
sage: R.is_field()
False
sage: FF = IntegerModRing(17)
sage: FF.is_field()
True
```

is_finite()

Return True since Z/NZ is finite for all positive N.

EXAMPLES:

```
sage: R = IntegerModRing(18)
sage: R.is_finite()
True
```

is_integral_domain()

Return True if and only if the order of self is prime.

EXAMPLES:

```
sage: Integers(389).is_integral_domain()
True
sage: Integers(389^2).is_integral_domain()
False
```

is_noetherian()

EXAMPLES:

```
sage: Integers(8).is_noetherian()
True
```

krull_dimension()

EXAMPLES:

```
sage: Integers(18).krull_dimension()
0
```

list_of_elements_of_multiplicative_group()

modulus()

Return the polynomial $x - 1$ over this ring.

Note: This function exists for consistency with the finite-field modulus function.

EXAMPLES:

```
sage: R = IntegerModRing(18)
sage: R.modulus()
x + 17
sage: R = IntegerModRing(17)
```

```
sage: R.modulus()
x + 16
```

multiplicative_generator()

Return a generator for the multiplicative group of this ring, assuming the multiplicative group is cyclic. Use the unit_gens function to obtain generators even in the non-cyclic case.

EXAMPLES:

```
sage: R = Integers(7); R
Ring of integers modulo 7
sage: R.multiplicative_generator()
3
sage: R = Integers(9)
sage: R.multiplicative_generator()
2
sage: Integers(8).multiplicative_generator()
...
ValueError: multiplicative group of this ring is not cyclic
sage: Integers(4).multiplicative_generator()
3
sage: Integers(25*3).multiplicative_generator()
...
ValueError: multiplicative group of this ring is not cyclic
sage: Integers(25*3).unit_gens()
[26, 52]
sage: Integers(162).unit_gens()
[83]
```

multiplicative_group_is_cyclic()

Return True if the multiplicative group of this field is cyclic. This is the case exactly when the order is less than 8, a power of an odd prime, or twice a power of an odd prime.

EXAMPLES:

```
sage: R = Integers(7); R
Ring of integers modulo 7
sage: R.multiplicative_group_is_cyclic()
True
sage: R = Integers(9)
sage: R.multiplicative_group_is_cyclic()
True
sage: Integers(8).multiplicative_group_is_cyclic()
False
sage: Integers(4).multiplicative_group_is_cyclic()
True
sage: Integers(25*3).multiplicative_group_is_cyclic()
False
```

We test that #5250 is fixed:

```
sage: Integers(162).multiplicative_group_is_cyclic()
True
```

multiplicative_subgroups()

Return generators for each subgroup of $(\mathbf{Z}/N\mathbf{Z})^*$.

EXAMPLES:

```
sage: Integers(5).multiplicative_subgroups()
[[2], [4], []]
sage: Integers(15).multiplicative_subgroups()
```

```
[[11, 7], [4, 11], [8], [11], [14], [7], [4], []]
sage: Integers(2).multiplicative_subgroups()
[[]]
sage: len(Integers(341).multiplicative_subgroups())
80
```

order()

quadratic_nonresidue()

Return a quadratic non-residue in self.

EXAMPLES:

```
sage: R = Integers(17)
sage: R.quadratic_nonresidue()
3
sage: R(3).is_square()
False
```

random_element(*bound=None*)

Return a random element of this ring.

If bound is not None, return the coercion of an integer in the interval [-bound, bound] into this ring.

EXAMPLES:

```
sage: R = IntegerModRing(18)
sage: R.random_element()
2
```

square_roots_of_one()

Return all square roots of 1 in self, i.e., all solutions to $x^2 - 1 = 0$.

OUTPUT:

- `tuple` - the square roots of 1 in self.

EXAMPLES:

```
sage: R = Integers(2^10)
sage: [x for x in R if x^2 == 1]
[1, 511, 513, 1023]
sage: R.square_roots_of_one()
(1, 511, 513, 1023)

sage: v = Integers(9*5).square_roots_of_one(); v
(1, 19, 26, 44)
sage: [x^2 for x in v]
[1, 1, 1, 1]
sage: v = Integers(9*5*8).square_roots_of_one(); v
(1, 19, 71, 89, 91, 109, 161, 179, 181, 199, 251, 269, 271, 289, 341, 359)
sage: [x^2 for x in v]
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
```

unit_gens()

Returns generators for the unit group $(\mathbf{Z}/N\mathbf{Z})^*$.

We compute the list of generators using a deterministic algorithm, so the generators list will always be the same. For each odd prime divisor of N there will be exactly one corresponding generator; if N is even there will be 0, 1 or 2 generators according to whether 2 divides N to order 1, 2 or ≥ 3.

INPUT: (none)

OUTPUT:

- `list` - a list of elements of self

EXAMPLES:

```
sage: R = IntegerModRing(18)
sage: R.unit_gens()
[11]
sage: R = IntegerModRing(17)
sage: R.unit_gens()
[3]
sage: IntegerModRing(next_prime(10^30)).unit_gens()
[5]
```

unit_group_exponent()
EXAMPLES:

```
sage: R = IntegerModRing(17)
sage: R.unit_group_exponent()
16
sage: R = IntegerModRing(18)
sage: R.unit_group_exponent()
6
```

unit_group_order()
Return the order of the unit group of this residue class ring.
EXAMPLES;

```
sage: R = Integers(500)
sage: R.unit_group_order()
200
```

crt(*v*)
INPUT: v - (list) a lift of elements of rings.IntegerMod(n), for various coprime moduli n.

is_IntegerModRing(*x*)
Return True if x is an integer modulo ring.
EXAMPLES:

```
sage: from sage.rings.integer_mod_ring import is_IntegerModRing
sage: R = IntegerModRing(17)
sage: is_IntegerModRing(R)
True
sage: is_IntegerModRing(GF(13))
True
sage: is_IntegerModRing(GF(4, 'a'))
False
sage: is_IntegerModRing(10)
False
sage: is_IntegerModRing(ZZ)
False
```

24.4 Elements of $\mathbb{Z}/n\mathbb{Z}$

An element of the integers modulo n.

There are three types of integer_mod classes, depending on the size of the modulus.

- `IntegerMod_int` stores its value in a `int_fast32_t` (typically an `int`); this is used if the modulus is less than $\sqrt{2^{31}-1}$.

- `IntegerMod_int64` stores its value in a `int_fast64_t` (typically a `long long`); this is used if the modulus is less than $2^{31} - 1$.
- `IntegerMod_gmp` stores its value in a `mpz_t`; this can be used for an arbitrarily large modulus.

All extend `IntegerMod_abstract`.

For efficency reasons, it stores the modulus (in all three forms, if possible) in a common (cdef) class `NativeIntStruct` rather than in the parent.

AUTHORS:

- Robert Bradshaw: most of the work
- Didier Deshommes: bit shifting
- William Stein: editing and polishing; new arith architecture
- Robert Bradshaw: implement native is_square and square_root
- William Stein: sqrt

TESTS:

```
sage: R = Integers(101^3)
sage: a = R(824362); b = R(205942)
sage: a * b
851127
```

class Int_to_IntegerMod()

EXAMPLES:

We make sure it works for every type.

```
sage: from sage.rings.integer_mod import Int_to_IntegerMod
sage: Rs = [Integers(2**k) for k in range(1,50,10)]
sage: [type(R(0)) for R in Rs]
[<type 'sage.rings.integer_mod.IntegerMod_int'>, <type 'sage.rings.integer_mod.IntegerMod_int'>,
sage: fs = [Int_to_IntegerMod(R) for R in Rs]
sage: [f(-1) for f in fs]
[1, 2047, 2097151, 2147483647, 2199023255551]
```

IntegerMod()

Create an integer modulo n with the given parent.

This is mainly for internal use.

class IntegerMod_abstract()

additive_order()

Returns the additive order of self.

This is the same as `self.order()`.

EXAMPLES:

```
sage: Integers(20)(2).additive_order()
10
sage: Integers(20)(7).additive_order()
20
sage: Integers(90308402384902)(2).additive_order()
45154201192451
```

charpoly()

Returns the characteristic polynomial of this element.

EXAMPLES:

```
sage: k = GF(3)
sage: a = k.gen()
sage: a.charpoly('x')
x + 2
sage: a + 2
0
```

AUTHORS:

- Craig Citro

crt()

Use the Chinese Remainder Theorem to find an element of the integers modulo the product of the moduli that reduces to `self` and to `other`. The modulus of `other` must be coprime to the modulus of `self`.

EXAMPLES:

```
sage: a = mod(3,5)
sage: b = mod(2,7)
sage: a.crt(b)
23

sage: a = mod(37,10^8)
sage: b = mod(9,3^8)
sage: a.crt(b)
125900000037

sage: b = mod(0,1)
sage: a.crt(b) == a
True
sage: a.crt(b).modulus()
100000000
```

AUTHORS:

- Robert Bradshaw

is_nilpotent()

Return `True` if `self` is nilpotent, i.e., some power of `self` is zero.

EXAMPLES:

```
sage: a = Integers(90384098234^3)
sage: factor(a.order())
2^3 * 191^3 * 236607587^3
sage: b = a(2*191)
sage: b.is_nilpotent()
False
sage: b = a(2*191*236607587)
sage: b.is_nilpotent()
True
```

ALGORITHM: Let $m \geq \log_2(n)$, where n is the modulus. Then $x \in \mathbf{Z}/n\mathbf{Z}$ is nilpotent if and only if $x^m = 0$.

PROOF: This is clear if you reduce to the prime power case, which you can do via the Chinese Remainder Theorem.

We could alternatively factor n and check to see if the prime divisors of n all divide x. This is asymptotically slower :-).

is_one()

is_square()

EXAMPLES:

```
sage: Mod(3,17).is_square()
False
sage: Mod(9,17).is_square()
True
sage: Mod(9,17*19^2).is_square()
True
sage: Mod(-1,17^30).is_square()
True
sage: Mod(1/9, next_prime(2^40)).is_square()
True
sage: Mod(1/25, next_prime(2^90)).is_square()
True
```

TESTS:

```
sage: Mod(1/25, 2^8).is_square()
True
sage: Mod(1/25, 2^40).is_square()
True
```

ALGORITHM: Calculate the Jacobi symbol $(\texttt{self}/p)$ at each prime p dividing n. It must be 1 or 0 for each prime, and if it is 0 mod p, where $p^k||n$, then $ord_p(\texttt{self})$ must be even or greater than k.

The case $p = 2$ is handled separately.

AUTHORS:

- Robert Bradshaw

is_unit()

log()

Return an integer x such that $b^x = a$, where a is `self`.

INPUT:

- `self` - unit modulo n
- `b` - a **generator** of the multiplicative group modulo n. If `b` is not given, `R.multiplicative_generator()` is used, where `R` is the parent of `self`.

OUTPUT: Integer x such that $b^x = a$.

Note: The base must not be too big or the current implementation, which is in PARI, will fail.

EXAMPLES:

```
sage: r = Integers(125)
sage: b = r.multiplicative_generator()^3
sage: a = b^17
sage: a.log(b)
17
sage: a.log()
63
```

A bigger example.

```
sage: FF = FiniteField(2^32+61)
sage: c = FF(4294967356)
sage: x = FF(2)
sage: a = c.log(x)
sage: a
2147483678
sage: x^a
4294967356
```

Things that can go wrong. E.g., if the base is not a generator for the multiplicative group, or not even a unit. You can also use the generic function `discrete_log`.

```
sage: a = Mod(9, 100); b = Mod(3,100)
sage: a.log(b)
...
ValueError: base (=3) for discrete log must generate multiplicative group
sage: sage.groups.generic.discrete_log(b^2,b)
2
sage: a = Mod(16, 100); b = Mod(4,100)
sage: a.log(b)
...
ValueError:  (8)
PARI failed to compute discrete log (perhaps base is not a generator or is too large)
sage: sage.groups.generic.discrete_log(a,b)
...
ZeroDivisionError: Inverse does not exist.
```

AUTHORS:

- David Joyner and William Stein (2005-11)
- William Stein (2007-01-27): update to use PARI as requested by David Kohel.

minimal_polynomial()

Returns the minimal polynomial of this element.

EXAMPLES: sage: GF(241, 'a')(1).minimal_polynomial(var = 'z') z + 240

minpoly()

Returns the minimal polynomial of this element.

EXAMPLES: sage: GF(241, 'a')(1).minpoly() x + 240

modulus()

EXAMPLES:

```
sage: Mod(3,17).modulus()
17
```

multiplicative_order()

Returns the multiplicative order of self.

EXAMPLES:

```
sage: Mod(-1,5).multiplicative_order()
2
sage: Mod(1,5).multiplicative_order()
1
sage: Mod(0,5).multiplicative_order()
...
ArithmeticError: multiplicative order of 0 not defined since it is not a unit modulo 5
```

norm()

Returns the norm of this element, which is itself. (This is here for compatibility with higher order finite fields.)

EXAMPLES:

```
sage: k = GF(691)
sage: a = k(389)
sage: a.norm()
389
```

AUTHORS:

- Craig Citro

nth_root()

Returns an nth root of `self`.

INPUT:

- `n` - integer ≥ 1 (must fit in C `int` type)
- `all` - bool (default: `False`); if `True`, return all nth roots of `self`, instead of just one.

OUTPUT: If self has an nth root, returns one (if `all` is false) or a list of all of them (if `all` is true). Otherwise, raises a `ValueError`.

AUTHORS:

- David Roe (2007-10-3)

EXAMPLES:

```
sage: k.<a> = GF(29)
sage: b = a^2 + 5*a + 1
sage: b.nth_root(5)
24
sage: b.nth_root(7)
...
ValueError: no nth root
sage: b.nth_root(4, all=True)
[21, 20, 9, 8]
```

pari()

polynomial()

Returns a constant polynomial representing this value.

EXAMPLES:

```
sage: k = GF(7)
sage: a = k.gen(); a
1
sage: a.polynomial()
1
sage: type(a.polynomial())
<type 'sage.rings.polynomial.polynomial_zmod_flint.Polynomial_zmod_flint'>
```

rational_reconstruction()

EXAMPLES:

```
sage: R = IntegerModRing(97)
sage: a = R(2) / R(3)
sage: a
33
sage: a.rational_reconstruction()
2/3
```

sqrt()

Returns square root or square roots of `self` modulo n.

INPUT:

- `extend` - bool (default: `True`); if `True`, return a square root in an extension ring, if necessary. Otherwise, raise a `ValueError` if the square root is not in the base ring.
- `all` - bool (default: `False`); if `True`, return {all} square roots of self, instead of just one.

ALGORITHM: Calculates the square roots mod p for each of the primes p dividing the order of the ring, then lifts them p-adically and uses the CRT to find a square root mod n.

See also `square_root_mod_prime_power` and `square_root_mod_prime` (in this module) for more algorithmic details.

EXAMPLES:

```
sage: mod(-1, 17).sqrt()
4
sage: mod(5, 389).sqrt()
86
sage: mod(7, 18).sqrt()
5
sage: a = mod(14, 5^60).sqrt()
sage: a*a
14
sage: mod(15, 389).sqrt(extend=False)
...
ValueError: self must be a square
sage: Mod(1/9, next_prime(2^40)).sqrt()^(-2)
9
sage: Mod(1/25, next_prime(2^90)).sqrt()^(-2)
25

sage: a = Mod(3,5); a
3
sage: x = Mod(-1, 360)
sage: x.sqrt(extend=False)
...
ValueError: self must be a square
sage: y = x.sqrt(); y
sqrt359
sage: y.parent()
Univariate Quotient Polynomial Ring in sqrt359 over Ring of integers modulo 360 with modulus
sage: y^2
359
```

We compute all square roots in several cases:

```
sage: R = Integers(5*2^3*3^2); R
Ring of integers modulo 360
sage: R(40).sqrt(all=True)
[20, 160, 200, 340]
sage: [x for x in R if x^2 == 40]  # Brute force verification
[20, 160, 200, 340]
sage: R(1).sqrt(all=True)
[1, 19, 71, 89, 91, 109, 161, 179, 181, 199, 251, 269, 271, 289, 341, 359]
sage: R(0).sqrt(all=True)
[0, 60, 120, 180, 240, 300]

sage: R = Integers(5*13^3*37); R
Ring of integers modulo 406445
sage: v = R(-1).sqrt(all=True); v
[78853, 111808, 160142, 193097, 213348, 246303, 294637, 327592]
sage: [x^2 for x in v]
[406444, 406444, 406444, 406444, 406444, 406444, 406444, 406444]
sage: v = R(169).sqrt(all=True); min(v), -max(v), len(v)
(13, 13, 104)
sage: all([x^2==169 for x in v])
True
```

Modulo a power of 2:

```
sage: R = Integers(2^7); R
Ring of integers modulo 128
sage: a = R(17)
```

```
sage: a.sqrt()
23
sage: a.sqrt(all=True)
[23, 41, 87, 105]
sage: [x for x in R if x^2==17]
[23, 41, 87, 105]
```

square_root()

Returns square root or square roots of `self` modulo n.

INPUT:

- `extend` - bool (default: `True`); if `True`, return a square root in an extension ring, if necessary. Otherwise, raise a `ValueError` if the square root is not in the base ring.
- `all` - bool (default: `False`); if `True`, return {all} square roots of self, instead of just one.

ALGORITHM: Calculates the square roots mod p for each of the primes p dividing the order of the ring, then lifts them p-adically and uses the CRT to find a square root mod n.

See also `square_root_mod_prime_power` and `square_root_mod_prime` (in this module) for more algorithmic details.

EXAMPLES:

```
sage: mod(-1, 17).sqrt()
4
sage: mod(5, 389).sqrt()
86
sage: mod(7, 18).sqrt()
5
sage: a = mod(14, 5^60).sqrt()
sage: a*a
14
sage: mod(15, 389).sqrt(extend=False)
...
ValueError: self must be a square
sage: Mod(1/9, next_prime(2^40)).sqrt()^(-2)
9
sage: Mod(1/25, next_prime(2^90)).sqrt()^(-2)
25

sage: a = Mod(3,5); a
3
sage: x = Mod(-1, 360)
sage: x.sqrt(extend=False)
...
ValueError: self must be a square
sage: y = x.sqrt(); y
sqrt359
sage: y.parent()
Univariate Quotient Polynomial Ring in sqrt359 over Ring of integers modulo 360 with modulus
sage: y^2
359
```

We compute all square roots in several cases:

```
sage: R = Integers(5*2^3*3^2); R
Ring of integers modulo 360
sage: R(40).sqrt(all=True)
[20, 160, 200, 340]
sage: [x for x in R if x^2 == 40]  # Brute force verification
[20, 160, 200, 340]
```

```
sage: R(1).sqrt(all=True)
[1, 19, 71, 89, 91, 109, 161, 179, 181, 199, 251, 269, 271, 289, 341, 359]
sage: R(0).sqrt(all=True)
[0, 60, 120, 180, 240, 300]

sage: R = Integers(5*13^3*37); R
Ring of integers modulo 406445
sage: v = R(-1).sqrt(all=True); v
[78853, 111808, 160142, 193097, 213348, 246303, 294637, 327592]
sage: [x^2 for x in v]
[406444, 406444, 406444, 406444, 406444, 406444, 406444, 406444]
sage: v = R(169).sqrt(all=True); min(v), -max(v), len(v)
(13, 13, 104)
sage: all([x^2==169 for x in v])
True
```

Modulo a power of 2:

```
sage: R = Integers(2^7); R
Ring of integers modulo 128
sage: a = R(17)
sage: a.sqrt()
23
sage: a.sqrt(all=True)
[23, 41, 87, 105]
sage: [x for x in R if x^2==17]
[23, 41, 87, 105]
```

trace()

Returns the trace of this element, which is itself. (This is here for compatibility with higher order finite fields.)

EXAMPLES:

```
sage: k = GF(691)
sage: a = k(389)
sage: a.trace()
389
```

AUTHORS:

- Craig Citro

class IntegerMod_gmp()

Elements of $\mathbf{Z}/n\mathbf{Z}$ for n not small enough to be operated on in word size.

AUTHORS:

- Robert Bradshaw (2006-08-24)

is_one()

Returns `True` if this is 1, otherwise `False`.

EXAMPLES:

```
sage: mod(1,5^23).is_one()
True
sage: mod(0,5^23).is_one()
False
```

is_unit()

Return True iff this element is a unit.

EXAMPLES:

```
sage: mod(13, 5^23).is_unit()
True
sage: mod(25, 5^23).is_unit()
False
```

lift()

Lift an integer modulo n to the integers.

EXAMPLES:

```
sage: a = Mod(8943, 2^70); type(a)
<type 'sage.rings.integer_mod.IntegerMod_gmp'>
sage: lift(a)
8943
sage: a.lift()
8943
```

class IntegerMod_hom()

class IntegerMod_int()

Elements of $\mathbf{Z}/n\mathbf{Z}$ for n small enough to be operated on in 32 bits

AUTHORS:

- Robert Bradshaw (2006-08-24)

is_one()

Returns `True` if this is 1, otherwise `False`.

EXAMPLES:

```
sage: mod(6,5).is_one()
True
sage: mod(0,5).is_one()
False
```

is_unit()

Return True iff this element is a unit

EXAMPLES:

```
sage: a=Mod(23,100)
sage: a.is_unit()
True
sage: a=Mod(24,100)
sage: a.is_unit()
False
```

lift()

Lift an integer modulo n to the integers.

EXAMPLES:

```
sage: a = Mod(8943, 2^10); type(a)
<type 'sage.rings.integer_mod.IntegerMod_int'>
sage: lift(a)
751
sage: a.lift()
751
```

sqrt()

Returns square root or square roots of `self` modulo n.

INPUT:

- `extend` - bool (default: `True`); if `True`, return a square root in an extension ring, if necessary. Otherwise, raise a `ValueError` if the square root is not in the base ring.
- `all` - bool (default: `False`); if `True`, return {all} square roots of self, instead of just one.

ALGORITHM: Calculates the square roots mod p for each of the primes p dividing the order of the ring, then lifts them p-adically and uses the CRT to find a square root mod n.

See also `square_root_mod_prime_power` and `square_root_mod_prime` (in this module) for more algorithmic details.

EXAMPLES:

```
sage: mod(-1, 17).sqrt()
4
sage: mod(5, 389).sqrt()
86
sage: mod(7, 18).sqrt()
5
sage: a = mod(14, 5^60).sqrt()
sage: a*a
14
sage: mod(15, 389).sqrt(extend=False)
...
ValueError: self must be a square
sage: Mod(1/9, next_prime(2^40)).sqrt()^(-2)
9
sage: Mod(1/25, next_prime(2^90)).sqrt()^(-2)
25

sage: a = Mod(3,5); a
3
sage: x = Mod(-1, 360)
sage: x.sqrt(extend=False)
...
ValueError: self must be a square
sage: y = x.sqrt(); y
sqrt359
sage: y.parent()
Univariate Quotient Polynomial Ring in sqrt359 over Ring of integers modulo 360 with modulus
sage: y^2
359
```

We compute all square roots in several cases:

```
sage: R = Integers(5*2^3*3^2); R
Ring of integers modulo 360
sage: R(40).sqrt(all=True)
[20, 160, 200, 340]
sage: [x for x in R if x^2 == 40]  # Brute force verification
[20, 160, 200, 340]
sage: R(1).sqrt(all=True)
[1, 19, 71, 89, 91, 109, 161, 179, 181, 199, 251, 269, 271, 289, 341, 359]
sage: R(0).sqrt(all=True)
[0, 60, 120, 180, 240, 300]

sage: R = Integers(5*13^3*37); R
Ring of integers modulo 406445
sage: v = R(-1).sqrt(all=True); v
[78853, 111808, 160142, 193097, 213348, 246303, 294637, 327592]
sage: [x^2 for x in v]
[406444, 406444, 406444, 406444, 406444, 406444, 406444, 406444]
```

```
sage: v = R(169).sqrt(all=True); min(v), -max(v), len(v)
(13, 13, 104)
sage: all([x^2==169 for x in v])
True
```

Modulo a power of 2:

```
sage: R = Integers(2^7); R
Ring of integers modulo 128
sage: a = R(17)
sage: a.sqrt()
23
sage: a.sqrt(all=True)
[23, 41, 87, 105]
sage: [x for x in R if x^2==17]
[23, 41, 87, 105]
```

class IntegerMod_int64()

Elements of $\mathbf{Z}/n\mathbf{Z}$ for n small enough to be operated on in 64 bits

AUTHORS:

- Robert Bradshaw (2006-09-14)

is_one()

Returns `True` if this is 1, otherwise `False`.

EXAMPLES:

```
sage: (mod(-1,5^10)^2).is_one()
True
sage: mod(0,5^10).is_one()
False
```

is_unit()

Return True iff this element is a unit.

EXAMPLES:

```
sage: mod(13, 5^10).is_unit()
True
sage: mod(25, 5^10).is_unit()
False
```

lift()

Lift an integer modulo n to the integers.

EXAMPLES:

```
sage: a = Mod(8943, 2^25); type(a)
<type 'sage.rings.integer_mod.IntegerMod_int64'>
sage: lift(a)
8943
sage: a.lift()
8943
```

class IntegerMod_to_IntegerMod()

Very fast IntegerMod to IntegerMod homomorphism.

EXAMPLES:

```
sage: from sage.rings.integer_mod import IntegerMod_to_IntegerMod
sage: Rs = [Integers(3**k) for k in range(1,30,5)]
sage: [type(R(0)) for R in Rs]
```

```
[<type 'sage.rings.integer_mod.IntegerMod_int'>, <type 'sage.rings.integer_mod.IntegerMod_int'>,
sage: fs = [IntegerMod_to_IntegerMod(S, R) for R in Rs for S in Rs if S is not R and S.order() >
sage: all([f(-1) == f.codomain()(-1) for f in fs])
True
sage: [f(-1) for f in fs]
[2, 2, 2, 2, 2, 728, 728, 728, 728, 177146, 177146, 177146, 43046720, 43046720, 10460353202]
```

class Integer_to_IntegerMod()

Fast $\mathbf{Z} \to \mathbf{Z}/n\mathbf{Z}$ morphism.

EXAMPLES:

We make sure it works for every type.

```
sage: from sage.rings.integer_mod import Integer_to_IntegerMod
sage: Rs = [Integers(10), Integers(10^5), Integers(10^10)]
sage: [type(R(0)) for R in Rs]
[<type 'sage.rings.integer_mod.IntegerMod_int'>, <type 'sage.rings.integer_mod.IntegerMod_int64'
sage: fs = [Integer_to_IntegerMod(R) for R in Rs]
sage: [f(-1) for f in fs]
[9, 99999, 9999999999]
```

Mod()

Return the equivalence class of n modulo m as an element of $\mathbf{Z}/m\mathbf{Z}$.

EXAMPLES:

```
sage: x = Mod(12345678, 32098203845329048)
sage: x
12345678
sage: x^100
1017322209155072
```

You can also use the lowercase version:

```
sage: mod(12,5)
2
```

class NativeIntStruct()

We store the various forms of the modulus here rather than in the parent for efficiency reasons.

We may also store a cached table of all elements of a given ring in this class.

precompute_table()

Function to compute and cache all elements of this class.

If inverses==True, also computes and caches the inverses of the invertible elments

fast_lucas()

Return $V_k(P, 1)$ where V_k is the Lucas function defined by the recursive relation

$V_k(P, Q) = PV_{k-1}(P, Q) - QV_{k-2}(P, Q)$

with $V_0 = 2, V_1(P_Q) = P$.

REFERENCES:

•H. Postl. 'Fast evaluation of Dickson Polynomials' Contrib. to General Algebra, Vol. 6 (1988) pp. 223-225

AUTHORS:

•Robert Bradshaw

TESTS:

```
sage: from sage.rings.integer_mod import fast_lucas, slow_lucas
sage: all([fast_lucas(k, a) == slow_lucas(k, a)
...        for a in Integers(23)
...        for k in range(13)])
True
```

is_IntegerMod()

Return `True` if and only if x is an integer modulo n.

EXAMPLES:

```
sage: from sage.rings.integer_mod import is_IntegerMod
sage: is_IntegerMod(5)
False
sage: is_IntegerMod(Mod(5,10))
True
```

makeNativeIntStruct()

Function to convert a Sage Integer into class NativeIntStruct.

Note: This function seems completely redundant, and is not used anywhere.

mod()

Return the equivalence class of n modulo m as an element of $\mathbf{Z}/m\mathbf{Z}$.

EXAMPLES:

```
sage: x = Mod(12345678, 32098203845329048)
sage: x
12345678
sage: x^100
1017322209155072
```

You can also use the lowercase version:

```
sage: mod(12,5)
2
```

slow_lucas()

Lucas function defined using the standard definition, for consistency testing.

square_root_mod_prime()

Calculates the square root of a, where a is an integer mod p; if a is not a perfect square, this returns an (incorrect) answer without checking.

ALGORITHM: Several cases based on residue class of $p \bmod 16$.

- $p \bmod 2 = 0$: $p = 2$ so $\sqrt{a} = a$.
- $p \bmod 4 = 3$: $\sqrt{a} = a^{(p+1)/4}$.
- $p \bmod 8 = 5$: $\sqrt{a} = \zeta i a$ where $\zeta = (2a)^{(p-5)/8}$, $i = \sqrt{-1}$.
- $p \bmod 16 = 9$: Similar, work in a bi-quadratic extension of $\mathbf{F}_p$ for small p, Tonelli and Shanks for large p.
- $p \bmod 16 = 1$: Tonelli and Shanks.

AUTHORS:

•Robert Bradshaw

TESTS: Every case appears in the first hundred primes.

```
sage: from sage.rings.integer_mod import square_root_mod_prime   # sqrt() uses brute force for s
sage: all([square_root_mod_prime(a*a)^2 == a*a
...        for p in prime_range(100)
...        for a in Integers(p)])
True
```

square_root_mod_prime_power()

Calculates the square root of a, where a is an integer mod p^e.

ALGORITHM: Perform p-adically by stripping off even powers of p to get a unit and lifting $\sqrt{unit} \bmod p$ via Newton's method.

AUTHORS:

•Robert Bradshaw

EXAMPLES:

```
sage: from sage.rings.integer_mod import square_root_mod_prime_power
sage: a=Mod(17,2^20)
sage: b=square_root_mod_prime_power(a,2,20)
sage: b^2 == a
True

sage: a=Mod(72,97^10)
sage: b=square_root_mod_prime_power(a,97,10)
sage: b^2 == a
True
```

24.5 Field Q of Rational Numbers.

The class `RationalField` represents the field **Q** of (arbitrary precision) rational numbers. Each rational number is an instance of the class `Rational`.

Interactively, an instance of `RationalField` is available as `QQ`.

```
sage: QQ
Rational Field
```

Values of various types can be converted to rational numbers by using the `__call__` method of `RationalField` (that is, by treating `QQ` as a function).

```
sage: RealField(9).pi()
3.1
sage: QQ(RealField(9).pi())
22/7
sage: QQ(RealField().pi())
245850922/78256779
sage: QQ(35)
35
sage: QQ('12/347')
12/347
sage: QQ(exp(pi*I))
-1
sage: x = polygen(ZZ)
sage: QQ((3*x)/(4*x))
3/4
```

TEST:

```
sage: Q = RationalField()
sage: Q == loads(dumps(Q))
True
sage: RationalField() is RationalField()
True
```

class RationalField()

The class RationalField represents the field **Q** of rational numbers.

EXAMPLES:

```
sage: a = long(90182430982109382109381209381092830918309183209 1)
sage: b = QQ(a); b
901824309821093821093812093810928309183091832091
sage: QQ(b)
901824309821093821093812093810928309183091832091
sage: QQ(int(93820984323))
93820984323
sage: QQ(ZZ(90182430982109382109381209381092830918309183209 1))
901824309821093821093812093810928309183091832091
sage: QQ('-930482/9320842317')
-930482/9320842317
sage: QQ((-930482, 9320842317))
-930482/9320842317
sage: QQ([9320842317])
9320842317
sage: QQ(pari(3902938402384092830948284209843028439824398239 4))
390293840238409283094828420984302843982439823 94
sage: QQ('sage')
...
TypeError: unable to convert sage to a rational
```

Coercion from the reals to the rational is done by default using continued fractions.

```
sage: QQ(RR(3929329/32))
3929329/32
sage: QQ(-RR(3929329/32))
-3929329/32
sage: QQ(RR(1/7)) - 1/7
0
```

If you specify an optional second base argument, then the string representation of the float is used.

```
sage: QQ(23.2, 2)
6530219459687219/281474976710656
sage: 6530219459687219.0/281474976710656
23.199999999999999
sage: a = 23.2; a
23.200000000000000
sage: QQ(a, 10)
116/5
```

Here's a nice example involving elliptic curves:

```
sage: E = EllipticCurve('11a')
sage: L = E.lseries().at1(300)[0]; L
0.253841860855911
sage: O = E.period_lattice().omega(); O
1.26920930427955
sage: t = L/O; t
0.200000000000...
sage: QQ(RealField(45)(t))
1/5
```

absolute_degree()

EXAMPLES:

```
sage: QQ.absolute_degree()
1
```

characteristic()

Return 0, since the rational field has characteristic 0.

EXAMPLES:

```
sage: c = QQ.characteristic(); c
0
sage: parent(c)
Integer Ring
```

class_number()

Return the class number of the field of rational numbers, which is 1.

EXAMPLES:

```
sage: QQ.class_number()
1
```

completion(*p, prec, extras={}*)

complex_embedding(*prec=53*)

Return embedding of the rational numbers into the complex numbers.

EXAMPLES:

```
sage: QQ.complex_embedding()
Ring morphism:
  From: Rational Field
  To:   Complex Field with 53 bits of precision
  Defn: 1 |--> 1.00000000000000
sage: QQ.complex_embedding(20)
Ring morphism:
  From: Rational Field
```

```
  To:   Complex Field with 20 bits of precision
  Defn: 1 |--> 1.0000
```

construction()

degree()

EXAMPLES:

```
sage: QQ.degree()
1
```

discriminant()

Return the discriminant of the field of rational numbers, which is 1.

EXAMPLES:

```
sage: QQ.discriminant()
1
```

embeddings(*K*)

Return list of the one embedding of $\mathbf{Q}$ into K, if it exists.

EXAMPLES:

```
sage: QQ.embeddings(QQ)
[Ring Coercion endomorphism of Rational Field]
sage: QQ.embeddings(CyclotomicField(5))
[Ring Coercion morphism:
  From: Rational Field
  To:   Cyclotomic Field of order 5 and degree 4]
```

K must have characteristic 0:

```
sage: QQ.embeddings(GF(3))
...
ValueError: no embeddings of the rational field into K.
```

extension(*poly, names, check=True, embedding=None*)

EXAMPLES:

We make a single absolute extension:

```
sage: K.<a> = QQ.extension(x^3 + 5); K
Number Field in a with defining polynomial x^3 + 5
```

We make an extension generated by roots of two polynomials:

```
sage: K.<a,b> = QQ.extension([x^3 + 5, x^2 + 3]); K
Number Field in a with defining polynomial x^3 + 5 over its base field
sage: b^2
-3
sage: a^3
-5
```

gen(*n=0*)

EXAMPLES:

```
sage: QQ.gen()
1
```

gens()

EXAMPLES:

```
sage: QQ.gens()
(1,)
```

is_absolute()
$\mathbf{Q}$ is an absolute extension of $\mathbf{Q}$.
EXAMPLES:

```
sage: QQ.is_absolute()
True
```

is_atomic_repr()

is_field()
Return `True`, since the rational field is a field.
EXAMPLES:

```
sage: QQ.is_field()
True
```

is_finite()
Return `False`, since the rational field is not finite.
EXAMPLES:

```
sage: QQ.is_finite()
False
```

is_prime_field()
Return `True`, since $\mathbf{Q}$ is a prime field.
EXAMPLES:

```
sage: QQ.is_prime_field()
True
```

is_subring(K)
Return `True` if $\mathbf{Q}$ is a subring of K.
We are only able to determine this in some cases, e.g., when K is a field or of positive characteristic.
EXAMPLES:

```
sage: QQ.is_subring(QQ)
True
sage: QQ.is_subring(QQ['x'])
True
sage: QQ.is_subring(GF(7))
False
sage: QQ.is_subring(CyclotomicField(7))
True
sage: QQ.is_subring(ZZ)
False
sage: QQ.is_subring(Frac(ZZ))
True
```

maximal_order()
Return the maximal order of the rational numbers, i.e., the ring $\mathbf{Z}$ of integers.
EXAMPLES:

```
sage: QQ.maximal_order()
Integer Ring
sage: QQ.ring_of_integers ()
Integer Ring
```

ngens()
EXAMPLES:

```
sage: QQ.ngens()
1
```

number_field()

Return the number field associated to $\mathbf{Q}$. Since $\mathbf{Q}$ is a number field, this just returns $\mathbf{Q}$ again.

EXAMPLES:

```
sage: QQ.number_field() is QQ
True
```

order()

EXAMPLES:

```
sage: QQ.order()
+Infinity
```

power_basis()

Return a power basis for this number field over its base field.

The power basis is always [1] for the rational field. This method is defined to make the rational field behave more like a number field.

EXAMPLES:

```
sage: QQ.power_basis()
[1]
```

random_element(*num_bound=None, den_bound=None, distribution=None*)

EXAMPLES:

```
sage: QQ.random_element(10,10) # random output
-5/3
```

range_by_height(*start, end=None*)

Range function for rational numbers, ordered by height.

Returns a Python generator for the list of rational numbers with heights in `range(start, end)`. Follows the same convention as Python range, see range? for details.

See also QQ.__iter__?

EXAMPLES:

All rational numbers with height strictly less than 4:

```
sage: list(QQ.range_by_height(4))
[0, 1, -1, 1/2, -1/2, 2, -2, 1/3, -1/3, 3, -3, 2/3, -2/3, 3/2, -3/2]
sage: [a.height() for a in QQ.range_by_height(4)]
[1, 1, 1, 2, 2, 2, 2, 3, 3, 3, 3, 3, 3, 3, 3]
```

All rational numbers with height 2:

```
sage: list(QQ.range_by_height(2, 3))
[1/2, -1/2, 2, -2]
```

Nonsensical integer arguments will return an empty generator:

```
sage: list(QQ.range_by_height(3, 3))
[]
sage: list(QQ.range_by_height(10, 1))
[]
```

There are no rational numbers with height ≤ 0:

```
sage: list(QQ.range_by_height(-10, 1))
[]
```

signature()
Return the signature of the rational field, which is (1,0), since there are 1 real and no complex embeddings.
EXAMPLES:

```
sage: QQ.signature()
(1, 0)
```

zeta(*n=2*)
Return a root of unity in `self`.
INPUT:

- `n` - integer (default: 2) order of the root of unity

EXAMPLES:

```
sage: QQ.zeta()
-1
sage: QQ.zeta(2)
-1
sage: QQ.zeta(1)
1
sage: QQ.zeta(3)
...
ValueError: no n-th root of unity in rational field
```

frac(*n, d*)

is_RationalField(*x*)

24.6 Rational Numbers

AUTHORS:

- William Stein (2005): first version
- William Stein (2006-02-22): floor and ceil (pure fast GMP versions).
- Gonzalo Tornaria and William Stein (2006-03-02): greatly improved python/GMP conversion; hashing
- William Stein and Naqi Jaffery (2006-03-06): height, sqrt examples, and improve behavior of sqrt.
- David Harvey (2006-09-15): added nth_root
- Pablo De Napoli (2007-04-01): corrected the implementations of multiplicative_order, is_one; optimized __nonzero__ ; documented: lcm,gcd

TESTS:

```
sage: a = -2/3
sage: a == loads(dumps(a))
True
```

class Q_to_Z()
TESTS:

```
sage: type(ZZ.convert_map_from(QQ))
<type 'sage.rings.rational.Q_to_Z'>
```

section()

EXAMPLES:

```
sage: sage.rings.rational.Q_to_Z(QQ, ZZ).section()
Natural morphism:
  From: Integer Ring
  To:   Rational Field
```

class **Rational**()

A Rational number.

Rational numbers are implemented using the GMP C library.

EXAMPLES:

```
sage: a = -2/3
sage: type(a)
<type 'sage.rings.rational.Rational'>
sage: parent(a)
Rational Field
sage: Rational('1/0')
...
TypeError: unable to convert 1/0 to a rational
sage: Rational(1.5)
3/2
sage: Rational('9/6')
3/2
sage: Rational((2^99,2^100))
1/2
sage: Rational(("2", "10"), 16)
1/8
sage: Rational(QQbar(125/8).nth_root(3))
5/2
sage: Rational(AA(209735/343 - 17910/49*golden_ratio).nth_root(3) + 3*golden_ratio)
53/7
sage: QQ(float(1.5))
3/2
sage: QQ(RDF(1.2))
6/5
```

Conversion from PARI:

```
sage: Rational(pari('-939082/3992923'))
-939082/3992923
```

additive_order()

Return the additive order of self.

OUTPUT: integer or infinity

EXAMPLES:

```
sage: QQ(0).additive_order()
1
sage: QQ(1).additive_order()
+Infinity
```

ceil()

Return the ceiling of this rational number.

OUTPUT: Integer

If this rational number is an integer, this returns this number, otherwise it returns the floor of this number +1.

EXAMPLES:

```
sage: n = 5/3; n.ceil()
2
sage: n = -17/19; n.ceil()
0
sage: n = -7/2; n.ceil()
-3
sage: n = 7/2; n.ceil()
4
sage: n = 10/2; n.ceil()
5
```

charpoly()

Return the characteristic polynomial of this rational number. This will always be just var - self; this is really here so that code written for number fields won't crash when applied to rational numbers.

INPUT:

- var - a string

OUTPUT: Polynomial

EXAMPLES:

```
sage: (1/3).charpoly('x')
 x - 1/3
```

AUTHORS:

- Craig Citro

conjugate()

Return the complex conjugate of this rational number, which is the number itself.

EXAMPLES:

```
sage: n = 23/11
sage: n.conjugate()
23/11
```

content()

Return the content of self and other, i.e. the unique positive rational number c such that self/c and other/c are coprime integers.

other can be a rational number or a list of rational numbers.

EXAMPLES:

```
sage: a = 2/3
sage: a.content(2/3)
2/3
sage: a.content(1/5)
1/15
sage: a.content([2/5, 4/9])
2/45
```

copy()

Return a copy of self.

OUTPUT: Rational

EXAMPLES:

```
sage: a = -17/37
sage: a.copy() is a
False
```

Coercion does not make a new copy:

```
sage: QQ(a) is a
True
```

The constructor also makes a new copy:

```
sage: Rational(a) is a
False
```

denom()

Returns the denominator of this rational number.

EXAMPLES:

```
sage: x = 5/13
sage: x.denom()
13
sage: x = -9/3
sage: x.denom()
1
```

denominator()

Returns the denominator of this rational number.

EXAMPLES:

```
sage: x = -5/11
sage: x.denominator()
11
sage: x = 9/3
sage: x.denominator()
1
```

factor()

Return the factorization of this rational number.

OUTPUT: Factorization

EXAMPLES:

```
sage: (-4/17).factor()
-1 * 2^2 * 17^-1
```

Trying to factor 0 gives an arithmetic error:

```
sage: (0/1).factor()
...
ArithmeticError: Prime factorization of 0 not defined.
```

floor()

Return the floor of this rational number as an integer.

OUTPUT: Integer

EXAMPLES:

```
sage: n = 5/3; n.floor()
1
sage: n = -17/19; n.floor()
-1
sage: n = -7/2; n.floor()
-4
sage: n = 7/2; n.floor()
3
sage: n = 10/2; n.floor()
5
```

gamma()

Return the gamma function evaluated at self. This value is exact for integers and half-integers, otherwise a numerical approximation is returned.

EXAMPLES:

```
sage: gamma(1/2)
sqrt(pi)
sage: gamma(7/2)
15/8*sqrt(pi)
sage: gamma(-3/2)
4/3*sqrt(pi)
sage: gamma(6/1)
120
sage: gamma(1/3)
2.67893853470775
```

This function accepts an optional precision argument:

```
sage: (1/3).gamma(prec=100)
2.6789385347077476336556929410
sage: (1/2).gamma(prec=100)
1.7724538509055160272981674833
```

gcd()

Return a gcd of the rational numbers self and other.

If self = other = 0, this is by convention 0. In all other cases it can (mathematically) be any nonzero rational number, but for simplicity we choose to always return 1.

EXAMPLES:

```
sage: gcd(1/3, 2/1)
1
sage: gcd(1/1, 0/1)
1
sage: gcd(0/1, 0/1)
0
```

height()

The max absolute value of the numerator and denominator of self, as an Integer.

OUTPUT: Integer

EXAMPLES:

```
sage: a = 2/3
sage: a.height()
3
sage: a = 34/3
sage: a.height()
34
sage: a = -97/4
sage: a.height()
97
```

AUTHORS:

- Naqi Jaffery (2006-03-05): examples

is_S_integral()

Determine if the rational number is S-integral.

x is S-integral if x.valuation(p)>=0 for all p not in S, i.e., the denominator of x is divisible only by the primes in S.

INPUT:

- S - list or tuple of primes.

OUTPUT: bool

Note: Primality of the entries in S is not checked.

EXAMPLES:

```
sage: QQ(1/2).is_S_integral()
False
sage: QQ(1/2).is_S_integral([2])
True
sage: [a for a in range(1,11) if QQ(101/a).is_S_integral([2,5])]
[1, 2, 4, 5, 8, 10]
```

is_S_unit()

Determine if the rational number is an S-unit.

x is an S-unit if x.valuation(p)==0 for all p not in S, i.e., the numerator and denominator of x are divisible only by the primes in S.

INPUT:

- S - list or tuple of primes.

OUTPUT: bool

Note: Primality of the entries in S is not checked.

EXAMPLES:

```
sage: QQ(1/2).is_S_unit()
False
sage: QQ(1/2).is_S_unit([2])
True
sage: [a for a in range(1,11) if QQ(10/a).is_S_unit([2,5])]
[1, 2, 4, 5, 8, 10]
```

is_integral()

Determine if a rational number is integral (i.e is in **Z**).

OUTPUT: bool

EXAMPLES:

```
sage: QQ(1/2).is_integral()
False
sage: QQ(4/4).is_integral()
True
```

is_nth_power()

Returns True if self is an nth power, else False.

INPUT:

- n - integer (must fit in C int type)

Note: Use this function when you nede test test if a rational number is an n'th power, but do not need to know the value of its n'th root. If the value is needed, use nth_root().

AUTHORS:

- John Cremona (2009-04-04)

EXAMPLES:

```
sage: QQ(25/4).is_nth_power(2)
True
sage: QQ(125/8).is_nth_power(3)
True
sage: QQ(-125/8).is_nth_power(3)
```

```
True
sage: QQ(25/4).is_nth_power(-2)
True

sage: QQ(9/2).is_nth_power(2)
False
sage: QQ(-25).is_nth_power(2)
False
```

is_one()

Determine if a rational number is one.

OUTPUT: bool

EXAMPLES:

```
sage: QQ(1/2).is_one()
False
sage: QQ(4/4).is_one()
True
```

is_padic_square()

Determines whether this rational number is a square in Q_p (or in R when p = infinity).

INPUT:

- p - a prime number, or infinity

EXAMPLES: sage: QQ(2).is_padic_square(7) True sage: QQ(98).is_padic_square(7) True sage: QQ(2).is_padic_square(5) False

TESTS: sage: QQ(5/7).is_padic_square(int(2)) False

is_perfect_power()

Returns True if self is a perfect power.

INPUT:

- **expected_value - (bool) whether or not this rational is expected** be a perfect power. This does not affect the correctness of the output, only the runtime.

If expected_value is False (default) it will check the smallest of the numerator and denominator is a perfect power as a first step, which is often faster than checking if the quotient is a perfect power.

EXAMPLES:

```
sage: (4/9).is_perfect_power()
True
sage: (144/1).is_perfect_power()
True
sage: (4/3).is_perfect_power()
False
sage: (2/27).is_perfect_power()
False
sage: (4/27).is_perfect_power()
False
sage: (-1/25).is_perfect_power()
False
sage: (-1/27).is_perfect_power()
True
sage: (0/1).is_perfect_power()
True
```

The second parameter does not change the result, but may change the runtime.

```
sage: (-1/27).is_perfect_power(True)
True
sage: (-1/25).is_perfect_power(True)
False
sage: (2/27).is_perfect_power(True)
False
sage: (144/1).is_perfect_power(True)
True
```

This test makes sure we workaround a bug in GMP (see trac #4612):

```
sage: [ -a for a in srange(100) if not QQ(-a^3).is_perfect_power() ]
[]
sage: [ -a for a in srange(100) if not QQ(-a^3).is_perfect_power(True) ]
[]
```

is_square()

Return whether or not this rational number is a square.

OUTPUT: bool

EXAMPLES:

```
sage: x = 9/4
sage: x.is_square()
True
sage: x = (7/53)^100
sage: x.is_square()
True
sage: x = 4/3
sage: x.is_square()
False
sage: x = -1/4
sage: x.is_square()
False
```

lcm()

Return the least common multiple of self and other.

One way to define this notion is the following:

Note that each rational positive rational number can be written as a product of primes with integer (positive or negative) powers in a unique way.

Then, the LCM of two rational numbers x,y can be defined by specifying that the exponent of every prime p in lcm(x,y) is the supremum of the exponents of p in x, and the exponent of p in y (The primes that does not appear in the decomposition of x or y are considered to have exponent zero).

This definition is consistent with the definition of the LCM in the rational integers. Our hopefully interesting notion of LCM for rational numbers is illustrated in the examples below.

EXAMPLES:

```
sage: lcm(2/3,1/5)
2
```

This is consistent with the definition above, since:

$$2/3 = 2^1 * 3^{-1} * 5^0$$

$$1/5 = 2^0 * 3^0 * 5^{-1}$$

and hence,

$$lcm(2/3, 1/5) = 2^1 * 3^0 * 5^0 = 2.$$

```
sage: lcm(2/3,7/5)
14
```

In this example:

$$2/3 = 2^1 * 3^{-1} * 5^0 * 7^0$$

$$7/5 = 2^0 * 3^0 * 5^{-1} * 7^1$$

$$lcm(2/3, 7/5) = 2^1 * 3^0 * 5^0 * 7^1 = 14$$

```
sage: lcm(1/3,1/5)
1
```

In this example:

$$1/3 = 3^{-1} * 5^0$$

$$1/5 = 3^0 * 5^{-1}$$

$$lcm(1/3, 1/5) = 3^0 * 5^0 = 1$$

```
sage: lcm(1/3,1/6)
1/3
```

In this example:

$$1/3 = 2^0 * 3^{-1}$$

$$1/6 = 2^{-1} * 3^{-1}$$

$$lcm(1/3, 1/6) = 2^0 * 3^{-1} = 1/3$$

list()

Return a list with the rational element in it, to be compatible with the method for number fields.

OUTPUT:

- `list` - the list [self]

EXAMPLES:

```
sage: m = 5/3
sage: m.list()
[5/3]
```

minpoly()

Return the minimal polynomial of this rational number. This will always be just x - self; this is really here so that code written for number fields won't crash when applied to rational numbers.

INPUT:

- `var` - a string

OUTPUT: Polynomial

EXAMPLES:

```
sage: (1/3).minpoly('x')
 x - 1/3
```

AUTHORS:

- Craig Citro

mod_ui()

Return the remainder upon division of self by the unsigned long integer n.

INPUT:

- n - an unsigned long integer

OUTPUT: integer

EXAMPLES:

```
sage: (-4/17).mod_ui(3)
1
sage: (-4/17).mod_ui(17)
...
ArithmeticError: The inverse of 0 modulo 17 is not defined.
```

multiplicative_order()

Return the multiplicative order of self.

OUTPUT: Integer or infinity

EXAMPLES:

```
sage: QQ(1).multiplicative_order()
1
sage: QQ('1/-1').multiplicative_order()
2
sage: QQ(0).multiplicative_order()
+Infinity
sage: QQ('2/3').multiplicative_order()
+Infinity
sage: QQ('1/2').multiplicative_order()
+Infinity
```

norm()

Returns the norm from Q to Q of x (which is just x). This was added for compatibility with NumberFields.

OUTPUT:

- Rational - reference to self

EXAMPLES:

```
sage: (1/3).norm()
 1/3
```

AUTHORS:

- Craig Citro

nth_root()

Computes the nth root of self, or raises a ValueError if self is not a perfect nth power.

INPUT:

- n - integer (must fit in C int type)

AUTHORS:

- David Harvey (2006-09-15)

EXAMPLES:

```
sage: (25/4).nth_root(2)
5/2
sage: (125/8).nth_root(3)
5/2
sage: (-125/8).nth_root(3)
-5/2
sage: (25/4).nth_root(-2)
2/5

sage: (9/2).nth_root(2)
...
ValueError: not a perfect 2nd power

sage: (-25/4).nth_root(2)
...
ValueError: cannot take even root of negative number
```

numer()

Return the numerator of this rational number.

EXAMPLE:

```
sage: x = -5/11
sage: x.numer()
-5
```

numerator()

Return the numerator of this rational number.

EXAMPLE:

```
sage: x = 5/11
sage: x.numerator()
5

sage: x = 9/3
sage: x.numerator()
3
```

period()

Return the period of the repeating part of the decimal expansion of this rational number.

ALGORITHM: When a rational number n/d with $(n, d) == 1$ is expanded, the period begins after s terms and has length t, where s and t are the smallest numbers satisfying $10^s = 10^(s + t)(modd)$. When d is coprime to 10, this becomes a purely periodic decimal with $10^t = 1(modd)$. (Lehmer 1941 and Mathworld).

EXAMPLES:

```
sage: (1/7).period()
6
sage: RR(1/7)
0.142857142857143
sage: (1/8).period()
1
sage: RR(1/8)
0.125000000000000
sage: RR(1/6)
0.166666666666667
sage: (1/6).period()
1
sage: x = 333/106
```

```
sage: x.period()
13
sage: RealField(200)(x)
3.14150943396226415094339622641509433962264150943396226415094
```

prime_to_S_part()

Returns self with all powers of all primes in S removed.

INPUT:

- S - list or tuple of primes.

OUTPUT: rational

Note: Primality of the entries in S is not checked.

EXAMPLES:

```
sage: QQ(3/4).prime_to_S_part()
3/4
sage: QQ(3/4).prime_to_S_part([2])
3
sage: QQ(-3/4).prime_to_S_part([3])
-1/4
sage: QQ(700/99).prime_to_S_part([2,3,5])
7/11
sage: QQ(-700/99).prime_to_S_part([2,3,5])
-7/11
sage: QQ(0).prime_to_S_part([2,3,5])
0
sage: QQ(-700/99).prime_to_S_part([])
-700/99
```

round()

Returns the nearest integer to self.

INPUT:

- self - a rational number
- mode - a rounding mode for half integers:
  - 'toward' (default) rounds toward zero
  - 'away' rounds away from zero
  - 'up' rounds up
  - 'down' rounds down
  - 'even' rounds toward the even integer
  - 'odd' rounds toward the odd integer

OUTPUT: Integer

EXAMPLES:

```
sage: n = 4/3; n.round()
1
sage: n = -17/4; n.round()
-4
sage: n = -5/2; n.round()
-2
sage: n.round("away")
-3
sage: n.round("up")
-2
sage: n.round("down")
-3
```

```
sage: n.round("even")
-2
sage: n.round("odd")
-3
```

sqrt()

The square root function.

INPUT:

- prec - integer (default: None): if None, returns an exact square root; otherwise returns a numerical square root if necessary, to the given bits of precision.
- extend - bool (default: True); if True, return a square root in an extension ring, if necessary. Otherwise, raise a ValueError if the square is not in the base ring.
- all - bool (default: False); if True, return all square roots of self, instead of just one.

EXAMPLES:

```
sage: x = 25/9
sage: x.sqrt()
5/3
sage: sqrt(x)
5/3
sage: x = 64/4
sage: x.sqrt()
4
sage: x = 100/1
sage: x.sqrt()
10
sage: x.sqrt(all=True)
[10, -10]
sage: x = 81/5
sage: x.sqrt()
9*sqrt(1/5)
sage: x = -81/3
sage: x.sqrt()
3*sqrt(-3)

sage: n = 2/3
sage: n.sqrt()
sqrt(2/3)
sage: n.sqrt(prec=10)
0.82
sage: n.sqrt(prec=100)
0.81649658092772603273242802490
sage: n.sqrt(prec=100)^2
0.66666666666666666666666666667
sage: n.sqrt(prec=53, all=True)
[0.816496580927726, -0.816496580927726]
sage: n.sqrt(extend=False, all=True)
...
ValueError: square root of 2/3 not a rational number
sage: sqrt(-2/3, all=True)
[sqrt(-2/3), -sqrt(-2/3)]
sage: sqrt(-2/3, prec=53)
0.816496580927726*I
sage: sqrt(-2/3, prec=53, all=True)
[0.816496580927726*I, -0.816496580927726*I]
```

AUTHORS:

•Naqi Jaffery (2006-03-05): some examples

sqrt_approx()

Return numerical approximation with given number of bits of precision to this rational number. If all is given, return both approximations.

INPUT:

•`prec` - integer

•`all` - bool

EXAMPLES:

```
sage: (5/3).sqrt_approx()
doctest:1172: DeprecationWarning: This function is deprecated.  Use sqrt with a given number
1.29099444873581
sage: (990829038092384908234098239048230984/4).sqrt_approx()
4.9770197862083713747374920870362581922510725585130996993055116540856385e17
sage: (5/3).sqrt_approx(prec=200)
1.2909944487358056283930884665941332036109739017638636088625
sage: (9/4).sqrt_approx()
3/2
```

squarefree_part()

Return the square free part of x, i.e., an integer z such that $x = zy^2$, for a perfect square y^2.

EXAMPLES:

```
sage: a = 1/2
sage: a.squarefree_part()
2
sage: b = a/a.squarefree_part()
sage: b, b.is_square()
(1/4, True)
sage: a = 24/5
sage: a.squarefree_part()
30
```

str()

INPUT:

•`base` - integer (default: 10); base must be between 2 and 36.

OUTPUT: string

EXAMPLES:

```
sage: (-4/17).str()
'-4/17'
sage: (-4/17).str(2)
'-100/10001'
```

Note that the base must be at most 36.

```
sage: (-4/17).str(40)
...
ValueError: base (=40) must be between 2 and 36
sage: (-4/17).str(1)
...
ValueError: base (=1) must be between 2 and 36
```

support()

Return a sorted list of the primes where this rational number has non-zero valuation.

OUTPUT: The set of primes appearing in the factorization of this rational with nonzero exponent, as a sorted list.

EXAMPLES:

```
sage: (-4/17).support()
[2, 17]
```

Trying to find the support of 0 gives an arithmetic error:

```
sage: (0/1).support()
...
ArithmeticError: Support of 0 not defined.
```

trace()

Returns the trace from Q to Q of x (which is just x). This was added for compatibility with NumberFields.

OUTPUT:

- Rational - reference to self

EXAMPLES:

```
sage: (1/3).trace()
 1/3
```

AUTHORS:

- Craig Citro

val_unit()

Returns a pair: the p-adic valuation of self, and the p-adic unit of self, as a Rational.

We do not require the p be prime, but it must be at least 2. For more documentation see Integer.val_unit

INPUT:

- p - a prime

OUTPUT:

- int - the p-adic valuation of this rational
- Rational - p-adic unit part of self

EXAMPLES:

```
sage: (-4/17).val_unit(2)
(2, -1/17)
sage: (-4/17).val_unit(17)
(-1, -4)
sage: (0/1).val_unit(17)
(+Infinity, 1)
```

AUTHORS:

- David Roe (2007-04-12)

valuation()

Return the largest power of p that divides self.

INPUT:

- p - a prime number

EXAMPLES:

```
sage: x = -5/9
sage: x.valuation(5)
1
sage: x.valuation(3)
-2
sage: x.valuation(2)
0
```

Some edge cases:

```
sage: (0/1).valuation(4)
+Infinity
sage: (7/16).valuation(4)
-2
```

class **Z_to_Q**()

section()
EXAMPLES:

```
sage: QQ.coerce_map_from(ZZ).section()
Generic map:
  From: Rational Field
  To:   Integer Ring
```

clear_mpz_globals()

gmp_randrange()

init_mpz_globals()

class **int_to_Q**()

integer_rational_power()
Compute a^b as an integer, if it is integral, or return None. The positive real root is taken for even denominators.

INPUT:

```
a -- an Integer
b -- a positive Rational
```

OUTPUT:

```
`a^b` as an Integer or None
```

EXAMPLES:

```
sage: from sage.rings.rational import integer_rational_power
sage: integer_rational_power(49, 1/2)
7
sage: integer_rational_power(27, 1/3)
3
sage: integer_rational_power(-27, 1/3) is None
True
sage: integer_rational_power(-27, 2/3) is None
True
sage: integer_rational_power(512, 7/9)
128

sage: integer_rational_power(27, 1/4) is None
True
sage: integer_rational_power(-16, 1/4) is None
True

sage: integer_rational_power(0, 7/9)
0
sage: integer_rational_power(1, 7/9)
1
sage: integer_rational_power(-1, 7/9) is None
True
```

```
sage: integer_rational_power(-1, 8/9) is None
True
sage: integer_rational_power(-1, 9/8) is None
True
```

make_rational()

Make a rational number from s (a string in base 32)

INPUT:

- s - string in base 32

OUTPUT: Rational

EXAMPLES:

```
sage: (-7/15).str(32)
'-7/f'
sage: sage.rings.rational.make_rational('-7/f')
-7/15
```

pyrex_rational_reconstruction()

Find the rational reconstruction of a mod m, if it exists.

INPUT:

- a - Integer
- m - Integer

OUTPUT:

- x - rings.rational.Rational

EXAMPLES:

```
sage: Integers(100)(2/3)
34
sage: sage.rings.rational.pyrex_rational_reconstruction(34, 100)
2/3
```

rational_power_parts()

Compute rationals or integers c and d such that $a^b = c * d^b$ with d small. This is used for simplifying radicals.

INPUT:

```
a -- a Rational or Integer
b -- a Rational
factor_limit -- the limit used in factoring a
```

EXAMPLES:

```
sage: from sage.rings.rational import rational_power_parts
sage: rational_power_parts(27, 1/2)
(3, 3)
sage: rational_power_parts(-128, 3/4)
(8, -8)
sage: rational_power_parts(-4, 1/2)
(2, -1)
sage: rational_power_parts(-4, 1/3)
(1, -4)
```

```
sage: rational_power_parts(9/1000, 1/2)
(3/10, 1/10)
```

24.7 Finite Fields

Sage supports arithmetic in finite prime and extension fields. Several implementation for prime fields are implemented natively in Sage for several sizes of primes p. These implementations are

- `sage.rings.integer_mod.IntegerMod_int`,
- `sage.rings.integer_mod.IntegerMod_int64`, and
- `sage.rings.integer_mod.IntegerMod_gmp`.

Small extension fields of cardinality $< 2^{16}$ are implemented using tables of Zech logs via the Givaro C++ library (`sage.rings.finite_field_givaro.FiniteField_givaro`). While this representation is very fast it is limited to finite fields of small cardinality. Larger finite extension fields of order $q >= 2^{16}$ are internally represented as polynomials over smaller finite prime fields. If the characteristic of such a field is 2 then NTL is used internally to represent the field (`sage.rings.finite_field_ntl_gf2e.FiniteField_ntl_gf2e`). In all other case the PARI C library is used (`sage.rings.finite_field_ext_pari.FiniteField_ext_pari`).

However, this distinction is internal only and the user usually does not have to worry about it because consistency across all implementations is aimed for. In all extension field implementations the user may either specify a minimal polynomial or leave the choice to Sage.

For small finite fields the default choice are Conway polynomials.

The Conway polynomial C_n is the lexicographically first monic irreducible, primitive polynomial of degree n over $GF(p)$ with the property that for a root α of C_n we have that $\beta = \alpha^{(p^n-1)/(p^m-1)}$ is a root of C_m for all m dividing n. Sage contains a database of Conway polynomials which also can be queried independently of finite field construction.

While Sage supports basic arithmetic in finite fields some more advanced features for computing with finite fields are still not implemented. For instance, Sage does not calculate embeddings of finite fields yet.

EXAMPLES:

```
sage: k = GF(5); type(k)
<class 'sage.rings.finite_field_prime_modn.FiniteField_prime_modn'>

sage: k = GF(5^2,'c'); type(k)
<type 'sage.rings.finite_field_givaro.FiniteField_givaro'>

sage: k = GF(2^16,'c'); type(k)
<type 'sage.rings.finite_field_ntl_gf2e.FiniteField_ntl_gf2e'>

sage: k = GF(3^16,'c'); type(k)
<class 'sage.rings.finite_field_ext_pari.FiniteField_ext_pari'>
```

Finite Fields support iteration, starting with 0.

```
sage: k = GF(9, 'a')
sage: for i,x in enumerate(k):  print i,x
0 0
1 2*a
2 a + 1
3 a + 2
4 2
5 a
6 2*a + 2
7 2*a + 1
8 1
sage: for a in GF(5):
...    print a
0
1
2
3
4
```

We output the base rings of several finite fields.

```
sage: k = GF(3); type(k)
<class 'sage.rings.finite_field_prime_modn.FiniteField_prime_modn'>
sage: k.base_ring()
Finite Field of size 3
```

```
sage: k = GF(9,'alpha'); type(k)
<type 'sage.rings.finite_field_givaro.FiniteField_givaro'>
sage: k.base_ring()
Finite Field of size 3
```

```
sage: k = GF(3^40,'b'); type(k)
<class 'sage.rings.finite_field_ext_pari.FiniteField_ext_pari'>
sage: k.base_ring()
Finite Field of size 3
```

Further examples:

```
sage: GF(2).is_field()
True
sage: GF(next_prime(10^20)).is_field()
True
sage: GF(19^20,'a').is_field()
True
sage: GF(8,'a').is_field()
True
```

AUTHORS:

- William Stein: initial version
- Robert Bradshaw: prime field implementation
- Martin Albrecht: Givaro and ntl.GF2E implementations

class FiniteFieldFactory()

Return the globally unique finite field of given order with generator labeled by the given name and possibly with given modulus.

INPUT:

- `order` - int
- `name` - string; must be specified if not a prime field
- `modulus` - (optional) defining polynomial for field, i.e., generator of the field will be a root of this polynomial; if not specified the choice of defininining polynomials can be arbitrary.
- `elem_cache` - cache all elements to avoid creation time (default: order < 500)
- `check_irreducible` - verify that the polynomial modulus is irreducible
- `args` - additional parameters passed to finite field implementations
- `kwds` - additional keyword parameters passed to finite field implementations

ALIAS: You can also use GF instead of FiniteField - they are identical.

EXAMPLES:

```
sage: k.<a> = FiniteField(9); k
Finite Field in a of size 3^2
sage: parent(a)
Finite Field in a of size 3^2
sage: charpoly(a, 'y')
y^2 + 2*y + 2
```

```
sage: F.<x> = GF(5)[]
sage: K.<a> = GF(5**5, name='a', modulus=x^5 - x +1 )
sage: f = K.modulus(); f
x^5 + 4*x + 1
sage: type(f)
 <type 'sage.rings.polynomial.polynomial_zmod_flint.Polynomial_zmod_flint'>
```

The modulus must be irreducible:

```
sage: K.<a> = GF(5**5, name='a', modulus=x^5 - x )
...
ValueError: finite field modulus must be irreducible but it is not
```

You can't accidently fool the constructor into thinking the modulus is irreducible when it isn't mod p, since it actually tests irreducibility modulo p.

```
sage: F.<x> = QQ[]
sage: factor(x^5+2)
x^5 + 2
sage: K.<a> = GF(5**5, name='a', modulus=x^5 + 2 )
...
ValueError: finite field modulus must be irreducible but it is not
```

If you wish to live dangerously, you can tell the constructor not to test irreducibility using check_irreducible=False, but this can easily lead to crashes and hangs - so do not do it unless you know that the modulus really is irreducible!

```
sage: F.<x> = GF(5)[]
sage: K.<a> = GF(5**2, name='a', modulus=x^2 + 2, check_irreducible=False)
```

For example, you may print finite field elements as integers. This currently only works if the order of field is $< 2^{16}$, though.

```
sage: k.<a> = GF(2^8,repr='int')
sage: a
2
```

The order of a finite field must be a prime power:

```
sage: GF(100)
...
ValueError: order of finite field must be a prime power
```

Finite fields with random modulus are not cached:

```
sage: k.<a> = GF(2^17,modulus='random')
sage: n.<a> = GF(2^17,modulus='random')
sage: n is k
False
```

We check that various ways of creating the same finite field yield the same object.

```
sage: K = GF(7, 'a')
sage: L = GF(7, 'b')
sage: K is L
True
sage: K = GF(4,'a'); K.modulus()
x^2 + x + 1
sage: L = GF(4,'a', K.modulus())
sage: K is L
True
sage: M = GF(4,'a', K.modulus().change_variable_name('y'))
sage: K is M
True
```

create_key_and_extra_args(*order, name=None, modulus=None, names=None, impl=None, **kwds*)

EXAMPLES:

```
sage: GF.create_key_and_extra_args(9, 'a')
((9, ('a',), None, None, '{}'), {})
sage: GF.create_key_and_extra_args(9, 'a', foo='value')
((9, ('a',), None, None, "{'foo': 'value'}"), {'foo': 'value'})
```

create_object(*version, key, check_irreducible=True, elem_cache=None, names=None, **kwds*)

EXAMPLES:

```
sage: K = GF(19)
sage: loads(dumps(K)) is K
True
```

other_keys(*key, K*)

EXAMPLES:

```
sage: key, extra = GF.create_key_and_extra_args(9, 'a'); key
(9, ('a',), None, None, '{}')
sage: K = GF.create_object(0, key); K
Finite Field in a of size 3^2
sage: GF.other_keys(key, K)
[(9, ('a',), x^2 + 2*x + 2, None, '{}'),
 (9, ('a',), x^2 + 2*x + 2, 'givaro', '{}')]
```

conway_polynomial(*p, n*)

Return the Conway polynomial of degree n over GF(p), which is loaded from a table.

If the requested polynomial is not known, this function raises a RuntimeError exception.

INPUT:

- p - int
- n - int

OUTPUT:

- Polynomial - a polynomial over the prime finite field GF(p).

Note: The first time this function is called a table is read from disk, which takes a fraction of a second. Subsequent calls do not require reloading the table.

See also the ConwayPolynomials() object, which is a table of Conway polynomials. For example, if c=ConwayPolynomials(), then c.primes() is a list of all primes for which the polynomials are known, and for a given prime p, c.degree(p) is a list of all degrees for which the Conway polynomials are known.

EXAMPLES:

```
sage: conway_polynomial(2,5)
x^5 + x^2 + 1
sage: conway_polynomial(101,5)
x^5 + 2*x + 99
sage: conway_polynomial(97,101)
...
RuntimeError: requested conway polynomial not in database.
```

exists_conway_polynomial(*p, n*)

Return True if the Conway polynomial over F_p of degree n is in the database and False otherwise.

If the Conway polynomial is in the database, to obtain it use the command conway_polynomial(p,n).

EXAMPLES:

```
sage: exists_conway_polynomial(2,3)
True
sage: exists_conway_polynomial(2,-1)
False
sage: exists_conway_polynomial(97,200)
False
sage: exists_conway_polynomial(6,6)
False
```

is_PrimeFiniteField(*x*)

Returns True if x is a prime finite field.

EXAMPLES:

```
sage: from sage.rings.finite_field import is_PrimeFiniteField
sage: is_PrimeFiniteField(QQ)
False
sage: is_PrimeFiniteField(GF(7))
True
sage: is_PrimeFiniteField(GF(7^2,'a'))
False
sage: is_PrimeFiniteField(GF(next_prime(10^90,proof=False)))
True
```

24.8 Elements of Finite Fields

EXAMPLES:

```
sage: K = FiniteField(2)
sage: V = VectorSpace(K,3)
sage: w = V([0,1,2])
sage: K(1)*w
(0, 1, 0)
```

We do some arithmetic involving a bigger field and a Conway polynomial, i.e., we verify compatibility condition.

```
sage: f = conway_polynomial(2,63)
sage: K.<a> = GF(2**63, name='a', modulus=f)
sage: n = f.degree()
sage: m = 3;
sage: e = (2^n - 1) / (2^m - 1)
sage: c = a^e
sage: conway = conway_polynomial(2,m)
sage: conway(c) == 0
True
```

class **FiniteField_ext_pariElement** (*parent, value, check=True*)

An element of a finite field.

Create elements by first defining the finite field F, then use the notation F(n), for n an integer. or let a = F.gen() and write the element in terms of a.

EXAMPLES:

```
sage: K = FiniteField(10007^10, 'a')
sage: a = K.gen(); a
a
sage: loads(a.dumps()) == a
True
sage: K = GF(10007)
sage: a = K(938); a
938
sage: loads(a.dumps()) == a
True
```

TESTS:

```
sage: K.<a> = GF(2^16)
sage: K(0).is_zero()
True
sage: (a - a).is_zero()
True
sage: a - a
0
sage: a == a
True
sage: a - a == 0
True
sage: a - a == K(0)
True
```

copy()
Return a copy of this element.
EXAMPLES:

```
sage: from sage.rings.finite_field_ext_pari import FiniteField_ext_pari
sage: k = FiniteField_ext_pari(3**3,'a')
sage: a = k(5)
sage: a
2
sage: a.copy()
2
sage: b = a.copy()
sage: a == b
True
sage: a is b
False
sage: a is a
True
```

is_square()
Returns True if and only if this element is a perfect square.
EXAMPLES:

```
sage: from sage.rings.finite_field_ext_pari import FiniteField_ext_pari
sage: k = FiniteField_ext_pari(3**2, 'a')
sage: a = k.gen()
sage: a.is_square()
False
sage: (a**2).is_square()
True
sage: k = FiniteField_ext_pari(2**2,'a')
sage: a = k.gen()
sage: (a**2).is_square()
True
sage: k = FiniteField_ext_pari(17**5,'a'); a = k.gen()
sage: (a**2).is_square()
True
sage: a.is_square()
False

sage: k(0).is_square()
True
```

lift()
If this element lies in a prime finite field, return a lift of this element to an integer.
EXAMPLES:

```
sage: from sage.rings.finite_field_ext_pari import FiniteField_ext_pari
sage: k = GF(next_prime(10**10))
sage: a = k(17)/k(19)
sage: b = a.lift(); b
7894736858
sage: b.parent()
Integer Ring
```

log(*base*)
Return x such that $b^x = a$, where x is a and b is the base.
INPUT:

- `self` - finite field element

- b - finite field element that generates the multiplicative group.

OUTPUT: Integer x such that $a^x = b$, if it exists. Raises a ValueError exception if no such x exists.

EXAMPLES:

```
sage: F = GF(17)
sage: F(3^11).log(F(3))
11
sage: F = GF(113)
sage: F(3^19).log(F(3))
19
sage: F = GF(next_prime(10000))
sage: F(23^997).log(F(23))
997

sage: F = FiniteField(2^10, 'a')
sage: g = F.gen()
sage: b = g; a = g^37
sage: a.log(b)
37
sage: b^37; a
a^8 + a^7 + a^4 + a + 1
a^8 + a^7 + a^4 + a + 1
```

AUTHORS:

- David Joyner and William Stein (2005-11)

multiplicative_order()

Returns the *multiplicative* order of this element, which must be nonzero.

EXAMPLES:

```
sage: from sage.rings.finite_field_ext_pari import FiniteField_ext_pari
sage: a = FiniteField_ext_pari(5**3, 'a').0
sage: a.multiplicative_order()
124
sage: a**124
1
```

nth_root(*n, extend=False, all=False*)

Returns an nth root of self.

INPUT:

- n - integer = 1 (must fit in C int type)
- extend - bool (default: True); if True, return an nth root in an extension ring, if necessary. Otherwise, raise a ValueError if the root is not in the base ring. Warning: this option is not implemented!
- all - bool (default: False); if True, return all nth roots of self, instead of just one.

OUTPUT: If self has an nth root, returns one (if all == False) or a list of all of them (if all == True). Otherwise, raises a ValueError (if extend = False) or a NotImplementedError (if extend = True).

Warning: The 'extend' option is not implemented (yet).

AUTHORS:

- David Roe (2007-10-3)

EXAMPLES:

```
sage: k.<a> = GF(29^5)
sage: b = a^2 + 5*a + 1
sage: b.nth_root(5)
```

```
19*a^4 + 2*a^3 + 2*a^2 + 16*a + 3
sage: b.nth_root(7)
...
ValueError: no nth root
sage: b.nth_root(4, all=True)
[]
```

polynomial()

Elements of a finite field are represented as a polynomial modulo a modulus. This function returns the representing polynomial as an element of the polynomial ring over the prime finite field, with the same variable as the finite field.

EXAMPLES:

The default variable is a:

```
sage: from sage.rings.finite_field_ext_pari import FiniteField_ext_pari
sage: k = FiniteField_ext_pari(3**2,'a')
sage: k.gen().polynomial()
a
```

The variable can be any string.

```
sage: k = FiniteField(3**4, "alpha")
sage: a = k.gen()
sage: a.polynomial()
alpha
sage: (a**2 + 1).polynomial()
alpha^2 + 1
sage: (a**2 + 1).polynomial().parent()
Univariate Polynomial Ring in alpha over Finite Field of size 3
```

rational_reconstruction()

If the parent field is a prime field, uses rational reconstruction to try to find a lift of this element to the rational numbers.

EXAMPLES:

```
sage: from sage.rings.finite_field_ext_pari import FiniteField_ext_pari
sage: k = GF(97)
sage: a = k(RationalField()('2/3'))
sage: a
33
sage: a.rational_reconstruction()
2/3
```

sqrt(*extend=False, all=False*)

See self.square_root().

INPUT:

- `extend` - ignored

square_root(*extend=False, all=False*)

The square root function.

INPUT:

- `extend` - bool (default: True); if True, return a square root in an extension ring, if necessary. Otherwise, raise a ValueError if the root is not in the base ring. Warning: this option is not implemented!
- `all` - bool (default: False); if True, return all square roots of self, instead of just one.

> **Warning:** The 'extend' option is not implemented (yet).

EXAMPLES:

```
sage: from sage.rings.finite_field_ext_pari import FiniteField_ext_pari
sage: F = FiniteField_ext_pari(7^2, 'a')
sage: F(2).square_root()
4
sage: F(3).square_root()
5*a + 1
sage: F(3).square_root()**2
3
sage: F(4).square_root()
5
sage: K = FiniteField_ext_pari(7^3, 'alpha')
sage: K(3).square_root()
...
ValueError: must be a perfect square.
```

is_FiniteFieldElement(*x*)

Returns if x is a finite field element.

EXAMPLE:

```
sage: from sage.rings.finite_field_element import is_FiniteFieldElement
sage: is_FiniteFieldElement(1)
False
sage: is_FiniteFieldElement(IntegerRing())
False
sage: is_FiniteFieldElement(GF(5)(2))
True
```

CHAPTER

TWENTYFIVE

FIXED AND ARBITRARY PRECISION NUMERICAL FIELDS

Sage supports two optimized fixed precision fields for numerical computation, the real double (RealDoubleField) and complex double fields (ComplexDoubleField). Sage also supports arbitrary precision real (RealField) and complex fields (ComplexField), and real and complex interval arithmetic (RealIntervalField and ComplexIntervalField).

Real and complex double elements are optimized implementations that use the GNU Scientific Library for arithmetic and some special functions. Arbitrary precision real and complex numbers are implemented using the MPFR library, which builds on GMP. (Note that Sage doesn't currently use the MPC library.) The interval arithmetic field is implemented using the MPFI library.

In many cases the PARI C-library is used to compute special functions when implementations aren't otherwise available.

25.1 Double Precision Real Numbers

EXAMPLES:

We create the real double vector space of dimension 3:

```
sage: V = RDF^3; V
Vector space of dimension 3 over Real Double Field
```

Notice that this space is unique.

```
sage: V is RDF^3
True
sage: V is FreeModule(RDF, 3)
True
sage: V is VectorSpace(RDF, 3)
True
```

Also, you can instantly create a space of large dimension.

```
sage: V = RDF^10000
```

class RealDoubleElement()

An approximation to a real number using double precision floating point numbers. Answers derived from calculations with such approximations may differ from what they would be if those calculations were performed with true real numbers. This is due to the rounding errors inherent to finite precision calculations.

NaN()

EXAMPLES:

```
sage: RDF.NaN()
NaN
```

abs()

Returns the absolute value of self.

EXAMPLES:

```
sage: RDF(1e10).abs()
10000000000.0
sage: RDF(-1e10).abs()
10000000000.0
```

acosh()

Returns the hyperbolic inverse cosine of this number

EXAMPLES:

```
sage: q = RDF.pi()/2
sage: i = q.cosh() ; i
2.50917847866
sage: abs(i.acosh()-q) < 1e-15
True
```

agm()

Return the arithmetic-geometric mean of self and other. The arithmetic-geometric mean is the common limit of the sequences u_n and v_n, where u_0 is self, v_0 is other, u_{n+1} is the arithmetic mean of u_n and v_n, and v_{n+1} is the geometric mean of u_n and v_n. If any operand is negative, the return value is `NaN`.

EXAMPLES:

```
sage: a = RDF(1.5)
sage: b = RDF(2.3)
sage: a.agm(b)
1.87864845581
```

The arithmetic-geometric mean always lies between the geometric and arithmetic mean.

```
sage: sqrt(a*b) < a.agm(b) < (a+b)/2
True
```

algdep()

Returns a polynomial of degree at most n which is approximately satisfied by this number. Note that the returned polynomial need not be irreducible, and indeed usually won't be if this number is a good approximation to an algebraic number of degree less than n.

ALGORITHM: Uses the PARI C-library algdep command.

EXAMPLE:

```
sage: r = RDF(2).sqrt(); r
1.41421356237
sage: r.algdep(5)
x^2 - 2
```

algebraic_dependency()

Returns a polynomial of degree at most n which is approximately satisfied by this number. Note that the returned polynomial need not be irreducible, and indeed usually won't be if this number is a good approximation to an algebraic number of degree less than n.

ALGORITHM: Uses the PARI C-library algdep command.

EXAMPLE:

```
sage: r = sqrt(RDF(2)); r
1.41421356237
sage: r.algdep(5)
x^2 - 2
```

arccos()
Returns the inverse cosine of this number
EXAMPLES:

```
sage: q = RDF.pi()/3
sage: i = q.cos()
sage: i.arccos() == q
True
```

arcsin()
Returns the inverse sine of this number
EXAMPLES:

```
sage: q = RDF.pi()/5
sage: i = q.sin()
sage: i.arcsin() == q
True
```

arcsinh()
Returns the hyperbolic inverse sine of this number
EXAMPLES:

```
sage: q = RDF.pi()/2
sage: i = q.sinh() ; i
2.30129890231
sage: abs(i.arcsinh()-q) < 1e-15
True
```

arctan()
Returns the inverse tangent of this number
EXAMPLES:

```
sage: q = RDF.pi()/5
sage: i = q.tan()
sage: i.arctan() == q
True
```

arctanh()
Returns the hyperbolic inverse tangent of this number
EXAMPLES:

```
sage: q = RDF.pi()/2
sage: i = q.tanh() ; i
0.917152335667
sage: i.arctanh() - q      # output is random, depending on arch.
-4.4408920985e-16
```

ceil()
Returns the ceiling of this number
OUTPUT: integer
EXAMPLES:

```
sage: RDF(2.99).ceil()
3
```

```
sage: RDF(2.00).ceil()
2
sage: RDF(-5/2).ceil()
-2
```

ceiling()
Returns the ceiling of this number
OUTPUT: integer
EXAMPLES:

```
sage: RDF(2.99).ceil()
3
sage: RDF(2.00).ceil()
2
sage: RDF(-5/2).ceil()
-2
```

cos()
Returns the cosine of this number
EXAMPLES:

```
sage: t=RDF.pi()/2
sage: t.cos()
6.12323399574e-17
```

cosh()
Returns the hyperbolic cosine of this number
EXAMPLES:

```
sage: q = RDF.pi()/12
sage: q.cosh()
1.0344656401
```

coth()
This function returns the hyperbolic cotangent.
EXAMPLES:

```
sage: RDF(pi).coth()
1.0037418732
sage: CDF(pi).coth()
1.0037418732
```

csch()
This function returns the hyperbolic cosecant.
EXAMPLES:

```
sage: RDF(pi).csch()
0.08658953753
sage: CDF(pi).csch()
0.08658953753
```

cube_root()
Return the cubic root (defined over the real numbers) of self.
EXAMPLES:

```
sage: r = RDF(125.0); r.cube_root()
5.0
sage: r = RDF(-119.0)
sage: r.cube_root()^3 - r          # output is random, depending on arch.
0.0
```

erf()
Returns the value of the error function on self.
EXAMPLES:

```
sage: RDF(6).erf()
1.0
```

exp()
Returns $e^{\texttt{self}}$
EXAMPLES:

```
sage: r = RDF(0.0)
sage: r.exp()
1.0

sage: r = RDF('32.3')
sage: a = r.exp(); a
1.06588847275e+14
sage: a.log()
32.3

sage: r = RDF('-32.3')
sage: r.exp()
9.3818445885e-15

sage: RDF(1000).exp()
+infinity
```

exp10()
Returns $10^{\texttt{self}}$
EXAMPLES:

```
sage: r = RDF(0.0)
sage: r.exp10()
1.0

sage: r = RDF(32.0)
sage: r.exp10()
1e+32

sage: r = RDF(-32.3)
sage: r.exp10()
5.01187233627e-33
```

exp2()
Returns $2^{\texttt{self}}$
EXAMPLES:

```
sage: r = RDF(0.0)
sage: r.exp2()
1.0

sage: r = RDF(32.0)
sage: r.exp2()
4294967296.0

sage: r = RDF(-32.3)
sage: r.exp2()
1.89117248253e-10
```

floor()
Returns the floor of this number
EXAMPLES:

```
sage: RDF(2.99).floor()
2
sage: RDF(2.00).floor()
2
sage: RDF(-5/2).floor()
-3
```

frac()
frac returns a real number > -1 and < 1. it satisfies the relation: x = x.trunc() + x.frac()
EXAMPLES:

```
sage: RDF(2.99).frac()
0.99
sage: RDF(2.50).frac()
0.5
sage: RDF(-2.79).frac()
-0.79
```

gamma()
The Euler gamma function. Return gamma of self.
EXAMPLES:

```
sage: RDF(6).gamma()
120.0
sage: RDF(1.5).gamma()
0.886226925453
```

hypot()
Computes the value $\sqrt{(self^2 + other^2)}$ in such a way as to avoid overflow.
EXAMPLES:

```
sage: x = RDF(4e300); y = RDF(3e300);
sage: x.hypot(y)
5e+300
sage: sqrt(x^2+y^2) # overflow
+infinity
```

imag()
Returns the imaginary part of this number. (hint: it's zero.)
EXAMPLES:

```
sage: a = RDF(3)
sage: a.imag()
0.0
```

integer_part()
If in decimal this number is written n.defg, returns n.
EXAMPLES:

```
sage: r = RDF('-1.6')
sage: a = r.integer_part(); a
-1
sage: type(a)
<type 'sage.rings.integer.Integer'>
sage: r = RDF(0.0/0.0)
sage: a = r.integer_part()
```

```
...
TypeError: Attempt to get integer part of NaN
```

is_NaN()
EXAMPLES:

```
sage: RDF(1).is_NaN()
False
sage: a = RDF(0)/RDF(0)
sage: a.is_NaN()
True
```

is_infinity()
EXAMPLES:

```
sage: a = RDF(2); b = RDF(0)
sage: (a/b).is_infinity()
True
sage: (b/a).is_infinity()
False
```

is_negative_infinity()
EXAMPLES:

```
sage: a = RDF(2)/RDF(0)
sage: a.is_negative_infinity()
False
sage: a = RDF(-3)/RDF(0)
sage: a.is_negative_infinity()
True
```

is_positive_infinity()
EXAMPLES:

```
sage: a = RDF(1)/RDF(0)
sage: a.is_positive_infinity()
True
sage: a = RDF(-1)/RDF(0)
sage: a.is_positive_infinity()
False
```

is_square()
Returns whether or not this number is a square in this field. For the real numbers, this is True if and only if self is non-negative.
EXAMPLES:

```
sage: RDF(3.5).is_square()
True
sage: RDF(0).is_square()
True
sage: RDF(-4).is_square()
False
```

log()
EXAMPLES:

```
sage: RDF(2).log()
0.69314718056
sage: RDF(2).log(2)
1.0
sage: RDF(2).log(pi)
```

```
0.605511561398
sage: RDF(2).log(10)
0.301029995664
sage: RDF(2).log(1.5)
1.70951129135
sage: RDF(0).log()
-infinity
sage: RDF(-1).log()
NaN
```

log10()

Returns log to the base 10 of self

EXAMPLES:

```
sage: r = RDF('16.0'); r.log10()
1.20411998266
sage: r.log() / RDF(log(10))
1.20411998266
sage: r = RDF('39.9'); r.log10()
1.60097289569
```

log2()

Returns log to the base 2 of self

EXAMPLES:

```
sage: r = RDF(16.0)
sage: r.log2()
4.0

sage: r = RDF(31.9); r.log2()
4.99548451888
```

logpi()

Returns log to the base pi of self

EXAMPLES:

```
sage: r = RDF(16); r.logpi()
2.42204624559
sage: r.log() / RDF(log(pi))
2.42204624559
sage: r = RDF('39.9'); r.logpi()
3.22030233461
```

multiplicative_order()

Returns n such that self^n == 1.

Only ± 1 have finite multiplicative order.

EXAMPLES:

```
sage: RDF(1).multiplicative_order()
1
sage: RDF(-1).multiplicative_order()
2
sage: RDF(3).multiplicative_order()
+Infinity
```

nan()

EXAMPLES:

```
sage: RDF.nan()
NaN
```

nth_root()

Returns the n^{th} root of self.

INPUT:

- n - an integer

OUTPUT: an real or complex double

The output is complex if self is negative and n is even.

EXAMPLES:

```
sage: r = RDF(-125.0); r.nth_root(3)
-5.0
sage: r.nth_root(5)
-2.6265278044
sage: RDF(-2).nth_root(5)^5
-2.0
sage: RDF(-1).nth_root(5)^5
-1.0
sage: RDF(3).nth_root(10)^10
3.0
sage: RDF(-1).nth_root(2)
6.12323399574e-17 + 1.0*I
sage: RDF(-1).nth_root(4)
0.707106781187 + 0.707106781187*I
```

parent()

Return the real double field, which is the parent of self.

EXAMPLES:

```
sage: a = RDF(2.3)
sage: a.parent()
Real Double Field
sage: parent(a)
Real Double Field
```

prec()

Returns the precision of this number in bits.

Always returns 53.

EXAMPLES:

```
sage: RDF(0).prec()
53
```

real()

Returns itself - we're already real.

EXAMPLES:

```
sage: a = RDF(3)
sage: a.real()
3.0
```

restrict_angle()

Returns a number congruent to self mod 2π that lies in the interval $(-\pi, \pi]$.

Specifically, it is the unique $x \in (-\pi, \pi]$ such that `self = x + 2pi n` for some $n \in \mathbf{Z}$.

EXAMPLES:

```
sage: RDF(pi).restrict_angle()
3.14159265359
sage: RDF(pi + 1e-10).restrict_angle()
-3.14159265349
sage: RDF(1+10^10*pi).restrict_angle()
0.9999977606...
```

round()

Given real number x, rounds up if fractional part is greater than .5, rounds down if fractional part is less than .5.

EXAMPLES:

```
sage: RDF(0.49).round()
0
sage: a=RDF(0.51).round(); a
1
```

sech()

This function returns the hyperbolic secant.

EXAMPLES:

```
sage: RDF(pi).sech()
0.0862667383341
sage: CDF(pi).sech()
0.0862667383341
```

sign()

Returns -1,0, or 1 if self is negative, zero, or positive; respectively.

EXAMPLES:

```
sage: RDF(-1.5).sign()
-1
sage: RDF(0).sign()
0
sage: RDF(2.5).sign()
1
```

sin()

Returns the sine of this number

EXAMPLES:

```
sage: RDF(2).sin()
0.909297426826
```

sincos()

Returns a pair consisting of the sine and cosine.

EXAMPLES:

```
sage: t = RDF.pi()/6
sage: t.sincos()
(0.5, 0.866025403784)
```

sinh()

Returns the hyperbolic sine of this number

EXAMPLES:

```
sage: q = RDF.pi()/12
sage: q.sinh()
0.264800227602
```

sqrt()

The square root function.

INPUT:

- `extend` - bool (default: True); if True, return a square root in a complex field if necessary if self is negative; otherwise raise a ValueError
- `all` - bool (default: False); if True, return a list of all square roots.

EXAMPLES:

```
sage: r = RDF(4.0)
sage: r.sqrt()
2.0
sage: r.sqrt()^2 == r
True

sage: r = RDF(4344)
sage: r.sqrt()
65.9090282131
sage: r.sqrt()^2 - r
0.0

sage: r = RDF(-2.0)
sage: r.sqrt()
1.41421356237*I

sage: RDF(2).sqrt(all=True)
[1.41421356237, -1.41421356237]
sage: RDF(0).sqrt(all=True)
[0.0]
sage: RDF(-2).sqrt(all=True)
[1.41421356237*I, -1.41421356237*I]
```

str()

Return string representation of self.

EXAMPLES:

```
sage: a = RDF('4.5'); a.str()
'4.5'
sage: a = RDF('49203480923840.2923904823048'); a.str()
'4.92034809238e+13'
sage: a = RDF(1)/RDF(0); a.str()
'+infinity'
sage: a = -RDF(1)/RDF(0); a.str()
'-infinity'
sage: a = RDF(0)/RDF(0); a.str()
'NaN'
```

We verify consistency with RR (mpfr reals):

```
sage: str(RR(RDF(1)/RDF(0))) == str(RDF(1)/RDF(0))
True
sage: str(RR(-RDF(1)/RDF(0))) == str(-RDF(1)/RDF(0))
True
sage: str(RR(RDF(0)/RDF(0))) == str(RDF(0)/RDF(0))
True
```

tan()

Returns the tangent of this number

EXAMPLES:

```
sage: q = RDF.pi()/3
sage: q.tan()
1.73205080757
sage: q = RDF.pi()/6
sage: q.tan()
0.57735026919
```

tanh()

Returns the hyperbolic tangent of this number

EXAMPLES:

```
sage: q = RDF.pi()/12
sage: q.tanh()
0.255977789246
```

trunc()

Truncates this number (returns integer part).

EXAMPLES:

```
sage: RDF(2.99).trunc()
2
sage: RDF(-2.00).trunc()
-2
sage: RDF(0.00).trunc()
0
```

ulp()

Returns the unit of least precision of self, which is the weight of the least significant bit of self. Unless self is exactly a power of two, it is gap between this number and the next closest distinct number that can be represented.

EXAMPLES:

```
sage: a = RDF(1)
sage: a - a.ulp() == a
False
sage: a - a.ulp()/2 == a
True

sage: a = RDF.pi()
sage: b = a + a.ulp()
sage: (a+b)/2 in [a,b]
True

sage: a = RDF(1)/RDF(0); a
+infinity
sage: a.ulp()
+infinity
sage: (-a).ulp()
+infinity
sage: a = RR('nan')
sage: a.ulp() is a
True
```

zeta()

Return the Riemann zeta function evaluated at this real number.

Note: PARI is vastly more efficient at computing the Riemann zeta function. See the example below for how to use it.

EXAMPLES:

```
sage: RDF(2).zeta()
1.64493406685
sage: RDF.pi()^2/6
1.64493406685
sage: RDF(-2).zeta()        # slightly random-ish arch dependent output
-2.37378795339e-18
sage: RDF(1).zeta()
+infinity
```

RealDoubleField()

Return the unique instance of the Real Double Field.

EXAMPLES:

```
sage: RealDoubleField() is RealDoubleField()
True
```

class **RealDoubleField_class**()

An approximation to the field of real numbers using double precision floating point numbers. Answers derived from calculations in this approximation may differ from what they would be if those calculations were performed in the true field of real numbers. This is due to the rounding errors inherent to finite precision calculations.

EXAMPLES:

```
sage: RR == RDF
False
sage: RDF == RealDoubleField()     # RDF is the shorthand
True

sage: RDF(1)
1.0
sage: RDF(2/3)
0.666666666667
```

A TypeError is raised if the coercion doesn't make sense:

```
sage: RDF(QQ['x'].0)
...
TypeError: cannot coerce nonconstant polynomial to float
sage: RDF(QQ['x'](3))
3.0
```

One can convert back and forth between double precision real numbers and higher-precision ones, though of course there may be loss of precision:

```
sage: a = RealField(200)(2).sqrt(); a
1.41421356237309504880168872420969807856967187537694807317667
sage: b = RDF(a); b
1.41421356237
sage: a.parent()(b)
1.41421356237309514547462185873882845044136047363281250000000
sage: a.parent()(b) == b
True
sage: b == RR(a)
True
```

NaN()

EXAMPLES:

```
sage: RDF.NaN()
NaN
```

algebraic_closure()
Returns the algebraic closure of self, ie, the complex double field.
EXAMPLES:

```
sage: RDF.algebraic_closure()
Complex Double Field
```

characteristic()
Returns 0, since the field of real numbers has characteristic 0.
EXAMPLES:

```
sage: RDF.characteristic()
0
```

complex_field()
Returns the complex field with the same precision as self, ie, the complex double field.
EXAMPLES:

```
sage: RDF.complex_field()
Complex Double Field
```

construction()
Returns the functorial construction of self, namely, completion of the rational numbers with respect to the prime at ∞.
Also preserves other information that makes this field unique (i.e. the Real Double Field).
EXAMPLES:

```
sage: c, S = RDF.construction(); S
Rational Field
sage: RDF == c(S)
True
```

euler_constant()
Returns Euler's gamma constant to double precision
EXAMPLES:

```
sage: RDF.euler_constant()
0.577215664902
```

factorial()
Return the factorial of the integer n as a real number.
EXAMPLES:

```
sage: RDF.factorial(100)
9.33262154439e+157
```

gen()
Return the generator of the real double field.
EXAMPLES:

```
sage: RDF.0
1.0
sage: RDF.gens()
(1.0,)
```

is_atomic_repr()
Returns True, to signify that elements of this field print without sums, so parenthesis aren't required, e.g., in coefficients of polynomials.
EXAMPLES:

```
sage: RDF.is_atomic_repr()
True
```

is_exact()
Returns False, because doubles are not exact.
EXAMPLE:

```
sage: RDF.is_exact()
False
```

is_finite()
Returns False, since the field of real numbers is not finite. Technical note: There exists an upper bound on the double representation.
EXAMPLES:

```
sage: RDF.is_finite()
False
```

log2()
Returns log(2) to the precision of this field.
EXAMPLES:

```
sage: RDF.log2()
0.69314718056
sage: RDF(2).log()
0.69314718056
```

name()

nan()
EXAMPLES:

```
sage: RDF.nan()
NaN
```

ngens()

pi()
Returns pi to double-precision.
EXAMPLES:

```
sage: RDF.pi()
3.14159265359
sage: RDF.pi().sqrt()/2
0.886226925453
```

prec()
Return the precision of this real double field in bits.
Always returns 53.
EXAMPLES:

```
sage: RDF.prec()
53
```

random_element()
Return a random element of this real double field in the interval [min, max].
EXAMPLES:

```
sage: RDF.random_element()
0.736945423566
sage: RDF.random_element(min=100, max=110)
102.815947352
```

to_prec()

Returns the real field to the specified precision. As doubles have fixed precision, this will only return a real double field if prec is exactly 53.

EXAMPLES:

```
sage: RDF.to_prec(52)
Real Field with 52 bits of precision
sage: RDF.to_prec(53)
Real Double Field
```

zeta()

Return an n-th root of unity in the real field, if one exists, or raise a ValueError otherwise.

EXAMPLES:

```
sage: RDF.zeta()
-1.0
sage: RDF.zeta(1)
1.0
sage: RDF.zeta(5)
...
ValueError: No 5th root of unity in self
```

class ToRDF()

is_RealDoubleElement()

is_RealDoubleField()

Returns True if x is the field of real double precision numbers.

EXAMPLE:

```
sage: from sage.rings.real_double import is_RealDoubleField
sage: is_RealDoubleField(RDF)
True
sage: is_RealDoubleField(RealField(53))
False
```

pool_stats()

time_alloc()

time_alloc_list()

25.2 Double Precision Complex Numbers

Sage supports arithmetic using double-precision complex numbers. A double-precision complex number is a complex number x + I*y with x, y 64-bit (8 byte) floating point numbers (double precision).

The field `ComplexDoubleField` implements the field of all double-precision complex numbers. You can refer to this field by the shorthand CDF. Elements of this field are of type `ComplexDoubleElement`. If x and y are coercible to doubles, you can create a complex double element using `ComplexDoubleElement(x,y)`. You can coerce more general objects z to complex doubles by typing either `ComplexDoubleField(x)` or `CDF(x)`.

EXAMPLES:

```
sage: ComplexDoubleField()
Complex Double Field
sage: CDF
Complex Double Field
sage: type(CDF.0)
<type 'sage.rings.complex_double.ComplexDoubleElement'>
sage: ComplexDoubleElement(sqrt(2),3)
1.41421356237 + 3.0*I
sage: parent(CDF(-2))
Complex Double Field
```

```
sage: CC == CDF
False
sage: CDF is ComplexDoubleField()      # CDF is the shorthand
True
sage: CDF == ComplexDoubleField()
True
```

The underlying arithmetic of complex numbers is implemented using functions and macros in GSL (the GNU Scientific Library), and should be very fast. Also, all standard complex trig functions, log, exponents, etc., are implemented using GSL, and are also robust and fast. Several other special functions, e.g. eta, gamma, incomplete gamma, etc., are implemented using the PARI C library.

AUTHORS:

- William Stein (2006-09): first version

class ComplexDoubleElement()

An approximation to a complex number using double precision floating point numbers. Answers derived from calculations with such approximations may differ from what they would be if those calculations were performed with true complex numbers. This is due to the rounding errors inherent to finite precision calculations.

abs()

This function returns the magnitude of the complex number z, $|z|$.

EXAMPLES:

```
sage: CDF(2,3).abs()    # slightly random-ish arch dependent output
3.6055512754639891
```

abs2()

This function returns the squared magnitude of the complex number z, $|z|^2$.

EXAMPLES:

```
sage: CDF(2,3).abs2()
13.0
```

agm()

Return the arithmetic geometry mean of self and right.

The principal square root is always chosen.

EXAMPLES:

```
sage: i = CDF(I)
sage: (1+i).agm(2-i)
1.62780548487 + 0.136827548397*I
```

algdep()

Returns a polynomial of degree at most n which is approximately satisfied by this complex number. Note

that the returned polynomial need not be irreducible, and indeed usually won't be if z is a good approximation to an algebraic number of degree less than n.

ALGORITHM: Uses the PARI C-library algdep command.

EXAMPLE:

```
sage: z = (1/2)*(1 + RDF(sqrt(3)) *CDF.0); z
0.5 + 0.866025403784*I
sage: p = z.algdep(5); p
x^5 + x^2
sage: p.factor()
(x + 1) * x^2 * (x^2 - x + 1)
sage: z^2 - z + 1
2.22044604925e-16...

sage: CDF(0,2).algdep(10)
x^2 + 4
sage: CDF(1,5).algdep(2)
x^2 - 2*x + 26
```

arccos()

This function returns the complex arccosine of the complex number z, $\arccos(z)$. The branch cuts are on the real axis, less than -1 and greater than 1.

EXAMPLES:

```
sage: CDF(1,1).arccos()
0.904556894302 - 1.06127506191*I
```

arccosh()

This function returns the complex hyperbolic arccosine of the complex number z, $\operatorname{arccosh}(z)$. The branch cut is on the real axis, less than 1.

EXAMPLES:

```
sage: CDF(1,1).arccosh()
1.06127506191 + 0.904556894302*I
```

arccot()

This function returns the complex arccotangent of the complex number z, $\operatorname{arccot}(z) = \arctan(1/z)$.

EXAMPLES:

```
sage: CDF(1,1).arccot()
0.553574358897 - 0.402359478109*I
```

arccoth()

This function returns the complex hyperbolic arccotangent of the complex number z, $\operatorname{arccoth}(z) = \operatorname{arctanh}(1/z)$.

EXAMPLES:

```
sage: CDF(1,1).arccoth()
0.402359478109 - 0.553574358897*I
```

arccsc()

This function returns the complex arccosecant of the complex number z, $\operatorname{arccsc}(z) = \arcsin(1/z)$.

EXAMPLES:

```
sage: CDF(1,1).arccsc()
0.452278447151 - 0.530637530953*I
```

arccsch()

This function returns the complex hyperbolic arccosecant of the complex number z, $\operatorname{arccsch}(z) = \arcsin(1/z)$.

EXAMPLES:

```
sage: CDF(1,1).arccsch()
0.530637530953 - 0.452278447151*I
```

arcsech()

This function returns the complex hyperbolic arcsecant of the complex number z, $\text{arcsech}(z) = \text{arccosh}(1/z)$.

EXAMPLES:

```
sage: CDF(1,1).arcsech()
0.530637530953 - 1.11851787964*I
```

arcsin()

This function returns the complex arcsine of the complex number z, $\arcsin(z)$. The branch cuts are on the real axis, less than -1 and greater than 1.

EXAMPLES:

```
sage: CDF(1,1).arcsin()
0.666239432493 + 1.06127506191*I
```

arcsinh()

This function returns the complex hyperbolic arcsine of the complex number z, $\text{arcsinh}(z)$. The branch cuts are on the imaginary axis, below -i and above i.

EXAMPLES:

```
sage: CDF(1,1).arcsinh()
1.06127506191 + 0.666239432493*I
```

arctan()

This function returns the complex arctangent of the complex number z, $\arctan(z)$. The branch cuts are on the imaginary axis, below $-i$ and above i.

EXAMPLES:

```
sage: CDF(1,1).arctan()
1.0172219679 + 0.402359478109*I
```

arctanh()

This function returns the complex hyperbolic arctangent of the complex number z, $\text{arctanh}(z)$. The branch cuts are on the real axis, less than -1 and greater than 1.

EXAMPLES:

```
sage: CDF(1,1).arctanh()
0.402359478109 + 1.0172219679*I
```

arg()

This function returns the argument of the complex number z, $\arg(z)$, where $-\pi < \arg(z) <= \pi$.

EXAMPLES:

```
sage: CDF(1,0).arg()
0.0
sage: CDF(0,1).arg()
1.57079632679
sage: CDF(0,-1).arg()
-1.57079632679
sage: CDF(-1,0).arg()
3.14159265359
```

argument()

This function returns the argument of the self, in the interval $-\pi < arg(self) \leq \pi$.

EXAMPLES:

```
sage: CDF(6).argument()
0.0
sage: CDF(i).argument()
1.57079632679
sage: CDF(-1).argument()
3.14159265359
sage: CDF(-1 - 0.000001*i).argument()
-3.14159165359
```

conj()

This function returns the complex conjugate of the complex number z, $\overline{z} = x - iy$.

EXAMPLES:

```
sage: z = CDF(2,3); z.conj()
2.0 - 3.0*I
```

conjugate()

This function returns the complex conjugate of the complex number z, $\overline{z} = x - iy$.

EXAMPLES:

```
sage: z = CDF(2,3); z.conjugate()
2.0 - 3.0*I
```

cos()

This function returns the complex cosine of the complex number z, $\cos(z) = (\exp(iz) + \exp(-iz))/2$.

EXAMPLES:

```
sage: CDF(1,1).cos()
0.833730025131 - 0.988897705763*I
```

cosh()

This function returns the complex hyperbolic cosine of the complex number z, $\cosh(z) = (\exp(z) + \exp(-z))/2$.

EXAMPLES:

```
sage: CDF(1,1).cosh()
0.833730025131 + 0.988897705763*I
```

cot()

This function returns the complex cotangent of the complex number z, $\cot(z) = 1/\tan(z)$.

EXAMPLES:

```
sage: CDF(1,1).cot()
0.217621561854 - 0.868014142896*I
```

coth()

This function returns the complex hyperbolic cotangent of the complex number z, $\coth(z) = 1/\tanh(z)$.

EXAMPLES:

```
sage: CDF(1,1).coth()
0.868014142896 - 0.217621561854*I
```

csc()

This function returns the complex cosecant of the complex number z, $\csc(z) = 1/\sin(z)$.

EXAMPLES:

```
sage: CDF(1,1).csc()
0.621518017171 - 0.303931001628*I
```

csch()

This function returns the complex hyperbolic cosecant of the complex number z, $\mathrm{csch}(z) = 1/\sinh(z)$.

EXAMPLES:

```
sage: CDF(1,1).csch()
0.303931001628 - 0.62151801717*I
```

dilog()

Returns the principal branch of the dilogarithm of x, i.e., analytic continuation of the power series

$$\log_2(x) = \sum_{n \geq 1} x^n/n^2.$$

EXAMPLES:

```
sage: CDF(1,2).dilog()
-0.0594747986738 + 2.07264797177*I
sage: CDF(10000000,10000000).dilog()
-134.411774491 + 38.793962999*I
```

eta()

Return the value of the Dedekind η function on self, intelligently computed using $\mathbb{SL}(2, \mathbf{Z})$ transformations.

INPUT:

- `self` - element of the upper half plane (if not, raises a ValueError).
- `omit_frac` - (bool, default: False), if True, omit the $e^{\pi i z/12}$ factor.

OUTPUT: a complex double number

ALGORITHM: Uses the PARI C library, but with some modifications so it always works instead of failing on easy cases involving large input (like PARI does).

The η function is

$$\eta(z) = e^{\pi i z/12} \prod_{n=1}^{\infty} (1 - e^{2\pi i n z})$$

EXAMPLES: We compute a few values of eta:

```
sage: CDF(0,1).eta()
0.768225422326
sage: CDF(1,1).eta()
0.742048775837 + 0.19883137023*I
sage: CDF(25,1).eta()
0.742048775837 + 0.19883137023*I
```

Eta works even if the inputs are large.

```
sage: CDF(0,10^15).eta()
0
sage: CDF(10^15,0.1).eta()      # slightly random-ish arch dependent output
-0.121339721991 - 0.19619461894*I
```

We compute a few values of eta, but with the fractional power of e omited.

```
sage: CDF(0,1).eta(True)
0.998129069926
```

We compute eta to low precision directly from the definition.

```
sage: z = CDF(1,1); z.eta()
0.742048775837 + 0.19883137023*I
sage: i = CDF(0,1); pi = CDF(pi)
```

```
sage: exp(pi * i * z / 12) * prod([1-exp(2*pi*i*n*z) for n in range(1,10)])
0.742048775837 + 0.19883137023*I
```

The optional argument allows us to omit the fractional part:

```
sage: z = CDF(1,1)
sage: z.eta(omit_frac=True)
0.998129069926
sage: pi = CDF(pi)
sage: prod([1-exp(2*pi*i*n*z) for n in range(1,10)])      # slightly random-ish arch depende
0.998129069926 + 4.5908467128e-19*I
```

We illustrate what happens when z is not in the upper half plane.

```
sage: z = CDF(1)
sage: z.eta()
...
ValueError: value must be in the upper half plane
```

You can also use functional notation.

```
sage: z = CDF(1,1) ; eta(z)
0.742048775837 + 0.19883137023*I
```

exp()

This function returns the complex exponential of the complex number z, $\exp(z)$.

EXAMPLES:

```
sage: CDF(1,1).exp()
1.46869393992 + 2.28735528718*I
```

We numerically verify a famous identity to the precision of a double.

```
sage: z = CDF(0, 2*pi); z
6.28318530718*I
sage: exp(z)          # somewhat random-ish output depending on platform
1.0 - 2.44921270764e-16*I
```

gamma()

Return the Gamma function evaluated at this complex number.

EXAMPLES:

```
sage: CDF(5,0).gamma()
24.0
sage: CDF(1,1).gamma()
0.498015668118 - 0.154949828302*I
sage: CDF(0).gamma()
Infinity
```

gamma_inc()

Return the incomplete Gamma function evaluated at this complex number.

EXAMPLES:

```
sage: CDF(1,1).gamma_inc(CDF(2,3))
0.00209691486365 - 0.0599819136554*I
sage: CDF(1,1).gamma_inc(5)
-0.00137813093622 + 0.00651982002312*I
sage: CDF(2,0).gamma_inc(CDF(1,1))
0.707092096346 - 0.42035364096*I
```

imag()

Return the imaginary part of this complex double.

EXAMPLES:

```
sage: a = CDF(3,-2)
sage: a.imag()
-2.0
```

is_square()

This function always returns true as $\mathbf{C}$ is algebraically closed.

EXAMPLES:

```
sage: CDF(-1).is_square()
True
```

log()

This function returns the complex natural logarithm to the given base of the complex number z, $\log(z)$. The branch cut is the negative real axis.

INPUT:

•`base` - default: e, the base of the natural logarithm

EXAMPLES:

```
sage: CDF(1,1).log()
0.34657359028 + 0.785398163397*I
```

log10()

This function returns the complex base-10 logarithm of the complex number z, $\log_{10}(z)$.

The branch cut is the negative real axis.

EXAMPLES:

```
sage: CDF(1,1).log10()
0.150514997832 + 0.34109408846*I
```

log_b()

This function returns the complex base-b logarithm of the complex number z, $\log_b(z)$. This quantity is computed as the ratio $\log(z)/\log(b)$.

The branch cut is the negative real axis.

EXAMPLES:

```
sage: CDF(1,1).log_b(10)
0.150514997832 + 0.34109408846*I
```

logabs()

This function returns the natural logarithm of the magnitude of the complex number z, $\log|z|$.

This allows for an accurate evaluation of $\log|z|$ when $|z|$ is close to 1. The direct evaluation of `log(abs(z))` would lead to a loss of precision in this case.

EXAMPLES:

```
sage: CDF(1.1,0.1).logabs()
0.0994254293726
sage: log(abs(CDF(1.1,0.1)))
0.0994254293726

sage: log(abs(ComplexField(200)(1.1,0.1)))
0.099425429372582595066319157757531449594489450091985182495705
```

norm()

This function returns the squared magnitude of the complex number z, $|z|^2$.

EXAMPLES:

```
sage: CDF(2,3).norm()
13.0
```

nth_root()

The n-th root function.

INPUT:

- `all` - bool (default: False); if True, return a list of all n-th roots.

EXAMPLES:

```
sage: a = CDF(125)
sage: a.nth_root(3)
5.0
sage: a = CDF(10, 2)
sage: [r^5 for r in a.nth_root(5, all=True)]
[10.0 + 2.0*I, 10.0 + 2.0*I, 10.0 + 2.0*I, 10.0 + 2.0*I, 10.0 + 2.0*I]
sage: abs(sum(a.nth_root(111, all=True))) # random but close to zero
6.00659385991e-14
```

parent()

Return the complex double field, which is the parent of self.

EXAMPLES:

```
sage: a = CDF(2,3)
sage: a.parent()
Complex Double Field
sage: parent(a)
Complex Double Field
```

prec()

Returns the precision of this number (to be more similar to ComplexNumber). Always returns 53.

EXAMPLES:

```
sage: CDF(0).prec()
53
```

real()

Return the real part of this complex double.

EXAMPLES:

```
sage: a = CDF(3,-2)
sage: a.real()
3.0
```

sec()

This function returns the complex secant of the complex number z, $\sec(z) = 1/\cos(z)$.

EXAMPLES:

```
sage: CDF(1,1).sec()
0.498337030555 + 0.591083841721*I
```

sech()

This function returns the complex hyperbolic secant of the complex number z, $\mathrm{sech}(z) = 1/\cosh(z)$.

EXAMPLES:

```
sage: CDF(1,1).sech()
0.498337030555 - 0.591083841721*I
```

sin()

This function returns the complex sine of the complex number z, $\sin(z) = (\exp(iz) - \exp(-iz))/(2i)$.

EXAMPLES:

```
sage: CDF(1,1).sin()
1.29845758142 + 0.634963914785*I
```

sinh()

This function returns the complex hyperbolic sine of the complex number z, $\sinh(z) = (\exp(z) - \exp(-z))/2$.

EXAMPLES:

```
sage: CDF(1,1).sinh()
0.634963914785 + 1.29845758142*I
```

sqrt()

The square root function.

INPUT:

- `all` - bool (default: False); if True, return a list of all square roots.

If all is False, the branch cut is the negative real axis. The result always lies in the right half of the complex plane.

EXAMPLES: We compute several square roots.

```
sage: a = CDF(2,3)
sage: b = a.sqrt(); b
1.67414922804 + 0.89597747613*I
sage: b^2
2.0 + 3.0*I
sage: a^(1/2)
1.67414922804 + 0.89597747613*I
```

We compute the square root of -1.

```
sage: a = CDF(-1)
sage: a.sqrt()
1.0*I
```

We compute all square roots:

```
sage: CDF(-2).sqrt(all=True)
[1.41421356237*I, -1.41421356237*I]
sage: CDF(0).sqrt(all=True)
[0]
```

tan()

This function returns the complex tangent of the complex number z, $\tan(z) = \sin(z)/\cos(z)$.

EXAMPLES:

```
sage: CDF(1,1).tan()
0.27175258532 + 1.08392332734*I
```

tanh()

This function returns the complex hyperbolic tangent of the complex number z, $\tanh(z) = \sinh(z)/\cosh(z)$.

EXAMPLES:

```
sage: CDF(1,1).tanh()
1.08392332734 + 0.27175258532*I
```

zeta()

Return the Riemann zeta function evaluated at this complex number.

EXAMPLES:

```
sage: z = CDF(1, 1)
sage: z.zeta()
0.582158059752 - 0.926848564331*I
sage: zeta(z)
0.582158059752 - 0.926848564331*I
```

ComplexDoubleField()

Returns the field of double precision complex numbers.

EXAMPLE:

```
sage: ComplexDoubleField()
Complex Double Field
sage: ComplexDoubleField() is CDF
True
```

class **ComplexDoubleField_class**()

An approximation to the field of complex numbers using double precision floating point numbers. Answers derived from calculations in this approximation may differ from what they would be if those calculations were performed in the true field of complex numbers. This is due to the rounding errors inherent to finite precision calculations.

ALGORITHMS: Arithmetic is done using GSL (the GNU Scientific Library).

characteristic()

Return the characteristic of this complex double field, which is 0.

EXAMPLES:

```
sage: CDF.characteristic()
0
```

construction()

Returns the functorial construction of self, namely, algebraic closure of the real double field.

EXAMPLES:

```
sage: c, S = CDF.construction(); S
Real Double Field
sage: CDF == c(S)
True
```

gen()

Return the generator of the complex double field.

EXAMPLES:

```
sage: CDF.0
1.0*I
sage: CDF.gens()
(1.0*I,)
```

is_exact()

Returns whether or not this field is exact, which is always false.

EXAMPLE:

```
sage: CDF.is_exact()
False
```

ngens()

The number of generators of this complex field as an RR-algebra.

There is one generator, namely sqrt(-1).

EXAMPLES:

```
sage: CDF.ngens()
1
```

pi()

Returns pi as a double precision complex number.

EXAMPLES:

```
sage: CDF.pi()
3.14159265359
```

prec()

Return the precision of this complex double field (to be more similar to ComplexField). Always returns 53.

EXAMPLES:

```
sage: CDF.prec()
53
```

random_element()

Return a random element this complex double field with real and imaginary part bounded by xmin, xmax, ymin, ymax.

EXAMPLES:

```
sage: CDF.random_element()
-0.436810529675 + 0.736945423566*I
sage: CDF.random_element(-10,10,-10,10)
-7.08874026302 - 9.54135400334*I
sage: CDF.random_element(-10^20,10^20,-2,2)
-7.58765473764e+19 + 0.925549022839*I
```

real_double_field()

The real double field, which you may view as a subfield of this complex double field.

EXAMPLES:

```
sage: CDF.real_double_field()
Real Double Field
```

to_prec()

Returns the complex field to the specified precision. As doubles have fixed precision, this will only return a complex double field if prec is exactly 53.

EXAMPLES:

```
sage: CDF.to_prec(53)
Complex Double Field
sage: CDF.to_prec(250)
Complex Field with 250 bits of precision
```

zeta()

Return a primitive n-th root of unity in this CDF, for $n \geq 1$.

INPUT:

- n - a positive integer (default: 2)

OUTPUT: a complex n-th root of unity.

EXAMPLES:

```
sage: CDF.zeta(7)
0.623489801859 + 0.781831482468*I
sage: CDF.zeta(1)
1.0
```

```
sage: CDF.zeta()
-1.0
sage: CDF.zeta() == CDF.zeta(2)
True

sage: CDF.zeta(0.5)
...
ValueError: n must be a positive integer
sage: CDF.zeta(0)
...
ValueError: n must be a positive integer
sage: CDF.zeta(-1)
...
ValueError: n must be a positive integer
```

class FloatToCDF()

Fast morphism from anything with a __float__ method to an RDF element.

EXAMPLES:

```
sage: f = CDF.coerce_map_from(ZZ); f
Native morphism:
  From: Integer Ring
  To:   Complex Double Field
sage: f(4)
4.0
sage: f = CDF.coerce_map_from(QQ); f
Native morphism:
  From: Rational Field
  To:   Complex Double Field
sage: f(1/2)
0.5
sage: f = CDF.coerce_map_from(int); f
Native morphism:
  From: Set of Python objects of type 'int'
  To:   Complex Double Field
sage: f(3r)
3.0
sage: f = CDF.coerce_map_from(float); f
Native morphism:
  From: Set of Python objects of type 'float'
  To:   Complex Double Field
sage: f(3.5)
3.5
```

is_ComplexDoubleElement()

Return True if x is a is_ComplexDoubleElement.

EXAMPLES:

```
sage: from sage.rings.complex_double import is_ComplexDoubleElement
sage: is_ComplexDoubleElement(0)
False
sage: is_ComplexDoubleElement(CDF(0))
True
```

is_ComplexDoubleField()

Return True if x is the complex double field.

EXAMPLE:

```
sage: from sage.rings.complex_double import is_ComplexDoubleField
sage: is_ComplexDoubleField(CDF)
True
sage: is_ComplexDoubleField(ComplexField(53))
False
```

25.3 Field of Arbitrary Precision Real Numbers

AUTHORS:

- Kyle Schalm (2005-09)
- William Stein: bug fixes, examples, maintenance
- Didier Deshommes (2006-03-19): examples
- David Harvey (2006-09-20): compatibility with Element._parent
- William Stein (2006-10): default printing truncates to avoid base-2 rounding confusing (fix suggested by Bill Hart)
- Didier Deshommes: special constructor for QD numbers
- Paul Zimmermann (2008-01): added new functions from mpfr-2.3.0, replaced some, e.g., sech = 1/cosh, by their original mpfr version.
- Carl Witty (2008-02): define floating-point rank and associated functions; add some documentation
- Robert Bradshaw (2009-09): decimal literals, optimizations

This is a binding for the MPFR arbitrary-precision floating point library.

We define a class `RealField`, where each instance of `RealField` specifies a field of floating-point numbers with a specified precision and rounding mode. Individual floating-point numbers are of class `RealNumber`.

In Sage (as in MPFR), floating-point numbers of precision p are of the form $sm2^{e-p}$, where $s \in \{-1, 1\}$, $2^{p-1} \leq m < 2^p$, and $-2^{30} + 1 \leq e \leq 2^{30} - 1$; plus the special values `+0`, `-0`, `+infinity`, `-infinity`, and `NaN` (which stands for Not-a-Number).

Operations in this module which are direct wrappers of MPFR functions are "correctly rounded"; we briefly describe what this means. Assume that you could perform the operation exactly, on real nunbers, to get a result r. If this result can be represented as a floating-point number, then we return that number.

Otherwise, the result r is between two floating-point numbers. For the directed rounding modes (round to plus infinity, round to minus infinity, round to zero), we return the floating-point number in the indicated direction from r. For round to nearest, we return the floating-point number which is nearest to r.

This leaves one case unspecified: in round to nearest mode, what happens if r is exactly halfway between the two nearest floating-point numbers? In that case, we round to the number with an even mantissa (the mantissa is the number m in the representation above).

Consider the ordered set of floating-point numbers of precision p. (Here we identify `+0` and `-0`, and ignore `NaN`.) We can give a bijection between these floating-point numbers and a segment of the integers, where 0 maps to 0 and adjacent floating-point numbers map to adjacent integers. We call the integer corresponding to a given floating-point number the "floating-point rank" of the number. (This is not standard terminology; I just made it up.)

EXAMPLES: A difficult conversion:

```
sage: RR(sys.maxint)
9.22337203685478e18      # 64-bit
2.14748364700000e9       # 32-bit
```

TESTS:

```
sage: -1e30
-1.00000000000000e30
```

Make sure we don't have a new field for every new literal:

```
sage: parent(2.0) is parent(2.0)
True
sage: RealField(100, rnd='RNDZ') is RealField(100, rnd='RNDD')
False
sage: RealField(100, rnd='RNDZ') is RealField(100, rnd='RNDZ')
True
```

class QQtoRR()

class RRtoRR()

section()

EXAMPLES:

```
sage: from sage.rings.real_mpfr import RRtoRR
sage: R10 = RealField(10)
sage: R100 = RealField(100)
sage: f = RRtoRR(R100, R10)
sage: f.section()
Generic map:
  From: Real Field with 10 bits of precision
  To:   Real Field with 100 bits of precision
```

class RealField()

An approximation to the field of real numbers using floating point numbers with any specified precision. Answers derived from calculations in this approximation may differ from what they would be if those calculations were performed in the true field of real numbers. This is due to the rounding errors inherent to finite precision calculations.

See the documentation for the module sage.rings.real_mpfr for more details.

algebraic_closure()

Returns the algebraic closure of self, ie the complex field with the same precision.

catalan_constant()

Returns Catalan's constant to the precision of this field.

EXAMPLES:

```
sage: RealField(100).catalan_constant()
0.91596559417721901505460351493
```

characteristic()

Returns 0, since the field of real numbers has characteristic 0.

EXAMPLES:

```
sage: RealField(10).characteristic()
0
```

complex_field()
Return complex field of the same precision.

construction()
Returns the functorial construction of self, namely, completion of the rational numbers with respect to the prime at ∞.

Also preserves other information that makes this field unique (e.g. precision, rounding, print mode).

EXAMPLES:

```
sage: R = RealField(100, rnd='RNDU')
sage: c, S = R.construction(); S
Rational Field
sage: R == c(S)
True
```

euler_constant()
Returns Euler's gamma constant to the precision of this field.

EXAMPLES:

```
sage: RealField(100).euler_constant()
0.57721566490153286060651209008
```

factorial()
Return the factorial of the integer n as a real number.

gen()

gens()

is_atomic_repr()
Returns True, to signify that elements of this field print without sums, so parenthesis aren't required, e.g., in coefficients of polynomials.

EXAMPLES:

```
sage: RealField(10).is_atomic_repr()
True
```

is_exact()

is_finite()
Returns False, since the field of real numbers is not finite.

EXAMPLES:

```
sage: RealField(10).is_finite()
False
```

log2()
Returns log(2) to the precision of this field.

EXAMPLES:

```
sage: R=RealField(100)
sage: R.log2()
0.69314718055994530941723212146
sage: R(2).log()
0.69314718055994530941723212146
```

name()

ngens()

pi()
Returns pi to the precision of this field.

EXAMPLES:

```
sage: R = RealField(100)
sage: R.pi()
3.1415926535897932384626433833
sage: R.pi().sqrt()/2
0.88622692545275801364908374167
sage: R = RealField(150)
sage: R.pi().sqrt()/2
0.886226925452758013649083741670572591398774737
```

prec()

precision()

random_element()

Returns a uniformly distributed random number between min and max (default -1 to 1).

EXAMPLES:

```
sage: RealField(100).random_element(-5, 10)
1.9305310520925994224072377281
sage: RealField(10).random_element()
-0.84
```

TESTS:

```
sage: RealField(31).random_element()
-0.207006278
sage: RealField(32).random_element()
-0.757827933
sage: RealField(33).random_element()
-0.530834221
sage: RealField(63).random_element()
0.918013195263849341
sage: RealField(64).random_element()
-0.805114150788947694
sage: RealField(65).random_element()
0.2035927570696802284
sage: RealField(10).random_element()
-0.59
sage: RealField(10).random_element()
0.57
sage: RR.random_element()
0.931242676441124
sage: RR.random_element()
0.979095507956490
```

rounding_mode()

scientific_notation()

Set or return the scientific notation printing flag. If this flag is True then real numbers with this space as parent print using scientific notation.

INPUT:

- `status` - (bool -) optional flag

to_prec()

Returns the real field that is identical to self, except at the specified precision.

EXAMPLES:

```
sage: RR.to_prec(212)
Real Field with 212 bits of precision
sage: R = RealField(30, rnd="RNDZ")
```

```
sage: R.to_prec(300)
Real Field with 300 bits of precision and rounding RNDZ
```

zeta()

Return an n-th root of unity in the real field, if one exists, or raise a ValueError otherwise.

EXAMPLES:

```
sage: R = RealField()
sage: R.zeta()
-1.00000000000000
sage: R.zeta(1)
1.00000000000000
sage: R.zeta(5)
...
ValueError: No 5th root of unity in self
```

RealField_constructor()

RealField(prec, sci_not, rnd):

INPUT:

- `prec` - (integer) precision; default = 53 prec is the number of bits used to represent the mantissa of a floating-point number. The precision can be any integer between mpfr_prec_min() and mpfr_prec_max(). In the current implementation, mpfr_prec_min() is equal to 2.
- `sci_not` - (default: False) if True, always display using scientific notation; if False, display using scientific notation only for very large or very small numbers
- `rnd` - (string) the rounding mode
- RNDN - (default) round to nearest: Knuth says this is the best choice to prevent "floating point drift".
- RNDD - round towards minus infinity
- RNDZ - round towards zero
- RNDU - round towards plus infinity

EXAMPLES:

```
sage: RealField(10)
Real Field with 10 bits of precision
sage: RealField()
Real Field with 53 bits of precision
sage: RealField(100000)
Real Field with 100000 bits of precision
```

Note: The default precision is 53, since according to the MPFR manual: 'mpfr should be able to exactly reproduce all computations with double-precision machine floating-point numbers (double type in C), except the default exponent range is much wider and subnormal numbers are not implemented.'

class **RealLiteral**()

base

literal

class **RealNumber**()

A floating point approximation to a real number using any specified precision. Answers derived from calculations with such approximations may differ from what they would be if those calculations were performed with true real numbers. This is due to the rounding errors inherent to finite precision calculations.

The approximation is printed to slightly fewer digits than its internal precision, in order to avoid confusing roundoff issues that occur because numbers are stored internally in binary.

agm()

Return the arithmetic-geometric mean of self and other. The arithmetic-geometric mean is the common limit of the sequences u_n and v_n, where u_0 is self, v_0 is other, u_{n+1} is the arithmetic mean of u_n and v_n, and v_{n+1} is the geometric mean of u_n and v_n. If any operand is negative, the return value is `NaN`.

algdep()

Returns a polynomial of degree at most n which is approximately satisfied by this number. Note that the returned polynomial need not be irreducible, and indeed usually won't be if this number is a good approximation to an algebraic number of degree less than n.

ALGORITHM: Uses the PARI C-library algdep command.

EXAMPLE:

```
sage: r = sqrt(2.0); r
1.41421356237310
sage: r.algdep(5)
x^2 - 2
```

algebraic_dependency()

Returns a polynomial of degree at most n which is approximately satisfied by this number. Note that the returned polynomial need not be irreducible, and indeed usually won't be if this number is a good approximation to an algebraic number of degree less than n.

ALGORITHM: Uses the PARI C-library algdep command.

EXAMPLE:

```
sage: r = sqrt(2.0); r
1.41421356237310
sage: r.algdep(5)
x^2 - 2
```

arccos()

Returns the inverse cosine of this number

EXAMPLES:

```
sage: q = RR.pi()/3
sage: i = q.cos()
sage: i.arccos() == q
True
```

arccosh()

Returns the hyperbolic inverse cosine of this number

EXAMPLES:

```
sage: q = RR.pi()/2
sage: i = q.cosh() ; i
2.50917847865806
sage: q == i.arccosh()
True
```

arccoth()

Returns the inverse hyperbolic cotangent of this number

EXAMPLES:

```
sage: q = RR.pi()/5
sage: i = q.coth()
sage: i.arccoth() == q
True
```

arccsch()
Returns the inverse hyperbolic cosecant of this number
EXAMPLES:

```
sage: i = RR.pi()/5
sage: q = i.csch()
sage: q.arccsch() == i
True
```

arcsech()
Returns the inverse hyperbolic secant of this number
EXAMPLES:

```
sage: i = RR.pi()/3
sage: q = i.sech()
sage: q.arcsech() == i
True
```

arcsin()
Returns the inverse sine of this number
EXAMPLES:

```
sage: q = RR.pi()/5
sage: i = q.sin()
sage: i.arcsin() == q
True
sage: i.arcsin() - q
0.000000000000000
```

arcsinh()
Returns the hyperbolic inverse sine of this number
EXAMPLES:

```
sage: q = RR.pi()/7
sage: i = q.sinh() ; i
0.464017630492991
sage: i.arcsinh() - q
0.000000000000000
```

arctan()
Returns the inverse tangent of this number
EXAMPLES:

```
sage: q = RR.pi()/5
sage: i = q.tan()
sage: i.arctan() == q
True
```

arctanh()
Returns the hyperbolic inverse tangent of this number
EXAMPLES:

```
sage: q = RR.pi()/7
sage: i = q.tanh() ; i
0.420911241048535
sage: i.arctanh() - q
0.000000000000000
```

ceil()
Returns the ceiling of this number

OUTPUT: integer

EXAMPLES:

```
sage: (2.99).ceil()
3
sage: (2.00).ceil()
2
sage: (2.01).ceil()
3

sage: ceil(10^16 * 1.0)
10000000000000000
sage: ceil(10^17 * 1.0)
100000000000000000
sage: ceil(RR(+infinity))
...
ValueError: Calling ceil() on infinity or NaN
```

ceiling()

conjugate()

Return the complex conjugate of this real number, which is the number itself.

EXAMPLES: sage: x = RealField(100)(1.238) sage: x.conjugate() 1.2380000000000000000000000000

cos()

Returns the cosine of this number

EXAMPLES:

```
sage: t=RR.pi()/2
sage: t.cos()
6.12323399573677e-17
```

cosh()

Returns the hyperbolic cosine of this number

EXAMPLES:

```
sage: q = RR.pi()/12
sage: q.cosh()
1.03446564009551
```

cot()

Returns the cotangent of this number

EXAMPLES:

```
sage: RealField(100)(2).cot()
-0.45765755436028576375027741043
```

coth()

Returns the hyperbolic cotangent of this number

EXAMPLES:

```
sage: RealField(100)(2).coth()
1.0373147207275480958778097648
```

csc()

Returns the cosecant of this number

EXAMPLES:

```
sage: RealField(100)(2).csc()
1.0997501702946164667566973970
```

csch()
Returns the hyperbolic cosecant of this number
EXAMPLES:

```
sage: RealField(100)(2).csch()
0.27572056477178320775835148216
```

cube_root()
Return the cubic root (defined over the real numbers) of self.
EXAMPLES:

```
sage: r = 125.0; r.cube_root()
5.00000000000000
sage: r = -119.0
sage: r.cube_root()^3 - r       # illustrates precision loss
-1.42108547152020e-14
```

eint()
Returns the exponential integral of this number.
EXAMPLES:

```
sage: r = 1.0
sage: r.eint()
1.89511781635594

sage: r = -1.0
sage: r.eint()
NaN
```

erf()
Returns the value of the error function on self.
EXAMPLES:

```
sage: R = RealField(53)
sage: R(2).erf()
0.995322265018953
sage: R(6).erf()
1.00000000000000
```

erfc()
Returns the value of the complementary error function on self, i.e., $1 -$ `erf(self)`.
EXAMPLES:

```
sage: R = RealField(53)
sage: R(2).erfc()
0.00467773498104727
sage: R(6).erfc()
2.15197367124989e-17
```

exact_rational()
Returns the exact rational representation of this floating-point number.
EXAMPLES:

```
sage: RR(0).exact_rational()
0
sage: RR(1/3).exact_rational()
6004799503160661/18014398509481984
sage: RR(37/16).exact_rational()
37/16
sage: RR(3^60).exact_rational()
```

```
42391158275216203520420085760
sage: RR(3^60).exact_rational() - 3^60
6125652559
sage: RealField(5)(-pi).exact_rational()
-25/8
```

TESTS:

```
sage: RR('nan').exact_rational()
...
ValueError: Cannot convert NaN or infinity to rational number
sage: RR('-infinity').exact_rational()
...
ValueError: Cannot convert NaN or infinity to rational number
```

exp()

Returns $e^{\texttt{self}}$

EXAMPLES:

```
sage: r = 0.0
sage: r.exp()
1.00000000000000

sage: r = 32.3
sage: a = r.exp(); a
1.06588847274864e14
sage: a.log()
32.3000000000000

sage: r = -32.3
sage: r.exp()
9.38184458849869e-15
```

exp10()

Returns $10^{\texttt{self}}$

EXAMPLES:

```
sage: r = 0.0
sage: r.exp10()
1.00000000000000

sage: r = 32.0
sage: r.exp10()
1.00000000000000e32

sage: r = -32.3
sage: r.exp10()
5.01187233627276e-33
```

exp2()

Returns $2^{\texttt{self}}$

EXAMPLES:

```
sage: r = 0.0
sage: r.exp2()
1.00000000000000

sage: r = 32.0
sage: r.exp2()
4.29496729600000e9
```

```
sage: r = -32.3
sage: r.exp2()
1.89117248253021e-10
```

expm1()

Returns $e^{\texttt{self}} - 1$, avoiding cancellation near 0.

EXAMPLES:

```
sage: r = 1.0
sage: r.expm1()
1.71828182845905

sage: r = 1e-16
sage: exp(r)-1
0.000000000000000
sage: r.expm1()
1.00000000000000e-16
```

floor()

Returns the floor of this number

EXAMPLES:

```
sage: R = RealField()
sage: (2.99).floor()
2
sage: (2.00).floor()
2
sage: floor(RR(-5/2))
-3
sage: floor(RR(+infinity))
...
ValueError: Calling floor() on infinity or NaN
```

fp_rank()

Returns the floating-point rank of this number. That is, if you list the floating-point numbers of this precision in order, and number them starting with $0.0 \to 0$ and extending the list to positive and negative infinity, returns the number corresponding to this floating-point number.

EXAMPLES:

```
sage: RR(0).fp_rank()
0
sage: RR(0).nextabove().fp_rank()
1
sage: RR(0).nextbelow().nextbelow().fp_rank()
-2
sage: RR(1).fp_rank()
48357032784585166988247 05
sage: RR(-1).fp_rank()
-48357032784585166988247 05
sage: RR(1).fp_rank() - RR(1).nextbelow().fp_rank()
1
sage: RR(-infinity).fp_rank()
-96714065524134337702789 13
sage: RR(-infinity).fp_rank() - RR(-infinity).nextabove().fp_rank()
-1
```

fp_rank_delta()

Return the floating-point rank delta between `self` and `other`. That is, if the return value is positive, this is the number of times you have to call `.nextabove()` to get from `self` to `other`.

EXAMPLES:

```
sage: [x.fp_rank_delta(x.nextabove()) for x in
...       (RR(-infinity), -1.0, 0.0, 1.0, RR(pi), RR(infinity))]
[1, 1, 1, 1, 1, 0]
```

In the 2-bit floating-point field, one subsegment of the floating-point numbers is: 1, 1.5, 2, 3, 4, 6, 8, 12, 16, 24, 32

```
sage: R2 = RealField(2)
sage: R2(1).fp_rank_delta(R2(2))
2
sage: R2(2).fp_rank_delta(R2(1))
-2
sage: R2(1).fp_rank_delta(R2(1048576))
40
sage: R2(24).fp_rank_delta(R2(4))
-5
sage: R2(-4).fp_rank_delta(R2(-24))
-5
```

There are lots of floating-point numbers around 0:

```
sage: R2(-1).fp_rank_delta(R2(1))
4294967298
```

frac()

frac returns a real number > -1 and < 1. it satisfies the relation: x = x.trunc() + x.frac()

EXAMPLES:

```
sage: (2.99).frac()
0.990000000000000
sage: (2.50).frac()
0.500000000000000
sage: (-2.79).frac()
-0.790000000000000
```

gamma()

The Euler gamma function. Return gamma of self.

EXAMPLES:

```
sage: R = RealField()
sage: R(6).gamma()
120.000000000000
sage: R(1.5).gamma()
0.886226925452758
```

integer_part()

If in decimal this number is written n.defg, returns n.

OUTPUT: a Sage Integer

EXAMPLE:

```
sage: a = 119.41212
sage: a.integer_part()
119
sage: a = -123.4567
sage: a.integer_part()
-123
```

A big number with no decimal point:

```
sage: a = RR(10^17); a
1.00000000000000e17
sage: a.integer_part()
100000000000000000
```

is_NaN()

is_infinity()

EXAMPLES:

```
sage: a = RR('1.494') / RR(0); a
+infinity
sage: a.is_infinity()
True
sage: a = -RR('1.494') / RR(0); a
-infinity
sage: a.is_infinity()
True
sage: RR(1.5).is_infinity()
False
```

is_negative_infinity()

EXAMPLES:

```
sage: a = RR('1.494') / RR(0); a
+infinity
sage: a.is_negative_infinity()
False
sage: a = -RR('1.494') / RR(0); a
-infinity
sage: RR(1.5).is_negative_infinity()
False
sage: a.is_negative_infinity()
True
```

is_positive_infinity()

EXAMPLES:

```
sage: a = RR('1.494') / RR(0); a
+infinity
sage: a.is_positive_infinity()
True
sage: a = -RR('1.494') / RR(0); a
-infinity
sage: RR(1.5).is_positive_infinity()
False
sage: a.is_positive_infinity()
False
```

is_real()

is_square()

Returns whether or not this number is a square in this field. For the real numbers, this is True if and only if self is non-negative.

EXAMPLES:

```
sage: r = 3.5
sage: r.is_square()
True
sage: r = 0.0
sage: r.is_square()
```

```
True
sage: r = -4.0
sage: r.is_square()
False
```

is_unit()

j0()

Returns the value of the Bessel J function of order 0 at self.

EXAMPLES:

```
sage: R = RealField(53)
sage: R(2).j0()
0.223890779141236
```

j1()

Returns the value of the Bessel J function of order 1 at self.

EXAMPLES:

```
sage: R = RealField(53)
sage: R(2).j1()
0.576724807756873
```

jn()

Returns the value of the Bessel J function of order n at self.

EXAMPLES:

```
sage: R = RealField(53)
sage: R(2).jn(3)
0.128943249474402
sage: R(2).jn(-17)
-2.65930780516787e-15
```

lngamma()

Return the logarithm of gamma of self.

EXAMPLES:

```
sage: R = RealField(53)
sage: R(6).lngamma()
4.78749174278205
sage: R(1e10).lngamma()
2.20258509288811e11
```

log()

EXAMPLES:

```
sage: R = RealField()
sage: R(2).log()
0.693147180559945
```

log10()

Returns log to the base 10 of self

EXAMPLES:

```
sage: r = 16.0; r.log10()
1.20411998265592
sage: r.log() / log(10.0)
1.20411998265592
```

```
sage: r = 39.9; r.log10()
1.60097289568675

sage: r = 0.0
sage: r.log10()
-infinity

sage: r = -1.0
sage: r.log10()
NaN
```

log1p()

Returns log of 1 + self

EXAMPLES:

```
sage: r = 15.0; r.log1p()
2.77258872223978
sage: (r+1).log()
2.77258872223978

sage: r = 38.9; r.log1p()
3.68637632389582

sage: r = -1.0
sage: r.log1p()
-infinity

sage: r = -2.0
sage: r.log1p()
NaN
```

log2()

Returns log to the base 2 of self

EXAMPLES:

```
sage: r = 16.0
sage: r.log2()
4.00000000000000

sage: r = 31.9; r.log2()
4.99548451887751

sage: r = 0.0
sage: r.log2()
-infinity
```

multiplicative_order()

nearby_rational()

Find a rational near to self. Exactly one of max_error or max_denominator must be specified. If max_error is specified, then this returns the simplest rational in the range [self-max_error .. self+max_error]. If max_denominator is specified, then this returns the rational closest to self with denominator at most max_denominator. (In case of ties, we pick the simpler rational.)

EXAMPLES:

```
sage: (0.333).nearby_rational(max_error=0.001)
1/3
sage: (0.333).nearby_rational(max_error=1)
0
```

```
sage: (-0.333).nearby_rational(max_error=0.0001)
-257/772

sage: (0.333).nearby_rational(max_denominator=100)
1/3
sage: RR(1/3 + 1/1000000).nearby_rational(max_denominator=2999999)
777780/2333333
sage: RR(1/3 + 1/1000000).nearby_rational(max_denominator=3000000)
1000003/3000000
sage: (-0.333).nearby_rational(max_denominator=1000)
-333/1000
sage: RR(3/4).nearby_rational(max_denominator=2)
1
sage: RR(pi).nearby_rational(max_denominator=120)
355/113
sage: RR(pi).nearby_rational(max_denominator=10000)
355/113
sage: RR(pi).nearby_rational(max_denominator=100000)
312689/99532
sage: RR(pi).nearby_rational(max_denominator=1)
3
sage: RR(-3.5).nearby_rational(max_denominator=1)
-3
```

TESTS:

```
sage: RR('nan').nearby_rational(max_denominator=1000)
...
ValueError: Cannot convert NaN or infinity to rational number
sage: RR('nan').nearby_rational(max_error=0.01)
...
ValueError: Cannot convert NaN or infinity to rational number
sage: RR('infinity').nearby_rational(max_denominator=1000)
...
ValueError: Cannot convert NaN or infinity to rational number
sage: RR('infinity').nearby_rational(max_error=0.01)
...
ValueError: Cannot convert NaN or infinity to rational number
```

nextabove()

Returns the next floating-point number larger than self.

EXAMPLES:

```
sage: RR('-infinity').nextabove()
-2.09857871646739e323228496
sage: RR(0).nextabove()
2.38256490488795e-323228497
sage: RR('+infinity').nextabove()
+infinity
sage: RR(-sqrt(2)).str(truncate=False)
'-1.4142135623730951'
sage: RR(-sqrt(2)).nextabove().str(truncate=False)
'-1.4142135623730949'
```

nextbelow()

Returns the next floating-point number smaller than self.

EXAMPLES:

```
sage: RR('-infinity').nextbelow()
-infinity
sage: RR(0).nextbelow()
-2.38256490488795e-323228497
sage: RR('+infinity').nextbelow()
2.09857871646739e323228496
sage: RR(-sqrt(2)).str(truncate=False)
'-1.4142135623730951'
sage: RR(-sqrt(2)).nextbelow().str(truncate=False)
'-1.4142135623730954'
```

nexttoward()

Returns the floating-point number adjacent to self which is closer to other. If self or other is NaN, returns NaN; if self equals other, returns self.

EXAMPLES:

```
sage: (1.0).nexttoward(2).str(truncate=False)
'1.0000000000000002'
sage: (1.0).nexttoward(RR('-infinity')).str(truncate=False)
'0.99999999999999989'
sage: RR(infinity).nexttoward(0)
2.09857871646739e323228496
sage: RR(pi).str(truncate=False)
'3.1415926535897931'
sage: RR(pi).nexttoward(22/7).str(truncate=False)
'3.1415926535897936'
sage: RR(pi).nexttoward(21/7).str(truncate=False)
'3.1415926535897927'
```

nth_root()

Returns an n^{th} root of self.

INPUT:

- n - A positive number, rounded down to the nearest integer. Note that n should be less than 'sys.maxint'.
- algorithm - Set this to 1 to call mpfr directly, set this to 2 to use interval arithmetic and logarithms, or leave it at the default of 0 to choose the algorithm which is estimated to be faster.

AUTHORS:

- Carl Witty (2007-10)

EXAMPLES:

```
sage: R = RealField()
sage: R(8).nth_root(3)
2.00000000000000
sage: R(8).nth_root(3.7)     # illustrate rounding down
2.00000000000000
sage: R(-8).nth_root(3)
-2.00000000000000
sage: R(0).nth_root(3)
0.000000000000000
sage: R(32).nth_root(-1)
...
ValueError: n must be positive
sage: R(32).nth_root(1.0)
32.0000000000000
sage: R(4).nth_root(4)
1.41421356237310
```

```
sage: R(4).nth_root(40)
1.03526492384138
sage: R(4).nth_root(400)
1.00347174850950
sage: R(4).nth_root(4000)
1.00034663365385
sage: R(4).nth_root(4000000)
1.00000034657365
sage: R(-27).nth_root(3)
-3.00000000000000
sage: R(-4).nth_root(3999999)
-1.00000034657374
```

Note that for negative numbers, any even root throws an exception

```
sage: R(-2).nth_root(6)
...
ValueError: taking an even root of a negative number
```

The n^{th} root of 0 is defined to be 0, for any n

```
sage: R(0).nth_root(6)
0.000000000000000

sage: R(0).nth_root(7)
0.000000000000000
```

TESTS: The old and new algorithms should give exactly the same results in all cases.

```
sage: def check(x, n):
...       answers = []
...       for sign in (1, -1):
...           if is_even(n) and sign == -1:
...               continue
...           for rounding in ('RNDN', 'RNDD', 'RNDU', 'RNDZ'):
...               fld = RealField(x.prec(), rnd=rounding)
...               fx = fld(sign * x)
...               alg_mpfr = fx.nth_root(n, algorithm=1)
...               alg_mpfi = fx.nth_root(n, algorithm=2)
...               assert(alg_mpfr == alg_mpfi)
...               if sign == 1: answers.append(alg_mpfr)
...       return answers
```

Check some perfect powers (and nearby numbers).

```
sage: check(16.0, 4)
[2.00000000000000, 2.00000000000000, 2.00000000000000, 2.00000000000000]
sage: check((16.0).nextabove(), 4)
[2.00000000000000, 2.00000000000000, 2.00000000000001, 2.00000000000000]
sage: check((16.0).nextbelow(), 4)
[2.00000000000000, 1.99999999999999, 2.00000000000000, 1.99999999999999]
sage: check(((9.0 * 256)^7), 7)
[2304.00000000000, 2304.00000000000, 2304.00000000000, 2304.00000000000]
sage: check(((9.0 * 256)^7).nextabove(), 7)
[2304.00000000000, 2304.00000000000, 2304.00000000001, 2304.00000000000]
sage: check(((9.0 * 256)^7).nextbelow(), 7)
[2304.00000000000, 2303.99999999999, 2304.00000000000, 2303.99999999999]
sage: check(((5.0 / 512)^17), 17)
[0.00976562500000000, 0.00976562500000000, 0.00976562500000000, 0.00976562500000000]
sage: check(((5.0 / 512)^17).nextabove(), 17)
[0.00976562500000000, 0.00976562500000000, 0.00976562500000001, 0.00976562500000000]
```

```
sage: check(((5.0 / 512)^17).nextbelow(), 17)
[0.00976562500000000, 0.00976562499999999, 0.00976562500000000, 0.00976562499999999]
```

And check some non-perfect powers:

```
sage: check(2.0, 3)
[1.25992104989487, 1.25992104989487, 1.25992104989488, 1.25992104989487]
sage: check(2.0, 4)
[1.18920711500272, 1.18920711500272, 1.18920711500273, 1.18920711500272]
sage: check(2.0, 5)
[1.14869835499704, 1.14869835499703, 1.14869835499704, 1.14869835499703]
```

And some different precisions:

```
sage: check(RealField(20)(22/7), 19)
[1.0621, 1.0621, 1.0622, 1.0621]
sage: check(RealField(200)(e), 4)
[1.2840254166877414840734205680624364583362808652814630892175, 1.2840254166877414840734205680
```

parent()

EXAMPLES:

```
sage: R = RealField()
sage: a = R('1.2456')
sage: a.parent()
Real Field with 53 bits of precision
```

prec()

real()

Return the real part of self.

(Since self is a real number, this simply returns self.)

round()

Rounds self to the nearest integer. The rounding mode of the parent field has no effect on this function.

EXAMPLES:

```
sage: RR(0.49).round()
0
sage: RR(0.5).round()
1
sage: RR(-0.49).round()
0
sage: RR(-0.5).round()
-1
```

sec()

Returns the secant of this number

EXAMPLES:

```
sage: RealField(100)(2).sec()
-2.4029979617223809897546004014
```

sech()

Returns the hyperbolic secant of this number

EXAMPLES:

```
sage: RealField(100)(2).sech()
0.26580222883407969212086273982
```

sign()

simplest_rational()

Returns the simplest rational which is equal to self (in the Sage sense). Recall that Sage defines the equality operator by coercing both sides to a single type and then comparing; thus, this finds the simplest rational which (when coerced to this RealField) is equal to self.

Given rationals a/b and c/d (both in lowest terms), the former is simpler if b<d or if b==d and $|a| < |c|$.

The effect of rounding modes is slightly counter-intuitive. Consider the case of round-toward-minus-infinity. This rounding is performed when coercing a rational to a floating-point number; so the simplest_rational() of a round-to-minus-infinity number will be either exactly equal to or slightly larger than the number.

EXAMPLES:

```
sage: RRd = RealField(53, rnd='RNDD')
sage: RRz = RealField(53, rnd='RNDZ')
sage: RRu = RealField(53, rnd='RNDU')
sage: def check(x):
...       rx = x.simplest_rational()
...       assert(x == rx)
...       return rx
sage: RRd(1/3) < RRu(1/3)
True
sage: check(RRd(1/3))
1/3
sage: check(RRu(1/3))
1/3
sage: check(RRz(1/3))
1/3
sage: check(RR(1/3))
1/3
sage: check(RRd(-1/3))
-1/3
sage: check(RRu(-1/3))
-1/3
sage: check(RRz(-1/3))
-1/3
sage: check(RR(-1/3))
-1/3
sage: check(RealField(20)(pi))
355/113
sage: check(RR(pi))
245850922/78256779
sage: check(RR(2).sqrt())

TESTS:

```
sage: RR('nan').simplest_rational()
...
ValueError: Cannot convert NaN or infinity to rational number
sage: RR('-infinity').simplest_rational()
...
ValueError: Cannot convert NaN or infinity to rational number
```

sin()

Returns the sine of this number

EXAMPLES:

```
sage: R = RealField(100)
sage: R(2).sin()
0.90929742682568169539601986591
```

sincos()

Returns a pair consisting of the sine and cosine.

EXAMPLES:

```
sage: R = RealField()
sage: t = R.pi()/6
sage: t.sincos()
(0.500000000000000, 0.866025403784439)
```

sinh()

Returns the hyperbolic sine of this number

EXAMPLES:

```
sage: q = RR.pi()/12
sage: q.sinh()
0.264800227602271
```

sqrt()

The square root function.

INPUT:

- `extend` - bool (default: True); if True, return a square root in a complex field if necessary if self is negative; otherwise raise a ValueError
- `all` - bool (default: False); if True, return a list of all square roots.

EXAMPLES:

```
sage: r = -2.0
sage: r.sqrt()
1.41421356237310*I

sage: r = 4.0
sage: r.sqrt()
2.00000000000000
sage: r.sqrt()^2 == r
True

sage: r = 4344
sage: r.sqrt()
2*sqrt(1086)

sage: r = 4344.0
sage: r.sqrt()^2 == r
True
sage: r.sqrt()^2 - r
0.000000000000000

sage: r = -2.0
sage: r.sqrt()
1.41421356237310*I
```

str()

INPUT:

- `base` - base for output
- `no_sci` - if 2, never print using scientific notation; if 1 or True, print using scientific notation only for very large or very small numbers; if 0 or False always print with scientific notation; if None (the default), print how the parent prints.
- `e` - symbol used in scientific notation; defaults to 'e' for base=10, and '@' otherwise
- `truncate` - if True, round off the last digits in printing to lessen confusing base-2 roundoff issues.
- `skip_zeroes` - if True, skip trailing zeroes in mantissa

EXAMPLES:

```
sage: a = 61/3.0; a
20.3333333333333
sage: a.str(truncate=False)
'20.333333333333332'
sage: a.str(2)
'10100.01010101010101010101010101010101010101010101010101'
sage: a.str(no_sci=False)
'2.03333333333333e1'
sage: a.str(16, no_sci=False)
'1.4555555555555@1'
sage: b = 2.0^99
sage: b.str()
'6.33825300114115e29'
sage: b.str(no_sci=False)
'6.33825300114115e29'
sage: b.str(no_sci=True)
'6.33825300114115e29'
sage: c = 2.0^100
sage: c.str()
'1.26765060022823e30'
sage: c.str(no_sci=False)
'1.26765060022823e30'
sage: c.str(no_sci=True)
'1.26765060022823e30'
sage: c.str(no_sci=2)
'126765060022823000000000000000.'
sage: 0.5^53
1.11022302462516e-16
sage: 0.5^54
5.55111512312578e-17
sage: (0.01).str()
'0.0100000000000000'
sage: (0.01).str(skip_zeroes=True)
'0.01'
sage: (-10.042).str()
'-10.0420000000000'
sage: (-10.042).str(skip_zeroes=True)
'-10.042'
sage: (389.0).str(skip_zeroes=True)
'389.'
```

tan()

Returns the tangent of this number

EXAMPLES:

```
sage: q = RR.pi()/3
sage: q.tan()
1.73205080756888
sage: q = RR.pi()/6
```

```
sage: q.tan()
0.577350269189626
```

tanh()

Returns the hyperbolic tangent of this number

EXAMPLES:

```
sage: q = RR.pi()/11
sage: q.tanh()
0.278079429295850
```

trunc()

Truncates this number

EXAMPLES:

```
sage: (2.99).trunc()
2
sage: (-0.00).trunc()
0
sage: (0.00).trunc()
0
```

ulp()

Returns the unit of least precision of self, which is the weight of the least significant bit of self. Unless self is exactly a power of two, it is gap between this number and the next closest distinct number that can be represented.

EXAMPLES: sage: a = 1.0 sage: a + a.ulp() == a False sage: a + a.ulp()/2 == a True
sage: a = RealField(500).pi() sage: b = a + a.ulp() sage: (a+b)/2 in [a,b] True
sage: a = RR(infinity) sage: a.ulp() +infinity sage: (-a).ulp() +infinity sage: a = RR('nan') sage: a.ulp() is a True

y0()

Returns the value of the Bessel Y function of order 0 at self.

EXAMPLES:

```
sage: R = RealField(53)
sage: R(2).y0()
0.510375672649745
```

y1()

Returns the value of the Bessel Y function of order 1 at self.

EXAMPLES:

```
sage: R = RealField(53)
sage: R(2).y1()
-0.107032431540938
```

yn()

Returns the value of the Bessel Y function of order n at self.

EXAMPLES:

```
sage: R = RealField(53)
sage: R(2).yn(3)
-1.12778377684043
sage: R(2).yn(-17)
7.09038821729481e12
```

zeta()

Return the Riemann zeta function evaluated at this real number.

EXAMPLES:

```
sage: R = RealField()
sage: R(2).zeta()
1.64493406684823
sage: R.pi()^2/6
1.64493406684823
sage: R(-2).zeta()
0.000000000000000
sage: R(1).zeta()
+infinity
```

Computing zeta using PARI is much more efficient in difficult cases. Here's how to compute zeta with at least a given precision:

```
sage: z = pari(2).zeta(precision=53); z
1.64493406684823
sage: pari(2).zeta(precision=128).python().prec()
128
sage: pari(2).zeta(precision=65).python().prec()
128                                                    # 64-bit
96                                                     # 32-bit
```

Note that the number of bits of precision in the constructor only effects the internal precision of the pari number, which is rounded up to the nearest multiple of 32 or 64. To increase the number of digits that gets displayed you must use `pari.set_real_precision`.

```
sage: type(z)
<type 'sage.libs.pari.gen.gen'>
sage: R(z)
1.64493406684823
```

class ZZtoRR()

create_RealField()

create_RealNumber()

Return the real number defined by the string s as an element of `RealField(prec=n)`, where n potentially has slightly more (controlled by pad) bits than given by s.

INPUT:

- `s` - a string that defines a real number (or something whose string representation defines a number)
- `base` - an integer between 2 and 36
- `pad` - an integer = 0.
- `rnd` - rounding mode: RNDN, RNDZ, RNDU, RNDD
- `min_prec` - number will have at least this many bits of precision, no matter what.

EXAMPLES:

```
sage: RealNumber('2.3')
2.30000000000000
sage: RealNumber(10)
10.0000000000000
sage: RealNumber('1.000000000000000000000000000000000')
1.00000000000000000000000000000000
sage: RealField(200)(1.2)
1.20000000000000000000000000000000000000000000000000000000000000
sage: (1.2).parent() is RR
True
```

class double_toRR()

class int_toRR()

is_RealField()

is_RealNumber()
Return True if x is of type RealNumber, meaning that it is an element of the MPFR real field with some precision.

EXAMPLES:

```
sage: from sage.rings.real_mpfr import is_RealNumber
sage: is_RealNumber(2.5)
True
sage: is_RealNumber(float(2.3))
False
sage: is_RealNumber(RDF(2))
False
sage: is_RealNumber(pi)
False
```

mpfr_prec_max()

mpfr_prec_min()
Return the mpfr variable MPFR_PREC_MIN.

25.4 Field of Arbitrary Precision Complex Numbers

AUTHORS:

- William Stein (2006-01-26): complete rewrite

ComplexField(*prec=53, names=None*)
Return the complex field with real and imaginary parts having prec *bits* of precision.

EXAMPLES:

```
sage: ComplexField()
Complex Field with 53 bits of precision
sage: ComplexField(100)
Complex Field with 100 bits of precision
sage: ComplexField(100).base_ring()
Real Field with 100 bits of precision
sage: i = ComplexField(200).gen()
sage: i^2
-1.0000000000000000000000000000000000000000000000000000000000000000000000000000
```

class ComplexField_class(*prec=53*)
An approximation to the field of complex numbers using floating point numbers with any specified precision. Answers derived from calculations in this approximation may differ from what they would be if those calculations were performed in the true field of complex numbers. This is due to the rounding errors inherent to finite precision calculations.

EXAMPLES:

```
sage: C = ComplexField(); C
Complex Field with 53 bits of precision
sage: Q = RationalField()
sage: C(1/3)
0.333333333333333
```

```
sage: C(1/3, 2)
0.333333333333333 + 2.00000000000000*I
sage: C(RR.pi())
3.14159265358979
sage: C(RR.log2(), RR.pi())
0.693147180559945 + 3.14159265358979*I
```

We can also coerce rational numbers and integers into C, but coercing a polynomial will raise an exception.

```
sage: Q = RationalField()
sage: C(1/3)
0.333333333333333
sage: S = PolynomialRing(Q, 'x')
sage: C(S.gen())
...
TypeError: unable to coerce to a ComplexNumber: <class 'sage.rings.polynomial.polynomial_element
```

This illustrates precision.

```
sage: CC = ComplexField(10); CC(1/3, 2/3)
0.33 + 0.67*I
sage: CC
Complex Field with 10 bits of precision
sage: CC = ComplexField(100); CC
Complex Field with 100 bits of precision
sage: z = CC(1/3, 2/3); z
0.33333333333333333333333333333 + 0.66666666666666666666666666667*I
```

We can load and save complex numbers and the complex field.

```
sage: loads(z.dumps()) == z
True
sage: loads(CC.dumps()) == CC
True
sage: k = ComplexField(100)
sage: loads(dumps(k)) == k
True
```

This illustrates basic properties of a complex field.

```
sage: CC = ComplexField(200)
sage: CC.is_field()
True
sage: CC.characteristic()
0
sage: CC.precision()
200
sage: CC.variable_name()
'I'
sage: CC == ComplexField(200)
True
sage: CC == ComplexField(53)
False
sage: CC == 1.1
False
```

characteristic()

construction()
Returns the functorial construction of self, namely, algebraic closure of the real field with the same precision.

EXAMPLES:

```
sage: c, S = CC.construction(); S
Real Field with 53 bits of precision
sage: CC == c(S)
True
```

gen(*n=0*)

is_exact()

is_field()
Return True, since the complex numbers are a field.

EXAMPLES:

```
sage: CC.is_field()
True
```

is_finite()
Return False, since the complex numbers are infinite.

EXAMPLES:

```
sage: CC.is_finite()
False
```

ngens()

pi()

prec()

precision()

random_element(*component_max=1*)
Returns a uniformly distributed random number inside a square centered on the origin (by default, the square [-1,1]x[-1,1]).

EXAMPLES:

```
sage: [CC.random_element() for _ in range(5)]
[-0.306077326077253 - 0.0759291930543202*I, -0.838081254900233 - 0.207006276657392*I, -0.757
sage: CC6 = ComplexField(6)
sage: [CC6.random_element(2^-20) for _ in range(5)]
[-5.7e-7 + 5.4e-7*I, 8.6e-7 + 9.2e-7*I, -5.7e-7 + 6.9e-7*I, -1.2e-7 - 6.9e-7*I, 2.7e-7 + 8.3
sage: [CC6.random_element(pi^20) for _ in range(5)]
[-5.0e9*I, 2.8e9 - 5.1e9*I, 2.7e8 + 6.3e9*I, 2.7e8 - 6.4e9*I, 6.7e8 + 1.7e9*I]
```

scientific_notation(*status=None*)

to_prec(*prec*)
Returns the complex field to the specified precision.

EXAMPLES:

```
sage: CC.to_prec(10)
Complex Field with 10 bits of precision
sage: CC.to_prec(100)
Complex Field with 100 bits of precision
```

zeta(*n=2*)
Return a primitive n-th root of unity.

INPUT:

- n - an integer (default: 2)

OUTPUT: a complex n-th root of unity.

is_ComplexField(*x*)

late_import()

25.5 Arbitrary Precision Complex Numbers

AUTHORS:

- William Stein (2006-01-26): complete rewrite
- Joel B. Mohler (2006-12-16): naive rewrite into pyrex
- William Stein(2007-01): rewrite of Mohler's rewrite

class CCtoCDF()

class ComplexNumber()

A floating point approximation to a complex number using any specified precision. Answers derived from calculations with such approximations may differ from what they would be if those calculations were performed with true complex numbers. This is due to the rounding errors inherent to finite precision calculations.

EXAMPLES:

```
sage: I = CC.0
sage: b = 1.5 + 2.5*I
sage: loads(b.dumps()) == b
True
```

additive_order()

EXAMPLES:

```
sage: CC(0).additive_order()
1
sage: CC.gen().additive_order()
+Infinity
```

agm()

EXAMPLES:

```
sage: (1+CC(I)).agm(2-I)
1.62780548487271 + 0.136827548397369*I
```

algdep()

Returns a polynomial of degree at most n which is approximately satisfied by this complex number. Note that the returned polynomial need not be irreducible, and indeed usually won't be if z is a good approximation to an algebraic number of degree less than n.

ALGORITHM: Uses the PARI C-library algdep command.

INPUT: Type algdep? at the top level prompt. All additional parameters are passed onto the top-level algdep command.

EXAMPLE:

```
sage: C = ComplexField()
sage: z = (1/2)*(1 + sqrt(3.0) *C.0); z
0.500000000000000 + 0.866025403784439*I
```

```
sage: p = z.algdep(5); p
x^5 + x^2
sage: p.factor()
(x + 1) * x^2 * (x^2 - x + 1)
sage: z^2 - z + 1
1.11022302462516e-16
```

algebraic_dependancy()

Returns a polynomial of degree at most n which is approximately satisfied by this complex number. Note that the returned polynomial need not be irreducible, and indeed usually won't be if z is a good approximation to an algebraic number of degree less than n.

ALGORITHM: Uses the PARI C-library algdep command.

INPUT: Type algdep? at the top level prompt. All additional parameters are passed onto the top-level algdep command.

EXAMPLE:

```
sage: C = ComplexField()
sage: z = (1/2)*(1 + sqrt(3.0) *C.0); z
0.500000000000000 + 0.866025403784439*I
sage: p = z.algebraic_dependancy(5); p
x^5 + x^2
sage: p.factor()
(x + 1) * x^2 * (x^2 - x + 1)
sage: z^2 - z + 1
1.11022302462516e-16
```

arccos()

EXAMPLES:

```
sage: (1+CC(I)).arccos()
0.904556894302381 - 1.06127506190504*I
```

arccosh()

EXAMPLES:

```
sage: (1+CC(I)).arccosh()
1.06127506190504 + 0.904556894302381*I
```

arccoth()

EXAMPLES:

```
sage: ComplexField(100)(1,1).arccoth()
0.40235947810852509365018983331 - 0.55357435889704525150853273009*I
```

arccsch()

EXAMPLES:

```
sage: ComplexField(100)(1,1).arccsch()
0.53063753095251782601650945811 - 0.45227844715119068206365839783*I
```

arcsech()

EXAMPLES:

```
sage: ComplexField(100)(1,1).arcsech()
-0.53063753095251782601650945811 + 1.1185178796437059371676632938*I
```

arcsin()

EXAMPLES:

```
sage: (1+CC(I)).arcsin()
0.666239432492515 + 1.06127506190504*I
```

arcsinh()
EXAMPLES:

```
sage: (1+CC(I)).arcsinh()
1.06127506190504 + 0.666239432492515*I
```

arctan()
EXAMPLES:

```
sage: (1+CC(I)).arctan()
1.01722196789785 + 0.402359478108525*I
```

arctanh()
EXAMPLES:

```
sage: (1+CC(I)).arctanh()
0.402359478108525 + 1.01722196789785*I
```

arg()
Same as argument.
EXAMPLES:

```
sage: i = CC.0
sage: (i^2).arg()
3.14159265358979
```

argument()
The argument (angle) of the complex number, normalized so that $-\pi < \theta \leq \pi$.
EXAMPLES:

```
sage: i = CC.0
sage: (i^2).argument()
3.14159265358979
sage: (1+i).argument()
0.785398163397448
sage: i.argument()
1.57079632679490
sage: (-i).argument()
-1.57079632679490
sage: (RR('-0.001') - i).argument()
-1.57179632646156
```

conjugate()
Return the complex conjugate of this complex number.
EXAMPLES:

```
sage: i = CC.0
sage: (1+i).conjugate()
1.00000000000000 - 1.00000000000000*I
```

cos()
EXAMPLES:

```
sage: (1+CC(I)).cos()
0.833730025131149 - 0.988897705762865*I
```

cosh()
EXAMPLES:

```
sage: (1+CC(I)).cosh()
0.833730025131149 + 0.988897705762865*I
```

cotan()

EXAMPLES:

```
sage: (1+CC(I)).cotan()
0.217621561854403 - 0.868014142895925*I
sage: i = ComplexField(200).0
sage: (1+i).cotan()
0.21762156185440268136513424360523807352075436916785404091068 - 0.86801414289592494863584920
sage: i = ComplexField(220).0
sage: (1+i).cotan()
0.21762156185440268136513424360523807352075436916785404091068124239 - 0.86801414289592494863
```

coth()

EXAMPLES:

```
sage: ComplexField(100)(1,1).coth()
0.86801414289592494863584920892 - 0.21762156185440268136513424361*I
```

csc()

EXAMPLES:

```
sage: ComplexField(100)(1,1).csc()
0.62151801717042842123490780586 - 0.30393100162842645033448560451*I
```

csch()

EXAMPLES:

```
sage: ComplexField(100)(1,1).csch()
0.30393100162842645033448560451 - 0.62151801717042842123490780586*I
```

dilog()

Returns the complex dilogarithm of self. The complex dilogarithm, or Spence's function, is defined by

$Li_2(z) = -\int_0^z \frac{\log|1-\zeta|}{\zeta} d(\zeta)$

$= \sum_{k=1}^{\infty} \frac{z^k}{k}$

Note that the series definition can only be used for $|z| < 1$

EXAMPLES:

```
sage: a = ComplexNumber(1,0)
sage: a.dilog()
1.64493406684823
sage: float(pi^2/6)
1.6449340668482262

sage: b = ComplexNumber(0,1)
sage: b.dilog()
-0.205616758356028 + 0.915965594177219*I

sage: c = ComplexNumber(0,0)
sage: c.dilog()
0
```

eta()

Return the value of the Dedekind η function on self, intelligently computed using $\mathbb{SL}(2, \mathbf{Z})$ transformations.

INPUT:

- `self` - element of the upper half plane (if not, raises a ValueError).

- `omit_frac` - (bool, default: False), if True, omit the $e^{\pi iz/12}$ factor.

OUTPUT: a complex number

The η function is

$$\eta(z) = e^{\pi iz/12} \prod_{n=1}^{\infty} (1 - e^{2\pi inz})$$

ALGORITHM: Uses the PARI C library.

EXAMPLES:

First we compute $\eta(1 + i)$:

```
sage: i = CC.0
sage: z = 1+i; z.eta()
0.742048775836565 + 0.198831370229911*I
```

We compute eta to low precision directly from the definition.

```
sage: z = 1 + i; z.eta()
0.742048775836565 + 0.198831370229911*I
sage: pi = CC(pi)        # otherwise we will get a symbolic result.
sage: exp(pi * i * z / 12) * prod([1-exp(2*pi*i*n*z) for n in range(1,10)])
0.742048775836565 + 0.198831370229911*I
```

The optional argument allows us to omit the fractional part:

```
sage: z = 1 + i
sage: z.eta(omit_frac=True)
0.998129069925959 - 8.12769318...e-22*I
sage: prod([1-exp(2*pi*i*n*z) for n in range(1,10)])
0.998129069925958 + 4.59099857829247e-19*I
```

We illustrate what happens when z is not in the upper half plane.

```
sage: z = CC(1)
sage: z.eta()
...
ValueError: value must be in the upper half plane
```

You can also use functional notation.

```
sage: eta(1+CC(I))
0.742048775836565 + 0.198831370229911*I
```

exp()

Compute exp(z).

EXAMPLES:

```
sage: i = ComplexField(300).0
sage: z = 1 + i
sage: z.exp()
1.46869393991588515713896759732660426132695673662900872279767567631093696585951213872272450
```

gamma()

Return the Gamma function evaluated at this complex number.

EXAMPLES:

```
sage: i = ComplexField(30).0
sage: (1+i).gamma()
0.49801567 - 0.15494983*I
```

TESTS:

```
sage: CC(0).gamma()
Infinity

sage: CC(-1).gamma()
Infinity
```

gamma_inc()

Return the incomplete Gamma function evaluated at this complex number.

EXAMPLES:

```
sage: C, i = ComplexField(30).objgen()
sage: (1+i).gamma_inc(2 + 3*i)
0.0020969149 - 0.059981914*I
sage: (1+i).gamma_inc(5)
-0.0013781309 + 0.0065198200*I
sage: C(2).gamma_inc(1 + i)
0.70709210 - 0.42035364*I
sage: gamma_inc(2, 1 + i)
0.70709210 - 0.42035364*I
sage: gamma_inc(2, 5)
0.0404276819945128
```

imag()

Return imaginary part of self.

EXAMPLES:

```
sage: i = ComplexField(100).0
sage: z = 2 + 3*i
sage: x = z.imag(); x
3.0000000000000000000000000000
sage: x.parent()
Real Field with 100 bits of precision
```

is_imaginary()

Return True if self is imaginary, i.e. has real part zero.

EXAMPLES:

```
sage: CC(1.23*i).is_imaginary()
True
sage: CC(1+i).is_imaginary()
False
```

is_real()

Return True if self is real, i.e. has imaginary part zero.

EXAMPLES:

```
sage: CC(1.23).is_real()
True
sage: CC(1+i).is_real()
False
```

is_square()

This function always returns true as $\mathbf{C}$ is algebraically closed.

EXAMPLES:

```
sage: a = ComplexNumber(2,1)
sage: a.is_square()
True
```

$\mathbf{C}$ is algebraically closed, hence every element is a square:

```
sage: b = ComplexNumber(5)
sage: b.is_square()
True
```

log()

Complex logarithm of z with branch chosen as follows: Write $z = \rho e^{i\theta} with` - \pi <= \theta < pi$. Then $\log(z) = \log(\rho) + i\theta$.

Warning: Currently the real log is computed using floats, so there is potential precision loss.

EXAMPLES:

```
sage: a = ComplexNumber(2,1)
sage: a.log()
0.804718956217050 + 0.463647609000806*I
sage: log(a.abs())
0.804718956217050
sage: a.argument()
0.463647609000806

sage: b = ComplexNumber(float(exp(42)),0)
sage: b.log()
41.99999999999971
```

multiplicative_order()

Return the multiplicative order of this complex number, if known, or raise a NotImplementedError.

EXAMPLES:

```
sage: C.<i> = ComplexField()
sage: i.multiplicative_order()
4
sage: C(1).multiplicative_order()
1
sage: C(-1).multiplicative_order()
2
sage: C(i^2).multiplicative_order()
2
sage: C(-i).multiplicative_order()
4
sage: C(2).multiplicative_order()
+Infinity
sage: w = (1+sqrt(-3.0))/2; w
0.500000000000000 + 0.866025403784439*I
sage: abs(w)
1.00000000000000
sage: w.multiplicative_order()
...
NotImplementedError: order of element not known
```

norm()

Returns the norm of self.

$norm(a + bi) = a^2 + b^2$

EXAMPLES: This indeed acts as the square function when the imaginary component of self is equal to zero:

```
sage: a = ComplexNumber(2,1)
sage: a.norm()
5.00000000000000
```

```
sage: b = ComplexNumber(4.2,0)
sage: b.norm()
17.6400000000000
sage: b^2
17.6400000000000
```

nth_root()

The n-th root function.

INPUT:

- `all` - bool (default: False); if True, return a list of all n-th roots.

EXAMPLES:

```
sage: a = CC(27)
sage: a.nth_root(3)
3.00000000000000
sage: a.nth_root(3, all=True)
[3.00000000000000, -1.50000000000000 + 2.59807621135332*I, -1.50000000000000 - 2.59807621135
sage: a = ComplexField(20)(2,1)
sage: [r^7 for r in a.nth_root(7, all=True)]
[2.0000 + 1.0000*I, 2.0000 + 1.0000*I, 2.0000 + 1.0000*I, 2.0000 + 1.0000*I, 2.0000 + 1.0000
```

prec()

Return precision of this complex number.

EXAMPLES:

```
sage: i = ComplexField(2000).0
sage: i.prec()
2000
```

real()

Return real part of self.

EXAMPLES:

```
sage: i = ComplexField(100).0
sage: z = 2 + 3*i
sage: x = z.real(); x
2.0000000000000000000000000000
sage: x.parent()
Real Field with 100 bits of precision
```

sec()

EXAMPLES:

```
sage: ComplexField(100)(1,1).sec()
0.49833703055518678521380589177 + 0.59108384172104504805039169297*I
```

sech()

EXAMPLES:

```
sage: ComplexField(100)(1,1).sech()
0.49833703055518678521380589177 - 0.59108384172104504805039169297*I
```

sin()

EXAMPLES:

```
sage: (1+CC(I)).sin()
1.29845758141598 + 0.634963914784736*I
```

sinh()

EXAMPLES:

```
sage: (1+CC(I)).sinh()
0.634963914784736 + 1.29845758141598*I
```

sqrt()

The square root function, taking the branch cut to be the negative real axis.

INPUT:

- `all` - bool (default: False); if True, return a list of all square roots.

EXAMPLES:

```
sage: C.<i> = ComplexField(30)
sage: i.sqrt()
0.70710678 + 0.70710678*I
sage: (1+i).sqrt()
1.0986841 + 0.45508986*I
sage: (C(-1)).sqrt()
1.0000000*I
sage: (1 + 1e-100*i).sqrt()^2
1.0000000 + 1.0000000e-100*I
sage: i = ComplexField(200).0
sage: i.sqrt()
0.70710678118654752440084436210484903928483593768847403658834 + 0.70710678118654752440084436
```

str()

Return a string representation of this number.

INPUTS:

- `base` - The base to use for printing (default 10)
- `truncate` - (default: `True`) Whether to print fewer digits than are available, to mask errors in the last bits.

EXAMPLES:

```
sage: a = CC(pi + I*e)
sage: a.str()
'3.14159265358979 + 2.71828182845905*I'
sage: a.str(truncate=False)
'3.1415926535897931 + 2.7182818284590451*I'
sage: a.str(base=2)
'11.001001000011111101101010100010001000010110100011000 + 10.101101111100001010100010110001
sage: CC(0.5 + 0.625*I).str(base=2)
'0.10000000000000000000000000000000000000000000000000000 + 0.10100000000000000000000000000000
sage: a.str(base=16)
'3.243f6a8885a30 + 2.b7e151628aed2*I'
sage: a.str(base=36)
'3.53i5ab8p5fc + 2.puw5nggjf8f*I'
```

tan()

EXAMPLES:

```
sage: (1+CC(I)).tan()
0.271752585319512 + 1.08392332733869*I
```

tanh()

EXAMPLES:

```
sage: (1+CC(I)).tanh()
1.08392332733869 + 0.271752585319512*I
```

zeta()

Return the Riemann zeta function evaluated at this complex number.

EXAMPLES:

```
sage: i = ComplexField(30).gen()
sage: z = 1 + i
sage: z.zeta()
0.58215806 - 0.92684856*I
sage: zeta(z)
0.58215806 - 0.92684856*I
```

class RRtoCC()

create_ComplexNumber()

Return the complex number defined by the strings s_real and s_imag as an element of ComplexField(prec=n), where n potentially has slightly more (controlled by pad) bits than given by s.

INPUT:

- s_real - a string that defines a real number (or something whose string representation defines a number)
- s_imag - a string that defines a real number (or something whose string representation defines a number)
- pad - an integer >= 0.
- min_prec - number will have at least this many bits of precision, no matter what.

EXAMPLES:

```
sage: ComplexNumber('2.3')
2.30000000000000
sage: ComplexNumber('2.3','1.1')
2.30000000000000 + 1.10000000000000*I
sage: ComplexNumber(10)
10.0000000000000
sage: ComplexNumber(10,10)
10.0000000000000 + 10.0000000000000*I
sage: ComplexNumber(1.00000000000000000000000000,2)
1.00000000000000000000000000 + 2.00000000000000000000000000*I
sage: ComplexNumber(1,2.00000000000000000000)
1.00000000000000000000 + 2.00000000000000000000*I

sage: sage.rings.complex_number.create_ComplexNumber(s_real=2,s_imag=1)
2.00000000000000 + 1.00000000000000*I
```

is_ComplexNumber()

Returns True if x is a complex number. In particular, if x is of the ComplexNumber type.

EXAMPLES:

```
sage: from sage.rings.complex_number import is_ComplexNumber
sage: a = ComplexNumber(1,2); a
1.00000000000000 + 2.00000000000000*I
sage: is_ComplexNumber(a)
True
sage: b = ComplexNumber(1); b
1.00000000000000
sage: is_ComplexNumber(b)
True
```

Note that the global element I is of type SymbolicConstant. However, elements of the class ComplexField_class are of type ComplexNumber:

```
sage: c = 1 + 2*I
sage: is_ComplexNumber(c)
False
sage: d = CC(1 + 2*I)
sage: is_ComplexNumber(d)
True
```

make_ComplexNumber0()

set_global_complex_round_mode()

25.6 Field of Arbitrary Precision Real Intervals

AUTHORS:

- Carl Witty (2007-01-21): based on `real_mpfr.pyx`; changed it to use mpfi rather than mpfr.
- William Stein (2007-01-24): modifications and clean up and docs, etc.

This is a straightforward binding to the MPFI library; it may be useful to refer to its documentation for more details.

An interval is represented as a pair of floating-point numbers a and b (where a <= b) and is printed as a standard floating-point number with a question mark (for instance, 3.1416?). The question mark indicates that the preceding digit may have an error of +/- 1. These floating-point numbers are implemented using MPFR (the same as the RealNumber elements of RealField).

There is also an alternate method of printing, where the interval prints as [a .. b] (for instance, [3.1415 .. 3.1416]).

The interval represents the set { x : a <= x <= b } (so if a == b, then the interval represents that particular floating-point number). The endpoints can include positive and negative infinity, with the obvious meaning. It is also possible to have a NaN (not-a-number) interval, which is represented by having either endpoint be NaN.

PRINTING:

There are two styles for printing intervals: 'brackets' style and 'question' style (the default).

In question style, we print the "known correct" part of the number, followed by a question mark. The question mark indicates that the preceding digit is possibly wrong by +/- 1.

```
sage: RIF(sqrt(2))
1.414213562373095?
```

However, if the interval is precise (its lower bound is equal to its upper bound) and equal to a not-too-large integer, then we just print that integer.

```
sage: RIF(0)
0
sage: RIF(654321)
654321
```

```
sage: RIF(123, 125)
124.?
sage: RIF(123, 126)
1.3?e2
```

As we see in the last example, question style can discard almost a whole digit's worth of precision. We can reduce this by allowing "error digits": an error following the question mark, that gives the maximum error of the digit(s) before the question mark. If the error is absent (which it always is in the default printing), then it is taken to be 1.

```
sage: RIF(123, 126).str(error_digits=1)
'125.?2'
sage: RIF(123, 127).str(error_digits=1)
'125.?2'
sage: v = RIF(-e, pi); v
0.?e1
sage: v.str(error_digits=1)
'1.?4'
sage: v.str(error_digits=5)
'0.2117?29300'
```

Error digits also sometimes let us indicate that the interval is actually equal to a single floating-point number.

```
sage: RIF(54321/256)
212.19140625000000?
sage: RIF(54321/256).str(error_digits=1)
'212.191406250000000?0'
```

In brackets style, intervals are printed with the left value rounded down and the right rounded up, which is conservative, but in some ways unsatisfying.

Consider a 3-bit interval containing exactly the floating-point number 1.25. In round-to-nearest or round-down, this prints as 1.2; in round-up, this prints as 1.3. The straightforward options, then, are to print this interval as [1.2 .. 1.2] (which does not even contain the true value, 1.25), or to print it as [1.2 .. 1.3] (which gives the impression that the upper and lower bounds are not equal, even though they really are). Neither of these is very satisfying, but we have chosen the latter.

```
sage: R = RealIntervalField(3)
sage: a = R(1.25)
sage: a.str(style='brackets')
'[1.2 .. 1.3]'
sage: a == 1.25
True
sage: a == 2
False
```

COMPARISONS:

Comparison operations (==,!=,<,<=,>,>=) return true if every value in the first interval has the given relation to every value in the second interval. The cmp(a, b) function works differently; it compares two intervals lexicographically. (However, the behavior is not specified if given a non-interval and an interval.)

This convention for comparison operators has good and bad points. The good:

- Expected transitivity properties hold (if a > b and b == c, then a > c; etc.)
- if a>b, then cmp(a, b) == 1; if a==b, then cmp(a,b) == 0; if a<b, then cmp(a, b) == -1
- a==0 is true if the interval contains only the floating-point number 0; similarly for a==1
- a>0 means something useful (that every value in the interval is greater than 0)

The bad:

- Trichotomy fails to hold: there are values (a,b) such that none of a<b, a==b, or a>b are true
- It is not the case that if cmp(a, b) == 0 then a==b, or that if cmp(a, b) == 1 then a>b, or that if cmp(a, b) == -1 then a<b
- There are values a,b such that a<=b but neither a<b nor a==b hold

Note that intervals a and b overlap iff not(a != b).

EXAMPLES:

```
sage: 0 < RIF(1, 2)
True
sage: 0 == RIF(0)
True
sage: not(0 == RIF(0, 1))
True
sage: not(0 != RIF(0, 1))
True
sage: 0 <= RIF(0, 1)
True
sage: not(0 < RIF(0, 1))
True
sage: cmp(RIF(0), RIF(0, 1))
-1
sage: cmp(RIF(0, 1), RIF(0))
1
sage: cmp(RIF(0, 1), RIF(1))
-1
sage: cmp(RIF(0, 1), RIF(0, 1))
0
```

RealInterval()

Return the real number defined by the string s as an element of `RealIntervalField(prec=n)`, where n potentially has slightly more (controlled by pad) bits than given by s.

INPUT:

- `s` - a string that defines a real number (or something whose string representation defines a number)
- `upper` - (default: None) - upper endpoint of interval if given, in which case s is the lower endpoint.
- `base` - an integer between 2 and 36
- `pad` - an integer = 0.
- `min_prec` - number will have at least this many bits of precision, no matter what.

EXAMPLES:

```
sage: RealInterval('2.3')
2.300000000000000?
sage: RealInterval(10)
10
sage: RealInterval('1.00000000000000000000000000000000')
1
sage: RealInterval('1.23456789012345678901234567890123450')
1.23456789012345678901234567890123450?
sage: RealInterval(29308290382930840239842390482, 3^20).str(style='brackets')
'[3.48678440100000000000000000000e9 .. 2.93082903829308402398423904820e28]'
```

RealIntervalField()
Construct a RealIntervalField_class, with caching.

INPUT:

- prec - (integer) precision; default = 53: The number of bits used to represent the mantissa of a floating-point number. The precision can be any integer between mpfr_prec_min() and mpfr_prec_max(). In the current implementation, mpfr_prec_min() is equal to 2.
- sci_not - (default: False) whether or not to display using scientific notation

EXAMPLES:

```
sage: RealIntervalField()
Real Interval Field with 53 bits of precision
sage: RealIntervalField(200, sci_not=True)
Real Interval Field with 200 bits of precision
sage: RealIntervalField(53) is RIF
True
sage: RealIntervalField(200) is RIF
False
sage: RealIntervalField(200) is RealIntervalField(200)
True
```

See the documentation for RealIntervalField_class for many more examples.

class **RealIntervalFieldElement**()
A real number interval.

absolute_diameter()
The diameter of this interval (for [a .. b], this is b-a), rounded upward, as a RealNumber.

EXAMPLES:

```
sage: RIF(1, pi).absolute_diameter()
2.14159265358979
```

alea()
RIF(a, b).alea() gives a floating-point number picked at random from the interval.

EXAMPLES:

```
sage: RIF(1, 2).alea() # random
1.34696133696137
```

algdep()
Returns a polynomial of degree at most n which is approximately satisfied by this number. Note that the returned polynomial need not be irreducible, and indeed usually won't be if this number is a good approximation to an algebraic number of degree less than n.

Pari needs to know the number of "known good bits" in the number; we automatically get that from the interval width.

ALGORITHM: Uses the PARI C-library algdep command.

EXAMPLE:

```
sage: r = sqrt(RIF(2)); r
1.414213562373095?
sage: r.algdep(5)
x^2 - 2
```

If we compute a wrong, but precise, interval, we get a wrong answer.

```
sage: r = sqrt(RealIntervalField(200)(2)) + (1/2)^40; r
1.41421356237400454350346165244761311763217187537694807331766802
sage: r.algdep(5)
7266488*x^5 + 22441629*x^4 - 90470501*x^3 + 23297703*x^2 + 45778664*x + 13681026
```

But if we compute an interval that includes the number we mean, we're much more likely to get the right answer, even if the interval is very imprecise.

```
sage: r = r.union(sqrt(2.0))
sage: r.algdep(5)
x^2 - 2
```

Even on this extremely imprecise interval we get an answer which is technically correct.

```
sage: RIF(-1, 1).algdep(5)
x
```

arccos()

Returns the inverse cosine of this number

EXAMPLES:

```
sage: q = RIF.pi()/3; q
1.047197551196598?
sage: i = q.cos(); i
0.500000000000000?
sage: q2 = i.arccos(); q2
1.047197551196598?
sage: q == q2
False
sage: q != q2
False
sage: q2.lower() == q.lower()
False
sage: q - q2
0.?e-15
sage: q in q2
True
```

arccosh()

Returns the hyperbolic inverse cosine of this number

EXAMPLES:

```
sage: q = RIF.pi()/2
sage: i = q.arccosh() ; i
1.023227478547551?
```

arccoth()

Returns the inverse hyperbolic cotangent of this number.

EXAMPLES:

```
sage: RealIntervalField(100)(2).arccoth()
0.54930614433405484569762261846?
sage: (2.0).arccoth()
0.549306144334055
```

arccsch()

Returns the inverse hyperbolic cosecant of this number.

EXAMPLES:

```
sage: RealIntervalField(100)(2).arccsch()
0.48121182505960344749775891342?
sage: (2.0).arccsch()
0.481211825059603
```

arcsech()

Returns the inverse hyperbolic secant of this number.

EXAMPLES:

```
sage: RealIntervalField(100)(0.5).arcsech()
1.3169578969248167086250463473?
sage: (0.5).arcsech()
1.31695789692482
```

arcsin()

Returns the inverse sine of this number

EXAMPLES:

```
sage: q = RIF.pi()/5; q
0.6283185307179587?
sage: i = q.sin(); i
0.587785252292474?
sage: q2 = i.arcsin(); q2
0.6283185307179593?
sage: q == q2
False
sage: q != q2
False
sage: q2.lower() == q.lower()
False
sage: q - q2
0.?e-15
sage: q in q2
True
```

arcsinh()

Returns the hyperbolic inverse sine of this number

EXAMPLES:

```
sage: q = RIF.pi()/7
sage: i = q.sinh() ; i
0.4640176304929913?
sage: i.arcsinh() - q
0.?e-15
```

arctan()

Returns the inverse tangent of this number

EXAMPLES:

```
sage: q = RIF.pi()/5; q
0.6283185307179587?
sage: i = q.tan(); i
0.7265425280053613?
sage: q2 = i.arctan(); q2
0.6283185307179593?
sage: q == q2
False
sage: q != q2
False
```

```
sage: q2.lower() == q.lower()
False
sage: q - q2
0.?e-15
sage: q in q2
True
```

arctanh()

Returns the hyperbolic inverse tangent of this number

EXAMPLES:

```
sage: q = RIF.pi()/7
sage: i = q.tanh() ; i
0.420911241048535?
sage: i.arctanh() - q
0.?e-15
```

ceil()

Returns the ceiling of this number

OUTPUT: integer

EXAMPLES:

```
sage: (2.99).ceil()
3
sage: (2.00).ceil()
2
sage: (2.01).ceil()
3
sage: R = RealIntervalField(30)
sage: a = R(-9.5, -11.3); a.str(style='brackets')
'[-11.300000012 .. -9.5000000000]'
sage: a.floor().str(style='brackets')
'[-12.000000000 .. -10.000000000]'
sage: a.ceil()
-10.?
sage: ceil(a).str(style='brackets')
'[-11.000000000 .. -9.0000000000]'
```

ceiling()

center()

RIF(a, b).center() == (a+b)/2

EXAMPLES:

```
sage: RIF(1, 2).center()
1.50000000000000
```

contains_zero()

Returns True if self is an interval containing zero.

EXAMPLES:

```
sage: RIF(0).contains_zero()
True
sage: RIF(1, 2).contains_zero()
False
sage: RIF(-1, 1).contains_zero()
True
sage: RIF(-1, 0).contains_zero()
True
```

cos()
Returns the cosine of this number.
EXAMPLES:

```
sage: t=RIF(pi)/2
sage: t.cos()
0.?e-15
sage: t.cos().str(style='brackets')
'[-1.6081226496766367e-16 .. 6.1232339957367661e-17]'
sage: t.cos().cos()
0.9999999999999999?
```

TESTS:
This looped forever with an earlier version of MPFI, but now it works.

```
sage: RIF(-1, 1).cos().str(style='brackets')
'[0.54030230586813965 .. 1.0000000000000000]'
```

cosh()
Returns the hyperbolic cosine of this number
EXAMPLES:

```
sage: q = RIF.pi()/12
sage: q.cosh()
1.034465640095511?
```

cot()
Returns the cotangent of this number.
EXAMPLES:

```
sage: RealIntervalField(100)(2).cot()
-0.45765755436028576375027741043 2?
```

coth()
Returns the hyperbolic cotangent of this number.
EXAMPLES:

```
sage: RealIntervalField(100)(2).coth()
1.0373147207275480958778097647 7?
```

csc()
Returns the cosecant of this number.
EXAMPLES:

```
sage: RealIntervalField(100)(2).csc()
1.0997501702946164667566973970 26?
```

csch()
Returns the hyperbolic cosecant of this number.
EXAMPLES:

```
sage: RealIntervalField(100)(2).csch()
0.27572056477178320775835148216 3?
```

diameter()
If (0 in self), returns self.absolute_diameter(), otherwise self.relative_diameter().
EXAMPLES:

```
sage: RIF(1, 2).diameter()
0.666666666666667
```

```
sage: RIF(1, 2).absolute_diameter()
1.00000000000000
sage: RIF(1, 2).relative_diameter()
0.666666666666667
sage: RIF(pi).diameter()
1.41357985842823e-16
sage: RIF(pi).absolute_diameter()
4.44089209850063e-16
sage: RIF(pi).relative_diameter()
1.41357985842823e-16
sage: (RIF(pi) - RIF(3, 22/7)).diameter()
0.142857142857144
sage: (RIF(pi) - RIF(3, 22/7)).absolute_diameter()
0.142857142857144
sage: (RIF(pi) - RIF(3, 22/7)).relative_diameter()
2.03604377705518
```

exp()

Returns $e^{\texttt{self}}$

EXAMPLES:

```
sage: r = RIF(0.0)
sage: r.exp()
1

sage: r = RIF(32.3)
sage: a = r.exp(); a
1.065888472748645?e14
sage: a.log()
32.300000000000000?

sage: r = RIF(-32.3)
sage: r.exp()
9.38184458849869?e-15
```

exp2()

Returns $2^{\texttt{self}}$

EXAMPLES:

```
sage: r = RIF(0.0)
sage: r.exp2()
1

sage: r = RIF(32.0)
sage: r.exp2()
4294967296

sage: r = RIF(-32.3)
sage: r.exp2()
1.891172482530207?e-10
```

floor()

Returns the floor of this number

EXAMPLES:

```
sage: R = RealIntervalField()
sage: (2.99).floor()
2
sage: (2.00).floor()
```

```
2
sage: floor(RR(-5/2))
-3
sage: R = RealIntervalField(100)
sage: a = R(9.5, 11.3); a.str(style='brackets')
'[9.5000000000000000000000000000000 .. 11.300000000000000710542735760101]'
sage: floor(a).str(style='brackets')
'[9.0000000000000000000000000000000 .. 11.000000000000000000000000000000]'
sage: a.floor()
10.?
sage: ceil(a)
11.?
sage: a.ceil().str(style='brackets')
'[10.000000000000000000000000000000 .. 12.000000000000000000000000000000]'
```

fp_rank_diameter()

Computes the diameter of this interval in terms of the "floating-point rank". That is, it gives the number of floating-point numbers (of the current precision) contained in the given interval, minus one. An `fp_rank_diameter` of 0 means that the interval is exact; an `fp_rank_diameter` of 1 means that the interval is as tight as possible, unless the number you're trying to represent is actually exactly representable as a floating-point number.

EXAMPLES:

```
sage: RIF(pi).fp_rank_diameter()
1
sage: RIF(12345).fp_rank_diameter()
0
sage: RIF(-sqrt(2)).fp_rank_diameter()
1
sage: RIF(5/8).fp_rank_diameter()
0
sage: RIF(5/7).fp_rank_diameter()
1
sage: a = RIF(pi)^12345; a
2.06622879260?e6137
sage: a.fp_rank_diameter()
30524
sage: (RIF(sqrt(2)) - RIF(sqrt(2))).fp_rank_diameter()
96714060885426721511178 26
```

Just because we have the best possible interval, doesn't mean the interval is actually small:

```
sage: a = RIF(pi)^1234567890; a
[2.0985787164673874e323228496 .. +infinity]
sage: a.fp_rank_diameter()
1
```

intersection()

Return the intersection of two intervals. If the intervals do not overlap, raises a ValueError.

EXAMPLES:

```
sage: RIF(1, 2).intersection(RIF(1.5, 3)).str(style='brackets')
'[1.5000000000000000 .. 2.0000000000000000]'
sage: RIF(1, 2).intersection(RIF(4/3, 5/3)).str(style='brackets')
'[1.3333333333333332 .. 1.6666666666666668]'
sage: RIF(1, 2).intersection(RIF(3, 4))
...
ValueError: intersection of non-overlapping intervals
```

is_NaN()

is_exact()

is_int()

OUTPUT:

- bool - True or False
- n - an integer

Checks to see whether this interval includes exactly one integer. If so, returns a tuple (True, n), where n is that integer; otherwise, returns (False, None).

EXAMPLES:

```
sage: a = RIF(0.8,1.5)
sage: a.is_int()
(True, 1)
sage: a = RIF(1.1,1.5)
sage: a.is_int()
(False, None)
sage: a = RIF(1,2)
sage: a.is_int()
(False, None)
sage: a = RIF(-1.1, -0.9)
sage: a.is_int()
(True, -1)
sage: a = RIF(0.1, 1.9)
sage: a.is_int()
(True, 1)
```

log()

EXAMPLES:

```
sage: R = RealIntervalField()
sage: R(2).log()
0.6931471805599453?
```

log10()

Returns log to the base 10 of self

EXAMPLES:

```
sage: r = RIF(16.0); r.log10()
1.204119982655925?
sage: r.log() / log(10.0)
1.204119982655925?

sage: r = RIF(39.9); r.log10()
1.600972895686749?

sage: r = RIF(0.0)
sage: r.log10()
[-infinity .. -infinity]

sage: r = RIF(-1.0)
sage: r.log10()
[.. NaN ..]
```

log2()

Returns log to the base 2 of self

EXAMPLES:

```
sage: r = RIF(16.0)
sage: r.log2()
4

sage: r = RIF(31.9); r.log2()
4.995484518877507?

sage: r = RIF(0.0, 2.0)
sage: r.log2()
[-infinity .. 1.0000000000000000]
```

lower()

Returns the lower bound of this interval

rnd - (string) the rounding mode

- RNDN - round to nearest
- RNDD - (default) round towards minus infinity
- RNDZ - round towards zero
- RNDU - round towards plus infinity

The rounding mode does not affect the value returned as a floating-point number, but it does control which variety of RealField the returned number is in, which affects printing and subsequent operations.

EXAMPLES:

```
sage: R = RealIntervalField(13)
sage: R.pi().lower().str(truncate=False)
'3.1411'

sage: x = R(1.2,1.3); x.str(style='brackets')
'[1.1999 .. 1.3001]'
sage: x.lower()
1.19
sage: x.lower('RNDU')
1.20
sage: x.lower('RNDN')
1.20
sage: x.lower('RNDZ')
1.19
sage: x.lower().parent()
Real Field with 13 bits of precision and rounding RNDD
sage: x.lower('RNDU').parent()
Real Field with 13 bits of precision and rounding RNDU
sage: x.lower() == x.lower('RNDU')
True
```

magnitude()

The largest absolute value of the elements of the interval.

EXAMPLES:

```
sage: RIF(-2, 1).magnitude()
2.00000000000000
sage: RIF(-1, 2).magnitude()
2.00000000000000
```

mignitude()

The smallest absolute value of the elements of the interval.

EXAMPLES:

```
sage: RIF(-2, 1).mignitude()
0.000000000000000
sage: RIF(-2, -1).mignitude()
1.00000000000000
sage: RIF(3, 4).mignitude()
3.00000000000000
```

multiplicative_order()

overlaps()

Returns true if self and other are intervals with at least one value in common. For intervals a and b, we have a.overlaps(b) iff not(a!=b).

EXAMPLES:

```
sage: RIF(0, 1).overlaps(RIF(1, 2))
True
sage: RIF(1, 2).overlaps(RIF(0, 1))
True
sage: RIF(0, 1).overlaps(RIF(2, 3))
False
sage: RIF(2, 3).overlaps(RIF(0, 1))
False
sage: RIF(0, 3).overlaps(RIF(1, 2))
True
sage: RIF(0, 2).overlaps(RIF(1, 3))
True
```

parent()

EXAMPLES:

```
sage: R = RealIntervalField()
sage: a = R('1.2456')
sage: a.parent()
Real Interval Field with 53 bits of precision
```

prec()

real()

Return the real part of self.

(Since self is a real number, this simply returns self.)

relative_diameter()

The relative diameter of this interval (for [a .. b], this is (b-a)/((a+b)/2)), rounded upward, as a RealNumber.

EXAMPLES:

```
sage: RIF(1, pi).relative_diameter()
1.03418797197910
```

sec()

Returns the secant of this number.

EXAMPLES:

```
sage: RealIntervalField(100)(2).sec()
-2.4029979617223809897546004014?
```

sech()

Returns the hyperbolic secant of this number.

EXAMPLES:

```
sage: RealIntervalField(100)(2).sech()
0.26580222883407969212086273982?
```

simplest_rational()

Returns the simplest rational in this interval. Given rationals a/b and c/d (both in lowest terms), the former is simpler if b<d or if b==d and $|a| < |c|$.

If optional parameters low_open or high_open are true, then treat this as an open interval on that end.

EXAMPLES:

```
sage: RealIntervalField(10)(pi).simplest_rational()
22/7
sage: RealIntervalField(20)(pi).simplest_rational()
355/113
sage: RIF(0.123, 0.567).simplest_rational()
1/2
sage: RIF(RR(1/3).nextabove(), RR(3/7)).simplest_rational()
2/5
sage: RIF(1234/567).simplest_rational()
1234/567
sage: RIF(-8765/432).simplest_rational()
-8765/432
sage: RIF(-1.234, 0.003).simplest_rational()
0
sage: RIF(RR(1/3)).simplest_rational()
6004799503160661/18014398509481984
sage: RIF(RR(1/3)).simplest_rational(high_open=True)
...
ValueError: simplest_rational() on open, empty interval
sage: RIF(1/3, 1/2).simplest_rational()
1/2
sage: RIF(1/3, 1/2).simplest_rational(high_open=True)
1/3
sage: phi = ((RealIntervalField(500)(5).sqrt() + 1)/2)
sage: phi.simplest_rational() == fibonacci(362)/fibonacci(361)
True
```

sin()

Returns the sine of this number

EXAMPLES:

```
sage: R = RealIntervalField(100)
sage: R(2).sin()
0.90929742682568169539601986591?
```

sinh()

Returns the hyperbolic sine of this number

EXAMPLES:

```
sage: q = RIF.pi()/12
sage: q.sinh()
0.2648002276022707?
```

sqrt()

Return a square root of self. Raises an error if self is nonpositive.

If you use self.square_root() then an interval will always be returned (though it will be NaN if self is nonpositive).

EXAMPLES:

```
sage: r = RIF(4.0)
sage: r.sqrt()
2
sage: r.sqrt()^2 == r
True

sage: r = RIF(4344)
sage: r.sqrt()
65.909028213136337
sage: r.sqrt()^2 == r
False
sage: r in r.sqrt()^2
True
sage: r.sqrt()^2 - r
0.?e-11
sage: (r.sqrt()^2 - r).str(style='brackets')
'[-9.0949470177292824e-13 .. 1.8189894035458565e-12]'

sage: r = RIF(-2.0)
sage: r.sqrt()
...
ValueError: self (=-2) is not >= 0

sage: r = RIF(-2, 2)
sage: r.sqrt()
...
ValueError: self (=0.?e1) is not >= 0
```

square()

Return the square of the interval. Note that squaring an interval is different than multiplying it by itself, because the square can never be negative.

EXAMPLES:

```
sage: RIF(1, 2).square().str(style='brackets')
'[1.0000000000000000 .. 4.0000000000000000]'
sage: RIF(-1, 1).square().str(style='brackets')
'[0.00000000000000000 .. 1.0000000000000000]'
sage: (RIF(-1, 1) * RIF(-1, 1)).str(style='brackets')
'[-1.0000000000000000 .. 1.0000000000000000]'
```

square_root()

Return a square root of self. An interval will always be returned (though it will be NaN if self is nonpositive).

EXAMPLES:

```
sage: r = RIF(-2.0)
sage: r.square_root()
[.. NaN ..]
sage: r.sqrt()
...
ValueError: self (=-2) is not >= 0
```

str()

INPUT:

- `base` - base for output
- `style` - The printing style; either 'brackets' or 'question' (or None, to use the current default).
- `no_sci` - if True do not print using scientific notation; if False print with scientific notation; if None (the default), print how the parent prints.

- `e` - symbol used in scientific notation
- `error_digits` - The number of digits of error to print, in 'question' style.

We support two different styles of printing; 'question' style and 'brackets' style. In question style (the default), we print the "known correct" part of the number, followed by a question mark:

```
sage: RIF(pi).str()
'3.1415926535897934?'
sage: RIF(pi, 22/7).str()
'3.142?'
sage: RIF(pi, 22/7).str(style='question')
'3.142?'
```

However, if the interval is precisely equal to some integer that's not too large, we just return that integer.

```
sage: RIF(-42).str()
'-42'
sage: RIF(0).str()
'0'
sage: RIF(12^5).str(base=3)
'110122100000'
```

Very large integers, however, revert to the normal question-style printing.

```
sage: RIF(3^7).str()
'2187'
sage: RIF(3^7 * 2^256).str()
'2.5323729916201052?e80'
```

In brackets style, we print the lower and upper bounds of the interval within brackets:

```
sage: RIF(237/16).str(style='brackets')
'[14.812500000000000 .. 14.812500000000000]'
```

Note that the lower bound is rounded down, and the upper bound is rounded up. So even if the lower and upper bounds are equal, they may print differently. (This is done so that the printed representation of the interval contains all the numbers in the internal binary interval.)

For instance, we find the best 10-bit floating point representation of 1/3:

```
sage: RR10 = RealField(10)
sage: RR(RR10(1/3))
0.333496093750000
```

And we see that the point interval containing only this floating-point number prints as a wider decimal interval, that does contain the number:

```
sage: RIF10 = RealIntervalField(10)
sage: RIF10(RR10(1/3)).str(style='brackets')
'[0.33349 .. 0.33350]'
```

We always use brackets style for NaN and infinities.

```
sage: RIF(pi, infinity)
[3.1415926535897931 .. +infinity]
sage: RIF(NaN)
[.. NaN ..]
```

Let's take a closer, formal look at the question style. In its full generality, a number printed in the question style looks like:

MANTISSA ?ERROR eEXPONENT

(without the spaces). The "eEXPONENT" part is optional; if it is missing, then the exponent is 0. (If the base is greater than 10, then the exponent separator is "@" instead of "e".)

The "ERROR" is optional; if it is missing, then the error is 1.

The mantissa is printed in base b, and always contains a decimal point (also known as a radix point, in bases other than 10). (The error and exponent are always printed in base 10.)

We define the "precision" of a floating-point printed representation to be the positional value of the last digit of the mantissa. For instance, in 2.7?e5, the precision is 10^4; in 8.?, the precision is 10^0; and in 9.35? the precision is 10^{-2}. This precision will always be 10^k for some k (or, for an arbitrary base b, b^k).

Then the interval is contained in the interval:

$$\text{mantissa} * b^{\text{exponent}} - \text{error} * b^k .. \text{mantissa} * b^{\text{exponent}} + \text{error} * b^k$$

To control the printing, we can specify a maximum number of error digits. The default is 0, which means that we do not print an error at all (so that the error is always the default, 1).

Now, consider the precisions needed to represent the endpoints (this is the precision that would be produced by `v.lower().str(no_sci=False, truncate=False)`). Our result is no more precise than the less precise endpoint, and is sufficiently imprecise that the error can be represented with the given number of decimal digits. Our result is the most precise possible result, given these restrictions. When there are two possible results of equal precision and with the same error width, then we pick the one which is farther from zero. (For instance, RIF(0, 123) with two error digits could print as 61.?62 or 62.?62. We prefer the latter because it makes it clear that the interval is known not to be negative.)

EXAMPLES:

```
sage: a = RIF(59/27); a
2.185185185185186?
sage: a.str()
'2.185185185185186?'
sage: a.str(style='brackets')
'[2.1851851851851851 .. 2.1851851851851856]'
sage: a.str(16)
'2.2f684bda12f69?'
sage: a.str(no_sci=False)
'2.185185185185186?e0'
sage: pi_appr = RIF(pi, 22/7)
sage: pi_appr.str(style='brackets')
'[3.1415926535897931 .. 3.1428571428571433]'
sage: pi_appr.str()
'3.142?'
sage: pi_appr.str(error_digits=1)
'3.1422?7'
sage: pi_appr.str(error_digits=2)
'3.14223?64'
sage: pi_appr.str(base=36)
'3.6?'
sage: RIF(NaN)
[.. NaN ..]
sage: RIF(pi, infinity)
[3.1415926535897931 .. +infinity]
sage: RIF(-infinity, pi)
[-infinity .. 3.1415926535897936]
sage: RealIntervalField(210)(3).sqrt()
1.732050807568877293527446341505872366942805253810380628055806980?
sage: RealIntervalField(210)(RIF(3).sqrt())
1.732050807568878?
sage: RIF(3).sqrt()
1.732050807568878?
sage: RIF(0, 3^-150)
1.?e-71
```

tan()

Returns the tangent of this number

EXAMPLES:

```
sage: q = RIF.pi()/3
sage: q.tan()
1.732050807568877?
sage: q = RIF.pi()/6
sage: q.tan()
0.577350269189626?
```

tanh()

Returns the hyperbolic tangent of this number

EXAMPLES:

```
sage: q = RIF.pi()/11
sage: q.tanh()
0.2780794292958503?
```

union()

Return the union of two intervals, or of an interval and a real number (more precisely, the convex hull).

EXAMPLES:

```
sage: RIF(1, 2).union(RIF(pi, 22/7)).str(style='brackets')
'[1.0000000000000000 .. 3.1428571428571433]'
sage: RIF(1, 2).union(pi).str(style='brackets')
'[1.0000000000000000 .. 3.1415926535897936]'
sage: RIF(1).union(RIF(0, 2)).str(style='brackets')
'[0.00000000000000000 .. 2.0000000000000000]'
sage: RIF(1).union(RIF(-1)).str(style='brackets')
'[-1.0000000000000000 .. 1.0000000000000000]'
```

upper()

Returns the upper bound of this interval

- RNDN - round to nearest
- RNDD - round towards minus infinity
- RNDZ - round towards zero
- RNDU - (default) round towards plus infinity

The rounding mode does not affect the value returned as a floating-point number, but it does control which variety of RealField the returned number is in, which affects printing and subsequent operations.

EXAMPLES:

```
sage: R = RealIntervalField(13)
sage: R.pi().upper().str(truncate=False)
'3.1417'

sage: R = RealIntervalField(13)
sage: x = R(1.2,1.3); x.str(style='brackets')
'[1.1999 .. 1.3001]'
sage: x.upper()
1.31
sage: x.upper('RNDU')
1.31
sage: x.upper('RNDN')
1.30
sage: x.upper('RNDD')
1.30
sage: x.upper('RNDZ')
1.30
sage: x.upper().parent()
```

```
Real Field with 13 bits of precision and rounding RNDU
sage: x.upper('RNDD').parent()
Real Field with 13 bits of precision and rounding RNDD
sage: x.upper() == x.upper('RNDD')
True
```

class RealIntervalField_class()

RealIntervalField(prec, sci_not, rnd):

INPUT:

- `prec` - (integer) precision; default = 53 prec is the number of bits used to represent the mantissa of a floating-point number. The precision can be any integer between mpfr_prec_min() and mpfr_prec_max(). In the current implementation, mpfr_prec_min() is equal to 2.
- `sci_not` - (default: False) whether or not to display using scientific notation

EXAMPLES:

```
sage: RealIntervalField(10)
Real Interval Field with 10 bits of precision
sage: RealIntervalField()
Real Interval Field with 53 bits of precision
sage: RealIntervalField(100000)
Real Interval Field with 100000 bits of precision
```

Note: The default precision is 53, since according to the GMP manual: 'mpfr should be able to exactly reproduce all computations with double-precision machine floating-point numbers (double type in C), except the default exponent range is much wider and subnormal numbers are not implemented.'

EXAMPLES: Creation of elements

First with default precision. First we coerce elements of various types, then we coerce intervals.

```
sage: RIF = RealIntervalField(); RIF
Real Interval Field with 53 bits of precision
sage: RIF(3)
3
sage: RIF(RIF(3))
3
sage: RIF(pi)
3.141592653589794?
sage: RIF(RealField(53)('1.5'))
1.5000000000000000?
sage: RIF(-2/19)
-0.1052631578947369?
sage: RIF(-3939)
-3939
sage: RIF(-3939r)
-3939
sage: RIF('1.5')
1.5000000000000000?
sage: R200 = RealField(200)
sage: RIF(R200.pi())
3.141592653589794?
```

The base must be explicitly specified as a named parameter:

```
sage: RIF('101101', base=2)
45
sage: RIF('+infinity')
[+infinity .. +infinity]
sage: RIF('[1..3]').str(style='brackets')
'[1.0000000000000000 .. 3.0000000000000000]'
```

Next we coerce some 2-tuples, which define intervals.

```
sage: RIF((-1.5, -1.3))
-1.4?
sage: RIF((RDF('-1.5'), RDF('-1.3')))
-1.4?
sage: RIF((1/3,2/3)).str(style='brackets')
'[0.33333333333333331 .. 0.66666666666666675]'
```

The extra paranthesis aren't needed.

```
sage: RIF(1/3,2/3).str(style='brackets')
'[0.33333333333333331 .. 0.66666666666666675]'
sage: RIF((1,2)).str(style='brackets')
'[1.0000000000000000 .. 2.0000000000000000]'
sage: RIF((1r,2r)).str(style='brackets')
'[1.0000000000000000 .. 2.0000000000000000]'
sage: RIF((pi, e)).str(style='brackets')
'[2.7182818284590455 .. 3.1415926535897932]'
```

Values which can be represented as an exact floating-point number (of the precision of this RealIntervalField) result in a precise interval, where the lower bound is equal to the upper bound (even if they print differently). Other values typically result in an interval where the lower and upper bounds are adjacent floating-point numbers.

```
sage: def check(x):
...       return (x, x.lower() == x.upper())
sage: check(RIF(pi))
(3.1415926535897932?, False)
sage: check(RIF(RR(pi)))
(3.1415926535897932?, True)
sage: check(RIF(1.5))
(1.5000000000000000?, True)
sage: check(RIF('1.5'))
(1.5000000000000000?, True)
sage: check(RIF(0.1))
(0.10000000000000001?, True)
sage: check(RIF(1/10))
(0.10000000000000000?, False)
sage: check(RIF('0.1'))
(0.10000000000000000?, False)
```

Similarly, when specifying both ends of an interval, the lower end is rounded down and the upper end is rounded up.

```
sage: outward = RIF(1/10, 7/10); outward.str(style='brackets')
'[0.09999999999999991 .. 0.70000000000000007]'
sage: nearest = RIF(RR(1/10), RR(7/10)); nearest.str(style='brackets')
'[0.10000000000000000 .. 0.69999999999999996]'
sage: nearest.lower() - outward.lower()
1.38777878078144e-17
```

```
sage: outward.upper() - nearest.upper()
1.11022302462516e-16
```

Some examples with a real interval field of higher precision:

```
sage: R = RealIntervalField(100)
sage: R(3)
3
sage: R(R(3))
3
sage: R(pi)
3.1415926535897932384626433832?
sage: R(-2/19)
-0.10526315789473684210526315789?
sage: R(e,pi).str(style='brackets')
'[2.71828182845904523536028747135?? .. 3.1415926535897932384626433832825]'
```

TESTS:

```
sage: RIF._lower_field() is RealField(53, rnd='RNDD')
True
sage: RIF._upper_field() is RealField(53, rnd='RNDU')
True
sage: RIF._middle_field() is RR
True
```

characteristic()

Returns 0, since the field of real numbers has characteristic 0.

EXAMPLES:

```
sage: RealIntervalField(10).characteristic()
0
```

complex_field()

Return complex field of the same precision.

EXAMPLES:

```
sage: RIF.complex_field()
Complex Interval Field with 53 bits of precision
```

construction()

Returns the functorial construction of self, namely, completion of the rational numbers with respect to the prime at ∞, and the note that this is an interval field.

Also preserves other information that makes this field unique (e.g. precision, print mode).

EXAMPLES:

```
sage: R = RealIntervalField(123)
sage: c, S = R.construction(); S
Rational Field
sage: R == c(S)
True
```

euler_constant()

Returns Euler's gamma constant to the precision of this field.

EXAMPLES:

```
sage: RealIntervalField(100).euler_constant()
0.57721566490153286060651209008?
```

gen()

gens()

is_atomic_repr()

Returns True, to signify that elements of this field print without sums, so parenthesis aren't required, e.g., in coefficients of polynomials.

EXAMPLES:

```
sage: RealIntervalField(10).is_atomic_repr()
True
```

is_exact()

is_finite()

Returns False, since the field of real numbers is not finite.

EXAMPLES:

```
sage: RealIntervalField(10).is_finite()
False
```

log2()

Returns log(2) to the precision of this field.

EXAMPLES:

```
sage: R=RealIntervalField(100)
sage: R.log2()
0.693147180559945309417232121458?
sage: R(2).log()
0.693147180559945309417232121458?
```

name()

ngens()

pi()

Returns pi to the precision of this field.

EXAMPLES:

```
sage: R = RealIntervalField(100)
sage: R.pi()
3.1415926535897932384626433832?
sage: R.pi().sqrt()/2
0.88622692545275801364908374167?
sage: R = RealIntervalField(150)
sage: R.pi().sqrt()/2
0.886226925452758013649083741670572591398774728?
```

prec()

Returns the precision of this field (in bits).

EXAMPLES:

```
sage: RIF.prec()
53
sage: RealIntervalField(200).prec()
200
```

precision()

random_element()

Returns a random element of self. Any arguments are passed onto the random element function in real field.

By default, this is uniformly distributed in $[-1, 1]$.

EXAMPLES:

```
sage: RIF.random_element()
-0.30607732607725314?
sage: RIF.random_element()
-0.075929193054320221?
sage: RIF.random_element(-100, 100)
-83.808125490023344?
```

scientific_notation()

Set or return the scientific notation printing flag. If this flag is True then real numbers with this space as parent print using scientific notation.

INPUT:

- `status` - (bool -) optional flag

to_prec()

Returns a real interval field to the given precision.

EXAMPLES:

```
sage: RIF.to_prec(200)
Real Interval Field with 200 bits of precision
sage: RIF.to_prec(20)
Real Interval Field with 20 bits of precision
sage: RIF.to_prec(53) is RIF
True
```

zeta()

Return an n-th root of unity in the real field, if one exists, or raise a ValueError otherwise.

EXAMPLES:

```
sage: R = RealIntervalField()
sage: R.zeta()
-1
sage: R.zeta(1)
1
sage: R.zeta(5)
...
ValueError: No 5th root of unity in self
```

is_RealIntervalField()

is_RealIntervalFieldElement()

CHAPTER

TWENTYSIX

ALGEBRAIC NUMBER FIELDS

26.1 Number Fields

AUTHORS:

- William Stein (2004, 2005): initial version
- Steven Sivek (2006-05-12): added support for relative extensions
- William Stein (2007-09-04): major rewrite and documentation
- Robert Bradshaw (2008-10): specified embeddings into ambient fields

Note: Unlike in PARI/GP, class group computations *in Sage* do *not* by default assume the Generalized Riemann Hypothesis. To do class groups computations not provably correctly you must often pass the flag proof=False to functions or call the function `proof.number_field(False)`. It can easily take 1000's of times longer to do computations with `proof=True` (the default).

This example follows one in the Magma reference manual:

```
sage: K.<y> = NumberField(x^4 - 420*x^2 + 40000)
sage: z = y^5/11; z
420/11*y^3 - 40000/11*y
sage: R.<y> = PolynomialRing(K)
sage: f = y^2 + y + 1
sage: L.<a> = K.extension(f); L
Number Field in a with defining polynomial y^2 + y + 1 over its base field
sage: KL.<b> = NumberField([x^4 - 420*x^2 + 40000, x^2 + x + 1]); KL
Number Field in b0 with defining polynomial x^4 - 420*x^2 + 40000 over its base field
```

We do some arithmetic in a tower of relative number fields:

```
sage: K.<cuberoot2> = NumberField(x^3 - 2)
sage: L.<cuberoot3> = K.extension(x^3 - 3)
sage: S.<sqrt2> = L.extension(x^2 - 2)
sage: S
Number Field in sqrt2 with defining polynomial x^2 - 2 over its base field
sage: sqrt2 * cuberoot3
cuberoot3*sqrt2
sage: (sqrt2 + cuberoot3)^5
(20*cuberoot3^2 + 15*cuberoot3 + 4)*sqrt2 + 3*cuberoot3^2 + 20*cuberoot3 + 60
sage: cuberoot2 + cuberoot3
cuberoot3 + cuberoot2
```

```
sage: cuberoot2 + cuberoot3 + sqrt2
sqrt2 + cuberoot3 + cuberoot2
sage: (cuberoot2 + cuberoot3 + sqrt2)^2
(2*cuberoot3 + 2*cuberoot2)*sqrt2 + cuberoot3^2 + 2*cuberoot2*cuberoot3 + cuberoot2^2 + 2
sage: cuberoot2 + sqrt2
sqrt2 + cuberoot2
sage: a = S(cuberoot2); a
cuberoot2
sage: a.parent()
Number Field in sqrt2 with defining polynomial x^2 - 2 over its base field
```

Warning: Doing arithmetic in towers of relative fields that depends on canonical coercions is currently VERY SLOW. It is much better to explicitly coerce all elements into a common field, then do arithmetic with them there (which is quite fast).

TESTS:

```
sage: y = polygen(QQ,'y'); K.<beta> = NumberField([y^3 - 3, y^2 - 2])
sage: K(y^10)
27*beta0
sage: beta^10
27*beta0
```

CyclotomicField(*n, names=None, embedding=True*)

Return the n-th cyclotomic field, where n is a positive integer.

INPUT:

- `n` - a positive integer
- `names` - name of generator (optional - defaults to zetan).
- `embedding` - bool or n-th root of unity in an ambient field (default True)

EXAMPLES: We create the 7th cyclotomic field $\mathbf{Q}(\zeta_7)$ with the default generator name.

```
sage: k = CyclotomicField(7); k
Cyclotomic Field of order 7 and degree 6
sage: k.gen()
zeta7
```

The default embedding sends the generator to the complex primative n^{th} root of unitiy of least argument.

```
sage: CC(k.gen())
0.623489801858734 + 0.781831482468030*I
```

Cyclotomic fields are of a special type.

```
sage: type(k)
<class 'sage.rings.number_field.number_field.NumberField_cyclotomic'>
```

We can specify a different generator name as follows.

```
sage: k.<z7> = CyclotomicField(7); k
Cyclotomic Field of order 7 and degree 6
sage: k.gen()
z7
```

The n must be an integer.

```
sage: CyclotomicField(3/2)
...
TypeError: no conversion of this rational to integer
```

The degree must be positive.

```
sage: CyclotomicField(0)
...
ValueError: n (=0) must be a positive integer
```

The special case $n = 1$ does *not* return the rational numbers:

```
sage: CyclotomicField(1)
Cyclotomic Field of order 1 and degree 1
```

Due to their default embedding into $\mathbf{C}$, cyclotomic number fields are all compatable.

```
sage: cf30 = CyclotomicField(30)
sage: cf5 = CyclotomicField(5)
sage: cf3 = CyclotomicField(3)
sage: cf30.gen() + cf5.gen() + cf3.gen()
zeta30^6 + zeta30^5 + zeta30 - 1
sage: cf6 = CyclotomicField(6) ; z6 = cf6.0
sage: cf3 = CyclotomicField(3) ; z3 = cf3.0
sage: cf3(z6)
zeta3 + 1
sage: cf6(z3)
zeta6 - 1
sage: cf9 = CyclotomicField(9) ; z9 = cf9.0
sage: cf18 = CyclotomicField(18) ; z18 = cf18.0
sage: cf18(z9)
zeta18^2
sage: cf9(z18)
-zeta9^5
sage: cf18(z3)
zeta18^3 - 1
sage: cf18(z6)
zeta18^3
sage: cf18(z6)**2
zeta18^3 - 1
sage: cf9(z3)
zeta9^3
```

NumberField(*polynomial, name=None, check=True, names=None, cache=True, embedding=None*)

Return *the* number field defined by the given irreducible polynomial and with variable with the given name. If check is True (the default), also verify that the defining polynomial is irreducible and over Q.

INPUT:

- `polynomial` - a polynomial over QQ or a number field, or a list of polynomials.
- `name` - a string (default: 'a'), the name of the generator
- `check` - bool (default: True); do type checking and irreducibility checking.
- `embedding` - image of the generator in an ambient field (default: None)

EXAMPLES:

```
sage: z = QQ['z'].0
sage: K = NumberField(z^2 - 2,'s'); K
Number Field in s with defining polynomial z^2 - 2
sage: s = K.0; s
s
sage: s*s
2
sage: s^2
2
```

Constructing a relative number field

```
sage: K.<a> = NumberField(x^2 - 2)
sage: R.<t> = K[]
sage: L.<b> = K.extension(t^3+t+a); L
Number Field in b with defining polynomial t^3 + t + a over its base field
sage: L.absolute_field('c')
Number Field in c with defining polynomial x^6 + 2*x^4 + x^2 - 2
sage: a*b
a*b
sage: L(a)
a
sage: L.lift_to_base(b^3 + b)
-a
```

Constructing another number field:

```
sage: k.<i> = NumberField(x^2 + 1)
sage: R.<z> = k[]
sage: m.<j> = NumberField(z^3 + i*z + 3)
sage: m
Number Field in j with defining polynomial z^3 + i*z + 3 over its base field
```

Number fields are globally unique.

```
sage: K.<a>= NumberField(x^3-5)
sage: a^3
5
sage: L.<a>= NumberField(x^3-5)
sage: K is L
True
```

Having different defining polynomials makes the fields different:

```
sage: x = polygen(QQ, 'x'); y = polygen(QQ, 'y')
sage: k.<a> = NumberField(x^2 + 3)
sage: m.<a> = NumberField(y^2 + 3)
sage: k
Number Field in a with defining polynomial x^2 + 3
sage: m
Number Field in a with defining polynomial y^2 + 3
```

One can also define number fields with specified embeddings, may be used for arithmetic and deduce relations with other number fields which would not be valid for an abstract number field:

```
sage: K.<a> = NumberField(x^3-2, embedding=1.2)
sage: RR.coerce_map_from(K)
Composite map:
```

```
  From: Number Field in a with defining polynomial x^3 - 2
  To:   Real Field with 53 bits of precision
  Defn:   Generic morphism:
          From: Number Field in a with defining polynomial x^3 - 2
          To:   Real Lazy Field
          Defn: a -> 1.259921049894873?
        then
          Conversion via _mpfr_ method map:
          From: Real Lazy Field
          To:   Real Field with 53 bits of precision
sage: RR(a)
1.25992104989487
sage: 1.1 + a
2.35992104989487
sage: b = 1/(a+1); b
1/3*a^2 - 1/3*a + 1/3
sage: RR(b)
0.442493334024442
sage: L.<b> = NumberField(x^6-2, embedding=1.1)
sage: L(a)
b^2
sage: a + b
b^2 + b
```

Note that the image only needs to be specified to enough precision to distinguish roots, and is exactly computed to any needed precision:

```
sage: RealField(200)(a)
1.2599210498948731647672106072782283505702514647015079800820
```

One can embed into any other field:

```
sage: K.<a> = NumberField(x^3-2, embedding=CC.gen()-0.6)
sage: CC(a)
-0.629960524947436 + 1.09112363597172*I
sage: L = Qp(5)
sage: f = polygen(L)^3 - 2
sage: K.<a> = NumberField(x^3-2, embedding=f.roots()[0][0])
sage: a + L(1)
4 + 2*5^2 + 2*5^3 + 3*5^4 + 5^5 + 4*5^6 + 2*5^8 + 3*5^9 + 4*5^12 + 4*5^14 + 4*5^15 + 3*5^16 + 5^
sage: L.<b> = NumberField(x^6-x^2+1/10, embedding=1)
sage: K.<a> = NumberField(x^3-x+1/10, embedding=b^2)
sage: a+b
b^2 + b
sage: CC(a) == CC(b)^2
True
sage: K.coerce_embedding()
Generic morphism:
  From: Number Field in a with defining polynomial x^3 - x + 1/10
  To:   Number Field in b with defining polynomial x^6 - x^2 + 1/10
  Defn: a -> b^2
```

The `QuadraticField` and `CyclotomicField` constructors create an embedding by default unless otherwise specified.

```
sage: K.<zeta> = CyclotomicField(15)
sage: CC(zeta)
0.913545457642601 + 0.406736643075800*I
```

```
sage: L.<sqrtn3> = QuadraticField(-3)
sage: K(sqrtn3)
2*zeta^5 + 1
sage: sqrtn3 + zeta
2*zeta^5 + zeta + 1
```

An example involving a variable name that defines a function in PARI:

```
sage: theta = polygen(QQ, 'theta')
sage: M.<z> = NumberField([theta^3 + 4, theta^2 + 3]); M
Number Field in z0 with defining polynomial theta^3 + 4 over its base field
```

TESTS:

```
sage: x = QQ['x'].gen()
sage: y = ZZ['y'].gen()
sage: K = NumberField(x^3 + x + 3, 'a'); K
Number Field in a with defining polynomial x^3 + x + 3
sage: K.defining_polynomial().parent()
Univariate Polynomial Ring in x over Rational Field
```

```
sage: L = NumberField(y^3 + y + 3, 'a'); L
Number Field in a with defining polynomial y^3 + y + 3
sage: L.defining_polynomial().parent()
Univariate Polynomial Ring in y over Rational Field
```

NumberFieldTower(*v, names, check=True, embeddings=None*)

Return the tower of number fields defined by the polynomials or number fields in the list v.

This is the field constructed first from v[0], then over that field from v[1], etc. If all is False, then each v[i] must be irreducible over the previous fields. Otherwise a list of all possible fields defined by all those polynomials is output.

If names defines a variable name a, say, then the generators of the intermediate number fields are a0, a1, a2, ...

INPUT:

- `v` - a list of polynomials or number fields
- `names` - variable names
- `check` - bool (default: True) only relevant if all is False. Then check irreducibility of each input polynomial.

OUTPUT: a single number field or a list of number fields

EXAMPLES:

```
sage: k.<a,b,c> = NumberField([x^2 + 1, x^2 + 3, x^2 + 5]); k
Number Field in a with defining polynomial x^2 + 1 over its base field
sage: a^2
-1
sage: b^2
-3
sage: c^2
-5
sage: (a+b+c)^2
(2*b + 2*c)*a + 2*c*b - 9
```

The Galois group is a product of 3 groups of order 2:

```
sage: k.galois_group(type="pari")
Galois group PARI group [8, 1, 3, "E(8)=2[x]2[x]2"] of degree 8 of the Number Field in a with de
```

Repeatedly calling base_field allows us to descend the internally constructed tower of fields:

```
sage: k.base_field()
Number Field in b with defining polynomial x^2 + 3 over its base field
sage: k.base_field().base_field()
Number Field in c with defining polynomial x^2 + 5
sage: k.base_field().base_field().base_field()
Rational Field
```

In the following example the second polynomial is reducible over the first, so we get an error:

```
sage: v = NumberField([x^3 - 2, x^3 - 2], names='a')
...
ValueError: defining polynomial (x^3 - 2) must be irreducible
```

We mix polynomial parent rings:

```
sage: k.<y> = QQ[]
sage: m = NumberField([y^3 - 3, x^2 + x + 1, y^3 + 2], 'beta')
sage: m
Number Field in beta0 with defining polynomial y^3 - 3 over its base field
sage: m.base_field ()
Number Field in beta1 with defining polynomial x^2 + x + 1 over its base field
```

A tower of quadratic fields:

```
sage: K.<a> = NumberField([x^2 + 3, x^2 + 2, x^2 + 1])
sage: K
Number Field in a0 with defining polynomial x^2 + 3 over its base field
sage: K.base_field()
Number Field in a1 with defining polynomial x^2 + 2 over its base field
sage: K.base_field().base_field()
Number Field in a2 with defining polynomial x^2 + 1
```

A bigger tower of quadratic fields.

```
sage: K.<a2,a3,a5,a7> = NumberField([x^2 + p for p in [2,3,5,7]]); K
Number Field in a2 with defining polynomial x^2 + 2 over its base field
sage: a2^2
-2
sage: a3^2
-3
sage: (a2+a3+a5+a7)^3
((6*a5 + 6*a7)*a3 + 6*a7*a5 - 47)*a2 + (6*a7*a5 - 45)*a3 - 41*a5 - 37*a7
```

class **NumberField_absolute**(*polynomial, name, latex_name=None, check=True, embedding=None*)

Minkowski_embedding(*B=None, prec=None*)

Return an nxn matrix over RDF whose columns are the images of the basis $\{1, \alpha, \ldots, \alpha^{n-1}\}$ of self over $\mathbf{Q}$ (as vector spaces), where here α is the generator of self over $\mathbf{Q}$, i.e. self.gen(0). If B is not None, return the images of the vectors in B as the columns instead. If prec is not None, use RealField(prec) instead of RDF.

This embedding is the so-called "Minkowski embedding" of a number field in $\mathbf{R}^n$: given the n embeddings $\sigma_1, \ldots, \sigma_n$ of self in $\mathbf{C}$, write $\sigma_1, \ldots, \sigma_r$ for the real embeddings, and $\sigma_{r+1}, \ldots, \sigma_{r+s}$ for choices of one

of each pair of complex conjugate embeddings (in our case, we simply choose the one where the image of α has positive real part). Here (r, s) is the signature of self. Then the Minkowski embedding is given by

$$x \mapsto (\sigma_1(x), \ldots, \sigma_r(x), \sqrt{2}\Re(\sigma_{r+1}(x)), \sqrt{2}\Im(\sigma_{r+1}(x)), \ldots, \sqrt{2}\Re(\sigma_{r+s}(x)), \sqrt{2}\Im(\sigma_{r+s}(x)))$$

Equivalently, this is an embedding of self in $\mathbf{R}^n$ so that the usual norm on $\mathbf{R}^n$ coincides with $|x| = \sum_i |\sigma_i(x)|^2$ on self.

TODO: This could be much improved by implementing homomorphisms over VectorSpaces.

EXAMPLES:

```
sage: F.<alpha> = NumberField(x^3+2)
sage: F.Minkowski_embedding()
[ 1.00000000000000 -1.25992104989487  1.58740105196820]
[ 1.41421356237... 0.8908987181... -1.12246204830...]
[0.000000000000000  1.54308184421...  1.94416129723...]
sage: F.Minkowski_embedding([1, alpha+2, alpha^2-alpha])
[ 1.00000000000000 0.740078950105127  2.84732210186307]
[ 1.41421356237...  3.7193258428... -2.01336076644...]
[0.000000000000000  1.54308184421... 0.40107945302...]
sage: F.Minkowski_embedding() * (alpha + 2).vector().transpose()
[0.740078950105127]
[ 3.7193258428...]
[ 1.54308184421...]
```

absolute_degree()

A synonym for degree.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2 + 1)
sage: K.absolute_degree()
2
```

absolute_different()

A synonym for different.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2 + 1)
sage: K.absolute_different()
Fractional ideal (2)
```

absolute_discriminant()

A synonym for discriminant.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2 + 1)
sage: K.absolute_discriminant()
-4
```

absolute_polynomial()

A synonym for polynomial.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2 + 1)
sage: K.absolute_polynomial()
x^2 + 1
```

absolute_vector_space()

A synonym for vector_space.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2 + 1)
sage: K.absolute_vector_space()
(Vector space of dimension 2 over Rational Field,
 Isomorphism map:
  From: Vector space of dimension 2 over Rational Field
  To:   Number Field in i with defining polynomial x^2 + 1,
 Isomorphism map:
  From: Number Field in i with defining polynomial x^2 + 1
  To:   Vector space of dimension 2 over Rational Field)
```

automorphisms()

Compute all Galois automorphisms of self.

This uses PARI's code{nfgaloisconj} and is much faster than root finding for many fields.

EXAMPLES:

```
sage: K.<a> = NumberField(x^2 + 10000)
sage: K.automorphisms()
[
Ring endomorphism of Number Field in a with defining polynomial x^2 + 10000
  Defn: a |--> a,
Ring endomorphism of Number Field in a with defining polynomial x^2 + 10000
  Defn: a |--> -a
]
```

Here's a larger example, that would take some time if we found roots instead of using PARI's specialized machinery:

```
sage: K = NumberField(x^6 - x^4 - 2*x^2 + 1, 'a')
sage: len(K.automorphisms())
2
```

L is the Galois closure of K:

```
sage: L = NumberField(x^24 - 84*x^22 + 2814*x^20 - 15880*x^18 - 409563*x^16 - 8543892*x^14 +
sage: len(L.automorphisms())
24
```

base_field()

Returns the base field of self, which is always QQ

EXAMPLES:

```
sage: K = CyclotomicField(5)
sage: K.base_field()
Rational Field
```

change_names(*names*)

Return number field isomorphic to self but with the given generator name.

INPUT:

- `names` - should be exactly one variable name.

Also, `K.structure()` returns from_K and to_K, where from_K is an isomorphism from K to self and to_K is an isomorphism from self to K.

EXAMPLES:

```
sage: K.<z> = NumberField(x^2 + 3); K
Number Field in z with defining polynomial x^2 + 3
sage: L.<ww> = K.change_names()
sage: L
Number Field in ww with defining polynomial x^2 + 3
sage: L.structure()[0]
```

```
Isomorphism given by variable name change map:
  From: Number Field in ww with defining polynomial x^2 + 3
  To:   Number Field in z with defining polynomial x^2 + 3
sage: L.structure()[0](ww + 5/3)
z + 5/3
```

embeddings(*K*)

Compute all field embeddings of self into the field K (which need not even be a number field, e.g., it could be the complex numbers). This will return an identical result when given K as input again.

If possible, the most natural embedding of self into K is put first in the list.

INPUT:

- K - a number field

EXAMPLES:

```
sage: K.<a> = NumberField(x^3 - 2)
sage: L.<a1> = K.galois_closure(); L
Number Field in a1 with defining polynomial x^6 + 40*x^3 + 1372
sage: K.embeddings(L)[0]
Ring morphism:
  From: Number Field in a with defining polynomial x^3 - 2
  To:   Number Field in a1 with defining polynomial x^6 + 40*x^3 + 1372
  Defn: a |--> 1/84*a1^4 + 13/42*a1
sage: K.embeddings(L)  is K.embeddings(L)
True
```

We embed a quadratic field into a cyclotomic field:

```
sage: L.<a> = QuadraticField(-7)
sage: K = CyclotomicField(7)
sage: L.embeddings(K)
[
Ring morphism:
  From: Number Field in a with defining polynomial x^2 + 7
  To:   Cyclotomic Field of order 7 and degree 6
  Defn: a |--> 2*zeta7^4 + 2*zeta7^2 + 2*zeta7 + 1,
Ring morphism:
  From: Number Field in a with defining polynomial x^2 + 7
  To:   Cyclotomic Field of order 7 and degree 6
  Defn: a |--> -2*zeta7^4 - 2*zeta7^2 - 2*zeta7 - 1
]
```

We embed a cubic field in the complex numbers:

```
sage: K.<a> = NumberField(x^3 - 2)
sage: K.embeddings(CC)
[
Ring morphism:
  From: Number Field in a with defining polynomial x^3 - 2
  To:   Complex Field with 53 bits of precision
  Defn: a |--> -0.62996052494743... - 1.09112363597172*I,
Ring morphism:
  From: Number Field in a with defining polynomial x^3 - 2
  To:   Complex Field with 53 bits of precision
  Defn: a |--> -0.62996052494743... + 1.09112363597172*I,
Ring morphism:
  From: Number Field in a with defining polynomial x^3 - 2
  To:   Complex Field with 53 bits of precision
  Defn: a |--> 1.25992104989487
]
```

galois_closure(*names=None, map=False*)

Return number field K that is the Galois closure of self, i.e., is generated by all roots of the defining polynomial of self, and possibly an embedding of self into K.

INPUT:

- `names` - variable name for Galois closure
- `map` - (default: False) also return an embedding of self into K

EXAMPLES:

```
sage: K.<a> = NumberField(x^4 - 2)
sage: M = K.galois_closure('b'); M
Number Field in b with defining polynomial x^8 + 28*x^4 + 2500
sage: L.<a2> = K.galois_closure(); L
Number Field in a2 with defining polynomial x^8 + 28*x^4 + 2500
sage: K.galois_group(names=("a3")).order()
8

sage: phi = K.embeddings(L)[0]
sage: phi(K.0)
1/120*a2^5 + 19/60*a2
sage: phi(K.0).minpoly()
x^4 - 2

sage: L, phi = K.galois_closure('b', map=True)
sage: L
Number Field in b with defining polynomial x^8 + 28*x^4 + 2500
sage: phi
Ring morphism:
  From: Number Field in a with defining polynomial x^4 - 2
  To:   Number Field in b with defining polynomial x^8 + 28*x^4 + 2500
  Defn: a |--> 1/240*b^5 - 41/120*b
```

TESTS:

Let's make sure we're renaming correctly:

```
sage: L, phi = K.galois_closure('cc', map=True)
sage: L
Number Field in cc with defining polynomial x^8 + 28*x^4 + 2500
sage: phi
Ring morphism:
  From: Number Field in a with defining polynomial x^4 - 2
  To:   Number Field in cc with defining polynomial x^8 + 28*x^4 + 2500
  Defn: a |--> 1/240*cc^5 - 41/120*cc
```

is_absolute()

Returns True since self is an absolute field.

EXAMPLES:

```
sage: K = CyclotomicField(5)
sage: K.is_absolute()
True
```

maximal_order(*v=None*)

Return the maximal order, i.e., the ring of integers, associated to this number field.

INPUT:

- `v` - (default: None) None, a prime, or a list of primes.
  - –if v is None, return the maximal order.
  - –if v is a prime, return an order that is p-maximal.

–if v is a list, return an order that is maximal at each prime in the list v.

EXAMPLES: In this example, the maximal order cannot be generated by a single element.

```
sage: k.<a> = NumberField(x^3 + x^2 - 2*x+8)
sage: o = k.maximal_order()
sage: o
Maximal Order in Number Field in a with defining polynomial x^3 + x^2 - 2*x + 8
```

We compute p-maximal orders for several p. Note that computing a p-maximal order is much faster in general than computing the maximal order:

```
sage: p = next_prime(10^22); q = next_prime(10^23)
sage: K.<a> = NumberField(x^3 - p*q)
sage: K.maximal_order([3]).basis()
[1/3*a^2 + 1/3*a + 1/3, a, a^2]
sage: K.maximal_order([2]).basis()
[1, a, a^2]
sage: K.maximal_order([p]).basis()
[1, a, a^2]
sage: K.maximal_order([q]).basis()
[1, a, a^2]
sage: K.maximal_order([p,3]).basis()
[1/3*a^2 + 1/3*a + 1/3, a, a^2]
```

An example with bigger discriminant:

```
sage: p = next_prime(10^97); q = next_prime(10^99)
sage: K.<a> = NumberField(x^3 - p*q)
sage: K.maximal_order(prime_range(10000)).basis()
[1, a, a^2]
```

optimized_representation(*names=None, both_maps=True*)

Return a field isomorphic to self with a better defining polynomial if possible, along with field isomorphisms from the new field to self and from self to the new field.

EXAMPLES: We construct a compositum of 3 quadratic fields, then find an optimized representation and transform elements back and forth.

```
sage: K = NumberField([x^2 + p for p in [5, 3, 2]],'a').absolute_field('b'); K
Number Field in b with defining polynomial x^8 + 40*x^6 + 352*x^4 + 960*x^2 + 576
sage: L, from_L, to_L = K.optimized_representation()
sage: L    # your answer may different, since algorithm is random
Number Field in a14 with defining polynomial x^8 + 4*x^6 + 7*x^4 + 36*x^2 + 81
sage: to_L(K.0)   # random
4/189*a14^7 - 1/63*a14^6 + 1/27*a14^5 + 2/9*a14^4 - 5/27*a14^3 + 8/9*a14^2 + 3/7*a14 + 3/7
sage: from_L(L.0)   # random
1/1152*a1^7 + 1/192*a1^6 + 23/576*a1^5 + 17/96*a1^4 + 37/72*a1^3 + 5/6*a1^2 + 55/24*a1 + 3/4
```

The transformation maps are mutually inverse isomorphisms.

```
sage: from_L(to_L(K.0))
b
sage: to_L(from_L(L.0))     # random
a14
```

optimized_subfields(*degree=0, name=None, both_maps=True*)

Return optimized representations of many (but *not* necessarily all!) subfields of self of degree 0, or of all possible degrees if degree is 0.

EXAMPLES:

```
sage: K = NumberField([x^2 + p for p in [5, 3, 2]],'a').absolute_field('b'); K
Number Field in b with defining polynomial x^8 + 40*x^6 + 352*x^4 + 960*x^2 + 576
```

```
sage: L = K.optimized_subfields(name='b')
sage: L[0][0]
Number Field in b0 with defining polynomial x - 1
sage: L[1][0]
Number Field in b1 with defining polynomial x^2 - x + 1
sage: [z[0] for z in L]          # random -- since algorithm is random
[Number Field in b0 with defining polynomial x - 1,
 Number Field in b1 with defining polynomial x^2 - x + 1,
 Number Field in b2 with defining polynomial x^4 - 5*x^2 + 25,
 Number Field in b3 with defining polynomial x^4 - 2*x^2 + 4,
 Number Field in b4 with defining polynomial x^8 + 4*x^6 + 7*x^4 + 36*x^2 + 81]
```

We examine one of the optimized subfields in more detail:

```
sage: M, from_M, to_M = L[2]
sage: M                              # random
Number Field in b2 with defining polynomial x^4 - 5*x^2 + 25
sage: from_M     # may be slightly random
Ring morphism:
  From: Number Field in b2 with defining polynomial x^4 - 5*x^2 + 25
  To:   Number Field in a1 with defining polynomial x^8 + 40*x^6 + 352*x^4 + 960*x^2 + 576
  Defn: b2 |--> -5/1152*a1^7 + 1/96*a1^6 - 97/576*a1^5 + 17/48*a1^4 - 95/72*a1^3 + 17/12*a1^
```

The to_M map is None, since there is no map from K to M:

```
sage: to_M
```

We apply the from_M map to the generator of M, which gives a rather large element of K:

```
sage: from_M(M.0)           # random
-5/1152*a1^7 + 1/96*a1^6 - 97/576*a1^5 + 17/48*a1^4 - 95/72*a1^3 + 17/12*a1^2 - 53/24*a1 - 1
```

Nevertheless, that large-ish element lies in a degree 4 subfield:

```
sage: from_M(M.0).minpoly()    # random
x^4 - 5*x^2 + 25
```

order(**gens, **kwds*)

Return the order with given ring generators in the maximal order of this number field.

INPUT:

- `gens` - list of elements of self; if no generators are given, just returns the cardinality of this number field (oo) for consistency.
- `check_is_integral` - bool (default: True), whether to check that each generator is integral.
- `check_rank` - bool (default: True), whether to check that the ring generated by gens is of full rank.
- `allow_subfield` - bool (default: False), if True and the generators do not generate an order, i.e., they generate a subring of smaller rank, instead of raising an error, return an order in a smaller number field.

EXAMPLES:

```
sage: k.<i> = NumberField(x^2 + 1)
sage: k.order(2*i)
Order in Number Field in i with defining polynomial x^2 + 1
sage: k.order(10*i)
Order in Number Field in i with defining polynomial x^2 + 1
sage: k.order(3)
...
ValueError: the rank of the span of gens is wrong
sage: k.order(i/2)
...
ValueError: each generator must be integral
```

Alternatively, an order can be constructed by adjoining elements to $\mathbf{Z}$:

places (*all_complex=False, prec=None*)

Return the collection of all places of self. By default, this returns the set of real places as homomorphisms into RIF first, followed by a choice of one of each pair of complex conjugate homomorphisms into CIF.

On the other hand, if prec is not None, we simply return places into RealField(prec) and ComplexField(prec) (or RDF, CDF if prec=53).

There is an optional flag all_complex, which defaults to False. If all_complex is True, then the real embeddings are returned as embeddings into CIF instead of RIF.

EXAMPLES:

```
sage: F.<alpha> = NumberField(x^3-100*x+1) ; F.places()
[Ring morphism:
From: Number Field in alpha with defining polynomial x^3 - 100*x + 1
To:   Real Field with 106 bits of precision
Defn: alpha |--> -10.004996254991811845733672192 80,
Ring morphism:
From: Number Field in alpha with defining polynomial x^3 - 100*x + 1
To:   Real Field with 106 bits of precision
Defn: alpha |--> 0.010000010000030000120000550002 73,
Ring morphism:
From: Number Field in alpha with defining polynomial x^3 - 100*x + 1
To:   Real Field with 106 bits of precision
Defn: alpha |--> 9.994996244991781845613530439509]

sage: F.<alpha> = NumberField(x^3+7) ; F.places()
[Ring morphism:
From: Number Field in alpha with defining polynomial x^3 + 7
To:   Real Field with 106 bits of precision
Defn: alpha |--> -1.91293118277238910119911683 9549,
Ring morphism:
From: Number Field in alpha with defining polynomial x^3 + 7
To:   Complex Field with 53 bits of precision
Defn: alpha |--> 0.956465591386195 + 1.65664699997230*I]

sage: F.<alpha> = NumberField(x^3+7) ; F.places(all_complex=True)
[Ring morphism:
From: Number Field in alpha with defining polynomial x^3 + 7
To:   Complex Field with 53 bits of precision
Defn: alpha |--> -1.91293118277239,
Ring morphism:
From: Number Field in alpha with defining polynomial x^3 + 7
To:   Complex Field with 53 bits of precision
Defn: alpha |--> 0.956465591386195 + 1.65664699997230*I]
sage: F.places(prec=10)
[Ring morphism:
From: Number Field in alpha with defining polynomial x^3 + 7
To:   Real Field with 10 bits of precision
Defn: alpha |--> -1.9,
Ring morphism:
From: Number Field in alpha with defining polynomial x^3 + 7
To:   Complex Field with 10 bits of precision
Defn: alpha |--> 0.96 + 1.7*I]
```

real_places (*prec=None*)

Return all real places of self as homomorphisms into RIF.

EXAMPLES:

```
sage: F.<alpha> = NumberField(x^4-7) ; F.real_places()
[Ring morphism:
From: Number Field in alpha with defining polynomial x^4 - 7
To:   Real Field with 106 bits of precision
Defn: alpha |--> -1.6265765616977857432112323454 94,
Ring morphism:
From: Number Field in alpha with defining polynomial x^4 - 7
To:   Real Field with 106 bits of precision
Defn: alpha |--> 1.6265765616977857432112323454 94]
```

relative_degree()

A synonym for degree.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2 + 1)
sage: K.relative_degree()
2
```

relative_different()

A synonym for different.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2 + 1)
sage: K.relative_different()
Fractional ideal (2)
```

relative_discriminant()

A synonym for discriminant.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2 + 1)
sage: K.relative_discriminant()
-4
```

relative_polynomial()

A synonym for polynomial.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2 + 1)
sage: K.relative_polynomial()
x^2 + 1
```

relative_vector_space()

A synonym for vector_space.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2 + 1)
sage: K.relative_vector_space()
(Vector space of dimension 2 over Rational Field,
 Isomorphism map:
  From: Vector space of dimension 2 over Rational Field
  To:   Number Field in i with defining polynomial x^2 + 1,
 Isomorphism map:
  From: Number Field in i with defining polynomial x^2 + 1
  To:   Vector space of dimension 2 over Rational Field)
```

relativize(*alpha, names*)

Given an element in self or an embedding of a subfield into self, return a relative number field K isomorphic to self that is relative over the absolute field $\mathbf{Q}(\alpha)$ or the domain of $alpha$, along with isomorphisms from K to self and from self to K.

INPUT:

- `alpha` - an element of self or an embedding of a subfield into self
- `names` - 2-tuple of names of generator for output field K and the subfield QQ(alpha) names[0] generators K and names[1] QQ(alpha).

OUTPUT:

K – relative number field

Also, code{K.structure()} returns from_K and to_K, where from_K is an isomorphism from K to self and to_K is an isomorphism from self to K.

EXAMPLES:

```
sage: K.<a> = NumberField(x^10 - 2)
sage: L.<c,d> = K.relativize(a^4 + a^2 + 2); L
Number Field in c with defining polynomial x^2 - 1/5*d^4 + 8/5*d^3 - 23/5*d^2 + 7*d - 18/5 o
sage: c.absolute_minpoly()
x^10 - 2
sage: d.absolute_minpoly()
x^5 - 10*x^4 + 40*x^3 - 90*x^2 + 110*x - 58
sage: (a^4 + a^2 + 2).minpoly()
x^5 - 10*x^4 + 40*x^3 - 90*x^2 + 110*x - 58
sage: from_L, to_L = L.structure()
sage: to_L(a)
c
sage: to_L(a^4 + a^2 + 2)
d
sage: from_L(to_L(a^4 + a^2 + 2))
a^4 + a^2 + 2
```

The following demonstrates distinct embeddings of a subfield into a larger field:

```
sage: K.<a> = NumberField(x^4 + 2*x^2 + 2)
sage: K0 = K.subfields(2)[0][0]; K0
Number Field in a0 with defining polynomial x^2 - 2*x + 2
sage: rho, tau = K0.embeddings(K)
sage: L0 = K.relativize(rho(K0.gen()), 'b'); L0
Number Field in b0 with defining polynomial x^2 - b1 + 2 over its base field
sage: L1 = K.relativize(rho, 'b'); L1
Number Field in b0 with defining polynomial x^2 - a0 + 2 over its base field
sage: L2 = K.relativize(tau, 'b'); L2
Number Field in b0 with defining polynomial x^2 + a0 over its base field
sage: L0.base_field() is K0
False
sage: L1.base_field() is K0
True
sage: L2.base_field() is K0
True
```

Here we see that with the different embeddings, the relative norms are different:

```
sage: a0 = K0.gen()
sage: L1_into_K, K_into_L1 = L1.structure()
sage: L2_into_K, K_into_L2 = L2.structure()
sage: len(K.factor(41))
4
sage: w1 = -a^2 + a + 1; P = K.ideal([w1])
sage: Pp = L1.ideal(K_into_L1(w1)).ideal_below(); Pp == K0.ideal([4*a0 + 1])
True
sage: Pp == w1.norm(rho)
True
```

```
sage: w2 = a^2 + a - 1; Q = K.ideal([w2])
sage: Qq = L2.ideal(K_into_L2(w2)).ideal_below(); Qq == K0.ideal([-4*a0 + 9])
True
sage: Qq == w2.norm(tau)
True

sage: Pp == Qq
False
```

TESTS:

We can relativize over the whole field:

```
sage: K.<a> = NumberField(x^4 + 2*x^2 + 2)
sage: K.relativize(K.gen(), 'a')
Number Field in a0 with defining polynomial x - a1 over its base field
sage: K.relativize(2*K.gen(), 'a')
Number Field in a0 with defining polynomial x - 1/2*a1 over its base field
```

We can relativize over the prime field:

```
sage: L = K.relativize(K(1), 'a'); L
Number Field in a0 with defining polynomial x^4 + 2*x^2 + 2 over its base field
sage: L.base_field()
Number Field in a1 with defining polynomial x - 1
sage: L.base_field().base_field()
Rational Field

sage: L = K.relativize(K(2), 'a'); L
Number Field in a0 with defining polynomial x^4 + 2*x^2 + 2 over its base field
sage: L.base_field()
Number Field in a1 with defining polynomial x - 2
sage: L.base_field().base_field()
Rational Field
```

We can relativize over a relative field:

```
sage: K.<z> = CyclotomicField(16)
sage: L, L_into_K, _ = K.subfields(4)[0]; L
Number Field in z0 with defining polynomial x^4 + 16
sage: F, F_into_L, _ = L.subfields(2)[0]; F
Number Field in z00 with defining polynomial x^2 + 64

sage: L_over_F = L.relativize(F_into_L, 'c'); L_over_F
Number Field in c0 with defining polynomial x^2 - 1/2*z00 over its base field
sage: L_over_F_into_L, _ = L_over_F.structure()

sage: K_over_rel = K.relativize(L_into_K * L_over_F_into_L, 'a'); K_over_rel
Number Field in a0 with defining polynomial x^2 - 1/2*c0 over its base field
sage: K_over_rel.base_field() is L_over_F
True
sage: K_over_rel.structure()
(Relative number field morphism:
  From: Number Field in a0 with defining polynomial x^2 - 1/2*c0 over its base field
  To:   Cyclotomic Field of order 16 and degree 8
  Defn: a0 |--> z
        c0 |--> 2*z^2
        z00 |--> 8*z^4, Ring morphism:
  From: Cyclotomic Field of order 16 and degree 8
  To:   Number Field in a0 with defining polynomial x^2 - 1/2*c0 over its base field
  Defn: z |--> a0)
```

We can relativize over a really large field. This requires great care to not factor or do any operation that would trigger a pari nfinit() internally:

```
sage: K.<a> = CyclotomicField(3^3*2^3)
sage: R = K.relativize(a^(3^2), 't'); R
Number Field in t0 with defining polynomial x^9 - t1 over its base field
sage: R.structure()
(Relative number field morphism:
  From: Number Field in t0 with defining polynomial x^9 - t1 over its base field
  To:   Cyclotomic Field of order 216 and degree 72
  Defn: t0 |--> a
        t1 |--> a^9,
 Ring morphism:
  From: Cyclotomic Field of order 216 and degree 72
  To:   Number Field in t0 with defining polynomial x^9 - t1 over its base field
  Defn: a |--> t0)
```

subfields(*degree=0, name=None*)

EXAMPLES:

```
sage: K.<a> = NumberField( [x^3 - 2, x^2 + x + 1] )
sage: K = K.absolute_field('b')
sage: S = K.subfields()
sage: len(S)
6
sage: [k[0].polynomial() for k in S]
[x - 3,
 x^2 - 3*x + 9,
 x^3 - 3*x^2 + 3*x + 1,
 x^3 - 3*x^2 + 3*x + 1,
 x^3 - 3*x^2 + 3*x - 17,
 x^6 - 3*x^5 + 6*x^4 - 11*x^3 + 12*x^2 + 3*x + 1]
 sage: R.<t> = QQ[]
 sage: L = NumberField(t^3 - 3*t + 1, 'c')
 sage: [k[1] for k in L.subfields()]
 [Ring morphism:
   From: Number Field in c0 with defining polynomial t
   To:   Number Field in c with defining polynomial t^3 - 3*t + 1
   Defn: 0 |--> 0,
  Ring morphism:
   From: Number Field in c1 with defining polynomial t^3 - 3*t + 1
   To:   Number Field in c with defining polynomial t^3 - 3*t + 1
   Defn: c1 |--> c]
```

vector_space()

Return a vector space V and isomorphisms self –> V and V –> self.

OUTPUT:

- V - a vector space over the rational numbers
- from_V - an isomorphism from V to self
- to_V - an isomorphism from self to V

EXAMPLES:

```
sage: k.<a> = NumberField(x^3 + 2)
sage: V, from_V, to_V  = k.vector_space()
sage: from_V(V([1,2,3]))
3*a^2 + 2*a + 1
sage: to_V(1 + 2*a + 3*a^2)
(1, 2, 3)
```

```
sage: V
Vector space of dimension 3 over Rational Field
sage: to_V
Isomorphism map:
  From: Number Field in a with defining polynomial x^3 + 2
  To:   Vector space of dimension 3 over Rational Field
sage: from_V(to_V(2/3*a - 5/8))
2/3*a - 5/8
sage: to_V(from_V(V([0,-1/7,0])))
(0, -1/7, 0)
```

NumberField_absolute_v1(*poly, name, latex_name, canonical_embedding=None*)

This is used in pickling generic number fields.

EXAMPLES:

```
sage: from sage.rings.number_field.number_field import NumberField_generic_v1
sage: R.<x> = QQ[]
sage: NumberField_generic_v1(x^2 + 1, 'i', 'i')
Number Field in i with defining polynomial x^2 + 1
```

class **NumberField_cyclotomic**(*n, names, embedding=None*)

Create a cyclotomic extension of the rational field.

The command CyclotomicField(n) creates the n-th cyclotomic field, obtained by adjoining an n-th root of unity to the rational field.

EXAMPLES:

```
sage: CyclotomicField(3)
Cyclotomic Field of order 3 and degree 2
sage: CyclotomicField(18)
Cyclotomic Field of order 18 and degree 6
sage: z = CyclotomicField(6).gen(); z
zeta6
sage: z^3
-1
sage: (1+z)^3
6*zeta6 - 3
```

```
sage: K = CyclotomicField(197)
sage: loads(K.dumps()) == K
True
sage: loads((z^2).dumps()) == z^2
True
```

```
sage: cf12 = CyclotomicField( 12 )
sage: z12 = cf12.0
sage: cf6 = CyclotomicField( 6 )
sage: z6 = cf6.0
sage: FF = Frac( cf12['x'] )
sage: x = FF.0
sage: z6*x^3/(z6 + x)
zeta12^2*x^3/(x + zeta12^2)
```

```
sage: cf6 = CyclotomicField(6) ; z6 = cf6.gen(0)
sage: cf3 = CyclotomicField(3) ; z3 = cf3.gen(0)
sage: cf3(z6)
```

```
zeta3 + 1
sage: cf6(z3)
zeta6 - 1
sage: type(cf6(z3))
<type 'sage.rings.number_field.number_field_element_quadratic.NumberFieldElement_quadratic'>
sage: cf1 = CyclotomicField(1) ; z1 = cf1.0
sage: cf3(z1)
1
sage: type(cf3(z1))
<type 'sage.rings.number_field.number_field_element_quadratic.NumberFieldElement_quadratic'>
```

complex_embedding(*prec=53*)

Return the embedding of this cyclotomic field into the approximate complex field with precision prec obtained by sending the generator ζ of self to exp(2*pi*i/n), where n is the multiplicative order of ζ.

If prec is 53 (the default), then the complex double field is used; otherwise the arbitrary precision (but slow) complex field is used. EXAMPLES:

```
sage: C = CyclotomicField(4)
sage: C.complex_embedding()
Ring morphism:
  From: Cyclotomic Field of order 4 and degree 2
  To:   Complex Double Field
  Defn: zeta4 |--> 6.12323399574e-17 + 1.0*I
```

Note in the example above that the way zeta is computed (using sin and cosine in MPFR) means that only the prec bits of the number after the decimal point are valid.

```
sage: K = CyclotomicField(3)
sage: phi = K.complex_embedding(10)
sage: phi(K.0)
-0.50 + 0.87*I
sage: phi(K.0^3)
1.0
sage: phi(K.0^3 - 1)
0
sage: phi(K.0^3 + 7)
8.0
```

complex_embeddings(*prec=53*)

Return all embeddings of this cyclotomic field into the approximate complex field with precision prec.

If prec is 53 (the default), then the complex double field is used; otherwise the arbitrary precision (but slow) complex field is used. If you want 53-bit arbitrary precision then do `self.embeddings(ComplexField(53))`.

EXAMPLES:

```
sage: CyclotomicField(5).complex_embeddings()
[
Ring morphism:
  From: Cyclotomic Field of order 5 and degree 4
  To:   Complex Double Field
  Defn: zeta5 |--> 0.309016994375 + 0.951056516295*I,
Ring morphism:
  From: Cyclotomic Field of order 5 and degree 4
  To:   Complex Double Field
  Defn: zeta5 |--> -0.809016994375 + 0.587785252292*I,
Ring morphism:
  From: Cyclotomic Field of order 5 and degree 4
  To:   Complex Double Field
```

```
  Defn: zeta5 |--> -0.809016994375 - 0.587785252292*I,
Ring morphism:
  From: Cyclotomic Field of order 5 and degree 4
  To:   Complex Double Field
  Defn: zeta5 |--> 0.309016994375 - 0.951056516295*I
]
```

different()

Returns the different ideal of the cyclotomic field self.

EXAMPLES:

```
sage: C20 = CyclotomicField(20)
sage: C20.different()
Fractional ideal (-4*zeta20^7 + 8*zeta20^5 - 12*zeta20^3 + 6*zeta20)
sage: C18 = CyclotomicField(18)
sage: D = C18.different().norm()
sage: D == C18.discriminant().abs()
True
```

discriminant(*v=None*)

Returns the discriminant of the ring of integers of the cyclotomic field self, or if v is specified, the determinant of the trace pairing on the elements of the list v.

Uses the formula for the discriminant of a prime power cyclotomic field and Hilbert Theorem 88 on the discriminant of composita.

INPUT:

- `v (optional)` - list of element of this number field

OUTPUT: Integer if v is omitted, and Rational otherwise.

EXAMPLES:

```
sage: CyclotomicField(20).discriminant()
4000000
sage: CyclotomicField(18).discriminant()
-19683
```

integral_basis(*v=None*)

Return a list of elements of this number field that are a basis for the full ring of integers.

This field is cyclomotic, so this is a trivial computation, since the power basis on the generator is an integral basis. Thus the v parameter is ignored.

EXAMPLES:

```
sage: CyclotomicField(5).integral_basis()
[1, zeta5, zeta5^2, zeta5^3]
```

is_galois()

Return True since all cyclotomic fields are automatically Galois.

EXAMPLES:

```
sage: CyclotomicField(29).is_galois()
True
```

is_isomorphic(*other*)

Return True if the cyclotomic field self is isomorphic as a number field to other.

EXAMPLES:

```
sage: CyclotomicField(11).is_isomorphic(CyclotomicField(22))
True
sage: CyclotomicField(11).is_isomorphic(CyclotomicField(23))
```

```
False
sage: CyclotomicField(3).is_isomorphic(NumberField(x^2 + x +1, 'a'))
True
```

next_split_prime(*p=2*)

Return the next prime integer p that splits completely in this cyclotomic field (and does not ramify).

EXAMPLES:

```
sage: K.<z> = CyclotomicField(3)
sage: K.next_split_prime(7)
13
```

number_of_roots_of_unity()

Return number of roots of unity in this cyclotomic field.

EXAMPLES:

```
sage: K.<a> = CyclotomicField(21)
sage: K.number_of_roots_of_unity()
42
```

primitive_root_of_unity()

Return a generator of the roots of unity in this field.

EXAMPLES:

```
sage: K.<a> = CyclotomicField(3)
sage: z = K.primitive_root_of_unity(); z
-a
sage: z.multiplicative_order()
6

sage: K.<a> = CyclotomicField(10)
sage: z = K.primitive_root_of_unity(); z
a
sage: z.multiplicative_order()
10
```

real_embeddings(*prec=53*)

Return all embeddings of this cyclotomic field into the approximate real field with precision prec.

If prec is 53 (the default), then the real double field is used; otherwise the arbitrary precision (but slow) real field is used.

Mostly, of course, there are no such embeddings.

EXAMPLES:

```
sage: CyclotomicField(4).real_embeddings()
[]
sage: CyclotomicField(2).real_embeddings()
[
Ring morphism:
  From: Cyclotomic Field of order 2 and degree 1
  To:   Real Double Field
  Defn: -1 |--> -1.0
]
```

roots_of_unity()

Return all the roots of unity in this cyclotomic field, primitive or not.

EXAMPLES:

```
sage: K.<a> = CyclotomicField(3)
sage: zs = K.roots_of_unity(); zs
[1, a, -a - 1, -1, -a, a + 1]
sage: [ z**K.number_of_roots_of_unity() for z in zs ]
[1, 1, 1, 1, 1, 1]
```

signature()

Return (r1, r2), where r1 and r2 are the number of real embeddings and pairs of complex embeddings of this cyclotomic field, respectively.

Trivial since, apart from QQ, cyclotomic fields are totally complex.

EXAMPLES:

```
sage: CyclotomicField(5).signature()
(0, 2)
sage: CyclotomicField(2).signature()
(1, 0)
```

zeta(*n=None, all=False*)

Returns an element of multiplicative order n in this this cyclotomic field, if there is one. Raises a ValueError if there is not.

INPUT:

- `n` - integer (default: None, returns element of maximal order)
- `all` - bool (default: False) - whether to return a list of all n-th roots.

OUTPUT: root of unity or list

EXAMPLES:

```
sage: k = CyclotomicField(7)
sage: k.zeta()
zeta7
sage: k.zeta().multiplicative_order()
7
sage: k = CyclotomicField(49)
sage: k.zeta().multiplicative_order()
49
sage: k.zeta(7).multiplicative_order()
7
sage: k.zeta()
zeta49
sage: k.zeta(7)
zeta49^7

sage: K.<a> = CyclotomicField(7)
sage: K.zeta(14, all=True)
[-a^4, -a^5, a^5 + a^4 + a^3 + a^2 + a + 1, -a, -a^2, -a^3]
sage: K.<a> = CyclotomicField(10)
sage: K.zeta(20, all=True)
...
ValueError: n (=20) does not divide order of generator

sage: K.<a> = CyclotomicField(5)
sage: K.zeta(4)
...
ValueError: n (=4) does not divide order of generator
sage: v = K.zeta(5, all=True); v
[a, a^2, a^3, -a^3 - a^2 - a - 1]
sage: [b^5 for b in v]
[1, 1, 1, 1]
```

zeta_order()
Return the order of the maximal root of unity contained in this cyclotomic field.
EXAMPLES:

```
sage: CyclotomicField(1).zeta_order()
2
sage: CyclotomicField(4).zeta_order()
4
sage: CyclotomicField(5).zeta_order()
10
sage: CyclotomicField(5)._n()
5
sage: CyclotomicField(389).zeta_order()
778
```

NumberField_cyclotomic_v1(*zeta_order, name, canonical_embedding=None*)
This is used in pickling cyclotomic fields.
EXAMPLES:

```
sage: from sage.rings.number_field.number_field import NumberField_cyclotomic_v1
sage: NumberField_cyclotomic_v1(5,'a')
Cyclotomic Field of order 5 and degree 4
sage: NumberField_cyclotomic_v1(5,'a').variable_name()
'a'
```

class **NumberField_generic**(*polynomial, name, latex_name=None, check=True, embedding=None*)
EXAMPLES:

```
sage: K.<a> = NumberField(x^3 - 2); K
Number Field in a with defining polynomial x^3 - 2
sage: loads(K.dumps()) == K
True
```

absolute_degree()
Return the degree of self over $\mathbf{Q}$.
EXAMPLES:

```
sage: NumberField(x^3 + x^2 + 997*x + 1, 'a').absolute_degree()
3
sage: NumberField(x + 1, 'a').absolute_degree()
1
sage: NumberField(x^997 + 17*x + 3, 'a', check=False).absolute_degree()
997
```

absolute_field(*names*)
Returns self as an absolute extension over QQ.
OUTPUT:

- K - this number field (since it is already absolute)

Also, `K.structure()` returns from_K and to_K, where from_K is an isomorphism from K to self and to_K is an isomorphism from self to K.
EXAMPLES:

```
sage: K = CyclotomicField(5)
sage: K.absolute_field('a')
Number Field in a with defining polynomial x^4 + x^3 + x^2 + x + 1
```

absolute_polynomial_ntl()

category()

Return the category of number fields.

EXAMPLES:

```
sage: NumberField(x^2 + 3, 'a').category()
Category of number fields
sage: category(NumberField(x^2 + 3, 'a'))
Category of number fields
```

The special types of number fields, e.g., quadratic fields, don't have their own category:

```
sage: QuadraticField(2,'d').category()
Category of number fields
```

change_generator(*alpha, name=None, names=None*)

Given the number field self, construct another isomorphic number field K generated by the element alpha of self, along with isomorphisms from K to self and from self to K.

EXAMPLES:

```
sage: L.<i> = NumberField(x^2 + 1); L
Number Field in i with defining polynomial x^2 + 1
sage: K, from_K, to_K = L.change_generator(i/2 + 3)
sage: K
Number Field in i0 with defining polynomial x^2 - 6*x + 37/4
sage: from_K
Ring morphism:
  From: Number Field in i0 with defining polynomial x^2 - 6*x + 37/4
  To:   Number Field in i with defining polynomial x^2 + 1
  Defn: i0 |--> 1/2*i + 3
sage: to_K
Ring morphism:
  From: Number Field in i with defining polynomial x^2 + 1
  To:   Number Field in i0 with defining polynomial x^2 - 6*x + 37/4
  Defn: i |--> 2*i0 - 6
```

We can also do

```
sage: K.<c>, from_K, to_K = L.change_generator(i/2 + 3); K
Number Field in c with defining polynomial x^2 - 6*x + 37/4
```

We compute the image of the generator $\sqrt{-1}$ of L.

```
sage: to_K(i)
2*c - 6
```

Note that the image is indeed a square root of -1.

```
sage: to_K(i)^2
-1
sage: from_K(to_K(i))
i
sage: to_K(from_K(c))
c
```

characteristic()

Return the characteristic of this number field, which is of course 0.

EXAMPLES:

```
sage: k.<a> = NumberField(x^99 + 2); k
Number Field in a with defining polynomial x^99 + 2
sage: k.characteristic()
0
```

class_group(*proof=None, names='c'*)

Return the class group of the ring of integers of this number field.

INPUT:

- `proof` - if True then compute the classgroup provably correctly. Default is True. Call number_field_proof to change this default globally.
- `names` - names of the generators of this class group.

OUTPUT: The class group of this number field.

EXAMPLES:

```
sage: K.<a> = NumberField(x^2 + 23)
sage: G = K.class_group(); G
Class group of order 3 with structure C3 of Number Field in a with defining polynomial x^2 +
sage: G.0
Fractional ideal class (2, 1/2*a - 1/2)
sage: G.gens()
[Fractional ideal class (2, 1/2*a - 1/2)]

sage: G.number_field()
Number Field in a with defining polynomial x^2 + 23
sage: G is K.class_group()
True
sage: G is K.class_group(proof=False)
False
sage: G.gens()
[Fractional ideal class (2, 1/2*a - 1/2)]
```

There can be multiple generators:

```
sage: k.<a> = NumberField(x^2 + 20072)
sage: G = k.class_group(); G
Class group of order 76 with structure C38 x C2 of Number Field in a with defining polynomia
sage: G.gens()
[Fractional ideal class (41, a + 10), Fractional ideal class (2, -1/2*a)]
sage: G.0
Fractional ideal class (41, a + 10)
sage: G.0^20
Fractional ideal class (43, a + 3)
sage: G.0^38
Trivial principal fractional ideal class
sage: G.1
Fractional ideal class (2, -1/2*a)
sage: G.1^2
Trivial principal fractional ideal class
```

Class groups of Hecke polynomials tend to be very small:

```
sage: f = ModularForms(97, 2).T(2).charpoly()
sage: f.factor()
(x - 3) * (x^3 + 4*x^2 + 3*x - 1) * (x^4 - 3*x^3 - x^2 + 6*x - 1)
sage: for g,_ in f.factor(): print NumberField(g,'a').class_group().order()
...
1
1
1
```

class_number(*proof=None*)

Return the class number of this number field, as an integer.

INPUT:

- `proof` - bool (default: True unless you called number_field_proof)

EXAMPLES:

```
sage: NumberField(x^2 + 23, 'a').class_number()
3
sage: NumberField(x^2 + 163, 'a').class_number()
1
sage: NumberField(x^3 + x^2 + 997*x + 1, 'a').class_number(proof=False)
1539
```

completion (*p, prec, extras={}*)

Returns the completion of self at p to the specified precision. Only implemented at archimedean places, and then only if an embedding has been fixed.

EXAMPLES:

```
sage: K.<a> = QuadraticField(2)
sage: K.completion(infinity, 100)
Real Field with 100 bits of precision
sage: K.<zeta> = CyclotomicField(12)
sage: K.completion(infinity, 53, extras={'type': 'RDF'})
Complex Double Field
sage: zeta + 1.5                              # implicit test
2.36602540378444 + 0.500000000000000*I
```

complex_embeddings (*prec=53*)

Return all homomorphisms of this number field into the approximate complex field with precision prec.

If prec is 53 (the default), then the complex double field is used; otherwise the arbitrary precision (but slow) complex field is used. If you want 53-bit arbitrary precision then do `self.embeddings(ComplexField(53))`.

EXAMPLES:

```
sage: k.<a> = NumberField(x^5 + x + 17)
sage: v = k.complex_embeddings()
sage: ls = [phi(k.0^2) for phi in v] ; ls # random order
[2.97572074038...,
 -2.40889943716 + 1.90254105304*I,
 -2.40889943716 - 1.90254105304*I,
 0.921039066973 + 3.07553311885*I,
 0.921039066973 - 3.07553311885*I]
sage: K.<a> = NumberField(x^3 + 2)
sage: ls = K.complex_embeddings() ; ls # random order
[
Ring morphism:
  From: Number Field in a with defining polynomial x^3 + 2
  To:   Complex Double Field
  Defn: a |--> -1.25992104989...,
Ring morphism:
  From: Number Field in a with defining polynomial x^3 + 2
  To:   Complex Double Field
  Defn: a |--> 0.629960524947 - 1.09112363597*I,
Ring morphism:
  From: Number Field in a with defining polynomial x^3 + 2
  To:   Complex Double Field
  Defn: a |--> 0.629960524947 + 1.09112363597*I
]
```

composite_fields (*other, names=None, both_maps=False, preserve_embedding=True*)

List of all possible composite number fields formed from self and other, as well as possibly embeddings into the compositum. See the documentation for both_maps below.

If preserve_embedding is code{True} and if self and other em{both} have embeddings into the same

ambient field, only compositums respecting both embeddings are returned. If one (or both) of self or other does not have an embedding, or they do not have embeddings into the same ambient field, or preserve_embedding is not code{True} all possible composite number fields are returned.

INPUT:

- `other` - a number field
- `names` - generator name for composite fields
- `both_maps` - (default: False) if True, return quadruples (F, self_into_F, other_into_F, k) such that self_into_F maps self into F, other_into_F maps other into F, and k is an integer such that other_into_F(other.gen()) + k*self_into_F(self.gen()) == F.gen()
- `preserve_embedding` - (default: True) return only compositums with compatible ambient embeddings.

OUTPUT:

- `list` - list of the composite fields, possibly with maps.

EXAMPLES:

```
sage: K.<a> = NumberField(x^4 - 2)
sage: K.composite_fields(K)
[Number Field in a0 with defining polynomial x^4 - 162,
 Number Field in a1 with defining polynomial x^4 - 2,
 Number Field in a2 with defining polynomial x^8 + 28*x^4 + 2500]
sage: k.<a> = NumberField(x^3 + 2)
sage: m.<b> = NumberField(x^3 + 2)
sage: k.composite_fields(m, 'c')
[Number Field in c0 with defining polynomial x^3 - 2,
 Number Field in c1 with defining polynomial x^6 - 40*x^3 + 1372]
```

Let's get the maps as well:

```
sage: Q1.<a> = NumberField(x^2 + 2, 'b').extension(x^2 + 3, 'c').absolute_field()
sage: Q2.<b> = NumberField(x^2 + 3, 'a').extension(x^2 + 5, 'c').absolute_field()
sage: Q1.composite_fields(Q2)
[Number Field in ab0 with defining polynomial x^8 + 64*x^6 + 904*x^4 + 3840*x^2 + 3600,
 Number Field in ab1 with defining polynomial x^8 + 160*x^6 + 6472*x^4 + 74880*x^2 + 1296]

sage: F, Q1_into_F, Q2_into_F, k = Q1.composite_fields(Q2, both_maps=True)[0]
sage: F
Number Field in ab0 with defining polynomial x^8 + 64*x^6 + 904*x^4 + 3840*x^2 + 3600
sage: Q1_into_F
Ring morphism:
  From: Number Field in a with defining polynomial x^4 + 10*x^2 + 1
  To:   Number Field in ab0 with defining polynomial x^8 + 64*x^6 + 904*x^4 + 3840*x^2 + 360
  Defn: a |--> 19/14400*ab0^7 + 137/1800*ab0^5 + 2599/3600*ab0^3 + 8/15*ab0
sage: Q2_into_F
Ring morphism:
  From: Number Field in b with defining polynomial x^4 + 16*x^2 + 4
  To:   Number Field in ab0 with defining polynomial x^8 + 64*x^6 + 904*x^4 + 3840*x^2 + 360
  Defn: b |--> 19/7200*ab0^7 + 137/900*ab0^5 + 2599/1800*ab0^3 + 31/15*ab0

sage: Q1_into_F.domain() is Q1
True
sage: Q2_into_F(b) + k*Q1_into_F(a) == F.gen()
True
```

Let's check something about the "other" composite field:

```
sage: F, Q1_into_F, Q2_into_F, k = Q1.composite_fields(Q2, both_maps=True)[1]
sage: Q1_into_F.domain() is Q1
```

```
True
sage: Q2_into_F(b) + k*Q1_into_F(a) == F.gen()
True
```

TESTS:

Let's check that embeddings are being respected:

```
sage: x = ZZ['x'].0
sage: K0.<b> = CyclotomicField(7, 'a').subfields(3)[0][0].change_names()
sage: K1.<a1> = K0.extension(x^2 - 2*b^2, 'a1').absolute_field()
sage: K2.<a2> = K0.extension(x^2 - 3*b^2, 'a2').absolute_field()
sage: K1
Number Field in a1 with defining polynomial x^6 - 10*x^4 + 24*x^2 - 8
sage: K2
Number Field in a2 with defining polynomial x^6 - 15*x^4 + 54*x^2 - 27
sage: K1.is_isomorphic(K2)
False
```

We need embeddings, so we redefine:

```
sage: L1.<a1> = NumberField(K1.polynomial(), 'a1', embedding=CC.0)
sage: CDF(a1)
-0.629384245426
sage: L2.<a2> = NumberField(K2.polynomial(), 'a2', embedding=CC.0)
sage: CDF(a2)
-0.77083512672

sage: F, L1_into_F, L2_into_F, k = L1.composite_fields(L2, both_maps=True)[0]
sage: CDF(F.gen())
-0.141450881294
```

Both subfield generators have correct embeddings:

```
sage: CDF(L1_into_F(L1.gen())), CDF(L1.gen())
(-0.629384245426, -0.629384245426)
sage: CDF(L2_into_F(L2.gen())), CDF(L2.gen())
(-0.77083512672, -0.77083512672)
```

On the other hand, without embeddings, there are more composite fields:

```
sage: M1.<a1> = NumberField(L1.polynomial(), 'a1')
sage: M2.<a2> = NumberField(L2.polynomial(), 'a2')
sage: M1.composite_fields(M2)
[Number Field in a1a20 with defining polynomial x^12 - 50*x^10 + 613*x^8 - 1270*x^6 + 526*x^
 Number Field in a1a21 with defining polynomial x^12 - 50*x^10 + 865*x^8 - 6730*x^6 + 24970*
 Number Field in a1a22 with defining polynomial x^12 - 50*x^10 + 865*x^8 - 6310*x^6 + 18670*
```

Here's another example:

```
sage: Q1.<a> = NumberField(x^4 + 10*x^2 + 1, embedding=CC.0); Q1, CDF(a)
(Number Field in a with defining polynomial x^4 + 10*x^2 + 1, 0.317837245196*I)
sage: Q2.<b> = NumberField(x^4 + 16*x^2 + 4, embedding=CC.0); Q2, CDF(b)
(Number Field in b with defining polynomial x^4 + 16*x^2 + 4, 0.504017169931*I)

sage: len(Q1.composite_fields(Q2))
1
sage: F, Q1_into_F, Q2_into_F, k2 = Q1.composite_fields(Q2, both_maps=True)[0]
sage: F, CDF(F.gen())
(Number Field in ab1 with defining polynomial x^8 + 160*x^6 + 6472*x^4 + 74880*x^2 + 1296,
 -0.131657320461*I)

sage: t = Q2_into_F(Q2.gen()) + k2*Q1_into_F(Q1.gen()); t, CDF(t)
```

```
(ab1, -0.131657320461*I)
sage: abs(t.minpoly()(CDF(t))) < 1e-8
True
```

Let's check that the preserve_embedding flag is respected:

```
sage: len(Q1.composite_fields(Q2))
1
sage: len(Q1.composite_fields(Q2, preserve_embedding=False))
2
```

Let's check that if only one field has an embedding, the resulting fields do not have an embedding:

```
sage: Q2.<b> = NumberField(x^4 + 16*x^2 + 4)
sage: Q2.coerce_embedding() is None
True

sage: Q1.composite_fields(Q2)
[Number Field in ab0 with defining polynomial x^8 + 64*x^6 + 904*x^4 + 3840*x^2 + 3600,
 Number Field in ab1 with defining polynomial x^8 + 160*x^6 + 6472*x^4 + 74880*x^2 + 1296]
sage: Q1.composite_fields(Q2)[0].coerce_embedding() is None
True
```

defining_polynomial()

Return the defining polynomial of this number field.

This is exactly the same as code{self.polynomal()}.

EXAMPLES:

```
sage: k5.<z> = CyclotomicField(5)
sage: k5.defining_polynomial()
x^4 + x^3 + x^2 + x + 1
sage: y = polygen(QQ,'y')
sage: k.<a> = NumberField(y^9 - 3*y + 5); k
Number Field in a with defining polynomial y^9 - 3*y + 5
sage: k.defining_polynomial()
y^9 - 3*y + 5
```

degree()

Return the degree of this number field.

EXAMPLES:

```
sage: NumberField(x^3 + x^2 + 997*x + 1, 'a').degree()
3
sage: NumberField(x + 1, 'a').degree()
1
sage: NumberField(x^997 + 17*x + 3, 'a', check=False).degree()
997
```

different()

Compute the different fractional ideal of this number field.

The codifferent is the fractional ideal of all x in K such that the the trace of xy is an integer for all $y \in O_K$.

The different is the integral ideal which is the inverse of the codifferent.

EXAMPLES:

```
sage: k.<a> = NumberField(x^2 + 23)
sage: d = k.different()
sage: d        # random sign in output
Fractional ideal (-a)
sage: d.norm()
```

```
23
sage: k.disc()
-23
```

The different is cached:

```
sage: d is k.different()
True
```

Another example:

```
sage: k.<b> = NumberField(x^2 - 123)
sage: d = k.different(); d
Fractional ideal (2*b)
sage: d.norm()
492
sage: k.disc()
492
```

disc(*v=None*)

Shortcut for self.discriminant.

EXAMPLES:

```
sage: k.<b> = NumberField(x^2 - 123)
sage: k.disc()
492
```

discriminant(*v=None*)

Returns the discriminant of the ring of integers of the number field, or if v is specified, the determinant of the trace pairing on the elements of the list v.

INPUT:

- `v (optional)` - list of element of this number field

OUTPUT: Integer if v is omitted, and Rational otherwise.

EXAMPLES:

```
sage: K.<t> = NumberField(x^3 + x^2 - 2*x + 8)
sage: K.disc()
-503
sage: K.disc([1, t, t^2])
-2012
sage: K.disc([1/7, (1/5)*t, (1/3)*t^2])
-2012/11025
sage: (5*7*3)^2
11025
```

elements_of_norm(*n, proof=None*)

Return a list of solutions modulo units of positive norm to $Norm(a) = n$, where a can be any integer in this number field.

INPUT:

- `proof` - default: True, unless you called number_field_proof and set it otherwise.

EXAMPLES:

```
sage: K.<a> = NumberField(x^2+1)
sage: K.elements_of_norm(3)
[]
sage: K.elements_of_norm(50)
[7*a - 1, -5*a + 5, a - 7]           # 32-bit
[7*a - 1, -5*a + 5, -7*a - 1]        # 64-bit
```

extension(*poly, name=None, names=None, check=True, embedding=None*)

Return the relative extension of this field by a given polynomial.

EXAMPLES:

```
sage: K.<a> = NumberField(x^3 - 2)
sage: R.<t> = K[]
sage: L.<b> = K.extension(t^2 + a); L
Number Field in b with defining polynomial t^2 + a over its base field
```

We create another extension.

```
sage: k.<a> = NumberField(x^2 + 1); k
Number Field in a with defining polynomial x^2 + 1
sage: y = var('y')
sage: m.<b> = k.extension(y^2 + 2); m
Number Field in b with defining polynomial y^2 + 2 over its base field
```

Note that b is a root of $y^2 + 2$:

```
sage: b.minpoly()
x^2 + 2
sage: b.minpoly('z')
z^2 + 2
```

A relative extension of a relative extension.

```
sage: k.<a> = NumberField([x^2 + 1, x^3 + x + 1])
sage: R.<z> = k[]
sage: L.<b> = NumberField(z^3 + 3 + a); L
Number Field in b with defining polynomial z^3 + a0 + 3 over its base field
```

factor(*n*)

Ideal factorization of the principal ideal of the ring of integers generated by n.

EXAMPLE: Here we show how to factor gaussian integers. First we form a number field defined by x^2+1:

```
sage: K.<I> = NumberField(x^2 + 1); K
Number Field in I with defining polynomial x^2 + 1
```

Here are the factors:

```
sage: fi, fj = K.factor(13); fi,fj
((Fractional ideal (-3*I - 2), 1), (Fractional ideal (3*I - 2), 1))
```

Now we extract the reduced form of the generators:

```
sage: zi = fi[0].gens_reduced()[0]; zi
-3*I - 2
sage: zj = fj[0].gens_reduced()[0]; zj
3*I - 2
```

We recover the integer that was factored in $\mathbf{Z}[i]$

```
sage: zi*zj
13
```

One can also factor elements of the number field:

```
sage: K.<a> = NumberField(x^2 + 1)
sage: K.factor(1/3)
Fractional ideal (3)^-1
sage: K.factor(1+a)
Fractional ideal (a + 1)
sage: K.factor(1+a/5)
(Fractional ideal (-3*a - 2)) * (Fractional ideal (a + 1)) * (Fractional ideal (-a - 2))^-1
```

AUTHORS:

- Alex Clemesha (2006-05-20): examples

fractional_ideal(**gens, **kwds*)

Return the ideal in $\mathcal{O}_K$ generated by gens. This overrides the `sage.rings.ring.Field` method to use the `sage.rings.ring.Ring` one instead, since we're not really concerned with ideals in a field but in its ring of integers.

INPUT:

- `gens` - a list of generators, or a number field ideal.

EXAMPLES:

```
sage: K.<a> = NumberField(x^3-2)
sage: K.fractional_ideal([1/a])
Fractional ideal (1/2*a^2)
```

One can also input in a number field ideal itself.

```
sage: K.fractional_ideal(K.ideal(a))
Fractional ideal (a)
```

The zero ideal is not a fractional ideal!

```
sage: K.fractional_ideal(0)
...
ValueError: gens must have a nonzero element (zero ideal is not a fractional ideal)
```

galois_group(*type=None, algorithm='pari', names=None*)

Return the Galois group of the Galois closure of this number field.

INPUT:

- `type` - `none`, `gap`, or `pari`. If None (the default), return an explicit group of automorphisms of self as a `GaloisGroup_v2` object. Otherwise, return a `GaloisGroup_v1` wrapper object based on a Pari or Gap transitive group object, which is quicker to compute, but rather less useful (in particular, it can't be made to act on self). If type = 'gap', the database_gap package should be installed.
- `algorithm` - 'pari', 'kash', 'magma'. (default: 'pari', except when the degree is >= 12 when 'kash' is tried.)
- `name` - a string giving a name for the generator of the Galois closure of self, when self is not Galois. This is ignored if type is not None.

Note that computing Galois groups as abstract groups is often much faster than computing them as explicit automorphism groups (but of course you get less information out!) For more (important!) documentation, so the documentation for Galois groups of polynomials over $\mathbf{Q}$, e.g., by typing `K.polynomial().galois_group?`, where K is a number field.

To obtain actual field homomorphisms from the number field to its splitting field, use type=None.

EXAMPLES:

With type `None`:

```
sage: k.<b> = NumberField(x^2 - 14) # a Galois extension
sage: G = k.galois_group(); G
Galois group of Number Field in b with defining polynomial x^2 - 14
sage: G.gen(0)
(1,2)
sage: G.gen(0)(b)
-b
sage: G.artin_symbol(k.primes_above(3)[0])
(1,2)

sage: k.<b> = NumberField(x^3 - x + 1) # not Galois
```

```
sage: G = k.galois_group(names='c'); G
Galois group of Galois closure in c of Number Field in b with defining polynomial x^3 - x +
sage: G.gen(0)
(1,2)(3,5)(4,6)
```

With type 'pari':

```
sage: NumberField(x^3-2, 'a').galois_group(type="pari")
Galois group PARI group [6, -1, 2, "S3"] of degree 3 of the Number Field in a with defining

sage: NumberField(x-1, 'a').galois_group(type="gap")    # optional - database_gap
Galois group Transitive group number 1 of degree 1 of the Number Field in a with defining po
sage: NumberField(x^2+2, 'a').galois_group(type="gap")  # optional - database_gap
Galois group Transitive group number 1 of degree 2 of the Number Field in a with defining po
sage: NumberField(x^3-2, 'a').galois_group(type="gap")  # optional - database_gap
Galois group Transitive group number 2 of degree 3 of the Number Field in a with defining po

sage: x = polygen(QQ)
sage: NumberField(x^3 + 2*x + 1, 'a').galois_group(pari_group=False)    # opticnal - databas
Galois group Transitive group number 2 of degree 3 of the Number Field in a with defining po
sage: NumberField(x^3 + 2*x + 1, 'a').galois_group(algorithm='magma')   # opticnal - magma,
Galois group Transitive group number 2 of degree 3 of the Number Field in a with defining po
```

EXPLICIT GALOIS GROUP: We compute the Galois group as an explicit group of automorphisms of the Galois closure of a field.

```
sage: K.<a> = NumberField(x^3 - 2)
sage: L.<b1> = K.galois_closure(); L
Number Field in b1 with defining polynomial x^6 + 40*x^3 + 1372
sage: G = End(L); G
Automorphism group of Number Field in b1 with defining polynomial x^6 + 40*x^3 + 1372
sage: G.list()
[
Ring endomorphism of Number Field in b1 with defining polynomial x^6 + 40*x^3 + 1372
  Defn: b1 |--> b1,
...
Ring endomorphism of Number Field in b1 with defining polynomial x^6 + 40*x^3 + 1372
  Defn: b1 |--> -2/63*b1^4 - 31/63*b1
]
sage: G[1](b1)
1/36*b1^4 + 1/18*b1
```

gen(*n=0*)

Return the generator for this number field.

INPUT:

- n - must be 0 (the default), or an exception is raised.

EXAMPLES:

```
sage: k.<theta> = NumberField(x^14 + 2); k
Number Field in theta with defining polynomial x^14 + 2
sage: k.gen()
theta
sage: k.gen(1)
...
IndexError: Only one generator.
```

gen_embedding()

If an embedding has been specified, return the image of the generator under that embedding. Otherwise return None.

EXAMPLES:

```
sage: QuadraticField(-7, 'a').gen_embedding()
2.645751311064591?*I
sage: NumberField(x^2+7, 'a').gen_embedding() # None
```

ideal(*gens, **kwds*)

K.ideal() returns a fractional ideal of the field, except for the zero ideal which is not a fractional ideal.

EXAMPLES:

```
sage: K.<i>=NumberField(x^2+1)
sage: K.ideal(2)
Fractional ideal (2)
sage: K.ideal(2+i)
Fractional ideal (i + 2)
sage: K.ideal(0)
Ideal (0) of Number Field in i with defining polynomial x^2 + 1
```

ideals_of_bdd_norm(*bound*)

All integral ideals of bounded norm.

INPUT:

- bound - a positive integer

OUTPUT: A dict of all integral ideals I such that Norm(I) <= bound, keyed by norm.

EXAMPLE:

```
sage: K.<a> = NumberField(x^2 + 23)
sage: d = K.ideals_of_bdd_norm(10)
sage: for n in d:
...       print n
...       for I in d[n]:
...           print I
1
Fractional ideal (1)
2
Fractional ideal (2, 1/2*a - 1/2)
Fractional ideal (2, 1/2*a + 1/2)
3
Fractional ideal (3, -1/2*a + 1/2)
Fractional ideal (3, -1/2*a - 1/2)
4
Fractional ideal (4, 1/2*a + 3/2)
Fractional ideal (2)
Fractional ideal (4, 1/2*a + 5/2)
5
6
Fractional ideal (-1/2*a + 1/2)
Fractional ideal (6, 1/2*a + 5/2)
Fractional ideal (6, 1/2*a + 7/2)
Fractional ideal (1/2*a + 1/2)
7
8
Fractional ideal (-1/2*a - 3/2)
Fractional ideal (4, a - 1)
Fractional ideal (4, a + 1)
Fractional ideal (1/2*a - 3/2)
9
Fractional ideal (9, 1/2*a + 11/2)
Fractional ideal (3)
```

```
Fractional ideal (9, 1/2*a + 7/2)
10
```

integral_basis(*v=None*)

Returns a list containing a ZZ-basis for the full ring of integers of this number field.

INPUT:

- v - None, a prime, or a list of primes. See the documentation for self.maximal_order.

EXAMPLES:

```
sage: K.<a> = NumberField(x^5 + 10*x + 1)
sage: K.integral_basis()
[1, a, a^2, a^3, a^4]
```

Next we compute the ring of integers of a cubic field in which 2 is an "essential discriminant divisor", so the ring of integers is not generated by a single element.

```
sage: K.<a> = NumberField(x^3 + x^2 - 2*x + 8)
sage: K.integral_basis()
[1, 1/2*a^2 + 1/2*a, a^2]
```

ALGORITHM: Uses the pari library.

is_absolute()

Returns True if self is an absolute field.

This function will be implemented in the derived classes.

EXAMPLES:

```
sage: K = CyclotomicField(5)
sage: K.is_absolute()
True
```

is_field()

Return True since a number field is a field.

EXAMPLES:

```
sage: NumberField(x^5 + x + 3, 'c').is_field()
True
```

is_galois()

Return True if this number field is a Galois extension of $\mathbf{Q}$.

EXAMPLES:

```
sage: NumberField(x^2 + 1, 'i').is_galois()
True
sage: NumberField(x^3 + 2, 'a').is_galois()
False
```

is_isomorphic(*other*)

Return True if self is isomorphic as a number field to other.

EXAMPLES:

```
sage: k.<a> = NumberField(x^2 + 1)
sage: m.<b> = NumberField(x^2 + 4)
sage: k.is_isomorphic(m)
True
sage: m.<b> = NumberField(x^2 + 5)
sage: k.is_isomorphic (m)
False
```

```
sage: k = NumberField(x^3 + 2, 'a')
sage: k.is_isomorphic(NumberField((x+1/3)^3 + 2, 'b'))
True
sage: k.is_isomorphic(NumberField(x^3 + 4, 'b'))
True
sage: k.is_isomorphic(NumberField(x^3 + 5, 'b'))
False
```

is_relative()

EXAMPLES:

```
sage: K.<a> = NumberField(x^10 - 2)
sage: K.is_absolute()
True
sage: K.is_relative()
False
```

is_totally_imaginary()

Return True if self is totally imaginary, and False otherwise.

Totally imaginary means that no isomorphic embedding of self into the complex numbers has image contained in the real numbers.

EXAMPLES:

```
sage: NumberField(x^2+2, 'alpha').is_totally_imaginary()
True
sage: NumberField(x^2-2, 'alpha').is_totally_imaginary()
False
sage: NumberField(x^4-2, 'alpha').is_totally_imaginary()
False
```

is_totally_real()

Return True if self is totally real, and False otherwise.

Totally real means that every isomorphic embedding of self into the complex numbers has image contained in the real numbers.

EXAMPLES:

```
sage: NumberField(x^2+2, 'alpha').is_totally_real()
False
sage: NumberField(x^2-2, 'alpha').is_totally_real()
True
sage: NumberField(x^4-2, 'alpha').is_totally_real()
False
```

latex_variable_name(*name=None*)

Return the latex representation of the variable name for this number field.

EXAMPLES:

```
sage: NumberField(x^2 + 3, 'a').latex_variable_name()
'a'
sage: NumberField(x^3 + 3, 'theta3').latex_variable_name()
'\theta_{3}'
sage: CyclotomicField(5).latex_variable_name()
'\zeta_{5}'
```

narrow_class_group(*proof=None*)

Return the narrow class group of this field.

INPUT:

- `proof` - default: None (use the global proof setting, which defaults to True).

EXAMPLES:

```
sage: NumberField(x^3+x+9, 'a').narrow_class_group()
Multiplicative Abelian Group isomorphic to C2
```

ngens()

Return the number of generators of this number field (always 1).

OUTPUT: the python integer 1.

EXAMPLES:

```
sage: NumberField(x^2 + 17,'a').ngens()
1
sage: NumberField(x + 3,'a').ngens()
1
sage: k.<a> = NumberField(x + 3)
sage: k.ngens()
1
sage: k.0
-3
```

number_of_roots_of_unity()

Return the number of roots of unity in this field.

Note: We do not create the full unit group since that can be expensive, but we do use it if it is already known.

EXAMPLES:

```
sage: F.<alpha> = NumberField(x**22+3)
sage: F.zeta_order()
6
sage: F.<alpha> = NumberField(x**2-7)
sage: F.zeta_order()
2
```

order()

Return the order of this number field (always +infinity).

OUTPUT: always positive infinity

EXAMPLES:

```
sage: NumberField(x^2 + 19,'a').order()
+Infinity
```

pari_bnf(*certify=False, units=True*)

PARI big number field corresponding to this field.

EXAMPLES:

```
sage: k.<a> = NumberField(x^2 + 1); k
Number Field in a with defining polynomial x^2 + 1
sage: len(k.pari_bnf())
10
sage: k.pari_bnf()[:4]
[[;], matrix(0,7), [;], ...]
sage: len(k.pari_nf())
9
```

pari_bnf_certify()

Run the PARI bnfcertify function to ensure the correctness of answers.

If this function returns True (and doesn't raise a ValueError), then certification succeeded, and results that use the PARI bnf structure with this field are supposed to be correct.

Warning: I wouldn't trust this to mean that everything computed involving this number field is actually correct.

EXAMPLES:

```
sage: k.<a> = NumberField(x^7 + 7); k
Number Field in a with defining polynomial x^7 + 7
sage: k.pari_bnf_certify()
True
```

pari_nf()

PARI number field corresponding to this field.

This is the number field constructed using nfinit. This is the same as the number field got by doing pari(self) or gp(self).

EXAMPLES:

```
sage: k.<a> = NumberField(x^4 - 3*x + 7); k
Number Field in a with defining polynomial x^4 - 3*x + 7
sage: k.pari_nf()[:4]
[x^4 - 3*x + 7, [0, 2], 85621, 1]
sage: pari(k)[:4]
[x^4 - 3*x + 7, [0, 2], 85621, 1]

sage: k.<a> = NumberField(x^4 - 3/2*x + 5/3); k
Number Field in a with defining polynomial x^4 - 3/2*x + 5/3
sage: k.pari_nf()
...
TypeError: Unable to coerce number field defined by non-integral polynomial to PARI.
sage: pari(k)
...
TypeError: Unable to coerce number field defined by non-integral polynomial to PARI.
sage: gp(k)
...
TypeError: Unable to coerce number field defined by non-integral polynomial to PARI.
```

pari_polynomial(*name='x'*)

PARI polynomial corresponding to polynomial that defines this field. By default, this is a polynomial in the variable "x".

EXAMPLES:

```
sage: y = polygen(QQ)
sage: k.<a> = NumberField(y^2 - 3/2*y + 5/3)
sage: k.pari_polynomial()
x^2 - 3/2*x + 5/3
sage: k.pari_polynomial('a')
a^2 - 3/2*a + 5/3
```

polynomial()

Return the defining polynomial of this number field.

This is exactly the same as `self.defining_polynomal()`.

EXAMPLES:

```
sage: NumberField(x^2 + (2/3)*x - 9/17,'a').polynomial()
x^2 + 2/3*x - 9/17
```

polynomial_ntl()

Return defining polynomial of this number field as a pair, an ntl polynomial and a denominator.

This is used mainly to implement some internal arithmetic.

EXAMPLES:

```
sage: NumberField(x^2 + (2/3)*x - 9/17,'a').polynomial_ntl()
([-27 34 51], 51)
```

polynomial_quotient_ring()

Return the polynomial quotient ring isomorphic to this number field.

EXAMPLES:

```
sage: K = NumberField(x^3 + 2*x - 5, 'alpha')
sage: K.polynomial_quotient_ring()
Univariate Quotient Polynomial Ring in alpha over Rational Field with modulus x^3 + 2*x - 5
```

polynomial_ring()

Return the polynomial ring that we view this number field as being a quotient of (by a principal ideal).

EXAMPLES: An example with an absolute field:

```
sage: k.<a> = NumberField(x^2 + 3)
sage: y = polygen(QQ, 'y')
sage: k.<a> = NumberField(y^2 + 3)
sage: k.polynomial_ring()
Univariate Polynomial Ring in y over Rational Field
```

An example with a relative field:

```
sage: y = polygen(QQ, 'y')
sage: M.<a> = NumberField([y^3 + 97, y^2 + 1]); M
Number Field in a0 with defining polynomial y^3 + 97 over its base field
sage: M.polynomial_ring()
Univariate Polynomial Ring in y over Number Field in a1 with defining polynomial y^2 + 1
```

power_basis()

Return a power basis for this number field over its base field.

If this number field is represented as $k[t]/f(t)$, then the basis returned is $1, t, t^2, \ldots, t^{d-1}$ where d is the degree of this number field over its base field.

EXAMPLES:

```
sage: K.<a> = NumberField(x^5 + 10*x + 1)
sage: K.power_basis()
[1, a, a^2, a^3, a^4]

sage: L.<b> = K.extension(x^2 - 2)
sage: L.power_basis()
[1, b]
sage: L.absolute_field('c').power_basis()
[1, c, c^2, c^3, c^4, c^5, c^6, c^7, c^8, c^9]

sage: M = CyclotomicField(15)
sage: M.power_basis()
[1, zeta15, zeta15^2, zeta15^3, zeta15^4, zeta15^5, zeta15^6, zeta15^7]
```

prime_above(*x*, *degree=None*)

Return a prime ideal of self lying over x.

INPUT:

- `x`: usually an element or ideal of self. It should be such that self.ideal(x) is sensible. This excludes x=0.
- `degree` (default: None): None or an integer. If one, find a prime above x of any degree. If an integer, find a prime above x such that the resulting residue field has exactly this degree.

OUTPUT: A prime ideal of self lying over x. If degree is specified and no such ideal exists, raises a ValueError.

Warning: At this time we factor the ideal x, which may not be supported for relative number fields.

EXAMPLES:

```
sage: x = ZZ['x'].gen()
sage: F.<t> = NumberField(x^3 - 2)

sage: P2 = F.prime_above(2)
sage: P2 # random
Fractional ideal (-t)
sage: 2 in P2
True
sage: P2.is_prime()
True
sage: P2.norm()
2

sage: P3 = F.prime_above(3)
sage: P3 # random
Fractional ideal (t + 1)
sage: 3 in P3
True
sage: P3.is_prime()
True
sage: P3.norm()
3
```

The ideal (3) is totally ramified in F, so there is no degree 2 prime above 3:

```
sage: F.prime_above(3, degree=2)
...
ValueError: No prime of degree 2 above Fractional ideal (3)
sage: [ id.residue_class_degree() for id, _ in F.ideal(3).factor() ]
[1]
```

Asking for a specific degree works:

```
sage: P5_1 = F.prime_above(5, degree=1)
sage: P5_1 # random
Fractional ideal (-t^2 - 1)
sage: P5_1.residue_class_degree()
1

sage: P5_2 = F.prime_above(5, degree=2)
sage: P5_2 # random
Fractional ideal (t^2 - 2*t - 1)
sage: P5_2.residue_class_degree()
2
```

Relative number fields are ok:

```
sage: G = F.extension(x^2 - 11, 'b')
sage: G.prime_above(7)
Fractional ideal (7, (3*t^2 + 2*t + 9)*b - t^2 - 31*t - 10)
```

TESTS:

It doesn't make sense to factor the ideal (0):

```
sage: F.prime_above(0)
...
AttributeError: 'NumberFieldIdeal' object has no attribute 'factor'
```

primes_above (*x, degree=None*)

Return prime ideals of self lying over x.

INPUT:

- x: usually an element or ideal of self. It should be such that self.ideal(x) is sensible. This excludes x=0.
- degree (default: None): None or an integer. If None, find all primes above x of any degree. If an integer, find all primes above x such that the resulting residue field has exactly this degree.

OUTPUT: A list of prime ideals of self lying over x. If degree is specified and no such ideal exists, returns the empty list.

EXAMPLES:

```
sage: x = ZZ['x'].gen()
sage: F.<t> = NumberField(x^3 - 2)

sage: P2s = F.primes_above(2)
sage: P2s # random
[Fractional ideal (-t)]
sage: all(2 in P2 for P2 in P2s)
True
sage: all(P2.is_prime() for P2 in P2s)
True
sage: [ P2.norm() for P2 in P2s ]
[2]

sage: P3s = F.primes_above(3)
sage: P3s # random
[Fractional ideal (t + 1)]
sage: all(3 in P3 for P3 in P3s)
True
sage: all(P3.is_prime() for P3 in P3s)
True
sage: [ P3.norm() for P3 in P3s ]
[3]
```

The ideal (3) is totally ramified in F, so there is no degree 2 prime above 3:

```
sage: F.primes_above(3, degree=2)
[]
sage: [ id.residue_class_degree() for id, _ in F.ideal(3).factor() ]
[1]
```

Asking for a specific degree works:

```
sage: P5_1s = F.primes_above(5, degree=1)
sage: P5_1s # random
[Fractional ideal (-t^2 - 1)]
sage: P5_1 = P5_1s[0]; P5_1.residue_class_degree()
1

sage: P5_2s = F.primes_above(5, degree=2)
sage: P5_2s # random
[Fractional ideal (t^2 - 2*t - 1)]
sage: P5_2 = P5_2s[0]; P5_2.residue_class_degree()
2
```

Works in relative extensions too:

```
sage: PQ.<X> = QQ[]
sage: F.<a, b> = NumberField([X^2 - 2, X^2 - 3])
sage: PF.<Y> = F[]
sage: K.<c> = F.extension(Y^2 - (1 + a)*(a + b)*a*b)
sage: I = F.ideal(a + 2*b)
sage: K.primes_above(I)
[Fractional ideal (2, ((-13*b - 45/2)*a - 37/2*b - 63/2)*c + 1),
 Fractional ideal (5, (5/2*b + 7/2)*a + 2*b + 10)]
sage: K.primes_above(I, degree=1)
[Fractional ideal (2, ((-13*b - 45/2)*a - 37/2*b - 63/2)*c + 1)]
sage: K.primes_above(I, degree=4)
[Fractional ideal (5, (5/2*b + 7/2)*a + 2*b + 10)]
```

TESTS:

It doesn't make sense to factor the ideal (0):

```
sage: F.primes_above(0)
...
AttributeError: 'NumberFieldIdeal' object has no attribute 'factor'
```

primes_of_degree_one_iter(*num_integer_primes=10000, max_iterations=100*)

Return an iterator yielding prime ideals of absolute degree one and small norm.

> **Warning:** It is possible that there are no primes of K of absolute degree one of small prime norm, and it possible that this algorithm will not find any primes of small norm.
> See module `sage.rings.number_field.small_primes_of_degree_one` for details.

INPUT:

- `num_integer_primes (default: 10000)` - an integer. We try to find primes of absolute norm no greater than the num_integer_primes-th prime number. For example, if num_integer_primes is 2, the largest norm found will be 3, since the second prime is 3.
- `max_iterations (default: 100)` - an integer. We test max_iterations integers to find small primes before raising StopIteration.

EXAMPLES:

```
sage: K.<z> = CyclotomicField(10)
sage: it = K.primes_of_degree_one_iter()
sage: Ps = [ it.next() for i in range(3) ]
sage: Ps # random
[Fractional ideal (z^3 + z + 1), Fractional ideal (3*z^3 - z^2 + z - 1), Fractional ideal (2
sage: [ P.norm() for P in Ps ] # random
[11, 31, 41]
sage: [ P.residue_class_degree() for P in Ps ]
[1, 1, 1]
```

primes_of_degree_one_list(*n, num_integer_primes=10000, max_iterations=100*)

Return a list of n prime ideals of absolute degree one and small norm.

> **Warning:** It is possible that there are no primes of K of absolute degree one of small prime norm, and it possible that this algorithm will not find any primes of small norm.
> See module `sage.rings.number_field.small_primes_of_degree_one` for details.

INPUT:

- `num_integer_primes (default: 10000)` - an integer. We try to find primes of absolute norm no greater than the num_integer_primes-th prime number. For example, if num_integer_primes is 2, the largest norm found will be 3, since the second prime is 3.

- max_iterations (default: 100) - an integer. We test max_iterations integers to find small primes before raising StopIteration.

EXAMPLES:

```
sage: K.<z> = CyclotomicField(10)
sage: Ps = K.primes_of_degree_one_list(3)
sage: Ps
[Fractional ideal (z^3 + z + 1), Fractional ideal (3*z^3 - z^2 + z - 1), Fractional ideal (2
sage: [ P.norm() for P in Ps ]
[11, 31, 41]
sage: [ P.residue_class_degree() for P in Ps ]
[1, 1, 1]
```

primitive_element()

Return a primitive element for this field, i.e., an element that generates it over $\mathbf{Q}$.

EXAMPLES:

```
sage: K.<a> = NumberField(x^3 + 2)
sage: K.primitive_element()
a
sage: K.<a,b,c> = NumberField([x^2-2,x^2-3,x^2-5])
sage: K.primitive_element()
a - b + c
sage: alpha = K.primitive_element(); alpha
a - b + c
sage: alpha.minpoly()
x^2 + (2*b - 2*c)*x - 2*c*b + 6
sage: alpha.absolute_minpoly()
x^8 - 40*x^6 + 352*x^4 - 960*x^2 + 576
```

primitive_root_of_unity()

Return a generator of the roots of unity in this field.

Note: We do not create the full unit group since that can be expensive, but we do use it if it is already known.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2+1)
sage: z = K.primitive_root_of_unity(); z
i
sage: z.multiplicative_order()
4

sage: K.<a> = NumberField(x^2+x+1)
sage: z = K.primitive_root_of_unity(); z
-a
sage: z.multiplicative_order()
6
```

random_element()

Return a random element of this number field.

EXAMPLES:

```
sage: K.<j> = NumberField(x^8+1)
sage: K.random_element()
1/2*j^7 - j^6 - 12*j^5 + 1/2*j^4 - 1/95*j^3 - 1/2*j^2 - 4

sage: K.<a,b,c> = NumberField([x^2-2,x^2-3,x^2-5])
sage: K.random_element()
((-c + 1)*b - c + 2/3)*a - 5/2*b + 2/3*c - 1/4
```

real_embeddings(*prec=53*)

Return all homomorphisms of this number field into the approximate real field with precision prec.

If prec is 53 (the default), then the real double field is used; otherwise the arbitrary precision (but slow) real field is used.

EXAMPLES:

```
sage: K.<a> = NumberField(x^3 + 2)
sage: K.real_embeddings()
[
Ring morphism:
  From: Number Field in a with defining polynomial x^3 + 2
  To:   Real Double Field
  Defn: a |--> -1.25992104989
]
 sage: K.real_embeddings(16)
 [
 Ring morphism:
   From: Number Field in a with defining polynomial x^3 + 2
   To:   Real Field with 16 bits of precision
   Defn: a |--> -1.260
 ]
sage: K.real_embeddings(100)
[
Ring morphism:
  From: Number Field in a with defining polynomial x^3 + 2
  To:   Real Field with 100 bits of precision
  Defn: a |--> -1.2599210498948731647672106073
]
```

reduced_basis(*prec=None*)

This function returns an LLL-reduced basis for the Minkowski-embedding of the maximal order of a number field.

INPUT:

- `self` - number field, the base field
- `prec (default: None)` - the precision with which to compute the Minkowski embedding. (See NOTE below.)

OUTPUT:

An LLL-reduced basis for the Minkowski-embedding of the maximal order of a number field, given by a sequence of (integral) elements from the field.

Note: In the non-totally-real case, the LLL routine we call is currently Pari's qflll(), which works with floating point approximations, and so the result is only as good as the precision promised by Pari. The matrix returned will always be integral; however, it may only be only "almost" LLL-reduced when the precision is not sufficiently high.

If the following run-time error occurs: "PariError: not a definite matrix in lllgram (42)" try increasing the prec parameter,

EXAMPLES:

```
sage: F.<t> = NumberField(x^6-7*x^4-x^3+11*x^2+x-1)
sage: F.maximal_order().basis()
[1/2*t^5 + 1/2*t^4 + 1/2*t^2 + 1/2, t, t^2, t^3, t^4, t^5]
sage: F.reduced_basis()
[-1, -1/2*t^5 + 1/2*t^4 + 3*t^3 - 3/2*t^2 - 4*t - 1/2, t, 1/2*t^5 + 1/2*t^4 - 4*t^3 - 5/2*t^

sage: F.<alpha> = NumberField(x^4+x^2+712312*x+131001238)
sage: F.integral_basis()
[1, alpha, 1/2*alpha^3 + 1/2*alpha^2, alpha^3]
```

```
sage: F.reduced_basis(prec=64)
[1, alpha, alpha^3 - 2*alpha^2 + 15*alpha, 16*alpha^3 - 31*alpha^2 + 469*alpha + 267109]
...                                                    # 64-bit
PariError: not a definite matrix in lllgram (42)   # 64-bit
sage: F.reduced_basis(prec=96)
[1, alpha, alpha^3 - 2*alpha^2 + 15*alpha, 16*alpha^3 - 31*alpha^2 + 469*alpha + 267109]
```

reduced_gram_matrix(*prec=None*)

This function returns the Gram matrix of an LLL-reduced basis for the Minkowski embedding of the maximal order of a number field.

INPUT:

- `self` - number field, the base field
- `prec (default: None)` - the precision with which to calculate the Minkowski embedding. (See NOTE below.)

OUTPUT: The Gram matrix $[< x_i, x_j >]$ of an LLL reduced basis for the maximal order of self, where the integral basis for self is given by $\{x_0, \ldots, x_{n-1}\}$. Here < , > is the usual inner product on $\mathbf{R}^n$, and self is embedded in $\mathbf{R}^n$ by the Minkowski embedding. See the docstring for `Minkowski_embedding()` for more information.

Note: In the non-totally-real case, the LLL routine we call is currently Pari's qflll(), which works with floating point approximations, and so the result is only as good as the precision promised by Pari. In particular, in this case, the returned matrix will *not* be integral, and may not have enough precision to recover the correct gram matrix (which is known to be integral for theoretical reasons). Thus the need for the prec flag above.

If the following run-time error occurs: "PariError: not a definite matrix in lllgram (42)" try increasing the prec parameter,

EXAMPLES:

```
sage: F.<t> = NumberField(x^6-7*x^4-x^3+11*x^2+x-1)
sage: F.reduced_gram_matrix()
[ 6  3  0  2  0  1]
[ 3  9  0  1  0 -2]
[ 0  0 14  6 -2  3]
[ 2  1  6 16 -3  3]
[ 0  0 -2 -3 16  6]
[ 1 -2  3  3  6 19]
sage: Matrix(6, [(x*y).trace() for x in F.integral_basis() for y in F.integral_basis()])
[2550  133  259  664 1368 3421]
[ 133   14    3   54   30  233]
[ 259    3   54   30  233  217]
[ 664   54   30  233  217 1078]
[1368   30  233  217 1078 1371]
[3421  233  217 1078 1371 5224]

sage: var('x')
x
sage: F.<alpha> = NumberField(x^4+x^2+712312*x+131001238)
sage: F.reduced_gram_matrix(prec=128)
[   4.0000000000000000000000000000000000000   0.0000000000000000000000000000000000000 -2.13
[  0.0000000000000000000000000000000000000    46721.539331563218381658483353092335550 -2.24
[-2.1369320000000000000000000000000000000e6 -2.2467769057394530109094755223395819322e7 7.070
[-3.3122478000000000000000000000000000000e7 -3.4807276041138450473611629088647496430e8 1.125
```

regulator(*proof=None*)

Return the regulator of this number field.

Note that PARI computes the regulator to higher precision than the Sage default.

INPUT:

- `proof` - default: True, unless you set it otherwise.

EXAMPLES:

```
sage: NumberField(x^2-2, 'a').regulator()
0.881373587019543
sage: NumberField(x^4+x^3+x^2+x+1, 'a').regulator()
0.962423650119207
```

residue_field(*prime, names=None, check=True*)

Return the residue field of this number field at a given prime, ie O_K/pO_K.

INPUT:

- `prime` - a prime ideal of the maximal order in this number field, or an element of the field which generates a principal prime ideal.
- `names` - the name of the variable in the residue field
- `check` - whether or not to check the primality of prime.

OUTPUT: The residue field at this prime.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: K.<a> = NumberField(x^4+3*x^2-17)
sage: P = K.ideal(61).factor()[0][0]
sage: K.residue_field(P)
Residue field in abar of Fractional ideal (-2*a^2 + 1)

sage: K.<i> = NumberField(x^2 + 1)
sage: K.residue_field(1+i)
Residue field of Fractional ideal (i + 1)
```

TESTS:

```
sage: L.<b> = NumberField(x^2 + 5)
sage: L.residue_field(P)
...
ValueError: Fractional ideal (-2*a^2 + 1) is not an ideal of Number Field in b with defining
sage: L.residue_field(2)
...
ValueError: Fractional ideal (2) is not a prime ideal

sage: L.residue_field(L.prime_above(5)^2)
...
ValueError: Fractional ideal (5) is not a prime ideal
```

roots_of_unity()

Return all the roots of unity in this field, primitive or not.

EXAMPLES:

```
sage: K.<b> = NumberField(x^2+1)
sage: zs = K.roots_of_unity(); zs
[b, -1, -b, 1]
sage: [ z**K.number_of_roots_of_unity() for z in zs ]
[1, 1, 1, 1]
```

signature()

Return (r1, r2), where r1 and r2 are the number of real embeddings and pairs of complex embeddings of this field, respectively.

EXAMPLES:

```
sage: NumberField(x^2+1, 'a').signature()
(0, 1)
sage: NumberField(x^3-2, 'a').signature()
(1, 1)
```

specified_complex_embedding()

Returns the embedding of this field into the complex numbers has been specified.

Fields created with the QuadraticField or CyclotomicField constructors come with an implicit embedding. To get one of these fields without the embedding, use the generic NumberField constructor.

EXAMPLES:

```
sage: QuadraticField(-1, 'I').specified_complex_embedding()
Generic morphism:
  From: Number Field in I with defining polynomial x^2 + 1
  To:   Complex Lazy Field
  Defn: I -> 1*I

sage: QuadraticField(3, 'a').specified_complex_embedding()
Generic morphism:
  From: Number Field in a with defining polynomial x^2 - 3
  To:   Real Lazy Field
  Defn: a -> 1.732050807568878?

sage: CyclotomicField(13).specified_complex_embedding()
Generic morphism:
  From: Cyclotomic Field of order 13 and degree 12
  To:   Complex Lazy Field
  Defn: zeta13 -> 0.885456025653210? + 0.464723172043769?*I
```

Most fields don't implicitly have embeddings unless explicitly specified:

```
sage: NumberField(x^2-2, 'a').specified_complex_embedding() is None
True
sage: NumberField(x^3-x+5, 'a').specified_complex_embedding() is None
True
sage: NumberField(x^3-x+5, 'a', embedding=2).specified_complex_embedding()
Generic morphism:
  From: Number Field in a with defining polynomial x^3 - x + 5
  To:   Real Lazy Field
  Defn: a -> -1.904160859134921?
sage: NumberField(x^3-x+5, 'a', embedding=CDF.0).specified_complex_embedding()
Generic morphism:
  From: Number Field in a with defining polynomial x^3 - x + 5
  To:   Complex Lazy Field
  Defn: a -> 0.952080429567461? + 1.311248044077123?*I
```

This function only returns complex embeddings:

```
sage: K.<a> = NumberField(x^2-2, embedding=Qp(7)(2).sqrt())
sage: K.specified_complex_embedding() is None
True
sage: K.gen_embedding()
3 + 7 + 2*7^2 + 6*7^3 + 7^4 + 2*7^5 + 7^6 + 2*7^7 + 4*7^8 + 6*7^9 + 6*7^10 + 2*7^11 + 7^12 +
sage: K.coerce_embedding()
Generic morphism:
  From: Number Field in a with defining polynomial x^2 - 2
  To:   7-adic Field with capped relative precision 20
  Defn: a -> 3 + 7 + 2*7^2 + 6*7^3 + 7^4 + 2*7^5 + 7^6 + 2*7^7 + 4*7^8 + 6*7^9 + 6*7^10 + 2*
```

structure()

Return fixed isomorphism or embedding structure on self.

This is used to record various isomorphisms or embeddings that arise naturally in other constructions.

EXAMPLES:

```
sage: K.<z> = NumberField(x^2 + 3)
sage: L.<a> = K.absolute_field(); L
Number Field in a with defining polynomial x^2 + 3
sage: L.structure()
(Isomorphism given by variable name change map:
  From: Number Field in a with defining polynomial x^2 + 3
  To:   Number Field in z with defining polynomial x^2 + 3,
 Isomorphism given by variable name change map:
  From: Number Field in z with defining polynomial x^2 + 3
  To:   Number Field in a with defining polynomial x^2 + 3)
```

subfield(*alpha, name=None, names=None*)

Return an absolute number field K isomorphic to QQ(alpha) and a map from K to self that sends the generator of K to alpha.

INPUT:

- `alpha` - an element of self, or something that coerces to an element of self.

OUTPUT:

- `K` - a number field
- `from_K` - a homomorphism from K to self that sends the generator of K to alpha.

EXAMPLES:

```
sage: K.<a> = NumberField(x^4 - 3); K
Number Field in a with defining polynomial x^4 - 3
sage: H.<b>, from_H = K.subfield(a^2)
sage: H
Number Field in b with defining polynomial x^2 - 3
sage: from_H(b)
a^2
sage: from_H
Ring morphism:
  From: Number Field in b with defining polynomial x^2 - 3
  To:   Number Field in a with defining polynomial x^4 - 3
  Defn: b |--> a^2
```

```
sage: K.<z> = CyclotomicField(5)
sage: K.subfield(z-z^2-z^3+z^4)
(Number Field in z0 with defining polynomial x^2 - 5,
Ring morphism:
From: Number Field in z0 with defining polynomial x^2 - 5
To:   Cyclotomic Field of order 5 and degree 4
Defn: z0 |--> -2*z^3 - 2*z^2 - 1)
```

You can also view a number field as having a different generator by just choosing the input to generate the whole field; for that it is better to use `self.change_generator`, which gives isomorphisms in both directions.

trace_pairing(*v*)

Return the matrix of the trace pairing on the elements of the list v.

EXAMPLES:

```
sage: K.<zeta3> = NumberField(x^2 + 3)
sage: K.trace_pairing([1,zeta3])
[ 2  0]
[ 0 -6]
```

uniformizer(*P, others='positive'*)

Returns an element of self with valuation 1 at the prime ideal P.

INPUT:

- `self` - a number field
- `P` - a prime ideal of self
- `others` - either "positive" (default), in which case the element will have non-negative valuation at all other primes of self, or "negative", in which case the element will have non-positive valuation at all other primes of self.

Note: When P is principal (e.g. always when self has class number one) the result may or may not be a generator of P!

EXAMPLES:

```
sage: K.<a> = NumberField(x^2 + 5); K
Number Field in a with defining polynomial x^2 + 5
sage: P,Q = K.ideal(3).prime_factors()
sage: P
Fractional ideal (3, a + 1)
sage: pi=K.uniformizer(P); pi
a + 1
sage: K.ideal(pi).factor()
(Fractional ideal (2, a + 1)) * (Fractional ideal (3, a + 1))
sage: pi=K.uniformizer(P,'negative'); pi
1/2*a + 1/2
sage: K.ideal(pi).factor()
(Fractional ideal (2, a + 1))^-1 * (Fractional ideal (3, a + 1))

sage: K = CyclotomicField(9)
sage: Plist=K.ideal(17).prime_factors()
sage: pilist = [K.uniformizer(P) for P in Plist]
sage: [pi.is_integral() for pi in pilist]
[True, True, True]
sage: [pi.valuation(P) for pi,P in zip(pilist,Plist)]
[1, 1, 1]
sage: [ pilist[i] in Plist[i] for i in range(len(Plist)) ]
[True, True, True]
```

unit_group(*proof=None*)

Return the unit group (including torsion) of this number field.

ALGORITHM: Uses PARI's bnfunit command.

INPUTS: proof – default: True

NOTE: the group is cached.

EXAMPLES:

```
sage: x = QQ['x'].0
sage: A = x^4 - 10*x^3 + 20*5*x^2 - 15*5^2*x + 11*5^3
sage: K = NumberField(A, 'a')
sage: U = K.unit_group(); U
Unit group with structure C10 x Z of Number Field in a with defining polynomial x^4 - 10*x^3
sage: U.gens()
[-1/275*a^3 + 7/55*a^2 - 6/11*a + 4, 8/275*a^3 - 12/55*a^2 + 15/11*a - 2]
sage: U.invariants()
[10, 0]
sage: [u.multiplicative_order() for u in U.gens()]
[10, +Infinity]
```

Sage might not be able to provably compute the unit group:

```
sage: K = NumberField(x^17 + 3, 'a')
sage: K.unit_group(proof=True) # default
...
PariError: not enough precomputed primes, need primelimit ~  (35)
```

In this case, one can ask for the conjectural unit group (correct if the Generalized Riemann Hypothesis is true):

```
sage: U = K.unit_group(proof=False); U; U.gens()
Unit group with structure C2 x Z x Z x Z x Z x Z x Z x Z x Z of Number Field in a with defin
[-1,
a^9 + a - 1,
a^16 - a^15 + a^14 - a^12 + a^11 - a^10 - a^8 + a^7 - 2*a^6 + a^4 - 3*a^3 + 2*a^2 - 2*a + 1,
2*a^16 - a^14 - a^13 + 3*a^12 - 2*a^10 + a^9 + 3*a^8 - 3*a^6 + 3*a^5 + 3*a^4 - 2*a^3 - 2*a^2
2*a^16 - 3*a^15 + 3*a^14 - 3*a^13 + 3*a^12 - a^11 + a^9 - 3*a^8 + 4*a^7 - 5*a^6 + 6*a^5 - 4*
a^15 - a^12 + a^10 - a^9 - 2*a^8 + 3*a^7 + a^6 - 3*a^5 + a^4 + 4*a^3 - 3*a^2 - 2*a + 2,
a^16 - a^15 - 3*a^14 - 4*a^13 - 4*a^12 - 3*a^11 - a^10 + 2*a^9 + 4*a^8 + 5*a^7 + 4*a^6 + 2*a
a^15 + a^14 + 2*a^11 + a^10 - a^9 + a^8 + 2*a^7 - a^5 + 2*a^3 - a^2 - 3*a + 1,
3*a^16 + 3*a^15 + 3*a^14 + 3*a^13 + 3*a^12 + 2*a^11 + 2*a^10 + 2*a^9 + a^8 - a^7 - 2*a^6 - 3
```

The provable and the conjectural results are cached separately (this fixes trac #2504):

```
sage: K.units(proof=True)
...
PariError: not enough precomputed primes, need primelimit ~  (35)
```

units (*proof=None*)

Return generators for the unit group modulo torsion.

ALGORITHM: Uses PARI's bnfunit command.

INPUTS: proof - default: True

NOTE: For more functionality see the unit_group() function.

EXAMPLES:

```
sage: x = QQ['x'].0
sage: A = x^4 - 10*x^3 + 20*5*x^2 - 15*5^2*x + 11*5^3
sage: K = NumberField(A, 'a')
sage: K.units()
[8/275*a^3 - 12/55*a^2 + 15/11*a - 2]
```

Sage might not be able to provably compute the unit group:

```
sage: K = NumberField(x^17 + 3, 'a')
sage: K.units(proof=True) # default
...
PariError: not enough precomputed primes, need primelimit ~  (35)
```

In this case, one can ask for the conjectural unit group (correct if the Generalized Riemann Hypothesis is true):

```
sage: K.units(proof=False)
[a^9 + a - 1,
a^16 - a^15 + a^14 - a^12 + a^11 - a^10 - a^8 + a^7 - 2*a^6 + a^4 - 3*a^3 + 2*a^2 - 2*a + 1,
2*a^16 - a^14 - a^13 + 3*a^12 - 2*a^10 + a^9 + 3*a^8 - 3*a^6 + 3*a^5 + 3*a^4 - 2*a^3 - 2*a^2
2*a^16 - 3*a^15 + 3*a^14 - 3*a^13 + 3*a^12 - a^11 + a^9 - 3*a^8 + 4*a^7 - 5*a^6 + 6*a^5 - 4*
a^15 - a^12 + a^10 - a^9 - 2*a^8 + 3*a^7 + a^6 - 3*a^5 + a^4 + 4*a^3 - 3*a^2 - 2*a + 2,
a^16 - a^15 - 3*a^14 - 4*a^13 - 4*a^12 - 3*a^11 - a^10 + 2*a^9 + 4*a^8 + 5*a^7 + 4*a^6 + 2*a
a^15 + a^14 + 2*a^11 + a^10 - a^9 + a^8 + 2*a^7 - a^5 + 2*a^3 - a^2 - 3*a + 1,
3*a^16 + 3*a^15 + 3*a^14 + 3*a^13 + 3*a^12 + 2*a^11 + 2*a^10 + 2*a^9 + a^8 - a^7 - 2*a^6 - 3
```

The provable and the conjectural results are cached separately (this fixes trac #2504):

```
sage: K.units(proof=True)
...
PariError: not enough precomputed primes, need primelimit ~  (35)
```

zeta(*n=2, all=False*)

Return one, or a list of all, primitive n-th root of unity in this field.

INPUT:

- n - positive integer
- all - bool. If False (default), return a primitive n-th root of unity in this field, or raise an ArithmeticError exception if there are none. If True, return a list of all primitive n-th roots of unity in this field (possibly empty).

Note: To obtain the maximal order of a root of unity in this field, use self.number_of_roots_of_unity().

Note: We do not create the full unit group since that can be expensive, but we do use it if it is already known.

EXAMPLES:

```
sage: K.<z> = NumberField(x^2 + 3)
sage: K.zeta(1)
1
sage: K.zeta(2)
-1
sage: K.zeta(2, all=True)
[-1]
sage: K.zeta(3)
1/2*z - 1/2
sage: K.zeta(3, all=True)
[1/2*z - 1/2, -1/2*z - 1/2]
sage: K.zeta(4)
...
ValueError: n (=4) does not divide order of generator

sage: r.<x> = QQ[]
sage: K.<b> = NumberField(x^2+1)
sage: K.zeta(4)
b
sage: K.zeta(4,all=True)
[b, -b]
sage: K.zeta(3)
...
ValueError: n (=3) does not divide order of generator
sage: K.zeta(3,all=True)
[]
```

zeta_coefficients(*n*)

Compute the first n coefficients of the Dedekind zeta function of this field as a Dirichlet series.

EXAMPLE:

```
sage: x = QQ['x'].0
sage: NumberField(x^2+1, 'a').zeta_coefficients(10)
[1, 1, 0, 1, 2, 0, 0, 1, 1, 2]
```

zeta_function(*prec=53, max_imaginary_part=0, max_asymp_coeffs=40*)

Return the Zeta function of this number field.

This actually returns an interface to Tim Dokchitser's program for computing with the Dedekind zeta function zeta_F(s) of the number field F.

INPUT:

- `prec` - integer (bits precision)
- `max_imaginary_part` - real number
- `max_asymp_coeffs` - integer

OUTPUT: The zeta function of this number field.

EXAMPLES:

```
sage: K.<a> = NumberField(ZZ['x'].0^2+ZZ['x'].0-1)
sage: Z = K.zeta_function()
sage: Z
Zeta function associated to Number Field in a with defining polynomial x^2 + x - 1
sage: Z(-1)
0.0333333333333333
```

zeta_order()

Return the number of roots of unity in this field.

Note: We do not create the full unit group since that can be expensive, but we do use it if it is already known.

EXAMPLES:

```
sage: F.<alpha> = NumberField(x**22+3)
sage: F.zeta_order()
6
sage: F.<alpha> = NumberField(x**2-7)
sage: F.zeta_order()
2
```

NumberField_generic_v1(*poly, name, latex_name, canonical_embedding=None*)

This is used in pickling generic number fields.

EXAMPLES:

```
sage: from sage.rings.number_field.number_field import NumberField_generic_v1
sage: R.<x> = QQ[]
sage: NumberField_generic_v1(x^2 + 1, 'i', 'i')
Number Field in i with defining polynomial x^2 + 1
```

class **NumberField_quadratic**(*polynomial, name=None, check=True, embedding=None*)

Create a quadratic extension of the rational field.

The command QuadraticField(a) creates the field Q(sqrt(a)).

EXAMPLES:

```
sage: QuadraticField(3, 'a')
Number Field in a with defining polynomial x^2 - 3
sage: QuadraticField(-4, 'b')
Number Field in b with defining polynomial x^2 + 4
```

class_number(*proof=None*)

Return the size of the class group of self.

If proof = False (*not* the default!) and the discriminant of the field is negative, then the following warning from the PARI manual applies:

> IMPORTANT WARNING: For $D < 0$, this function may give incorrect results when the class group has a low exponent (has many cyclic factors), because implementing Shank's method in full generality slows it down immensely.

EXAMPLES:

```
sage: QuadraticField(-23,'a').class_number()
3
```

These are all the primes so that the class number of $\mathbf{Q}(\sqrt{-p})$ is 1:

```
sage: [d for d in prime_range(2,300) if not is_square(d) and QuadraticField(-d,'a').class_nu
[2, 3, 7, 11, 19, 43, 67, 163]
```

It is an open problem to *prove* that there are infinity many positive square-free d such that $\mathbf{Q}(\sqrt{d})$ has class number 1:n

```
sage: len([d for d in range(2,200) if not is_square(d) and QuadraticField(d,'a').class_numbe
121
```

TESTS:

```
sage: type(QuadraticField(-23,'a').class_number())
<type 'sage.rings.integer.Integer'>
sage: type(NumberField(x^3 + 23, 'a').class_number())
<type 'sage.rings.integer.Integer'>
sage: type(NumberField(x^3 + 23, 'a').extension(x^2 + 5, 'b').class_number())
<type 'sage.rings.integer.Integer'>
sage: type(CyclotomicField(10).class_number())
<type 'sage.rings.integer.Integer'>
```

discriminant(*v=None*)

Returns the discriminant of the ring of integers of the number field, or if v is specified, the determinant of the trace pairing on the elements of the list v.

INPUT:

- `v (optional)` - list of element of this number field

OUTPUT: Integer if v is omitted, and Rational otherwise.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2+1)
sage: K.discriminant()
-4
sage: K.<a> = NumberField(x^2+5)
sage: K.discriminant()
-20
sage: K.<a> = NumberField(x^2-5)
sage: K.discriminant()
5
```

hilbert_class_field(*names*)

Returns the Hilbert class field of this quadratic field as a relative extension of this field.

Note: For the polynomial that defines this field as a relative extension, see the `hilbert_class_field_defining_polynomial` command, which is vastly faster than this command, since it doesn't construct a relative extension.

EXAMPLES:

```
sage: K.<a> = NumberField(x^2 + 23)
sage: L = K.hilbert_class_field('b'); L
Number Field in b with defining polynomial x^3 + x^2 - 1 over its base field
sage: L.absolute_field('c')
Number Field in c with defining polynomial x^6 + 2*x^5 + 70*x^4 + 90*x^3 + 1631*x^2 + 1196*x
sage: K.hilbert_class_field_defining_polynomial()
x^3 + x^2 - 1
```

hilbert_class_field_defining_polynomial(*name='x'*)

Returns a polynomial over $\mathbf{Q}$ whose roots generate Hilbert class field of this quadratic field as an extension of this quadratic field.

Note: Computed using PARI via Schertz's method. This implementation is quite fast.

EXAMPLES:

```
sage: K.<b> = QuadraticField(-23)
sage: K.hilbert_class_field_defining_polynomial()
x^3 + x^2 - 1
```

Note that this polynomial is not the actual Hilbert class polynomial.

```
sage: magma(K.discriminant()).HilbertClassPolynomial()       # optional - magma
$.1^3 + 3491750*$.1^2 - 5151296875*$.1 + 12771880859375

sage: K.<a> = QuadraticField(-431)
sage: K.class_number()
21
sage: K.hilbert_class_field_defining_polynomial(name='z')
z^21 + z^20 - 13*z^19 - 50*z^18 + 592*z^17 - 2403*z^16 + 5969*z^15 - 10327*z^14 + 13253*z^13
```

hilbert_class_polynomial(*name='x'*)

Compute the Hilbert class polynomial of this quadratic field.

Right now, this is only implemented for imaginary quadratic fields.

EXAMPLES:

```
sage: K.<a> = QuadraticField(-3)
sage: K.hilbert_class_polynomial()
x

sage: K.<a> = QuadraticField(-31)
sage: K.hilbert_class_polynomial(name='z')
z^3 + 39491307*z^2 - 58682638134*z + 1566028350940383
```

is_galois()

Return True since all quadratic fields are automatically Galois.

EXAMPLES:

```
sage: QuadraticField(1234,'d').is_galois()
True
```

NumberField_quadratic_v1(*poly, name, canonical_embedding=None*)

This is used in pickling quadratic fields.

EXAMPLES:

```
sage: from sage.rings.number_field.number_field import NumberField_quadratic_v1
sage: R.<x> = QQ[]
sage: NumberField_quadratic_v1(x^2 - 2, 'd')
Number Field in d with defining polynomial x^2 - 2
```

QuadraticField(*D, names, check=True, embedding=True*)

Return a quadratic field obtained by adjoining a square root of D to the rational numbers, where D is not a perfect square.

INPUT:

- `D` - a rational number
- `names` - variable name
- `check` - bool (default: True)

- `embedding` - bool or square root of D in an ambient field (default: True)

OUTPUT: A number field defined by a quadratic polynomial. Unless otherwise specified, it has an embedding into $\mathbf{R}$ or $\mathbf{C}$ by sending the generator to the positive root.

EXAMPLES:

```
sage: QuadraticField(3, 'a')
Number Field in a with defining polynomial x^2 - 3
sage: K.<theta> = QuadraticField(3); K
Number Field in theta with defining polynomial x^2 - 3
sage: RR(theta)
1.73205080756888
sage: QuadraticField(9, 'a')
...
ValueError: D must not be a perfect square.
sage: QuadraticField(9, 'a', check=False)
Number Field in a with defining polynomial x^2 - 9
```

Quadratic number fields derive from general number fields.

```
sage: from sage.rings.number_field.number_field import is_NumberField
sage: type(K)
<class 'sage.rings.number_field.number_field.NumberField_quadratic'>
sage: is_NumberField(K)
True
```

Quadratic number fields are cached:

```
sage: QuadraticField(-11, 'a') is QuadraticField(-11, 'a')
True
```

gp()

Return the unique copy of the gp (PARI) interpreter used for number field computations.

EXAMPLES:

```
sage: from sage.rings.number_field.number_field import gp
sage: gp()
GP/PARI interpreter
```

is_AbsoluteNumberField(*x*)

Return True if x is an absolute number field.

EXAMPLES:

```
sage: from sage.rings.number_field.number_field import is_AbsoluteNumberField
sage: is_AbsoluteNumberField(NumberField(x^2+1,'a'))
True
sage: is_AbsoluteNumberField(NumberField([x^3 + 17, x^2+1],'a'))
False
```

The rationals are a number field, but they're not of the absolute number field class.

```
sage: is_AbsoluteNumberField(QQ)
False
```

is_CyclotomicField(*x*)

Return True if x is a cyclotomic field, i.e., of the special cyclotomic field class. This function does not return True for a number field that just happens to be isomorphic to a cyclotomic field.

EXAMPLES:

```
sage: from sage.rings.number_field.number_field import is_CyclotomicField
sage: is_CyclotomicField(NumberField(x^2 + 1,'zeta4'))
False
sage: is_CyclotomicField(CyclotomicField(4))
True
sage: is_CyclotomicField(CyclotomicField(1))
True
sage: is_CyclotomicField(QQ)
False
sage: is_CyclotomicField(7)
False
```

is_QuadraticField(*x*)

Return True if x is of the quadratic *number* field type.

EXAMPLES:

```
sage: from sage.rings.number_field.number_field import is_QuadraticField
sage: is_QuadraticField(QuadraticField(5,'a'))
True
sage: is_QuadraticField(NumberField(x^2 - 5, 'b'))
True
sage: is_QuadraticField(NumberField(x^3 - 5, 'b'))
False
```

A quadratic field specially refers to a number field, not a finite field:

```
sage: is_QuadraticField(GF(9,'a'))
False
```

is_fundamental_discriminant(*D*)

Return True if the integer D is a fundamental discriminant, i.e., if $D \cong 0, 1 \pmod 4$, and $D \neq 0, 1$ and either (1) D is square free or (2) we have $D \cong 0 \pmod 4$ with $D/4 \cong 2, 3 \pmod 4$ and $D/4$ square free. These are exactly the discriminants of quadratic fields.

EXAMPLES:

```
sage: [D for D in range(-15,15) if is_fundamental_discriminant(D)]
[-15, -11, -8, -7, -4, -3, 5, 8, 12, 13]
sage: [D for D in range(-15,15) if not is_square(D) and QuadraticField(D,'a').disc() == D]
[-15, -11, -8, -7, -4, -3, 5, 8, 12, 13]
```

proof_flag(*t*)

Used for easily determining the correct proof flag to use.

Returns t if t is not None, otherwise returns the system-wide proof-flag for number fields (default: True).

EXAMPLES:

```
sage: from sage.rings.number_field.number_field import proof_flag
sage: proof_flag(True)
True
sage: proof_flag(False)
False
sage: proof_flag(None)
```

```
True
sage: proof_flag("banana")
'banana'
```

put_natural_embedding_first(*v*)

Helper function for embeddings() functions for number fields.

INPUT: a list of embeddings of a number field

OUTPUT: None. The list is altered in-place, so that, if possible, the first embedding has been switched with one of the others, so that if there is an embedding which preserves the generator names then it appears first.

EXAMPLES:

```
sage: K.<a> = CyclotomicField(7)
sage: embs = K.embeddings(K)
sage: [e(a) for e in embs] # random - there is no natural sort order
[a, a^2, a^3, a^4, a^5, -a^5 - a^4 - a^3 - a^2 - a - 1]
sage: id = [ e for e in embs if e(a) == a ][0]; id
Ring endomorphism of Cyclotomic Field of order 7 and degree 6
  Defn: a |--> a
sage: permuted_embs = list(embs); permuted_embs.remove(id); permuted_embs.append(id)
sage: [e(a) for e in permuted_embs] # random - but natural map is not first
[a^2, a^3, a^4, a^5, -a^5 - a^4 - a^3 - a^2 - a - 1, a]
sage: permuted_embs[0] != a
True
sage: from sage.rings.number_field.number_field import put_natural_embedding_first
sage: put_natural_embedding_first(permuted_embs)
sage: [e(a) for e in permuted_embs] # random - but natural map is first
[a, a^3, a^4, a^5, -a^5 - a^4 - a^3 - a^2 - a - 1, a^2]
sage: permuted_embs[0] == id
True
```

refine_embedding(*e, prec=None*)

Given an embedding e: K->RR or CC, returns an equivalent embedding with higher precision.

INPUT:

- `e` - an embedding of a number field into either RR or CC (with some precision)
- **`prec` - (default None) the desired precision; if None,** current precision is doubled; if Infinity, the equivalent embedding into either `QQbar` or `AA` is returned.

EXAMPLES:

```
sage: from sage.rings.number_field.number_field import refine_embedding
sage: K = CyclotomicField(3)
sage: e10 = K.complex_embedding(10)
sage: e10.codomain().precision()
10
sage: e25 = refine_embedding(e10, prec=25)
sage: e25.codomain().precision()
25
```

An example where we extend a real enmbedding into `AA`:

```
sage: K.<a> = NumberField(x^3-2)
sage: K.signature()
(1, 1)
sage: e = K.embeddings(RR)[0]; e
Ring morphism:
```

```
From: Number Field in a with defining polynomial x^3 - 2
To:   Real Field with 53 bits of precision
Defn: a |--> 1.25992104989487
sage: e = refine_embedding(e,Infinity); e
Ring morphism:
From: Number Field in a with defining polynomial x^3 - 2
To:   Algebraic Real Field
Defn: a |--> 1.259921049894873?
```

Now we can obtain abitrary precision values with no trouble:

```
sage: RealField(150)(e(a))
1.2599210498948731647672106072782283505702515
sage: _^3
2.0000000000000000000000000000000000000000000000
sage: RealField(200)(e(a^2-3*a+7))
4.807637902283579980450073817437623208680738933795329069562 4
```

Complex enmbeddings can be extended into `QQbar`:

```
sage: e = K.embeddings(CC)[0]; e
Ring morphism:
From: Number Field in a with defining polynomial x^3 - 2
To:   Complex Field with 53 bits of precision
Defn: a |--> -0.629960524947436 - 1.09112363597172*I
sage: e = refine_embedding(e,Infinity); e
Ring morphism:
From: Number Field in a with defining polynomial x^3 - 2
To:   Algebraic Field
Defn: a |--> -0.6299605249474365? - 1.091123635971722?*I
sage: ComplexField(200)(e(a))
-0.62996052494743658238360530363911417528512573235075399004099 - 1.0911236359717214035600726141 8
sage: e(a)^3
2
```

26.2 Number Field Elements

AUTHORS:

- William Stein: version before it got Cython'd
- Joel B. Mohler (2007-03-09): First reimplementation in Cython
- William Stein (2007-09-04): add doctests
- Robert Bradshaw (2007-09-15): specialized classes for relative and absolute elements

class **CoordinateFunction**()

alpha()

class **NumberFieldElement**()

An element of a number field.

EXAMPLES:

```
sage: k.<a> = NumberField(x^3 + x + 1)
sage: a^3
-a - 1
```

abs()

Return the absolute value of this element with respect to the ith complex embedding of parent, to the given precision.

If prec is 53 (the default), then the complex double field is used; otherwise the arbitrary precision (but slow) complex field is used.

INPUT:

- `prec` - (default: 53) integer bits of precision
- `i` - (default:) integer, which embedding to use

EXAMPLES:

```
sage: z = CyclotomicField(7).gen()
sage: abs(z)
1.0
sage: abs(z^2 + 17*z - 3)
16.06044268
sage: K.<a> = NumberField(x^3+17)
sage: abs(a)
2.57128159066
sage: a.abs(prec=100)
2.5712815906582353554531872087
sage: a.abs(prec=100,i=1)
2.5712815906582353554531872087
sage: a.abs(100, 2)
2.5712815906582353554531872087
```

Here's one where the absolute value depends on the embedding.

```
sage: K.<b> = NumberField(x^2-2)
sage: a = 1 + b
sage: a.abs(i=0)
0.414213562373
sage: a.abs(i=1)
2.41421356237
```

additive_order()

Return the additive order of this element (i.e. infinity if self != 0, 1 if self == 0)

EXAMPLES:

```
sage: K.<u> = NumberField(x^4 - 3*x^2 + 3)
sage: u.additive_order()
+Infinity
sage: K(0).additive_order()
1
sage: K.ring_of_integers().characteristic() # implicit doctest
0
```

charpoly()

complex_embedding()

Return the i-th embedding of self in the complex numbers, to the given precision.

EXAMPLES:

```
sage: k.<a> = NumberField(x^3 - 2)
sage: a.complex_embedding()
```

```
-0.629960524947 - 1.09112363597*I
sage: a.complex_embedding(10)
-0.63 - 1.1*I
sage: a.complex_embedding(100)
-0.62996052494743658238360530364 - 1.0911236359717214035600726142*I
sage: a.complex_embedding(20, 1)
-0.62996 + 1.0911*I
sage: a.complex_embedding(20, 2)
1.2599
```

complex_embeddings()

Return the images of this element in the floating point complex numbers, to the given bits of precision.

INPUT:

- prec - integer (default: 53) bits of precision

EXAMPLES:

```
sage: k.<a> = NumberField(x^3 - 2)
sage: a.complex_embeddings()
[-0.629960524947 - 1.09112363597*I, -0.629960524947 + 1.09112363597*I, 1.25992104989]
sage: a.complex_embeddings(10)
[-0.63 - 1.1*I, -0.63 + 1.1*I, 1.3]
sage: a.complex_embeddings(100)
[-0.62996052494743658238360530364 - 1.0911236359717214035600726142*I, -0.629960524947436582
```

conjugate()

Return the complex conjugate of the number field element. Currently, this is implemented for cyclotomic fields and quadratic extensions of Q. It seems likely that there are other number fields for which the idea of a conjugate would be easy to compute.

EXAMPLES:

```
sage: k.<I> = QuadraticField(-1)
sage: I.conjugate()
-I
sage: (I/(1+I)).conjugate()
-1/2*I + 1/2
sage: z6=CyclotomicField(6).gen(0)
sage: (2*z6).conjugate()
-2*zeta6 + 2

sage: K.<b> = NumberField(x^3 - 2)
sage: b.conjugate()
...
NotImplementedError: complex conjugation is not implemented (or doesn't make sense).
```

coordinates_in_terms_of_powers()

Let α be self. Return a Python function that takes any element of the parent of self in $\mathbf{Q}(\alpha)$ and writes it in terms of the powers of α: $1, \alpha, \alpha^2, ...$

(NOT CACHED).

EXAMPLES:

This function allows us to write elements of a number field in terms of a different generator without having to construct a whole separate number field.

```
sage: y = polygen(QQ,'y'); K.<beta> = NumberField(y^3 - 2); K
Number Field in beta with defining polynomial y^3 - 2
sage: alpha = beta^2 + beta + 1
sage: c = alpha.coordinates_in_terms_of_powers(); c
Coordinate function that writes elements in terms of the powers of beta^2 + beta + 1
```

```
sage: c(beta)
[-2, -3, 1]
sage: c(alpha)
[0, 1, 0]
sage: c((1+beta)^5)
[3, 3, 3]
sage: c((1+beta)^10)
[54, 162, 189]
```

This function works even if self only generates a subfield of this number field.

```
sage: k.<a> = NumberField(x^6 - 5)
sage: alpha = a^3
sage: c = alpha.coordinates_in_terms_of_powers()
sage: c((2/3)*a^3 - 5/3)
[-5/3, 2/3]
sage: c
Coordinate function that writes elements in terms of the powers of a^3
sage: c(a)
...
ArithmeticError: vector is not in free module
```

denominator()

Return the denominator of this element, which is by definition the denominator of the corresponding polynomial representation. I.e., elements of number fields are represented as a polynomial (in reduced form) modulo the modulus of the number field, and the denominator is the denominator of this polynomial.

EXAMPLES:

```
sage: K.<z> = CyclotomicField(3)
sage: a = 1/3 + (1/5)*z
sage: print a.denominator()
15
```

galois_conjugates()

Return all Gal(Qbar/Q)-conjugates of this number field element in the field K.

EXAMPLES:

In the first example the conjugates are obvious:

```
sage: K.<a> = NumberField(x^2 - 2)
sage: a.galois_conjugates(K)
[a, -a]
sage: K(3).galois_conjugates(K)
[3]
```

In this example the field is not Galois, so we have to pass to an extension to obtain the Galois conjugates.

```
sage: K.<a> = NumberField(x^3 - 2)
sage: c = a.galois_conjugates(K); c
[a]
sage: K.<a> = NumberField(x^3 - 2)
sage: c = a.galois_conjugates(K.galois_closure('a1')); c
[1/84*a1^4 + 13/42*a1, -1/252*a1^4 - 55/126*a1, -1/126*a1^4 + 8/63*a1]
sage: c[0]^3
2
sage: parent(c[0])
Number Field in a1 with defining polynomial x^6 + 40*x^3 + 1372
sage: parent(c[0]).is_galois()
True
```

There is only one Galois conjugate of $\sqrt[3]{2}$ in $\mathbf{Q}(\sqrt[3]{2})$.

```
sage: a.galois_conjugates(K)
[a]
```

Galois conjugates of $\sqrt[3]{2}$ in the field $\mathbf{Q}(\zeta_3, \sqrt[3]{2})$:

```
sage: L.<a> = CyclotomicField(3).extension(x^3 - 2)
sage: a.galois_conjugates(L)
[a, (-zeta3 - 1)*a, zeta3*a]
```

is_integral()

Determine if a number is in the ring of integers of this number field.

EXAMPLES:

```
sage: K.<a> = NumberField(x^2 + 23)
sage: a.is_integral()
True
sage: t = (1+a)/2
sage: t.is_integral()
True
sage: t.minpoly()
x^2 - x + 6
sage: t = a/2
sage: t.is_integral()
False
sage: t.minpoly()
x^2 + 23/4
```

An example in a relative extension:

```
sage: K.<a,b> = NumberField([x^2+1, x^2+3])
sage: (a+b).is_integral()
True
sage: ((a-b)/2).is_integral()
False
```

is_square()

Return True if self is a square in its parent number field and otherwise return False.

INPUT:

- `root` - if True, also return a square root (or None if self is not a perfect square)

EXAMPLES:

```
sage: m.<b> = NumberField(x^4 - 1789)
sage: b.is_square()
False
sage: c = (2/3*b + 5)^2; c
4/9*b^2 + 20/3*b + 25
sage: c.is_square()
True
sage: c.is_square(True)
(True, 2/3*b + 5)
```

We also test the functional notation.

```
sage: is_square(c, True)
(True, 2/3*b + 5)
sage: is_square(c)
True
sage: is_square(c+1)
False
```

is_totally_positive()

Returns True if self is positive for all real embeddings of its parent number field. We do nothing at complex places, so e.g. any element of a totally complex number field will return True.

EXAMPLES:

```
sage: F.<b> = NumberField(x^3-3*x-1)
sage: b.is_totally_positive()
False
sage: (b^2).is_totally_positive()
True
```

list()

Return the list of coefficients of self written in terms of a power basis.

matrix()

If base is None, return the matrix of right multiplication by the element on the power basis $1, x, x^2, \ldots, x^{d-1}$ for the number field. Thus the *rows* of this matrix give the images of each of the x^i.

If base is not None, then base must be either a field that embeds in the parent of self or a morphism to the parent of self, in which case this function returns the matrix of multiplication by self on the power basis, where we view the parent field as a field over base.

INPUT:

- `base` - field or morphism

EXAMPLES:

Regular number field:

```
sage: K.<a> = NumberField(QQ['x'].0^3 - 5)
sage: M = a.matrix(); M
[0 1 0]
[0 0 1]
[5 0 0]
sage: M.base_ring() is QQ
True
```

Relative number field:

```
sage: L.<b> = K.extension(K['x'].0^2 - 2)
sage: M = b.matrix(); M
[0 1]
[2 0]
sage: M.base_ring() is K
True
```

Absolute number field:

```
sage: M = L.absolute_field('c').gen().matrix(); M
[  0   1   0   0   0   0]
[  0   0   1   0   0   0]
[  0   0   0   1   0   0]
[  0   0   0   0   1   0]
[  0   0   0   0   0   1]
[-17 -60 -12 -10   6   0]
sage: M.base_ring() is QQ
True
```

More complicated relative number field:

```
sage: L.<b> = K.extension(K['x'].0^2 - a); L
Number Field in b with defining polynomial x^2 - a over its base field
sage: M = b.matrix(); M
```

```
[0 1]
[a 0]
sage: M.base_ring() is K
True
```

An example where we explicitly give the subfield or the embedding:

```
sage: K.<a> = NumberField(x^4 + 1); L.<a2> = NumberField(x^2 + 1)
sage: a.matrix(L)
[ 0  1]
[a2  0]
```

Notice that if we compute all embeddings and choose a different one, then the matrix is changed as it should be:

```
sage: v = L.embeddings(K)
sage: a.matrix(v[1])
[  0   1]
[-a2   0]
```

The norm is also changed:

```
sage: a.norm(v[1])
a2
sage: a.norm(v[0])
-a2
```

TESTS:

```
sage: F.<z> = CyclotomicField(5) ; t = 3*z**3 + 4*z**2 + 2
sage: t.matrix(F)
[3*z^3 + 4*z^2 + 2]
```

minpoly()

Return the minimal polynomial of this number field element.

EXAMPLES:

```
sage: K.<a> = NumberField(x^2+3)
sage: a.minpoly('x')
x^2 + 3
sage: R.<X> = K['X']
sage: L.<b> = K.extension(X^2-(22 + a))
sage: b.minpoly('t')
t^2 - a - 22
sage: b.absolute_minpoly('t')
t^4 - 44*t^2 + 487
sage: b^2 - (22+a)
0
```

multiplicative_order()

Return the multiplicative order of this number field element.

EXAMPLES:

```
sage: K.<z> = CyclotomicField(5)
sage: z.multiplicative_order()
5
sage: (-z).multiplicative_order()
10
sage: (1+z).multiplicative_order()
+Infinity
```

```
sage: x = polygen(QQ)
sage: K.<a>=NumberField(x^40 - x^20 + 4)
sage: u = 1/4*a^30 + 1/4*a^10 + 1/2
sage: u.multiplicative_order()
6
sage: a.multiplicative_order()
+Infinity
```

An example in a relative extension:

sage: K.<a, b> = NumberField([x^2 + x + 1, x^2 - 3]) sage: z = (a - 1)*b/3 sage: z.multiplicative_order() 12 sage: z^12==1 and z^6!=1 and z^4!=1 True

norm()

Return the absolute or relative norm of this number field element.

If K is given then K must be a subfield of the parent L of self, in which case the norm is the relative norm from L to K. In all other cases, the norm is the absolute norm down to QQ.

EXAMPLES:

```
sage: K.<a> = NumberField(x^3 + x^2 + x - 132/7); K
Number Field in a with defining polynomial x^3 + x^2 + x - 132/7
sage: a.norm()
132/7
sage: factor(a.norm())
2^2 * 3 * 7^-1 * 11
sage: K(0).norm()
0
```

Some complicated relatives norms in a tower of number fields.

```
sage: K.<a,b,c> = NumberField([x^2 + 1, x^2 + 3, x^2 + 5])
sage: L = K.base_field(); M = L.base_field()
sage: a.norm()
1
sage: a.norm(L)
1
sage: a.norm(M)
1
sage: a
a
sage: (a+b+c).norm()
121
sage: (a+b+c).norm(L)
2*c*b - 7
sage: (a+b+c).norm(M)
-11
```

We illustrate that norm is compatible with towers:

```
sage: z = (a+b+c).norm(L); z.norm(M)
-11
```

If we are in an order, the norm is an integer:

```
sage: K.<a> = NumberField(x^3-2)
sage: a.norm().parent()
Rational Field
sage: R = K.ring_of_integers()
sage: R(a).norm().parent()
Integer Ring
```

TESTS:

```
sage: F.<z> = CyclotomicField(5)
sage: t = 3*z**3 + 4*z**2 + 2
sage: t.norm(F)
3*z^3 + 4*z^2 + 2
```

nth_root()

Return an nth root of self in the given number field.

EXAMPLES:

```
sage: K.<a> = NumberField(x^4-7)
sage: K(7).nth_root(2)
a^2
sage: K((a-3)^5).nth_root(5)
a - 3
```

ALGORITHM: Use Pari to factor x^n - `self` in K.

polynomial()

Return the underlying polynomial corresponding to this number field element.

The resulting polynomial is currently *not* cached.

EXAMPLES:

```
sage: K.<a> = NumberField(x^5 - x - 1)
sage: f = (-2/3 + 1/3*a)^4; f
1/81*a^4 - 8/81*a^3 + 8/27*a^2 - 32/81*a + 16/81
sage: g = f.polynomial(); g
1/81*x^4 - 8/81*x^3 + 8/27*x^2 - 32/81*x + 16/81
sage: parent(g)
Univariate Polynomial Ring in x over Rational Field
```

Note that the result of this function is not cached (should this be changed?):

```
sage: g is f.polynomial()
False
```

sqrt()

Returns the square root of this number in the given number field.

EXAMPLES:

```
sage: K.<a> = NumberField(x^2 - 3)
sage: K(3).sqrt()
a
sage: K(3).sqrt(all=True)
[a, -a]
sage: K(a^10).sqrt()
9*a
sage: K(49).sqrt()
7
sage: K(1+a).sqrt()
...
ValueError: a + 1 not a square in Number Field in a with defining polynomial x^2 - 3
sage: K(0).sqrt()
0
sage: K((7+a)^2).sqrt(all=True)
[a + 7, -a - 7]

sage: K.<a> = CyclotomicField(7)
sage: a.sqrt()
a^4
```

```
sage: K.<a> = NumberField(x^5 - x + 1)
sage: (a^4 + a^2 - 3*a + 2).sqrt()
a^3 - a^2
```

ALGORITHM: Use Pari to factor x^2 - `self` in K.

support()

Return the support of this number field element.

OUTPUT: A sorted list of the primes ideals at which this number field element has nonzero valuation. An error is raised if the element is zero.

EXAMPLES:

```
sage: x = ZZ['x'].gen()
sage: F.<t> = NumberField(x^3 - 2)

sage: P5s = F(5).support()
sage: P5s
[Fractional ideal (-t^2 - 1), Fractional ideal (t^2 - 2*t - 1)]
sage: all(5 in P5 for P5 in P5s)
True
sage: all(P5.is_prime() for P5 in P5s)
True
sage: [ P5.norm() for P5 in P5s ]
[5, 25]
```

TESTS:

It doesn't make sense to factor the ideal (0):

```
sage: F(0).support()
...
ArithmeticError: Support of 0 is not defined.
```

trace()

Return the absolute or relative trace of this number field element.

If K is given then K must be a subfield of the parent L of self, in which case the trace is the relative trace from L to K. In all other cases, the trace is the absolute trace down to QQ.

EXAMPLES:

```
sage: K.<a> = NumberField(x^3 -132/7*x^2 + x + 1); K
Number Field in a with defining polynomial x^3 - 132/7*x^2 + x + 1
sage: a.trace()
132/7
sage: (a+1).trace() == a.trace() + 3
True
```

If we are in an order, the trace is an integer:

```
sage: K.<zeta> = CyclotomicField(17)
sage: R = K.ring_of_integers()
sage: R(zeta).trace().parent()
Integer Ring
```

TESTS:

```
sage: F.<z> = CyclotomicField(5) ; t = 3*z**3 + 4*z**2 + 2
sage: t.trace(F)
3*z^3 + 4*z^2 + 2
```

valuation()

Returns the valuation of self at a given prime ideal P.

INPUT:

- P - a prime ideal of the parent of self

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: K.<a> = NumberField(x^4+3*x^2-17)
sage: P = K.ideal(61).factor()[0][0]
sage: b = a^2 + 30
sage: b.valuation(P)
1
sage: type(b.valuation(P))
<type 'sage.rings.integer.Integer'>
```

vector()

Return vector representation of self in terms of the basis for the ambient number field.

EXAMPLES:

```
sage: K.<a> = NumberField(x^2 + 1)
sage: (2/3*a - 5/6).vector()
(-5/6, 2/3)
sage: (-5/6, 2/3)
(-5/6, 2/3)
sage: O = K.order(2*a)
sage: (O.1).vector()
(0, 2)
sage: K.<a,b> = NumberField([x^2 + 1, x^2 - 3])
sage: (a + b).vector()
(b, 1)
sage: O = K.order([a,b])
sage: (O.1).vector()
(-b, 1)
sage: (O.2).vector()
(1, -b)
```

class **NumberFieldElement_absolute**()

absolute_charpoly()

Return the characteristic polynomial of this element over

For the meaning of the optional argument algorithm, see charpoly().

EXAMPLES:

```
sage: x = ZZ['x'].0
sage: K.<a> = NumberField(x^4 + 2, 'a')
sage: a.absolute_charpoly()
x^4 + 2
sage: a.absolute_charpoly('y')
y^4 + 2
sage: (-a^2).absolute_charpoly()
x^4 + 4*x^2 + 4
sage: (-a^2).absolute_minpoly()
x^2 + 2

sage: a.absolute_charpoly(algorithm='pari') == a.absolute_charpoly(algorithm='sage')
True
```

absolute_minpoly()

Return the minimal polynomial of this element over $\mathbf{Q}$.

For the meaning of the optional argument algorithm, see charpoly().

EXAMPLES:

```
sage: x = ZZ['x'].0
sage: f = x^10 - 5*x^9 + 15*x^8 - 68*x^7 + 81*x^6 - 221*x^5 + 141*x^4 - 242*x^3 - 13*x^2 - 3
sage: K.<a> = NumberField(f, 'a')
sage: a.absolute_charpoly()
x^10 - 5*x^9 + 15*x^8 - 68*x^7 + 81*x^6 - 221*x^5 + 141*x^4 - 242*x^3 - 13*x^2 - 33*x - 135
sage: a.absolute_charpoly('y')
y^10 - 5*y^9 + 15*y^8 - 68*y^7 + 81*y^6 - 221*y^5 + 141*y^4 - 242*y^3 - 13*y^2 - 33*y - 135
sage: b = -79/9995*a^9 + 52/9995*a^8 + 271/9995*a^7 + 1663/9995*a^6 + 13204/9995*a^5 + 5573/
sage: b.absolute_charpoly()
x^10 + 10*x^9 + 25*x^8 - 80*x^7 - 438*x^6 + 80*x^5 + 2950*x^4 + 1520*x^3 - 10439*x^2 - 5130*
sage: b.absolute_minpoly()
x^5 + 5*x^4 - 40*x^2 - 19*x + 135

sage: b.absolute_minpoly(algorithm='pari') == b.absolute_minpoly(algorithm='sage')
True
```

charpoly()

The characteristic polynomial of this element, over $\mathbf{Q}$ if self is an element of a field, and over $\mathbf{Z}$ is self is an element of an order.

This is the same as `self.absolute_charpoly` since this is an element of an absolute extension.

The optional argument algorithm controls how the characteristic polynomial is computed: 'pari' uses Pari, 'sage' uses charpoly for Sage matrices. The default value None means that 'pari' is used for small degrees (up to the value of the constant TUNE_CHARPOLY_NF, currently at 25), otherwise 'sage' is used. The constant TUNE_CHARPOLY_NF should give reasonable performance on all architectures; however, if you feel the need to customize it to your own machine, see trac ticket 5213 for a tuning script.

EXAMPLES:

We compute the characteristic polynomial of the cube root of 2.

```
sage: R.<x> = QQ[]
sage: K.<a> = NumberField(x^3-2)
sage: a.charpoly('x')
x^3 - 2
sage: a.charpoly('y').parent()
Univariate Polynomial Ring in y over Rational Field
```

TESTS:

```
sage: R = K.ring_of_integers()
sage: R(a).charpoly()
x^3 - 2
sage: R(a).charpoly().parent()
Univariate Polynomial Ring in x over Integer Ring

sage: R(a).charpoly(algorithm='pari') == R(a).charpoly(algorithm='sage')
True
```

list()

Return the list of coefficients of self written in terms of a power basis.

EXAMPLE:

```
sage: K.<z> = CyclotomicField(3)
sage: (2+3/5*z).list()
[2, 3/5]
sage: (5*z).list()
[0, 5]
sage: K(3).list()
[3, 0]
```

minpoly()

Return the minimal polynomial of this number field element.

For the meaning of the optional argument algorithm, see charpoly().

EXAMPLES:

We compute the characteristic polynomial of cube root of 2.

```
sage: R.<x> = QQ[]
sage: K.<a> = NumberField(x^3-2)
sage: a.minpoly('x')
x^3 - 2
sage: a.minpoly('y').parent()
Univariate Polynomial Ring in y over Rational Field
```

TESTS:

```
sage: R = K.ring_of_integers()
sage: R(a).minpoly()
x^3 - 2
sage: R(a).minpoly().parent()
Univariate Polynomial Ring in x over Integer Ring

sage: R(a).minpoly(algorithm='pari') == R(a).minpoly(algorithm='sage')
True
```

class **NumberFieldElement_relative**()

The current relative number field element implementation does everything in terms of absolute polynomials.

All conversions from relative polynomials, lists, vectors, etc should happen in the parent.

absolute_charpoly()

The characteristic polynomial of this element over $\mathbf{Q}$.

We construct a relative extension and find the characteristic polynomial over $\mathbf{Q}$.

The optional argument algorithm controls how the characteristic polynomial is computed: 'pari' uses Pari, 'sage' uses charpoly for Sage matrices. The default value None means that 'pari' is used for small degrees (up to the value of the constant TUNE_CHARPOLY_NF, currently at 25), otherwise 'sage' is used. The constant TUNE_CHARPOLY_NF should give reasonable performance on all architectures; however, if you feel the need to customize it to your own machine, see trac ticket 5213 for a tuning script.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: K.<a> = NumberField(x^3-2)
sage: S.<X> = K[]
sage: L.<b> = NumberField(X^3 + 17); L
Number Field in b with defining polynomial X^3 + 17 over its base field
sage: b.absolute_charpoly()
x^9 + 51*x^6 + 867*x^3 + 4913
sage: b.charpoly()(b)
0
sage: a = L.0; a
b
sage: a.absolute_charpoly('x')
x^9 + 51*x^6 + 867*x^3 + 4913
sage: a.absolute_charpoly('y')
y^9 + 51*y^6 + 867*y^3 + 4913

sage: a.absolute_charpoly(algorithm='pari') == a.absolute_charpoly(algorithm='sage')
True
```

absolute_minpoly()

Return the minimal polynomial over $\mathbf{Q}$ of this element.

For the meaning of the optional argument algorithm, see absolute_charpoly().

EXAMPLES:

```
sage: K.<a, b> = NumberField([x^2 + 2, x^2 + 1000*x + 1])
sage: y = K['y'].0
sage: L.<c> = K.extension(y^2 + a*y + b)
sage: c.absolute_charpoly()
x^8 - 1996*x^6 + 996006*x^4 + 1997996*x^2 + 1
sage: c.absolute_minpoly()
x^8 - 1996*x^6 + 996006*x^4 + 1997996*x^2 + 1
sage: L(a).absolute_charpoly()
x^8 + 8*x^6 + 24*x^4 + 32*x^2 + 16
sage: L(a).absolute_minpoly()
x^2 + 2
sage: L(b).absolute_charpoly()
x^8 + 4000*x^7 + 6000004*x^6 + 4000012000*x^5 + 1000012000006*x^4 + 4000012000*x^3 + 6000004
sage: L(b).absolute_minpoly()
x^2 + 1000*x + 1
```

charpoly()

The characteristic polynomial of this element over its base field.

EXAMPLES:

```
sage: x = ZZ['x'].0
sage: K.<a, b> = QQ.extension([x^2 + 2, x^5 + 400*x^4 + 11*x^2 + 2])
sage: a.charpoly()
x^2 + 2
sage: b.charpoly()
x^2 - 2*b*x + b^2
sage: b.minpoly()
x - b

sage: K.<a, b> = NumberField([x^2 + 2, x^2 + 1000*x + 1])
sage: y = K['y'].0
sage: L.<c> = K.extension(y^2 + a*y + b)
sage: c.charpoly()
x^2 + a*x + b
sage: c.minpoly()
x^2 + a*x + b
sage: L(a).charpoly()
x^2 - 2*a*x - 2
sage: L(a).minpoly()
x - a
sage: L(b).charpoly()
x^2 - 2*b*x - 1000*b - 1
sage: L(b).minpoly()
x - b
```

list()

Return the list of coefficients of self written in terms of a power basis.

EXAMPLES:

```
sage: K.<a,b> = NumberField([x^3+2, x^2+1])
sage: a.list()
[0, 1, 0]
sage: v = (K.base_field().0 + a)^2 ; v
a^2 + 2*b*a - 1
sage: v.list()
[-1, 2*b, 1]
```

class `OrderElement_absolute`()

Element of an order in an absolute number field.

EXAMPLES:

```
sage: K.<a> = NumberField(x^2 + 1)
sage: O2 = K.order(2*a)
sage: w = O2.1; w
2*a
sage: parent(w)
Order in Number Field in a with defining polynomial x^2 + 1

sage: w.absolute_charpoly()
x^2 + 4
sage: w.absolute_charpoly().parent()
Univariate Polynomial Ring in x over Integer Ring
sage: w.absolute_minpoly()
x^2 + 4
sage: w.absolute_minpoly().parent()
Univariate Polynomial Ring in x over Integer Ring
```

`inverse_mod`()

Return an inverse of self modulo the given ideal.

INPUT:

- `I` - may be an ideal of self.parent(), or an element or list of elements of self.parent() generating a nonzero ideal. A TypeError is raised if I is non-integral, and a ValueError if the generators are all zero. A ZeroDivisionError is raised if I + (x) != (1).

EXAMPLES:

```
sage: OE = NumberField(x^3 - x + 2, 'w').ring_of_integers()
sage: w = OE.ring_generators()[0]
sage: w.inverse_mod(13*OE)
-7*w^2 - 13*w + 7
sage: w * (w.inverse_mod(13)) - 1 in 13*OE
True
sage: w.inverse_mod(2*OE)
...
ZeroDivisionError: w is not invertible modulo Fractional ideal (2)
```

class `OrderElement_relative`()

Element of an order in a relative number field.

EXAMPLES:

```
sage: O = EquationOrder([x^2 + x + 1, x^3 - 2],'a,b')
sage: c = O.1; c
(-2*b^2 - 2)*a - 2*b^2 - b
sage: type(c)
<type 'sage.rings.number_field.number_field_element.OrderElement_relative'>
```

`absolute_charpoly`()

The absolute characteristic polynomial of this order element over ZZ.

EXAMPLES:

```
sage: x = ZZ['x'].0
sage: K.<a,b> = NumberField([x^2 + 1, x^2 - 3])
sage: OK = K.maximal_order()
sage: _, u, _, v = OK.basis()
```

```
sage: t = 2*u - v; t
-b
sage: t.absolute_charpoly()
x^4 - 6*x^2 + 9
sage: t.absolute_minpoly()
x^2 - 3
sage: t.absolute_charpoly().parent()
Univariate Polynomial Ring in x over Integer Ring
```

absolute_minpoly()

The absolute minimal polynomial of this order element over ZZ.

EXAMPLES:

```
sage: x = ZZ['x'].0
sage: K.<a,b> = NumberField([x^2 + 1, x^2 - 3])
sage: OK = K.maximal_order()
sage: _, u, _, v = OK.basis()
sage: t = 2*u - v; t
-b
sage: t.absolute_charpoly()
x^4 - 6*x^2 + 9
sage: t.absolute_minpoly()
x^2 - 3
sage: t.absolute_minpoly().parent()
Univariate Polynomial Ring in x over Integer Ring
```

charpoly()

The characteristic polynomial of this order element over its base ring.

This special implementation works around bug #4738. At this time the base ring of relative order elements is ZZ; it should be the ring of integers of the base field.

EXAMPLES:

```
sage: x = ZZ['x'].0
sage: K.<a,b> = NumberField([x^2 + 1, x^2 - 3])
sage: OK = K.maximal_order(); OK.basis()
[1, 1/2*a - 1/2*b, -1/2*b*a + 1/2, a]
sage: charpoly(OK.1)
x^2 + b*x + 1
sage: charpoly(OK.1).parent()
Univariate Polynomial Ring in x over Maximal Order in Number Field in b with defining polync
sage: [ charpoly(t) for t in OK.basis() ]
[x^2 - 2*x + 1, x^2 + b*x + 1, x^2 - x + 1, x^2 + 1]
```

minpoly()

The minimal polynomial of this order element over its base ring.

This special implementation works around bug #4738. At this time the base ring of relative order elements is ZZ; it should be the ring of integers of the base field.

EXAMPLES:

```
sage: x = ZZ['x'].0
sage: K.<a,b> = NumberField([x^2 + 1, x^2 - 3])
sage: OK = K.maximal_order(); OK.basis()
[1, 1/2*a - 1/2*b, -1/2*b*a + 1/2, a]
sage: minpoly(OK.1)
x^2 + b*x + 1
sage: charpoly(OK.1).parent()
Univariate Polynomial Ring in x over Maximal Order in Number Field in b with defining polync
sage: _, u, _, v = OK.basis()
```

```
sage: t = 2*u - v; t
-b
sage: t.charpoly()
x^2 + 2*b*x + 3
sage: t.minpoly()
x + b

sage: t.absolute_charpoly()
x^4 - 6*x^2 + 9
sage: t.absolute_minpoly()
x^2 - 3
```

is_NumberFieldElement()

Return True if x is of type NumberFieldElement, i.e., an element of a number field.

EXAMPLES:

```
sage: from sage.rings.number_field.number_field_element import is_NumberFieldElement
sage: is_NumberFieldElement(2)
False
sage: k.<a> = NumberField(x^7 + 17*x + 1)
sage: is_NumberFieldElement(a+1)
True
```

26.3 Number Field Ideals

AUTHORS:

- Steven Sivek (2005-05-16)
- William Stein (2007-09-06): vastly improved the doctesting
- William Stein and John Cremona (2007-01-28): new class NumberFieldFractionalIdeal now used for all except the 0 ideal

We test that pickling works:

```
sage: K.<a> = NumberField(x^2 - 5)
sage: I = K.ideal(2/(5+a))
sage: I == loads(dumps(I))
True
```

class LiftMap(*OK, M_OK_map, Q, I*)

Class to hold data needed by lifting maps from residue fields to number field orders.

class NumberFieldFractionalIdeal(*field, gens, coerce=True*)

A fractional ideal in a number field.

denominator()

Return the denominator ideal of this fractional ideal. Each fractional ideal has a unique expression as N/D where N, D are coprime integral ideals; the denominator is D.

EXAMPLES:

```
sage: K.<i>=NumberField(x^2+1)
sage: I = K.ideal((3+4*i)/5); I
Fractional ideal (4/5*i + 3/5)
```

```
sage: I.denominator()
Fractional ideal (2*i + 1)
sage: I.numerator()
Fractional ideal (-i - 2)
sage: I.numerator().is_integral() and I.denominator().is_integral()
True
sage: I.numerator() + I.denominator() == K.unit_ideal()
True
sage: I.numerator()/I.denominator() == I
True
```

divides(*other*)

Returns True if this ideal divides other and False otherwise.

EXAMPLES:

```
sage: K.<a> = CyclotomicField(11); K
Cyclotomic Field of order 11 and degree 10
sage: I = K.factor(31)[0][0]; I
Fractional ideal (-3*a^7 - 4*a^5 - 3*a^4 - 3*a^2 - 3*a - 3)
sage: I.divides(I)
True
sage: I.divides(31)
True
sage: I.divides(29)
False
```

element_1_mod(*other*)

Returns an element r in this ideal such that 1-r is in other

An error is raised if either ideal is not integral of if they are not coprime.

INPUT: other – another ideal of the same field, or generators of an ideal.

OUTPUT: r – an element of the ideal self such that 1-r is in the ideal other

AUTHOR: Maite Aranes

EXAMPLES:

```
sage: K.<a> = NumberField(x^3-2)
sage: A = K.ideal(a+1); A; A.norm()
Fractional ideal (a + 1)
3
sage: B = K.ideal(a^2-4*a+2); B; B.norm()
Fractional ideal (a^2 - 4*a + 2)
68
sage: r = A.element_1_mod(B); r
a^2 + 5
sage: r in A
True
sage: 1-r in B
True
```

TESTS:

```
sage: K.<a> = NumberField(x^3-2)
sage: A = K.ideal(a+1)
sage: B = K.ideal(a^2-4*a+1); B; B.norm()
Fractional ideal (a^2 - 4*a + 1)
99
sage: A.element_1_mod(B)
...
TypeError: Fractional ideal (a + 1), Fractional ideal (a^2 - 4*a + 1) are not coprime ideals
```

```
sage: B = K.ideal(1/a); B
Fractional ideal (1/2*a^2)
sage: A.element_1_mod(B)
Traceback (most recent call last):
TypeError: element_1_mod only defined for integral ideals
```

euler_phi()

Returns the Euler φ-function of this integral ideal.

This is the order of the multiplicative group of the quotient modulo the ideal.

An error is raised if the ideal is not integral.

EXAMPLES:

```
sage: K.<i>=NumberField(x^2+1)
sage: I = K.ideal(2+i)
sage: [r for r in I.residues() if I.is_coprime(r)]
[-2, -1, 1, 2]
sage: I.euler_phi()
4
sage: J = I^3
sage: J.euler_phi()
100
sage: len([r for r in J.residues() if J.is_coprime(r)])
100
sage: J = K.ideal(3-2*i)
sage: I.is_coprime(J)
True
sage: I.euler_phi()*J.euler_phi() == (I*J).euler_phi()
True
sage: L.<b> = K.extension(x^2 - 7)
sage: L.ideal(3).euler_phi()
64
```

factor()

Factorization of this ideal in terms of prime ideals.

EXAMPLES:

```
sage: K.<a> = NumberField(x^4 + 23); K
Number Field in a with defining polynomial x^4 + 23
sage: I = K.ideal(19); I
Fractional ideal (19)
sage: F = I.factor(); F
(Fractional ideal (a^2 + 2*a + 2)) * (Fractional ideal (a^2 - 2*a + 2))
sage: type(F)
<class 'sage.structure.factorization.Factorization'>
sage: list(F)
[(Fractional ideal (a^2 + 2*a + 2), 1), (Fractional ideal (a^2 - 2*a + 2), 1)]
sage: F.prod()
Fractional ideal (19)
```

idealcoprime(*J*)

Returns l such that l*self is coprime to J.

INPUT:

- J - another integral ideal of the same field as self, which must also be integral.

OUTPUT:

- l - an element such that l*self is coprime to the ideal J

TODO: Extend the implementation to non-integral ideals.

EXAMPLES:

```
sage: k.<a> = NumberField(x^2 + 23)
sage: A = k.ideal(a+1)
sage: B = k.ideal(3)
sage: A.is_coprime(B)
False
sage: lam = A.idealcoprime(B); lam
-1/6*a + 1/6
sage: (lam*A).is_coprime(B)
True
```

ALGORITHM: Uses Pari function `idealcoprime`.

ideallog(*x*)

Returns the discrete logarithm of x with respect to the generators given in the `bid` structure of the ideal self.

INPUT:

- **x - a non-zero element of the number field of self,** which must have valuation equal to 0 at all prime ideals in the support of the ideal self.

OUTPUT:

- `l` - a list of integers (x_i) such that $0 \leq x_i < d_i$ and $x = \prod_i g_i^{x_i}$ in $(R/I)^*$, where I = self, R = ring of integers of the field, and g_i are the generators of $(R/I)^*$, of orders d_i respectively, as given in the `bid` structure of the ideal self.

EXAMPLES:

```
sage: k.<a> = NumberField(x^3 - 11)
sage: A = k.ideal(5)
sage: G = A.idealstar(2)
sage: l = A.ideallog(a^2 +3)
sage: r = prod([G.gens()[i]**l[i] for i in range(len(l))])
sage: (a^2 + 3) - r in A
True
sage: A.small_residue(r) # random
a^2 - 2
```

ALGORITHM: Uses Pari function `ideallog`

idealstar(*flag=1*)

Returns the finite abelian group $(O_K/I)^*$, where I is the ideal self of the number field K, and O_K is the ring of integers of K.

INPUT:

- flag – when flag=2, it also computes the generators of the group $(O_K/I)^*$, which takes more time. By default flag=1 (no generators are computed). In both cases the special pari structure `bid` is computed as well. If flag=0 (deprecated) it computes only the group structure of $(O_K/I)^*$ (with generators) and not the special `bid` structure. OUTPUT: The finite abelian group $(O_K/I)^*$.

Note: Uses the pari function `idealstar`. The pari function outputs a special `bid` structure which is stored in the internal field `_bid` of the ideal (when flag=1,2). The special structure `bid` is used in the pari function `ideallog` to compute discrete logarithms.

EXAMPLES:

```
sage: k.<a> = NumberField(x^3 - 11)
sage: A = k.ideal(5)
sage: G = A.idealstar(); G
Multiplicative Abelian Group isomorphic to C24 x C4
sage: G.gens()
(f0, f1)
```

```
sage: G = A.idealstar(2)
sage: all([G.gens()[i] in k for i in range(G.ngens())])
True
```

ALGORITHM: Uses Pari function `idealstar`

invertible_residues(*reduce=True*)

Returns a iterator through a list of invertible residues modulo this integral ideal.

An error is raised if this fractional ideal is not integral.

INPUT:

- `reduce` - bool. If True (default), use `small_residue` to get small representatives of the residues.

OUTPUT:

- An iterator through a list of invertible residues modulo this ideal I, i.e. a list of elements in the ring of integers R representing the elements of $(R/I)^*$.

METHOD: Use pari's `idealstar` to find the group structure and generators of the multiplicative group modulo the ideal.

EXAMPLES:

```
sage: K.<i>=NumberField(x^2+1)
sage: ires =  K.ideal(2).invertible_residues(); ires  # random address
<generator object at 0xa2feb6c>
sage: list(ires)
[-1, -i]
sage: list(K.ideal(2+i).invertible_residues())
[1, 2, -1, -2]
sage: list(K.ideal(i).residues())
[0]
sage: list(K.ideal(i).invertible_residues())
[1]
sage: I = K.ideal(3+6*i)
sage: units=I.invertible_residues()
sage: len(list(units))==I.euler_phi()
True

sage: K.<a> = NumberField(x^3-10)
sage: I = K.ideal(a-1)
sage: len(list(I.invertible_residues())) == I.euler_phi()
True

sage: K.<z> = CyclotomicField(10)
sage: len(list(K.primes_above(3)[0].invertible_residues()))
80
```

AUTHOR: John Cremona

invertible_residues_mod(*subgp_gens=, [], reduce=True*)

Returns a iterator through a list of representatives for the invertible residues modulo this integral ideal, modulo the subgroup generated by the elements in the list `subgp_gens`.

INPUT:

- `subgp_gens` - either None or a list of elements of the number field of self. These need not be integral, but should be coprime to the ideal self. If the list is empty or None, the function returns an iterator through a list of representatives for the invertible residues modulo the integral ideal self.
- `reduce` - bool. If True (default), use `small_residues` to get small representatives of the residues.

Note: See also invertible_residues() for a simpler version without the subgroup.

OUTPUT:

- An iterator through a list of representatives for the invertible residues modulo self and modulo the group generated by `subgp_gens`, i.e. a list of elements in the ring of integers R representing the elements of $(R/I)^*/U$, where I is this ideal and U is the subgroup of $(R/I)^*$ generated by `subgp_gens`.

EXAMPLES:

```
sage: k.<a> = NumberField(x^2 +23)
sage: I = k.ideal(a)
sage: list(I.invertible_residues_mod([-1]))
[1, 5, 2, 10, 4, -3, 8, -6, -7, 11, 9]
sage: list(I.invertible_residues_mod([1/2]))
[1, 5]
sage: list(I.invertible_residues_mod([23]))
...
TypeError: the element must be invertible mod the ideal

sage: K.<a> = NumberField(x^3-10)
sage: I = K.ideal(a-1)
sage: len(list(I.invertible_residues_mod([]))) == I.euler_phi()
True

sage: I = K.ideal(1)
sage: list(I.invertible_residues_mod([]))
[1]

sage: K.<z> = CyclotomicField(10)
sage: len(list(K.primes_above(3)[0].invertible_residues_mod([])))
80
```

AUTHOR: Maite Aranes.

is_coprime(*other*)

Returns True if this ideal is coprime to the other, else False.

INPUT: other – another ideal of the same field, or generators of an ideal.

OUTPUT: True if self and other are coprime, else False.

NOTE: This function works for fractional ideals as well as integral ideals.

AUTHOR: John Cremona

EXAMPLES:

```
sage: K.<i>=NumberField(x^2+1)
sage: I = K.ideal(2+i)
sage: J = K.ideal(2-i)
sage: I.is_coprime(J)
True
sage: (I^-1).is_coprime(J^3)
True
sage: I.is_coprime(5)
False
sage: I.is_coprime(6+i)
True

# See trac \# 4536:
sage: E.<a> = NumberField(x^5 + 7*x^4 + 18*x^2 + x - 3)
sage: OE = E.ring_of_integers()
sage: i,j,k = [u[0] for u in factor(3*OE)]
sage: (i/j).is_coprime(j/k)
False
sage: (j/k).is_coprime(j/k)
```

```
False

sage: F.<a, b> = NumberField([x^2 - 2, x^2 - 3])
sage: F.ideal(3 - a*b).is_coprime(F.ideal(3))
False
```

is_maximal()

Return True if this ideal is maximal. This is equivalent to self being prime, since it is nonzero.

EXAMPLES:

```
sage: K.<a> = NumberField(x^3 + 3); K
Number Field in a with defining polynomial x^3 + 3
sage: K.ideal(5).is_maximal()
False
sage: K.ideal(7).is_maximal()
True
```

is_trivial(*proof=None*)

Returns True if this is a trivial ideal.

EXAMPLES:

```
sage: F.<a> = QuadraticField(-5)
sage: I = F.ideal(3)
sage: I.is_trivial()
False
sage: J = F.ideal(5)
sage: J.is_trivial()
False
sage: (I+J).is_trivial()
True
```

numerator()

Return the numerator ideal of this fractional ideal.

Each fractional ideal has a unique expression as N/D where N, D are coprime integral ideals. The numerator is N.

EXAMPLES:

```
sage: K.<i>=NumberField(x^2+1)
sage: I = K.ideal((3+4*i)/5); I
Fractional ideal (4/5*i + 3/5)
sage: I.denominator()
Fractional ideal (2*i + 1)
sage: I.numerator()
Fractional ideal (-i - 2)
sage: I.numerator().is_integral() and I.denominator().is_integral()
True
sage: I.numerator() + I.denominator() == K.unit_ideal()
True
sage: I.numerator()/I.denominator() == I
True
```

prime_factors()

Return a list of the prime ideal factors of self

OUTPUT: list – list of prime ideals (a new list is returned each time this function is called)

EXAMPLES:

```
sage: K.<w> = NumberField(x^2 + 23)
sage: I = ideal(w+1)
```

```
sage: I.prime_factors()
[Fractional ideal (2, 1/2*w - 1/2),
Fractional ideal (2, 1/2*w + 1/2),
Fractional ideal (3, -1/2*w - 1/2)]
```

prime_to_idealM_part(*M*)

Version for integral ideals of the prime_to_m_part function over ZZ. Returns the largest divisor of self that is coprime to the ideal M.

INPUT: M – an integral ideal of the same field, or generators of an ideal

OUTPUT: An ideal which is the largest divisor of self that is coprime to M.

AUTHOR: Maite Aranes

EXAMPLES:

```
sage: k.<a> = NumberField(x^2 + 23)
sage: I = k.ideal(a+1)
sage: M = k.ideal(2, 1/2*a - 1/2)
sage: J = I.prime_to_idealM_part(M); J
Fractional ideal (12, 1/2*a + 13/2)
sage: J.is_coprime(M)
True

sage: J = I.prime_to_idealM_part(2); J
Fractional ideal (3, -1/2*a - 1/2)
sage: J.is_coprime(M)
True
```

ramification_index()

Return the ramification index of this fractional ideal, assuming it is prime. Otherwise, raise a ValueError.

The ramification index is the power of this prime appearing in the factorization of the prime in $\mathbf{Z}$ that this prime lies over.

EXAMPLES:

```
sage: K.<a> = NumberField(x^2 + 2); K
Number Field in a with defining polynomial x^2 + 2
sage: f = K.factor(2); f
(Fractional ideal (-a))^2
sage: f[0][0].ramification_index()
2
sage: K.ideal(13).ramification_index()
1
sage: K.ideal(17).ramification_index()
...
ValueError: the fractional ideal (= Fractional ideal (17)) is not prime
```

residue_class_degree()

Return the residue class degree of this fractional ideal, assuming it is prime. Otherwise, raise a ValueError.

The residue class degree of a prime ideal I is the degree of the extension O_K/I of its prime subfield.

EXAMPLES:

```
sage: K.<a> = NumberField(x^5 + 2); K
Number Field in a with defining polynomial x^5 + 2
sage: f = K.factor(19); f
(Fractional ideal (a^2 + a - 3)) * (Fractional ideal (-2*a^4 - a^2 + 2*a - 1)) * (Fractional
sage: [i.residue_class_degree() for i, _ in f]
[2, 2, 1]
```

residue_field(*names=None*)

Return the residue class field of this fractional ideal, which must be prime.

EXAMPLES:

```
sage: K.<a> = NumberField(x^3-7)
sage: P = K.ideal(29).factor()[0][0]
sage: P.residue_field()
Residue field in abar of Fractional ideal (2*a^2 + 3*a - 10)
sage: P.residue_field('z')
Residue field in z of Fractional ideal (2*a^2 + 3*a - 10)
```

Another example:

```
sage: K.<a> = NumberField(x^3-7)
sage: P = K.ideal(389).factor()[0][0]; P
Fractional ideal (389, a^2 - 44*a - 9)
sage: P.residue_class_degree()
2
sage: P.residue_field()
Residue field in abar of Fractional ideal (389, a^2 - 44*a - 9)
sage: P.residue_field('z')
Residue field in z of Fractional ideal (389, a^2 - 44*a - 9)
sage: FF.<w> = P.residue_field()
sage: FF
Residue field in w of Fractional ideal (389, a^2 - 44*a - 9)
sage: FF((a+1)^390)
36
sage: FF(a)
w
```

An example of reduction maps to the residue field: these are defined on the whole valuation ring, i.e. the subring of the number field consisting of elements with non-negative valuation. This shows that the issue raised in trac #1951 has been fixed:

```
sage: K.<i> = NumberField(x^2 + 1)
sage: P1, P2 = [g[0] for g in K.factor(5)]; (P1,P2)
(Fractional ideal (-i - 2), Fractional ideal (2*i + 1))
sage: a = 1/(1+2*i)
sage: F1, F2 = [g.residue_field() for g in [P1,P2]]; (F1,F2)
(Residue field of Fractional ideal (-i - 2),
Residue field of Fractional ideal (2*i + 1))
sage: a.valuation(P1)
0
sage: F1(i/7)
4
sage: F1(a)
3
sage: a.valuation(P2)
-1
sage: F2(a)
Traceback (most recent call last):
ZeroDivisionError: Cannot reduce field element -2/5*i + 1/5 modulo Fractional ideal (2*i + 1
```

residues()

Returns a iterator through a complete list of residues modulo this integral ideal.

An error is raised if this fractional ideal is not integral.

AUTHOR: John Cremona

EXAMPLES:

```
sage: K.<i>=NumberField(x^2+1)
sage: res =  K.ideal(2).residues(); res  # random address
xmrange_iter([[0, 1], [0, 1]], <function <lambda> at 0xa252144>)
```

```
sage: list(res)
[0, 1, i, i + 1]
sage: list(K.ideal(2+i).residues())
[-2, -1, 0, 1, 2]
sage: list(K.ideal(i).residues())
[0]
sage: I = K.ideal(3+6*i)
sage: reps=I.residues()
sage: len(list(reps)) == I.norm()
True
sage: all([r==s or not (r-s) in I for r in reps for s in reps])
True

sage: K.<a> = NumberField(x^3-10)
sage: I = K.ideal(a-1)
sage: len(list(I.residues())) == I.norm()
True

sage: K.<z> = CyclotomicField(11)
sage: len(list(K.primes_above(3)[0].residues())) == 3**5
True
```

small_residue(*f*)

Given an element f of the ambient number field, returns an element g such that f - g belongs to the ideal self (which must be integral), and g is small.

Note: The reduced representative returned is not uniquely determined.

ALGORITHM: Uses Pari function `nfeltreduce`.

EXAMPLES:

```
sage: k.<a> = NumberField(x^2 + 5)
sage: I = k.ideal(a)
sage: I.small_residue(14)
-1

sage: K.<a> = NumberField(x^5 + 7*x^4 + 18*x^2 + x - 3)
sage: I = K.ideal(5)
sage: I.small_residue(a^2 -13)
a^2 + 5*a - 3
```

class **NumberFieldIdeal**(*field, gens, coerce=True*)

An ideal of a number field.

absolute_norm()

A synonym for norm.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2 + 1)
sage: K.ideal(1 + 2*i).absolute_norm()
5
```

absolute_ramification_index()

A synonym for ramification_index.

EXAMPLES:

```
sage: K.<i> = NumberField(x^2 + 1)
sage: K.ideal(1 + i).absolute_ramification_index()
2
```

artin_symbol()

Return the Artin symbol (K / Q, self), where K is the number field of self. This is the unique element s of the decomposition group of self such that s(x) = x^p mod self where p is the residue characteristic of self. (Here self should be prime and unramified.)

See the artin_symbol method of the GaloisGroup_v2 class for further documentation and examples.

EXAMPLE:

```
sage: QuadraticField(-23, 'w').primes_above(7)[0].artin_symbol()
(1,2)
```

basis()

Return an immutable sequence of elements of this ideal (note: their parent is the number field) that form a basis for this ideal viewed as a ZZ-module.

OUTPUT: basis – an immutable sequence.

EXAMPLES:

```
sage: K.<z> = CyclotomicField(7)
sage: I = K.factor(11)[0][0]
sage: I.basis()           # warning -- choice of basis can be somewhat random
[11, 11*z, 11*z^2, z^3 + 5*z^2 + 4*z + 10, z^4 + z^2 + z + 5, z^5 + z^4 + z^3 + 2*z^2 + 6*z
```

An example of a non-integral ideal.:

```
sage: J = 1/I
sage: J          # warning -- choice of generators can be somewhat random
Fractional ideal (2/11*z^5 + 2/11*z^4 + 3/11*z^3 + 2/11)
sage: J.basis()           # warning -- choice of basis can be somewhat random
[1, z, z^2, 1/11*z^3 + 7/11*z^2 + 6/11*z + 10/11, 1/11*z^4 + 1/11*z^2 + 1/11*z + 7/11, 1/11*
```

coordinates(*x*)

Returns the coordinate vector of x with respect to this ideal.

INPUT: x – an element of the number field (or ring of integers) of this ideal.

OUTPUT: A vector of length n (the degree of the field) giving the coordinates of x with respect to the integral basis of the ideal. In general this will be a vector of rationals; it will consist of integers if and only if x is in the ideal.

AUTHOR: John Cremona 2008-10-31 Uses linear algebra. The change-of-basis matrix is cached. Provides simpler implementations for _contains_(), is_integral() and smallest_integer().

EXAMPLES:

```
sage: K.<i> = QuadraticField(-1)
sage: I = K.ideal(7+3*i)
sage: Ibasis = I.integral_basis(); Ibasis
[58, i + 41]
sage: a = 23-14*i
sage: acoords = I.coordinates(a); acoords
(597/58, -14)
sage: sum([Ibasis[j]*acoords[j] for j in range(2)]) == a
True
sage: b = 123+456*i
sage: bcoords = I.coordinates(b); bcoords
(-18573/58, 456)
sage: sum([Ibasis[j]*bcoords[j] for j in range(2)]) == b
True
```

decomposition_group()

Return the decomposition group of self, as a subset of the automorphism group of the number field of self. Raises an error if the field isn't Galois. See the decomposition_group method of the GaloisGroup_v2 class for further examples and doctests.

EXAMPLE:

```
sage: QuadraticField(-23, 'w').primes_above(7)[0].decomposition_group()
Galois group of Number Field in w with defining polynomial x^2 + 23
```

free_module()

Return the free ZZ-module contained in the vector space associated to the ambient number field, that corresponds to this ideal.

EXAMPLES:

```
sage: K.<z> = CyclotomicField(7)
sage: I = K.factor(11)[0][0]; I
Fractional ideal (-2*z^4 - 2*z^2 - 2*z + 1)
sage: A = I.free_module()
sage: A              # warning -- choice of basis can be somewhat random
Free module of degree 6 and rank 6 over Integer Ring
User basis matrix:
[11  0  0  0  0  0]
[ 0 11  0  0  0  0]
[ 0  0 11  0  0  0]
[10  4  5  1  0  0]
[ 5  1  1  0  1  0]
[ 5  6  2  1  1  1]
```

However, the actual ZZ-module is not at all random:

```
sage: A.basis_matrix().change_ring(ZZ).echelon_form()
[ 1  0  0  5  1  1]
[ 0  1  0  1  1  7]
[ 0  0  1  7  6 10]
[ 0  0  0 11  0  0]
[ 0  0  0  0 11  0]
[ 0  0  0  0  0 11]
```

The ideal doesn't have to be integral:

```
sage: J = I^(-1)
sage: B = J.free_module()
sage: B.echelonized_basis_matrix()
[ 1/11     0     0  7/11  1/11  1/11]
[    0  1/11     0  1/11  1/11  5/11]
[    0     0  1/11  5/11  4/11 10/11]
[    0     0     0     1     0     0]
[    0     0     0     0     1     0]
[    0     0     0     0     0     1]
```

This also works for relative extensions:

```
sage: K.<a,b> = NumberField([x^2 + 1, x^2 + 2])
sage: I = K.fractional_ideal(4)
sage: I.free_module()
Free module of degree 4 and rank 4 over Integer Ring
User basis matrix:
[  4   0   0   0]
[ -3   7  -1   1]
[  3   7   1   1]
[  0 -10   0  -2]
sage: J = I^(-1); J.free_module()
Free module of degree 4 and rank 4 over Integer Ring
User basis matrix:
[  1/4     0     0     0]
[-3/16  7/16 -1/16  1/16]
```

```
[ 3/16  7/16  1/16  1/16]
[    0  -5/8     0  -1/8]
```

An example of intersecting ideals by intersecting free modules.:

```
sage: K.<a> = NumberField(x^3 + x^2 - 2*x + 8)
sage: I = K.factor(2)
sage: p1 = I[0][0]; p2 = I[1][0]
sage: N = p1.free_module().intersection(p2.free_module()); N
Free module of degree 3 and rank 3 over Integer Ring
Echelon basis matrix:
[  1 1/2 1/2]
[  0   1   1]
[  0   0   2]
sage: N.index_in(p1.free_module()).abs()
2
```

TESTS:

Sage can find the free module associated to quite large ideals quickly (see trac #4627):

```
sage: y = polygen(ZZ)
sage: M.<a> = NumberField(y^20 - 2*y^19 + 10*y^17 - 15*y^16 + 40*y^14 - 64*y^13 + 46*y^12 +
sage: M.ideal(prod(prime_range(6000, 6200))).free_module()
Free module of degree 20 and rank 20 over Integer Ring
User basis matrix:
20 x 20 dense matrix over Rational Field
```

gens_reduced(*proof=None*)

Express this ideal in terms of at most two generators, and one if possible.

Note that if the ideal is not principal, then this uses PARI's `idealtwoelt` function, which takes exponential time, the first time it is called for each ideal. Also, this indirectly uses `bnfisprincipal`, so set `proof=True` if you want to prove correctness (which *is* the default).

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: K.<i> = NumberField(x^2+1, 'i')
sage: J = K.ideal([i+1, 2])
sage: J.gens()
(i + 1, 2)
sage: J.gens_reduced()
(i + 1,)
```

TESTS:

```
sage: all(j.parent() is K for j in J.gens())
True
sage: all(j.parent() is K for j in J.gens_reduced())
True

sage: K.<a> = NumberField(x^4 + 10*x^2 + 20)
sage: J = K.prime_above(5)
sage: J.is_principal()
False
sage: J.gens_reduced()
(5, a)
sage: all(j.parent() is K for j in J.gens())
True
sage: all(j.parent() is K for j in J.gens_reduced())
True
```

inertia_group()

Return the inertia group of self, i.e. the set of elements s of the Galois group of the number field of self (which we assume is Galois) such that s acts trivially modulo self. This is the same as the 0th ramification group of self. See the inertia_group method of the GaloisGroup_v2 class for further examples and doctests.

EXAMPLE:

```
sage: QuadraticField(-23, 'w').primes_above(23)[0].inertia_group()
Galois group of Number Field in w with defining polynomial x^2 + 23
```

integral_basis()

Return a list of generators for this ideal as a $\mathbf{Z}$-module.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: K.<i> = NumberField(x^2 + 1)
sage: J = K.ideal(i+1)
sage: J.integral_basis()
[2, i + 1]
```

integral_split()

Return a tuple (I, d), where I is an integral ideal, and d is the smallest positive integer such that this ideal is equal to I/d.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: K.<a> = NumberField(x^2-5)
sage: I = K.ideal(2/(5+a))
sage: I.is_integral()
False
sage: J,d = I.integral_split()
sage: J
Fractional ideal (-1/2*a + 5/2)
sage: J.is_integral()
True
sage: d
5
sage: I == J/d
True
```

is_integral()

Return True if this ideal is integral.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: K.<a> = NumberField(x^5-x+1)
sage: K.ideal(a).is_integral()
True
sage: (K.ideal(1) / (3*a+1)).is_integral()
False
```

is_maximal()

Return True if this ideal is maximal. This is equivalent to self being prime and nonzero.

EXAMPLES:

```
sage: K.<a> = NumberField(x^3 + 3); K
Number Field in a with defining polynomial x^3 + 3
sage: K.ideal(5).is_maximal()
False
```

```
sage: K.ideal(7).is_maximal()
True
```

is_prime()

Return True if this ideal is prime.

EXAMPLES:

```
sage: K.<a> = NumberField(x^2 - 17); K
Number Field in a with defining polynomial x^2 - 17
sage: K.ideal(5).is_prime()
True
sage: K.ideal(13).is_prime()
False
sage: K.ideal(17).is_prime()
False
```

is_principal(*proof=None*)

Return True if this ideal is principal.

Since it uses the PARI method code{bnfisprincipal}, specify code{proof=True} (this is the default setting) to prove the correctness of the output.

EXAMPLES:

We create equal ideals in two different ways, and note that they are both actually principal ideals.:

```
sage: K = QuadraticField(-119,'a')
sage: P = K.ideal([2]).factor()[1][0]
sage: I = P^5
sage: I.is_principal()
True
```

is_zero()

Return True iff self is the zero ideal

EXAMPLES:

```
sage: K.<a> = NumberField(x^2 + 2); K
Number Field in a with defining polynomial x^2 + 2
sage: K.ideal(3).is_zero()
False
sage: I=K.ideal(0); I.is_zero()
True
sage: I
Ideal (0) of Number Field in a with defining polynomial x^2 + 2

(0 is a NumberFieldIdeal, not a NumberFieldFractionIdeal)
```

norm()

Return the norm of this fractional ideal as a rational number.

EXAMPLES:

```
sage: K.<a> = NumberField(x^4 + 23); K
Number Field in a with defining polynomial x^4 + 23
sage: I = K.ideal(19); I
Fractional ideal (19)
sage: factor(I.norm())
19^4
sage: F = I.factor()
sage: F[0][0].norm().factor()
19^2
```

number_field()
Return the number field that this is a fractional ideal in.
EXAMPLES:

```
sage: K.<a> = NumberField(x^2 + 2); K
Number Field in a with defining polynomial x^2 + 2
sage: K.ideal(3).number_field()
Number Field in a with defining polynomial x^2 + 2
sage: K.ideal(0).number_field() # not tested (not implemented)
Number Field in a with defining polynomial x^2 + 2
```

pari_hnf()
Return PARI's representation of this ideal in Hermite normal form.
EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: K.<a> = NumberField(x^3 - 2)
sage: I = K.ideal(2/(5+a))
sage: I.pari_hnf()
[2, 0, 50/127; 0, 2, 244/127; 0, 0, 2/127]
```

ramification_group(v)
Return the vth ramification group of self, i.e. the set of elements s of the Galois group of the number field of self (which we assume is Galois) such that s acts trivially modulo self^(v+1). See the ramification_group method of the GaloisGroup class for further examples and doctests.
EXAMPLE:

```
sage: QuadraticField(-23, 'w').primes_above(23)[0].ramification_group(0)
Galois group of Number Field in w with defining polynomial x^2 + 23
sage: QuadraticField(-23, 'w').primes_above(23)[0].ramification_group(1)
Subgroup [()] of Galois group of Number Field in w with defining polynomial x^2 + 23
```

reduce_equiv()
Return a small ideal that is equivalent to self in the group of fractional ideals modulo principal ideals. Very often (but not always) if self is principal then this function returns the unit ideal.
ALGORITHM: Calls pari's idealred function.
EXAMPLES:

```
sage: K.<w> = NumberField(x^2 + 23)
sage: I = ideal(w*23^5); I
Fractional ideal (6436343*w)
sage: I.reduce_equiv()
Fractional ideal (1)
sage: I = K.class_group().0.ideal()^10; I
Fractional ideal (1024, 1/2*w + 979/2)
sage: I.reduce_equiv()
Fractional ideal (2, 1/2*w - 1/2)
```

relative_norm()
A synonym for norm.
EXAMPLES:

```
sage: K.<i> = NumberField(x^2 + 1)
sage: K.ideal(1 + 2*i).relative_norm()
5
```

relative_ramification_index()
A synonym for ramification_index.
EXAMPLES:

```
sage: K.<i> = NumberField(x^2 + 1)
sage: K.ideal(1 + i).relative_ramification_index()
2
```

smallest_integer()

Return the smallest non-negative integer in $I \cap \mathbf{Z}$, where I is this ideal. If $I = 0$, returns 0.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: K.<a> = NumberField(x^2+6)
sage: I = K.ideal([4,a])/7
sage: I.smallest_integer()
2

sage: K.<i> = QuadraticField(-1)
sage: P1, P2 = [P for P,e in K.factor(13)]
sage: all([(P1^i*P2^j).smallest_integer() == 13^max(i,j,0) for i in range(-3,3) for j in ran
True
sage: I = K.ideal(0)
sage: I.smallest_integer()
0

# See trac\# 4392:
sage: K.<a>=QuadraticField(-5)
sage: I=K.ideal(7)
sage: I.smallest_integer()
7

sage: K.<z> = CyclotomicField(13)
sage: a = K([-8, -4, -4, -6, 3, -4, 8, 0, 7, 4, 1, 2])
sage: I = K.ideal(a)
sage: I.smallest_integer()
146196692151
sage: I.norm()
1315770229359
sage: I.norm() / I.smallest_integer()
9
```

valuation(p)

Return the valuation of this fractional ideal at the prime $\mathfrak{p}$. If $\mathfrak{p}$ is not prime, raise a ValueError.

INPUT: p – a prime ideal of this number field.

OUTPUT: integer

EXAMPLES:

```
sage: K.<a> = NumberField(x^5 + 2); K
Number Field in a with defining polynomial x^5 + 2
sage: i = K.ideal(38); i
Fractional ideal (38)
sage: i.valuation(K.factor(19)[0][0])
1
sage: i.valuation(K.factor(2)[0][0])
5
sage: i.valuation(K.factor(3)[0][0])
0
sage: i.valuation(0)
...
ValueError: p (= 0) must be nonzero
```

class QuotientMap(*K, M_OK_change, Q, I*)

Class to hold data needed by quotient maps from number field orders to residue fields. These are only partial maps: the exact domain is the appropriate valuation ring. For examples, see residue_field().

basis_to_module(*B, K*)

Given a basis B of elements for a ZZ-submodule of a number field K, return the corresponding ZZ-submodule.

EXAMPLES:

```
sage: K.<w> = NumberField(x^4 + 1)
sage: from sage.rings.number_field.number_field_ideal import basis_to_module
sage: basis_to_module([K.0, K.0^2 + 3], K)
Free module of degree 4 and rank 2 over Integer Ring
User basis matrix:
[0 1 0 0]
[3 0 1 0]
```

convert_from_zk_basis(*field, hnf*)

Used internally in the number field ideal implementation for converting from the order basis to the number field basis.

INPUT:

- `field` - a number field
- `hnf` - a pari HNF matrix, output by the pari_hnf() function.

EXAMPLES:

```
sage: from sage.rings.number_field.number_field_ideal import convert_from_zk_basis
sage: k.<a> = NumberField(x^2 + 23)
sage: I = k.factor(3)[0][0]; I
Fractional ideal (3, -1/2*a + 1/2)
sage: hnf = I.pari_hnf(); hnf
[3, 0; 0, 1]
sage: convert_from_zk_basis(k, hnf)
[3, 1/2*x - 1/2]
```

is_NumberFieldFractionalIdeal(*x*)

Return True if x is a fractional ideal of a number field.

EXAMPLES:

```
sage: from sage.rings.number_field.number_field_ideal import is_NumberFieldFractionalIdeal
sage: is_NumberFieldFractionalIdeal(2/3)
False
sage: is_NumberFieldFractionalIdeal(ideal(5))
False
sage: k.<a> = NumberField(x^2 + 2)
sage: I = k.ideal([a + 1]); I
Fractional ideal (a + 1)
sage: is_NumberFieldFractionalIdeal(I)
True
sage: Z = k.ideal(0); Z
Ideal (0) of Number Field in a with defining polynomial x^2 + 2
sage: is_NumberFieldFractionalIdeal(Z)
False
```

is_NumberFieldIdeal(*x*)

Return True if x is an ideal of a number field.

EXAMPLES:

```
sage: from sage.rings.number_field.number_field_ideal import is_NumberFieldIdeal
sage: is_NumberFieldIdeal(2/3)
False
sage: is_NumberFieldIdeal(ideal(5))
False
sage: k.<a> = NumberField(x^2 + 2)
sage: I = k.ideal([a + 1]); I
Fractional ideal (a + 1)
sage: is_NumberFieldIdeal(I)
True
sage: Z = k.ideal(0); Z
Ideal (0) of Number Field in a with defining polynomial x^2 + 2
sage: is_NumberFieldIdeal(Z)
True
```

quotient_char_p(*I*, *p*)

Given an integral ideal I that contains a prime number p, compute a vector space V = (OK mod p) / (I mod p), along with a homomorphism OK –> V and a section V –> OK.

EXAMPLES:

```
sage: from sage.rings.number_field.number_field_ideal import quotient_char_p

sage: K.<i> = NumberField(x^2 + 1); O = K.maximal_order(); I = K.fractional_ideal(15)
sage: quotient_char_p(I, 5)[0]
Vector space quotient V/W of dimension 2 over Finite Field of size 5 where
V: Vector space of dimension 2 over Finite Field of size 5
W: Vector space of degree 2 and dimension 0 over Finite Field of size 5
Basis matrix:
[]
sage: quotient_char_p(I, 3)[0]
Vector space quotient V/W of dimension 2 over Finite Field of size 3 where
V: Vector space of dimension 2 over Finite Field of size 3
W: Vector space of degree 2 and dimension 0 over Finite Field of size 3
Basis matrix:
[]

sage: I = K.factor(13)[0][0]; I
Fractional ideal (-3*i - 2)
sage: I.residue_class_degree()
1
sage: quotient_char_p(I, 13)[0]
Vector space quotient V/W of dimension 1 over Finite Field of size 13 where
V: Vector space of dimension 2 over Finite Field of size 13
W: Vector space of degree 2 and dimension 1 over Finite Field of size 13
Basis matrix:
[1 8]
```

26.4 Class Groups of Number Fields

EXAMPLES:

```
sage: K.<a> = NumberField(x^2 + 23)
sage: I = K.class_group().gen(); I
Fractional ideal class (2, 1/2*a - 1/2)
```

```
sage: J = I * I; J
Fractional ideal class (2, 1/2*a + 1/2)
sage: O = K.OK(); O
Maximal Order in Number Field in a with defining polynomial x^2 + 23
sage: O*(2, 1/2*a + 1/2)
Fractional ideal (2, 1/2*a + 1/2)
sage: (O*(2, 1/2*a + 1/2)).is_principal()
False
sage: (O*(2, 1/2*a + 1/2))^3
Fractional ideal (1/2*a - 3/2)
```

class ClassGroup (*invariants, names, number_field, gens*)

The class group of a number field.

gen (*i=0*)

Return the i-th generator for this class group.

EXAMPLES:

```
sage: C = NumberField(x^2 + 120071, 'a').class_group(); C
Class group of order 500 with structure C250 x C2 of Number Field in a with defining polynom
sage: C.gen(0)
Fractional ideal class (130, 1/2*a + 137/2)
sage: C.gen(1)
Fractional ideal class (7, a)
```

gens ()

Return generators for the class group.

EXAMPLES:

```
sage: K.<a> = NumberField(x^4 + 23)
sage: K.class_group().gens()   # random gens (platform dependent)
[Fractional ideal class (2, 1/2*a^2 - a + 3/2)]
```

ngens ()

Return the number of generators of the class group.

EXAMPLES:

```
sage: C = NumberField(x^2 + x + 23899, 'a').class_group(); C
Class group of order 68 with structure C34 x C2 of Number Field in a with defining polynomia
sage: C.ngens()
2
```

number_field ()

Return the number field that this class group is attached to.

EXAMPLES:

```
sage: C = NumberField(x^2 + 23, 'w').class_group(); C
Class group of order 3 with structure C3 of Number Field in w with defining polynomial x^2 +
sage: C.number_field()
Number Field in w with defining polynomial x^2 + 23
```

class FractionalIdealClass (*ideal, class_group*)

A fractional ideal class in a number field.

EXAMPLES:

```
sage: G = NumberField(x^2 + 23,'a').class_group(); G
Class group of order 3 with structure C3 of Number Field in a with defining polynomial x^2 + 23
sage: I = G.0; I
```

```
Fractional ideal class (2, 1/2*a - 1/2)
sage: I*I
Fractional ideal class (2, 1/2*a + 1/2)
sage: I*I*I
Trivial principal fractional ideal class
```

gens()

Return generators for a representative ideal in this ideal class.

EXAMPLES:

```
sage: K.<w>=QuadraticField(-23)
sage: OK=K.ring_of_integers()
sage: C=OK.class_group()
sage: P2a,P2b=[P for P,e in (2*OK).factor()]
sage: c=C(P2a); c
Fractional ideal class (2, 1/2*w - 1/2)
sage: c.gens()
(2, 1/2*w - 1/2)
```

ideal()

Return a representative ideal in this ideal class.

EXAMPLE:

```
sage: K.<w>=QuadraticField(-23)
sage: OK=K.ring_of_integers()
sage: C=OK.class_group()
sage: P2a,P2b=[P for P,e in (2*OK).factor()]
sage: c=C(P2a); c
Fractional ideal class (2, 1/2*w - 1/2)
sage: c.ideal()
Fractional ideal (2, 1/2*w - 1/2)
```

is_principal()

Returns True iff this ideal class is the trivial (principal) class

EXAMPLES:

```
sage: K.<w>=QuadraticField(-23)
sage: OK=K.ring_of_integers()
sage: C=OK.class_group()
sage: P2a,P2b=[P for P,e in (2*OK).factor()]
sage: c=C(P2a)
sage: c.is_principal()
False
sage: (c^2).is_principal()
False
sage: (c^3).is_principal()
True
```

multiplicative_order()

Return the order of this ideal class in the class group.

EXAMPLE:

```
sage: K.<w>=QuadraticField(-23)
sage: OK=K.ring_of_integers()
sage: C=OK.class_group()
sage: h=C.order(); h
3
sage: P2a,P2b=[P for P,e in (2*OK).factor()]
```

```
sage: c=C(P2a); c
Fractional ideal class (2, 1/2*w - 1/2)
sage: c.order()
3

sage: k.<a> = NumberField(x^2 + 20072); G = k.class_group(); G
Class group of order 76 with structure C38 x C2 of Number Field in a with defining polynomia
sage: [c.order() for c in G.gens()]
[38, 2]
```

order()

Return the order of this ideal class in the class group.

EXAMPLE:

```
sage: K.<w>=QuadraticField(-23)
sage: OK=K.ring_of_integers()
sage: C=OK.class_group()
sage: h=C.order(); h
3
sage: P2a,P2b=[P for P,e in (2*OK).factor()]
sage: c=C(P2a); c
Fractional ideal class (2, 1/2*w - 1/2)
sage: c.order()
3

sage: k.<a> = NumberField(x^2 + 20072); G = k.class_group(); G
Class group of order 76 with structure C38 x C2 of Number Field in a with defining polynomia
sage: [c.order() for c in G.gens()]
[38, 2]
```

reduce()

Return representative for this ideal class that has been reduced using PARI's idealred.

EXAMPLES:

```
sage: k.<a> = NumberField(x^2 + 20072); G = k.class_group(); G
Class group of order 76 with structure C38 x C2 of Number Field in a with defining polynomia
sage: I = G.0; I
Fractional ideal class (41, a + 10)
sage: J = G(I.ideal()^5); J
Fractional ideal class (115856201, 1/2*a + 40407883)
sage: J.reduce()
Fractional ideal class (57, 1/2*a + 44)
```

26.5 Galois Groups of Number Fields

AUTHORS:

- William Stein (2004, 2005): initial version
- David Loeffler (2009): rewrite to give explicit homomorphism groups

TESTS:

Standard test of pickleability:

```
sage: G = NumberField(x^3 + 2, 'alpha').galois_group(type="pari"); G
Galois group PARI group [6, -1, 2, "S3"] of degree 3 of the Number Field in alpha with defining polyn
sage: G == loads(dumps(G))
True

sage: G = NumberField(x^3 + 2, 'alpha').galois_group(names='beta'); G
Galois group of Galois closure in beta of Number Field in alpha with defining polynomial x^3 + 2
sage: G == loads(dumps(G))
True
```

class GaloisGroup (*group, number_field*)

A wrapper around a class representing an abstract transitive group.

This is just a fairly minimal object at present. To get the underlying group, do `G.group()`, and to get the corresponding number field do `G.number_field()`. For a more sophisticated interface use the `type=None` option.

EXAMPLES:

```
sage: K = QQ[2^(1/3)]
sage: G = K.galois_group(type="pari"); G
Galois group PARI group [6, -1, 2, "S3"] of degree 3 of the Number Field in a with defining poly
sage: G.order()
6
sage: G.group()
PARI group [6, -1, 2, "S3"] of degree 3
sage: G.number_field()
Number Field in a with defining polynomial x^3 - 2
```

group()

Return the underlying abstract group.

EXAMPLES:

```
sage: G = NumberField(x^3 + 2*x + 2, 'theta').galois_group(type="pari")
sage: H = G.group(); H
PARI group [6, -1, 2, "S3"] of degree 3
sage: P = H.permutation_group(); P  # optional -- requires Gap optional databases
Transitive group number 2 of degree 3
sage: list(P)                       # optional
[(), (2,3), (1,2), (1,2,3), (1,3,2), (1,3)]
```

number_field()

Return the number field of which this is the Galois group.

EXAMPLES:

```
sage: G = NumberField(x^6 + 2, 't').galois_group(type="pari"); G
Galois group PARI group [12, -1, 3, "D(6) = S(3)[x]2"] of degree 6 of the Number Field in t
sage: G.number_field()
Number Field in t with defining polynomial x^6 + 2
```

order()

Return the order of this Galois group.

EXAMPLES:

```
sage: G = NumberField(x^5 + 2, 'theta_1').galois_group(type="pari"); G
Galois group PARI group [20, -1, 3, "F(5) = 5:4"] of degree 5 of the Number Field in theta_1
sage: G.order()
20
```

class GaloisGroupElement()

An element of a Galois group. This is stored as a permutation, but may also be made to act on elements of the field (generally returning elements of its Galois closure).

EXAMPLE:

```
sage: K.<w> = QuadraticField(-7); G = K.galois_group()
sage: G[1]
(1,2)
sage: G[1](w + 2)
-w + 2

sage: L.<v> = NumberField(x^3 - 2); G = L.galois_group(names='y')
sage: G[1]
(1,2)(3,4)(5,6)
sage: G[1](v)
1/84*y^4 + 13/42*y
sage: G[1]( G[1](v) )
-1/252*y^4 - 55/126*y
```

as_hom()

Return the homomorphism L -> L corresponding to self, where L is the Galois closure of the ambient number field.

EXAMPLE:

```
sage: G = QuadraticField(-7,'w').galois_group()
sage: G[1].as_hom()
Ring endomorphism of Number Field in w with defining polynomial x^2 + 7
Defn: w |--> -w
```

ramification_degree(*P*)

Return the greatest value of v such that s acts trivially modulo P^v. Should only be used if P is prime and s is in the decomposition group of P.

EXAMPLE:

```
sage: K.<b> = NumberField(x^3 - 3,'a').galois_closure()
sage: G=K.galois_group()
sage: P = K.primes_above(3)[0]
sage: s = hom(K, K, 1/54*b^4 + 1/18*b)
sage: G(s).ramification_degree(P)
4
```

class GaloisGroup_subgroup(*ambient, elts*)

A subgroup of a Galois group, as returned by functions such as `decomposition_group`.

fixed_field()

Return the fixed field of this subgroup (as a subfield of the Galois closure of the number field associated to the ambient Galois group).

EXAMPLE:

```
sage: L.<a> = NumberField(x^4 + 1)
sage: G = L.galois_group()
sage: H = G.decomposition_group(L.primes_above(3)[0])
sage: H.fixed_field()
(Number Field in a0 with defining polynomial x^2 + 2, Ring morphism:
From: Number Field in a0 with defining polynomial x^2 + 2
To:   Number Field in a with defining polynomial x^4 + 1
Defn: a0 |--> a^3 + a)
```

class GaloisGroup_v1 (*group, number_field*)

A wrapper around a class representing an abstract transitive group.

This is just a fairly minimal object at present. To get the underlying group, do `G.group()`, and to get the corresponding number field do `G.number_field()`. For a more sophisticated interface use the `type=None` option.

EXAMPLES:

```
sage: K = QQ[2^(1/3)]
sage: G = K.galois_group(type="pari"); G
Galois group PARI group [6, -1, 2, "S3"] of degree 3 of the Number Field in a with defining poly
sage: G.order()
6
sage: G.group()
PARI group [6, -1, 2, "S3"] of degree 3
sage: G.number_field()
Number Field in a with defining polynomial x^3 - 2
```

group()

Return the underlying abstract group.

EXAMPLES:

```
sage: G = NumberField(x^3 + 2*x + 2, 'theta').galois_group(type="pari")
sage: H = G.group(); H
PARI group [6, -1, 2, "S3"] of degree 3
sage: P = H.permutation_group(); P  # optional -- requires Gap optional databases
Transitive group number 2 of degree 3
sage: list(P)                       # optional
[(), (2,3), (1,2), (1,2,3), (1,3,2), (1,3)]
```

number_field()

Return the number field of which this is the Galois group.

EXAMPLES:

```
sage: G = NumberField(x^6 + 2, 't').galois_group(type="pari"); G
Galois group PARI group [12, -1, 3, "D(6) = S(3)[x]2"] of degree 6 of the Number Field in t
sage: G.number_field()
Number Field in t with defining polynomial x^6 + 2
```

order()

Return the order of this Galois group.

EXAMPLES:

```
sage: G = NumberField(x^5 + 2, 'theta_1').galois_group(type="pari"); G
Galois group PARI group [20, -1, 3, "F(5) = 5:4"] of degree 5 of the Number Field in theta_1
sage: G.order()
20
```

class GaloisGroup_v2 (*number_field, names=None*)

The Galois group of an (absolute) number field.

Note: We define the Galois group of a non-normal field K to be the Galois group of its Galois closure L, and elements are stored as permutations of the roots of the defining polynomial of L, *not* as permutations of the roots (in L) of the defining polynomial of K. The latter would probably be preferable, but is harder to implement. Thus the permutation group that is returned is always simply-transitive.

The 'arithmetical' features (decomposition and ramification groups, Artin symbols etc) are only available for Galois fields.

artin_symbol(*P*)

Return the Artin symbol $\left(\frac{K/\mathbf{Q}}{\mathfrak{P}}\right)$, where K is the number field of self, and $\mathfrak{P}$ is an unramified prime ideal. This is the unique element s of the decomposition group of $\mathfrak{P}$ such that $s(x) = x^p \bmod \mathfrak{P}$, where p is the residue characteristic of $\mathfrak{P}$.

EXAMPLES:

```
sage: K.<b> = NumberField(x^4 - 2*x^2 + 2, 'a').galois_closure()
sage: G = K.galois_group()
sage: [G.artin_symbol(P) for P in K.primes_above(7)]
[(1,4)(2,3)(5,8)(6,7), (1,4)(2,3)(5,8)(6,7), (1,5)(2,6)(3,7)(4,8), (1,5)(2,6)(3,7)(4,8)]
sage: G.artin_symbol(17)
...
ValueError: Fractional ideal (17) is not prime
sage: QuadraticField(-7,'c').galois_group().artin_symbol(13)
(1,2)
sage: G.artin_symbol(K.primes_above(2)[0])
...
ValueError: Fractional ideal (...) is ramified
```

decomposition_group(*P*)

Decomposition group of a prime ideal P, i.e. the subgroup of elements that map P to itself. This is the same as the Galois group of the extension of local fields obtained by completing at P.

This function will raise an error if P is not prime or the given number field is not Galois.

EXAMPLE:

```
sage: K.<a> = NumberField(x^4 - 2*x^2 + 2,'b').galois_closure()
sage: P = K.ideal([17, a^2])
sage: G = K.galois_group()
sage: G.decomposition_group(P)
Subgroup [(), (1,8)(2,7)(3,6)(4,5)] of Galois group of Number Field in a with defining polyr
sage: G.decomposition_group(P^2)
...
ValueError: Fractional ideal (...) is not prime
sage: G.decomposition_group(17)
...
ValueError: Fractional ideal (17) is not prime
```

inertia_group(*P*)

Return the inertia group of the prime P, i.e. the group of elements acting trivially modulo P. This is just the 0th ramification group of P.

EXAMPLE:

```
sage: K.<b> = NumberField(x^2 - 3,'a')
sage: G = K.galois_group()
sage: G.inertia_group(K.primes_above(2)[0])
Galois group of Number Field in b with defining polynomial x^2 - 3
sage: G.inertia_group(K.primes_above(5)[0])
Subgroup [()] of Galois group of Number Field in b with defining polynomial x^2 - 3
```

is_galois()

Return True if the underlying number field of self is actually Galois.

EXAMPLE:

```
sage: NumberField(x^3 - x + 1,'a').galois_group(names='b').is_galois()
False
sage: NumberField(x^2 - x + 1,'a').galois_group().is_galois()
True
```

list()
List of the elements of self.
EXAMPLE:

```
sage: NumberField(x^3 - 3*x + 1,'a').galois_group().list()
[(), (1,2,3), (1,3,2)]
```

ngens()
Number of generators of self.
EXAMPLE:

```
sage: QuadraticField(-23, 'a').galois_group().ngens()
1
```

number_field()
The ambient number field.
EXAMPLE:

```
sage: K = NumberField(x^3 - x + 1, 'a')
sage: K.galois_group(names='b').number_field() is K
True
```

ramification_breaks(*P*)
Return the set of ramification breaks of the prime ideal P, i.e. the set of indices i such that the ramification group $G_{i+1} \neq G_i$. This is only defined for Galois fields.
EXAMPLE:

```
sage: K.<b> = NumberField(x^8 - 20*x^6 + 104*x^4 - 40*x^2 + 1156)
sage: G = K.galois_group()
sage: P = K.primes_above(2)[0]
sage: G.ramification_breaks(P)
{1, 3, 5}
sage: min( [ G.ramification_group(P, i).order() / G.ramification_group(P, i+1).order() for i
2
```

ramification_group(*P*, *v*)
Return the vth ramification group of self for the prime P, i.e. the set of elements s of self such that s acts trivially modulo P^(v+1). This is only defined for Galois fields.
EXAMPLE:

```
sage: K.<b> = NumberField(x^3 - 3,'a').galois_closure()
sage: G=K.galois_group()
sage: P = K.primes_above(3)[0]
sage: G.ramification_group(P, 3)
Subgroup [(), (1,3,6)(2,4,5), (1,6,3)(2,5,4)] of Galois group of Number Field in b with defi
sage: G.ramification_group(P, 5)
Subgroup [()] of Galois group of Number Field in b with defining polynomial x^6 + 60*x^3 + 3
```

splitting_field()
The Galois closure of the ambient number field.
EXAMPLE:

```
sage: K = NumberField(x^3 - x + 1, 'a')
sage: K.galois_group(names='b').splitting_field()
Number Field in b with defining polynomial x^6 - 14*x^4 - 20*x^3 + 49*x^2 + 140*x + 307
sage: L = QuadraticField(-23, 'c'); L.galois_group().splitting_field() is L
True
```

subgroup(*elts*)
Return the subgroup of self with the given elements. Mostly for internal use.

EXAMPLE:

```
sage: G = NumberField(x^3 - x - 1,'a').galois_closure('b').galois_group()
sage: G.subgroup([ G(1), G([(1,5,2),(3,4,6)]), G([(1,2,5),(3,6,4)])])
Subgroup [(), (1,5,2)(3,4,6), (1,2,5)(3,6,4)] of Galois group of Number Field in b with defi
```

26.6 Field of Algebraic Numbers

AUTHOR:

- Carl Witty (2007-01-27): initial version
- Carl Witty (2007-10-29): massive rewrite to support complex as well as real numbers

This is an implementation of the algebraic numbers (the complex numbers which are the zero of a polynomial in $\mathbf{Z}[x]$; in other words, the algebraic closure of $\mathbf{Q}$, with an embedding into $\mathbf{C}$). All computations are exact. We also include an implementation of the algebraic reals (the intersection of the algebraic numbers with $\mathbf{R}$). The field of algebraic numbers $\overline{\mathbf{Q}}$ is available with abbreviation `QQbar`; the field of algebraic reals has abbreviation `AA`.

As with many other implementations of the algebraic numbers, we try hard to avoid computing a number field and working in the number field; instead, we use floating-point interval arithmetic whenever possible (basically whenever we need to prove non-equalities), and resort to symbolic computation only as needed (basically to prove equalities).

Algebraic numbers exist in one of the following forms:

- a rational number
- the product of a rational number and an n'th root of unity
- the sum, difference, product, or quotient of algebraic numbers
- the negation, inverse, absolute value, norm, real part, imaginary part, or complex conjugate of an algebraic number
- a particular root of a polynomial, given as a polynomial with algebraic coefficients together with an isolating interval (given as a `RealIntervalFieldElement`) which encloses exactly one root, and the multiplicity of the root
- a polynomial in one generator, where the generator is an algebraic number given as the root of an irreducible polynomial with integral coefficients and the polynomial is given as a `NumberFieldElement`.

The multiplicative subgroup of the algebraic numbers generated by the rational numbers and the roots of unity is handled particularly efficiently, as long as these roots of unity come from the `QQbar.zeta()` method. Cyclotomic fields in general are fairly efficient, again as long as they are derived from `QQbar.zeta()`.

An algebraic number can be coerced into `ComplexIntervalField` (or `RealIntervalField`, for algebraic reals); every algebraic number has a cached interval of the highest precision yet calculated.

Everything is done with intervals except for comparisons. By default, comparisons compute the two algebraic numbers with 128-bit precision intervals; if this does not suffice to prove that the numbers are different, then we fall back on exact computation.

Note that division involves an implicit comparison of the divisor against zero, and may thus trigger exact computation.

Also, using an algebraic number in the leading coefficient of a polynomial also involves an implicit comparison against zero, which again may trigger exact computation.

Note that we work fairly hard to avoid computing new number fields; to help, we keep a lattice of already-computed number fields and their inclusions.

EXAMPLES:

```
sage: sqrt(AA(2)) > 0
True
sage: (sqrt(5 + 2*sqrt(QQbar(6))) - sqrt(QQbar(3)))^2 == 2
True
sage: AA((sqrt(5 + 2*sqrt(6)) - sqrt(3))^2) == 2
True
```

For a monic cubic polynomial $x^3 + bx^2 + cx + d$ with roots $s1$, $s2$, $s3$, the discriminant is defined as $(s1 - s2)^2(s1 - s3)^2(s2 - s3)^2$ and can be computed as $b^2c^2 - 4b^3d - 4c^3 + 18bcd - 27d^2$. We can test that these definitions do give the same result:

```
sage: def disc1(b, c, d):
...       return b^2*c^2 - 4*b^3*d - 4*c^3 + 18*b*c*d - 27*d^2
sage: def disc2(s1, s2, s3):
...       return ((s1-s2)*(s1-s3)*(s2-s3))^2
sage: x = polygen(AA)
sage: p = x*(x-2)*(x-4)
sage: cp = AA.common_polynomial(p)
sage: d, c, b, _ = p.list()
sage: s1 = AA.polynomial_root(cp, RIF(-1, 1))
sage: s2 = AA.polynomial_root(cp, RIF(1, 3))
sage: s3 = AA.polynomial_root(cp, RIF(3, 5))
sage: disc1(b, c, d) == disc2(s1, s2, s3)
True
sage: p = p + 1
sage: cp = AA.common_polynomial(p)
sage: d, c, b, _ = p.list()
sage: s1 = AA.polynomial_root(cp, RIF(-1, 1))
sage: s2 = AA.polynomial_root(cp, RIF(1, 3))
sage: s3 = AA.polynomial_root(cp, RIF(3, 5))
sage: disc1(b, c, d) == disc2(s1, s2, s3)
True
sage: p = (x-sqrt(AA(2)))*(x-AA(2).nth_root(3))*(x-sqrt(AA(3)))
sage: cp = AA.common_polynomial(p)
sage: d, c, b, _ = p.list()
sage: s1 = AA.polynomial_root(cp, RIF(1.4, 1.5))
sage: s2 = AA.polynomial_root(cp, RIF(1.7, 1.8))
sage: s3 = AA.polynomial_root(cp, RIF(1.2, 1.3))
sage: disc1(b, c, d) == disc2(s1, s2, s3)
True
```

We can coerce from symbolic expressions:

```
sage: QQbar(sqrt(-5))
2.236067977499790?*I
sage: AA(sqrt(2) + sqrt(3))
3.146264369941973?
sage: AA(sqrt(2)) + sqrt(3)
3.146264369941973?
sage: sqrt(2) + QQbar(sqrt(3))
3.146264369941973?
sage: QQbar(I)
1*I
sage: AA(I)
...
TypeError: Illegal initializer for algebraic number
```

```
sage: QQbar(I * golden_ratio)
1.618033988749895?*I
sage: AA(golden_ratio)^2 - AA(golden_ratio)
1
sage: QQbar((-8)^(1/3))
1.000000000000000? + 1.732050807568878?*I
sage: AA((-8)^(1/3))
-2
sage: QQbar((-4)^(1/4))
1 + 1*I
sage: AA((-4)^(1/4))
...
ValueError: Cannot coerce algebraic number with non-zero imaginary part to algebraic real
```

Note the different behavior in taking roots: for `AA` we prefer real roots if they exist, but for `QQbar` we take the principal root:

```
sage: AA(-1)^(1/3)
-1
sage: QQbar(-1)^(1/3)
0.500000000000000? + 0.866025403784439?*I
```

We can explicitly coerce from $\mathbf{Q}[I]$. (Technically, this is not quite kosher, since $\mathbf{Q}[I]$ doesn't come with an embedding; we do not know whether the field generator is supposed to map to $+I$ or $-I$. We assume that for any quadratic field with polynomial $x^2 + 1$, the generator maps to $+I$.):

```
sage: K.<im> = QQ[I]
sage: pythag = QQbar(3/5 + 4*im/5); pythag
4/5*I + 3/5
sage: pythag.abs() == 1
True
```

However, implicit coercion from $\mathbf{Q}[I]$ is not allowed:

```
sage: QQbar(1) + im
...
TypeError: unsupported operand parent(s) for '+': 'Algebraic Field' and 'Number Field in I with defi
```

We can implicitly coerce from algebraic reals to algebraic numbers:

```
sage: a = QQbar(1); print a, a.parent()
1 Algebraic Field
sage: b = AA(1); print b, b.parent()
1 Algebraic Real Field
sage: c = a + b; print c, c.parent()
2 Algebraic Field
```

Some computation with radicals:

```
sage: phi = (1 + sqrt(AA(5))) / 2
sage: phi^2 == phi + 1
True
sage: tau = (1 - sqrt(AA(5))) / 2
sage: tau^2 == tau + 1
True
sage: phi + tau == 1
```

```
True
sage: tau < 0
True

sage: rt23 = sqrt(AA(2/3))
sage: rt35 = sqrt(AA(3/5))
sage: rt25 = sqrt(AA(2/5))
sage: rt23 * rt35 == rt25
True
```

The Sage rings `AA` and `QQbar` can decide equalities between radical expressions (over the reals and complex numbers respectively):

```
sage: a = AA((2/(3*sqrt(3)) + 10/27)^(1/3) - 2/(9*(2/(3*sqrt(3)) + 10/27)^(1/3)) + 1/3)
sage: a
1.000000000000000?
sage: a == 1
True
```

Algebraic numbers which are known to be rational print as rationals; otherwise they print as intervals (with 53-bit precision):

```
sage: AA(2)/3
2/3
sage: QQbar(5/7)
5/7
sage: QQbar(1/3 - 1/4*I)
-1/4*I + 1/3
sage: two = QQbar(4).nth_root(4)^2; two
2.000000000000000?
sage: two == 2; two
True
2
sage: phi
1.618033988749895?
```

We can find the real and imaginary parts of an algebraic number (exactly):

```
sage: r = QQbar.polynomial_root(x^5 - x - 1, CIF(RIF(0.1, 0.2), RIF(1.0, 1.1))); r
0.1812324444698754? + 1.083954101317711?*I
sage: r.real()
0.1812324444698754?
sage: r.imag()
1.083954101317711?
sage: r.minpoly()
x^5 - x - 1
sage: r.real().minpoly()
x^10 + 3/16*x^6 + 11/32*x^5 - 1/64*x^2 + 1/128*x - 1/1024
sage: r.imag().minpoly() # this takes a long time (143s on my laptop)
x^20 - 5/8*x^16 - 95/256*x^12 - 625/1024*x^10 - 5/512*x^8 - 1875/8192*x^6 + 25/4096*x^4 - 625/32768*x
```

We can find the absolute value and norm of an algebraic number exactly. (Note that we define the norm as the product of a number and its complex conjugate; this is the algebraic definition of norm, if we view `QQbar` as `AA[I]`.):

```
sage: R.<x> = QQ[]
sage: r = (x^3 + 8).roots(QQbar, multiplicities=False)[2]; r
```

```
1.000000000000000? + 1.732050807568878?*I
sage: r.abs() == 2
True
sage: r.norm() == 4
True
sage: (r+I).norm().minpoly()
x^2 - 10*x + 13
sage: r = AA.polynomial_root(x^2 - x - 1, RIF(-1, 0)); r
-0.6180339887498895?
sage: r.abs().minpoly()
x^2 + x - 1
```

We can compute the multiplicative order of an algebraic number:

```
sage: QQbar(-1/2 + I*sqrt(3)/2).multiplicative_order()
3
sage: QQbar(-sqrt(3)/2 + I/2).multiplicative_order()
12
sage: QQbar.zeta(12345).multiplicative_order()
12345
```

Cyclotomic fields are very fast as long as we only multiply and divide:

```
sage: z3_3 = QQbar.zeta(3) * 3
sage: z4_4 = QQbar.zeta(4) * 4
sage: z5_5 = QQbar.zeta(5) * 5
sage: z6_6 = QQbar.zeta(6) * 6
sage: z20_20 = QQbar.zeta(20) * 20
sage: z3_3 * z4_4 * z5_5 * z6_6 * z20_20
7200
```

And they are still pretty fast even if you add and subtract, and trigger exact computation:

```
sage: (z3_3 + z4_4 + z5_5 + z6_6 + z20_20)._exact_value()
4*zeta60^15 + 5*zeta60^12 + 9*zeta60^10 + 20*zeta60^3 - 3 where a^16 + a^14 - a^10 - a^8 - a^6 + a^2
```

The paper "ARPREC: An Arbitrary Precision Computation Package" by Bailey, Yozo, Li and Thompson discusses this result. Evidently it is difficult to find, but we can easily verify it.

```
sage: alpha = QQbar.polynomial_root(x^10 + x^9 - x^7 - x^6 - x^5 - x^4 - x^3 + x + 1, RIF(1, 1.2))
sage: lhs = alpha^630 - 1
sage: rhs_num = (alpha^315 - 1) * (alpha^210 - 1) * (alpha^126 - 1)^2 * (alpha^90 - 1) * (alpha^3 - 1
sage: rhs_den = (alpha^35 - 1) * (alpha^15 - 1)^2 * (alpha^14 - 1)^2 * (alpha^5 - 1)^6 * alpha^68
sage: rhs = rhs_num / rhs_den
sage: lhs
2.642040335819351?e44
sage: rhs
2.642040335819351?e44
sage: lhs - rhs
0.?e29
sage: lhs == rhs
True
sage: lhs - rhs
0
sage: lhs._exact_value()
-2424946098563164022648228330623508477694745 40*a^9 + 8622954720682894724916548377859479062346807 03*a
```

Given an algebraic number, we can produce a string that will reproduce that algebraic number if you type the string into Sage. We can see that until exact computation is triggered, an algebraic number keeps track of the computation steps used to produce that number:

```
sage: rt2 = AA(sqrt(2))
sage: rt3 = AA(sqrt(3))
sage: n = (rt2 + rt3)^5; n
308.30180017229752?
sage: sage_input(n)
v1 = sqrt(AA(2)) + sqrt(AA(3))
v2 = v1*v1
v2*v2*v1
```

But once exact computation is triggered, the computation tree is discarded, and we get a way to produce the number directly:

```
sage: n == 109*rt2 + 89*rt3
True
sage: sage_input(n)
R.<x> = AA[]
v = AA.polynomial_root(AA.common_polynomial(x^4 - 4*x^2 + 1), RIF(RR(0.51763809020504148), RR(0.5176
-109*v^3 - 89*v^2 + 327*v + 178
```

We can also see that some computations (basically, those which are easy to perform exactly) are performed directly, instead of storing the computation tree:

```
sage: z3_3 = QQbar.zeta(3) * 3
sage: z4_4 = QQbar.zeta(4) * 4
sage: z5_5 = QQbar.zeta(5) * 5
sage: sage_input(z3_3 * z4_4 * z5_5)
-60*QQbar.zeta(60)^17
```

Note that the `verify=True` argument to `sage_input` will always trigger exact computation, so running `sage_input` twice in a row on the same number will actually give different answers. In the following, running `sage_input` on `n` will also trigger exact computation on `rt2`, as you can see by the fact that the third output is different than the first:

```
sage: rt2 = AA(sqrt(2))
sage: n = rt2^2
sage: sage_input(n, verify=True)
# Verified
v = sqrt(AA(2))
v*v
sage: sage_input(n, verify=True)
# Verified
AA(2)
sage: n = rt2^2
sage: sage_input(n, verify=True)
# Verified
AA(2)
```

Just for fun, let's try `sage_input` on a very complicated expression:

```
sage: rt2 = sqrt(AA(2))
sage: rt3 = sqrt(QQbar(3))
sage: x = polygen(QQbar)
```

```
sage: nrt3 = AA.polynomial_root((x-rt2)*(x+rt3), RIF(-2, -1))
sage: one = AA.polynomial_root((x-rt2)*(x-rt3)*(x-nrt3)*(x-1-rt3-nrt3), RIF(0.9, 1.1))
sage: one
1.000000000000000?
sage: sage_input(one, verify=True)
# Verified
R.<x> = QQbar[]
v1 = AA(2)
v2 = QQbar(sqrt(v1))
v3 = QQbar(3)
v4 = sqrt(v3)
v5 = v2*v4
v6 = (1 - v2)*(1 - v4) - 1 - v5
v7 = QQbar(sqrt(v1))
v8 = sqrt(v3)
si1 = v7*v8
cp = AA.common_polynomial(x^2 + ((1 - v7)*(1 + v8) - 1 + si1)*x - si1)
v9 = QQbar.polynomial_root(cp, RIF(-RR(1.7320508075688774), -RR(1.7320508075688772)))
v10 = 1 - v9
v11 = v6 + (v10 - 1)
v12 = -1 - v4 - QQbar.polynomial_root(cp, RIF(-RR(1.7320508075688774), -RR(1.7320508075688772)))
v13 = 1 + v12
v14 = v10*(v6 + v5) - (v6 - v5*v9)
si2 = v5*v9
AA.polynomial_root(AA.common_polynomial(x^4 + (v11 + (v13 - 1))*x^3 + (v14 + (v13*v11 - v11))*x^2 +
sage: one
1
```

We can pickle and unpickle algebraic fields (and they are globally unique):

```
sage: loads(dumps(AlgebraicField())) is AlgebraicField()
True
sage: loads(dumps(AlgebraicRealField())) is AlgebraicRealField()
True
```

We can pickle and unpickle algebraic numbers:

```
sage: loads(dumps(QQbar(10))) == QQbar(10)
True
sage: loads(dumps(QQbar(5/2))) == QQbar(5/2)
True
sage: loads(dumps(QQbar.zeta(5))) == QQbar.zeta(5)
True

sage: t = QQbar(sqrt(2)); type(t._descr)
<class 'sage.rings.qqbar.ANRoot'>
sage: loads(dumps(t)) == QQbar(sqrt(2))
True

sage: t.exactify(); type(t._descr)
<class 'sage.rings.qqbar.ANExtensionElement'>
sage: loads(dumps(t)) == QQbar(sqrt(2))
True

sage: t = ~QQbar(sqrt(2)); type(t._descr)
<class 'sage.rings.qqbar.ANUnaryExpr'>
sage: loads(dumps(t)) == 1/QQbar(sqrt(2))
```

```
True

sage: t = QQbar(sqrt(2)) + QQbar(sqrt(3)); type(t._descr)
<class 'sage.rings.qqbar.ANBinaryExpr'>
sage: loads(dumps(t)) == QQbar(sqrt(2)) + QQbar(sqrt(3))
True
```

We can convert elements of QQbar and AA into the following types: float, complex, RDF, CDF, RR, CC, RIF, CIF, ZZ, and QQ, with a few exceptions. (For the arbitrary-precision types, RR, CC, RIF, and CIF, it can convert into a field of arbitrary precision.)

Converting from QQbar to a real type (float, RDF, RR, RIF, ZZ, or QQ) succeeds only if the QQbar is actually real (has an imaginary component of exactly zero). Converting from either AA or QQbar to ZZ or QQ succeeds only if the number actually is an integer or rational. If conversion fails, a ValueError will be raised.

Here are examples of all of these conversions:

```
sage: all_vals = [AA(42), AA(22/7), AA(golden_ratio), QQbar(-13), QQbar(89/55), QQbar(-sqrt(7)), QQba
sage: def convert_test_all(ty):
...       def convert_test(v):
...           try:
...               return ty(v)
...           except ValueError:
...               return None
...       return map(convert_test, all_vals)
sage: convert_test_all(float)
[42.0, 3.1428571428571432, 1.6180339887498949, -13.0, 1.6181818181818182, -2.6457513110645907, None]
sage: convert_test_all(complex)
[(42+0j), (3.1428571428571432+0j), (1.6180339887498949+0j), (-13+0j), (1.6181818181818182+0j), (-2.64
sage: convert_test_all(RDF)
[42.0, 3.14285714286, 1.61803398875, -13.0, 1.61818181818, -2.64575131106, None]

```

class ANBinaryExpr (*left, right, op*)

exactify()

TESTS:

We check to make sure that this method still works even. We do this by increasing the recursion level at each step and decrease it before we return:

```
sage: import sys; sys.getrecursionlimit()
1000
sage: s = SFASchur(QQ)
sage: a=s([3,2]).expand(8)(flatten([[QQbar.zeta(3)^d for d in range(3)], [QQbar.zeta(5)^d fo
```

```
sage: a.exactify(); a #long
0
sage: sys.getrecursionlimit()
1000
```

handle_sage_input(*sib, coerce, is_qqbar*)

Produce an expression which will reproduce this value when evaluated, and an indication of whether this value is worth sharing (always True for ANBinaryExpr).

EXAMPLES:

```
sage: sage_input(2 + sqrt(AA(2)), verify=True)
# Verified
2 + sqrt(AA(2))
sage: sage_input(sqrt(AA(2)) + 2, verify=True)
# Verified
sqrt(AA(2)) + 2
sage: sage_input(2 - sqrt(AA(2)), verify=True)
# Verified
2 - sqrt(AA(2))
sage: sage_input(2 / sqrt(AA(2)), verify=True)
# Verified
2/sqrt(AA(2))
sage: sage_input(2 + (-1*sqrt(AA(2))), verify=True)
# Verified
2 - sqrt(AA(2))
sage: sage_input(2*sqrt(AA(2)), verify=True)
# Verified
2*sqrt(AA(2))
sage: rt2 = sqrt(AA(2))
sage: one = rt2/rt2
sage: n = one+3
sage: sage_input(n)
v = sqrt(AA(2))
v/v + 3
sage: one == 1
True
sage: sage_input(n)
1 + AA(3)
sage: rt3 = QQbar(sqrt(3))
sage: one = rt3/rt3
sage: n = sqrt(AA(2))+one
sage: one == 1
True
sage: sage_input(n)
QQbar(sqrt(AA(2))) + 1
sage: from sage.rings.qqbar import *
sage: from sage.misc.sage_input import SageInputBuilder
sage: sib = SageInputBuilder()
sage: binexp = ANBinaryExpr(AA(3), AA(5), '*')
sage: binexp.handle_sage_input(sib, False, False)
({binop:* {atomic:3} {call: {atomic:AA}({atomic:5})}}, True)
sage: binexp.handle_sage_input(sib, False, True)
({call: {atomic:QQbar}({binop:* {atomic:3} {call: {atomic:AA}({atomic:5})}})}, True)
```

is_complex()

kind()

class **ANDescr**()

An AlgebraicNumber or AlgebraicReal is a wrapper around an ANDescr object. ANDescr is an

abstract base class, which should never be directly instantiated; its concrete subclasses are ANRational, ANBinaryExpr, ANUnaryExpr, ANRootOfUnity, ANRoot, and ANExtensionElement. ANDescr and all of its subclasses are private, and should not be used directly.

abs(*n*)

conjugate(*n*)

imag(*n*)

invert(*n*)

is_exact()

Returns True if self is an ANRational, ANRootOfUnity, or ANExtensionElement.

EXAMPLES:

```
sage: from sage.rings.qqbar import ANRational
sage: ANRational(1/2).is_exact()
True
sage: QQbar(3+I)._descr.is_exact()
True
sage: QQbar.zeta(17)._descr.is_exact()
True
```

is_field_element()

Returns True if self is an ANExtensionElement.

EXAMPLES:

```
sage: from sage.rings.qqbar import ANExtensionElement, ANRoot, AlgebraicGenerator
sage: _.<y> = QQ['y']
sage: x = polygen(QQbar)
sage: nf2 = NumberField(y^2 - 2, name='a', check=False)
sage: root2 = ANRoot(x^2 - 2, RIF(1, 2))
sage: gen2 = AlgebraicGenerator(nf2, root2)
sage: sqrt2 = ANExtensionElement(gen2, nf2.gen())
sage: sqrt2.is_field_element()
True
```

is_rational()

Returns True if self is an ANRational object. (Note that the constructors for ANExtensionElement and ANRootOfUnity will actually return ANRational objects for rational numbers.)

EXAMPLES:

```
sage: from sage.rings.qqbar import ANRational
sage: ANRational(3/7).is_rational()
True
```

is_simple()

Checks whether this descriptor represents a value with the same algebraic degree as the number field associated with the descriptor.

Returns True if self is an ANRational, ANRootOfUnit, or a minimal ANExtensionElement.

EXAMPLES:

```
sage: from sage.rings.qqbar import ANRational
sage: ANRational(1/2).is_simple()
True
sage: rt2 = AA(sqrt(2))
sage: rt3 = AA(sqrt(3))
sage: rt2b = rt3 + rt2 - rt3
sage: rt2.exactify()
```

```
sage: rt2._descr.is_simple()
True
sage: rt2b.exactify()
sage: rt2b._descr.is_simple()
False
sage: rt2b.simplify()
sage: rt2b._descr.is_simple()
True
```

neg(*n*)

norm(*n*)

real(*n*)

class **ANExtensionElement**(*generator, value*)

The subclass of ANDescr that represents a number field element in terms of a specific generator. Consists of a polynomial with rational coefficients in terms of the generator, and the generator itself, an AlgebraicGenerator.

abs(*n*)

conjugate(*n*)

exactify()

field_element_value()

gaussian_value()

generator()

handle_sage_input(*sib, coerce, is_qqbar*)

Produce an expression which will reproduce this value when evaluated, and an indication of whether this value is worth sharing (always True, for ANExtensionElement).

EXAMPLES:

```
sage: I = QQbar(I)
sage: sage_input(3+4*I, verify=True)
# Verified
QQbar(3 + 4*I)
sage: v = QQbar.zeta(3) + QQbar.zeta(5)
sage: v - v == 0
True
sage: sage_input(vector(QQbar, (4-3*I, QQbar.zeta(7))), verify=True)
# Verified
vector(QQbar, [4 - 3*I, QQbar.zeta(7)])
sage: sage_input(v, verify=True)
# Verified
v = QQbar.zeta(15)
v^5 + v^3
sage: v = QQbar(sqrt(AA(2)))
sage: v.exactify()
sage: sage_input(v, verify=True)
# Verified
R.<x> = AA[]
QQbar(AA.polynomial_root(AA.common_polynomial(x^2 - 2), RIF(RR(1.4142135623730949), RR(1.414
sage: from sage.rings.qqbar import *
sage: from sage.misc.sage_input import SageInputBuilder
sage: sib = SageInputBuilder()
sage: extel = ANExtensionElement(QQbar_I_generator, QQbar_I_generator.field().gen() + 1)
sage: extel.handle_sage_input(sib, False, True)
({call: {atomic:QQbar}({binop:+ {atomic:1} {atomic:I}})}, True)
```

invert(*n*)

is_complex()

is_exact()

is_field_element()

is_simple()

Checks whether this descriptor represents a value with the same algebraic degree as the number field associated with the descriptor.

For `ANExtensionElement` elements, we check this by comparing the degree of the minimal polynomial to the degree of the field.

EXAMPLES:

```
sage: rt2 = AA(sqrt(2))
sage: rt3 = AA(sqrt(3))
sage: rt2b = rt3 + rt2 - rt3
sage: rt2.exactify()
sage: rt2._descr
a where a^2 - 2 = 0 and a in 1.414213562373095?
sage: rt2._descr.is_simple()
True

sage: rt2b.exactify()
sage: rt2b._descr
a^3 - 3*a where a^4 - 4*a^2 + 1 = 0 and a in 1.931851652578137?
sage: rt2b._descr.is_simple()
False
```

kind()

minpoly()

Compute the minimal polynomial of this algebraic number.

EXAMPLES:

```
sage: a = AA(sqrt(2)) + QQbar(I); a
1.414213562373095? + 1*I
sage: p = a.minpoly(); p
x^4 - 2*x^2 + 9
sage: p(a)
0
```

neg(*n*)

norm(*n*)

rational_argument(*n*)

If the argument of self is 2π times some rational number, return that rational; otherwise, return None.

simplify(*n*)

Compute an exact representation for this descriptor, in the smallest possible number field.

INPUT:

- n – The element of `AA` or `QQbar` corresponding to this descriptor.

EXAMPLES:

```
sage: rt2 = AA(sqrt(2))
sage: rt3 = AA(sqrt(3))
sage: rt2b = rt3 + rt2 - rt3
sage: rt2b.exactify()
sage: rt2b._descr
a^3 - 3*a where a^4 - 4*a^2 + 1 = 0 and a in 1.931851652578137?
```

```
sage: rt2b._descr.simplify(rt2b)
a where a^2 - 2 = 0 and a in 1.414213562373095?
```

class ANRational(*x*)

The subclass of ANDescr that represents an arbitrary rational. This class is private, and should not be used directly.

abs(*n*)

angle()

exactify()

gaussian_value()

generator()

handle_sage_input(*sib, coerce, is_qqbar*)

Produce an expression which will reproduce this value when evaluated, and an indication of whether this value is worth sharing (always False, for rationals).

EXAMPLES:

```
sage: sage_input(QQbar(22/7), verify=True)
# Verified
QQbar(22/7)
sage: sage_input(-AA(3)/5, verify=True)
# Verified
AA(-3/5)
sage: sage_input(vector(AA, (0, 1/2, 1/3)), verify=True)
# Verified
vector(AA, [0, 1/2, 1/3])
sage: from sage.rings.qqbar import *
sage: from sage.misc.sage_input import SageInputBuilder
sage: sib = SageInputBuilder()
sage: rat = ANRational(9/10)
sage: rat.handle_sage_input(sib, False, True)
({call: {atomic:QQbar}({binop:/ {atomic:9} {atomic:10}})}, False)
```

invert(*n*)

is_complex()

is_exact()

is_rational()

is_simple()

Checks whether this descriptor represents a value with the same algebraic degree as the number field associated with the descriptor.

This is always true for rational numbers.

EXAMPLES:

```
sage: AA(1/2)._descr.is_simple()
True
```

kind()

minpoly()

neg(*n*)

rational_argument(*n*)

rational_value()

scale()

class ANRoot (*poly, interval, multiplicity=1, is_pow=None*)

The subclass of ANDescr that represents a particular root of a polynomial with algebraic coefficients. This class is private, and should not be used directly.

conjugate (*n*)

exactify ()

Returns either an ANRational or an ANExtensionElement with the same value as this number.

EXAMPLES:

```
sage: from sage.rings.qqbar import ANRoot
sage: x = polygen(QQbar)
sage: two = ANRoot((x-2)*(x-sqrt(QQbar(2))), RIF(1.9, 2.1))
sage: two.exactify()
2
sage: two.exactify().rational_value()
2
sage: strange = ANRoot(x^2 + sqrt(QQbar(3))*x - sqrt(QQbar(2)), RIF(-0, 1))
sage: strange.exactify()
a where a^8 - 6*a^6 + 5*a^4 - 12*a^2 + 4 = 0 and a in 0.6051012265139511?
```

handle_sage_input (*sib, coerce, is_qqbar*)

Produce an expression which will reproduce this value when evaluated, and an indication of whether this value is worth sharing (always True, for ANRoot).

EXAMPLES:

```
sage: sage_input((AA(3)^(1/2))^(1/3), verify=True)
# Verified
sqrt(AA(3)).nth_root(3)
```

These two examples are too big to verify quickly. (Verification would create a field of degree 28.):

```
sage: sage_input((sqrt(AA(3))^(5/7))^(9/4))
(sqrt(AA(3))^(5/7))^(9/4)
sage: sage_input((sqrt(QQbar(-7))^(5/7))^(9/4))
(sqrt(QQbar(-7))^(5/7))^(9/4)
sage: x = polygen(QQ)
sage: sage_input(AA.polynomial_root(x^2-x-1, RIF(1, 2)), verify=True)
# Verified
R.<x> = AA[]
AA.polynomial_root(AA.common_polynomial(x^2 - x - 1), RIF(RR(1.6180339887498947), RR(1.61803
sage: sage_input(QQbar.polynomial_root(x^3-5, CIF(RIF(-3, 0), RIF(0, 3))), verify=True)
# Verified
R.<x> = AA[]
QQbar.polynomial_root(AA.common_polynomial(x^3 - 5), CIF(RIF(-RR(0.85498797333834853), -RR(0
sage: from sage.rings.qqbar import *
sage: from sage.misc.sage_input import SageInputBuilder
sage: sib = SageInputBuilder()
sage: rt = ANRoot(x^3 - 2, RIF(0, 4))
sage: rt.handle_sage_input(sib, False, True)
({call: {getattr: {atomic:QQbar}.polynomial_root}({call: {getattr: {atomic:AA}.common_polync
```

is_complex ()

kind ()

refine_interval (*interval, prec*)

class ANRootOfUnity (*angle, scale*)

The subclass of ANDescr that represents a rational multiplied by a root of unity. This class is private, and should not be used directly.

Such numbers are represented by a "rational angle" and a rational scale. The "rational angle" is the argument of the number, divided by 2π; so given angle α and scale s, the number is: $s(\cos(2\pi\alpha) + \sin(2\pi\alpha)i)$; or equivalently $s(e^{2\pi\alpha i})$.

We normalize so that $0 < \alpha < \frac{1}{2}$; this requires allowing both positive and negative scales. (Attempts to create an `ANRootOfUnity` with an angle which is a multiple of $\frac{1}{2}$ end up creating an `ANRational` instead.)

abs(*n*)

angle()

conjugate(*n*)

exactify()

field_element_value()

gaussian_value()

generator()

handle_sage_input(*sib, coerce, is_qqbar*)

Produce an expression which will reproduce this value when evaluated, and an indication of whether this value is worth sharing (False for imaginary numbers, True for others).

EXAMPLES:

```
sage: sage_input(22/7*QQbar.zeta(4), verify=True)
# Verified
QQbar(22/7*I)
sage: sage_input((2*QQbar.zeta(12))^4, verify=True)
# Verified
16*QQbar.zeta(3)
sage: sage_input(QQbar.zeta(5)^2, verify=True)
# Verified
QQbar.zeta(5)^2
sage: sage_input(QQbar.zeta(5)^3, verify=True)
# Verified
-QQbar.zeta(10)
sage: sage_input(vector(QQbar, (I, 3*QQbar.zeta(9))), verify=True)
# Verified
vector(QQbar, [I, 3*QQbar.zeta(9)])
sage: from sage.rings.qqbar import *
sage: from sage.misc.sage_input import SageInputBuilder
sage: sib = SageInputBuilder()
sage: rtofunity = ANRootOfUnity(137/500, 1/1000)
sage: rtofunity.handle_sage_input(sib, False, True)
({binop:* {binop:/ {atomic:1} {atomic:1000}} {binop:** {call: {getattr: {atomic:QQbar}.zeta}
```

invert(*n*)

is_complex()

is_exact()

is_simple()

Checks whether this descriptor represents a value with the same algebraic degree as the number field associated with the descriptor.

This is always true for `ANRootOfUnity` elements.

EXAMPLES:

```
sage: a = QQbar.zeta(17)^5 * 4/3; a._descr
4/3*e^(2*pi*I*5/17)
sage: a._descr.is_simple()
True
```

kind()

minpoly()

EXAMPLES:

```
sage: a = QQbar.zeta(7) * 2; a
1.246979603717467? + 1.563662964936060?*I
sage: a.minpoly()
x^6 + 2*x^5 + 4*x^4 + 8*x^3 + 16*x^2 + 32*x + 64
sage: a.minpoly()(a)
0.?e-15 + 0.?e-15*I
sage: a.minpoly()(a) == 0
True
```

neg(*n*)

norm(*n*)

rational_argument(*n*)

scale()

class **ANUnaryExpr**(*arg*, *op*)

exactify()

handle_sage_input(*sib*, *coerce*, *is_qqbar*)

Produce an expression which will reproduce this value when evaluated, and an indication of whether this value is worth sharing (always True for `ANUnaryExpr`).

EXAMPLES:

```
sage: sage_input(-sqrt(AA(2)), verify=True)
# Verified
-sqrt(AA(2))
sage: sage_input(~sqrt(AA(2)), verify=True)
# Verified
~sqrt(AA(2))
sage: sage_input(sqrt(QQbar(-3)).conjugate(), verify=True)
# Verified
sqrt(QQbar(-3)).conjugate()
sage: sage_input(QQbar.zeta(3).real(), verify=True)
# Verified
QQbar.zeta(3).real()
sage: sage_input(QQbar.zeta(3).imag(), verify=True)
# Verified
QQbar.zeta(3).imag()
sage: sage_input(abs(sqrt(QQbar(-3))), verify=True)
# Verified
abs(sqrt(QQbar(-3)))
sage: sage_input(sqrt(QQbar(-3)).norm(), verify=True)
# Verified
sqrt(QQbar(-3)).norm()
sage: sage_input(QQbar(QQbar.zeta(3).real()), verify=True)
# Verified
QQbar(QQbar.zeta(3).real())
sage: from sage.rings.qqbar import *
sage: from sage.misc.sage_input import SageInputBuilder
sage: sib = SageInputBuilder()
sage: unexp = ANUnaryExpr(sqrt(AA(2)), '~')
sage: unexp.handle_sage_input(sib, False, False)
({unop:~ {call: {atomic:sqrt}({call: {atomic:AA}({atomic:2})})}}, True)
```

```
sage: unexp.handle_sage_input(sib, False, True)
({call: {atomic:QQbar}({unop:~ {call: {atomic:sqrt}({call: {atomic:AA}({atomic:2})})}})}, Tr
```

is_complex()

kind()

class **AlgebraicField**()

The field of algebraic numbers.

algebraic_closure()

EXAMPLES:

```
sage: QQbar.algebraic_closure()
Algebraic Field
```

completion(*p, prec, extras={}*)

EXAMPLES:

```
sage: QQbar.completion(infinity, 500)
Complex Field with 500 bits of precision
sage: QQbar.completion(infinity, prec=53, extras={'type':'RDF'})
Complex Double Field
sage: QQbar.completion(infinity, 53) is CC
True
sage: QQbar.completion(3, 20)
...
NotImplementedError
```

gen(*n=0*)

gens()

has_coerce_map_from_impl(*from_par*)

is_atomic_repr()

ngens()

polynomial_root(*poly, interval, multiplicity=1*)

Given a polynomial with algebraic coefficients and an interval enclosing exactly one root of the polynomial, constructs an algebraic real representation of that root.

The polynomial need not be irreducible, or even squarefree; but if the given root is a multiple root, its multiplicity must be specified. (IMPORTANT NOTE: Currently, multiplicity-k roots are handled by taking the $(k-1)$-st derivative of the polynomial. This means that the interval must enclose exactly one root of this derivative.)

The conditions on the arguments (that the interval encloses exactly one root, and that multiple roots match the given multiplicity) are not checked; if they are not satisfied, an error may be thrown (possibly later, when the algebraic number is used), or wrong answers may result.

Note that if you are constructing multiple roots of a single polynomial, it is better to use `QQbar.common_polynomial` to get a shared polynomial.

EXAMPLES:

```
sage: x = polygen(QQbar)
sage: phi = QQbar.polynomial_root(x^2 - x - 1, RIF(0, 2)); phi
1.618033988749895?
sage: p = (x-1)^7 * (x-2)
sage: r = QQbar.polynomial_root(p, RIF(9/10, 11/10), multiplicity=7)
sage: r; r == 1
1
True
sage: p = (x-phi)*(x-sqrt(QQbar(2)))
```

```
sage: r = QQbar.polynomial_root(p, RIF(1, 3/2))
sage: r; r == sqrt(QQbar(2))
1.4142135623730951?
True
```

zeta(*n=4*)

Returns a primitive n'th root of unity, specifically $\exp(2 * \pi * i/n)$.

EXAMPLES:

```
sage: QQbar.zeta(1)
1
sage: QQbar.zeta(2)
-1
sage: QQbar.zeta(3)
-0.500000000000000? + 0.866025403784439?*I
sage: QQbar.zeta(4)
1*I
sage: QQbar.zeta()
1*I
sage: QQbar.zeta(5)
0.3090169943749474? + 0.9510565162951536?*I
sage: QQbar.zeta(314159)
0.9999999997999997? + 0.00002000001689195824?*I
```

class **AlgebraicField_common**()

characteristic()

common_polynomial(*poly*)

Given a polynomial with algebraic coefficients, returns a wrapper that caches high-precision calculations and factorizations. This wrapper can be passed to polynomial_root in place of the polynomial.

Using `common_polynomial` makes no semantic difference, but will improve efficiency if you are dealing with multiple roots of a single polynomial.

EXAMPLES:

```
sage: x = polygen(ZZ)
sage: p = AA.common_polynomial(x^2 - x - 1)
sage: phi = AA.polynomial_root(p, RIF(1, 2))
sage: tau = AA.polynomial_root(p, RIF(-1, 0))
sage: phi + tau == 1
True
sage: phi * tau == -1
True

sage: x = polygen(SR)
sage: p = (x - sqrt(-5)) * (x - sqrt(3)); p
x^2 + (-sqrt(-5) - sqrt(3))*x + sqrt(-5)*sqrt(3)
sage: p = QQbar.common_polynomial(p)
sage: a = QQbar.polynomial_root(p, CIF(RIF(-0.1, 0.1), RIF(2, 3))); a
0.?e-18 + 2.236067977499790?*I
sage: b = QQbar.polynomial_root(p, RIF(1, 2)); b
1.732050807568878?
```

These "common polynomials" can be shared between real and complex roots:

```
sage: p = AA.common_polynomial(x^3 - x - 1)
sage: r1 = AA.polynomial_root(p, RIF(1.3, 1.4)); r1
1.3247179572447467?
```

```
sage: r2 = QQbar.polynomial_root(p, CIF(RIF(-0.7, -0.6), RIF(0.5, 0.6))); r2
-0.6623589786223730? + 0.5622795120623013?*I
```

default_interval_prec()

is_finite()

order()

class AlgebraicGenerator(*field, root*)

An `AlgebraicGenerator` represents both an algebraic number α and the number field $\mathbf{Q}[\alpha]$. There is a single `AlgebraicGenerator` representing $\mathbf{Q}$ (with $\alpha = 0$).

The `AlgebraicGenerator` class is private, and should not be used directly.

conjugate()

If this generator is for the algebraic number α, return a generator for the complex conjugate of α.

field()

is_complex()

is_trivial()

Returns true iff this is the trivial generator (alpha == 1), which does not actually extend the rationals.

EXAMPLES:

```
sage: from sage.rings.qqbar import qq_generator
sage: qq_generator.is_trivial()
True
```

pari_field()

root_as_algebraic()

set_cyclotomic(*n*)

super_poly(*super, checked=None*)

Given a generator `gen` and another generator `super`, where `super` is the result of a tree of `union()` operations where one of the leaves is `gen`, `gen.super_poly(super)` returns a polynomial expressing the value of `gen` in terms of the value of `super` (except that if `gen` is `qq_generator`, `super_poly()` always returns None.)

EXAMPLES:

```
sage: from sage.rings.qqbar import AlgebraicGenerator, ANRoot, qq_generator
sage: _.<y> = QQ['y']
sage: x = polygen(QQbar)
sage: nf2 = NumberField(y^2 - 2, name='a', check=False)
sage: root2 = ANRoot(x^2 - 2, RIF(1, 2))
sage: gen2 = AlgebraicGenerator(nf2, root2)
sage: gen2
Number Field in a with defining polynomial y^2 - 2 with a in 1.414213562373095?
sage: nf3 = NumberField(y^2 - 3, name='a', check=False)
sage: root3 = ANRoot(x^2 - 3, RIF(1, 2))
sage: gen3 = AlgebraicGenerator(nf3, root3)
sage: gen3
Number Field in a with defining polynomial y^2 - 3 with a in 1.732050807568878?
sage: gen2_3 = gen2.union(gen3)
sage: gen2_3
Number Field in a with defining polynomial y^4 - 4*y^2 + 1 with a in 0.5176380902050415?
sage: qq_generator.super_poly(gen2) is None
True
sage: gen2.super_poly(gen2_3)
-a^3 + 3*a
sage: gen3.super_poly(gen2_3)
-a^2 + 2
```

union(*other*)

Given generators `alpha` and `beta`, `alpha.union(beta)` gives a generator for the number field $\mathbf{Q}[\alpha][\beta]$.

EXAMPLES:

```
sage: from sage.rings.qqbar import ANRoot, AlgebraicGenerator, qq_generator
sage: _.<y> = QQ['y']
sage: x = polygen(QQbar)
sage: nf2 = NumberField(y^2 - 2, name='a', check=False)
sage: root2 = ANRoot(x^2 - 2, RIF(1, 2))
sage: gen2 = AlgebraicGenerator(nf2, root2)
sage: gen2
Number Field in a with defining polynomial y^2 - 2 with a in 1.4142135623730950?
sage: nf3 = NumberField(y^2 - 3, name='a', check=False)
sage: root3 = ANRoot(x^2 - 3, RIF(1, 2))
sage: gen3 = AlgebraicGenerator(nf3, root3)
sage: gen3
Number Field in a with defining polynomial y^2 - 3 with a in 1.7320508075688780?
sage: gen2.union(qq_generator) is gen2
True
sage: qq_generator.union(gen3) is gen3
True
sage: gen2.union(gen3)
Number Field in a with defining polynomial y^4 - 4*y^2 + 1 with a in 0.5176380902050415?
```

class AlgebraicGeneratorRelation(*child1, child1_poly, child2, child2_poly, parent*)

A simple class for maintaining relations in the lattice of algebraic extensions.

class AlgebraicNumber(*x*)

The class for algebraic numbers (complex numbers which are the roots of a polynomial with integer coefficients). Much of its functionality is inherited from `AlgebraicNumber_base`.

complex_exact(*field*)

Given a `ComplexField`, return the best possible approximation of this number in that field. Note that if either component is sufficiently close to the halfway point between two floating-point numbers in the corresponding `RealField`, then this will trigger exact computation, which may be very slow.

EXAMPLES:

```
sage: a = QQbar.zeta(9) + I + QQbar.zeta(9).conjugate(); a
1.532088886237957? + 1.000000000000000?*I
sage: a.complex_exact(CIF)
1.532088886237957? + 1*I
```

complex_number(*field*)

Given a `ComplexField`, compute a good approximation to self in that field. The approximation will be off by at most two ulp's in each component, except for components which are very close to zero, which will have an abolute error at most `2**(-(field.prec()-1))`.

EXAMPLES:

```
sage: a = QQbar.zeta(5)
sage: a.complex_number(CIF)
0.309016994374947 + 0.951056516295154*I
sage: (a + a.conjugate()).complex_number(CIF)
0.618033988749895 - 5.42101086242752e-20*I
```

conjugate()

Returns the complex conjugate of self.

EXAMPLES:

```
sage: QQbar(3 + 4*I).conjugate()
3 - 4*I
sage: QQbar.zeta(7).conjugate()
0.6234898018587335? - 0.7818314824680299?*I
sage: QQbar.zeta(7) + QQbar.zeta(7).conjugate()
1.246979603717467? + 0.?e-18*I
```

imag()

interval_exact(*field*)

Given a ComplexIntervalField, compute the best possible approximation of this number in that field. Note that if either the real or imaginary parts of this number are sufficiently close to some floating-point number (and, in particular, if either is exactly representable in floating-point), then this will trigger exact computation, which may be very slow.

EXAMPLES:

```
sage: a = QQbar(I).sqrt(); a
0.7071067811865475? + 0.7071067811865475?*I
sage: a.interval_exact(CIF)
0.7071067811865475? + 0.7071067811865475?*I
sage: b = QQbar((1+I)*sqrt(2)/2)
sage: (a - b).interval(CIF)
0.?e-19 + 0.?e-18*I
sage: (a - b).interval_exact(CIF)
0
```

multiplicative_order()

Compute the multiplicative order of this algebraic real number. That is, find the smallest positive integer n such that $x^n = 1$. If there is no such n, returns +Infinity.

We first check that abs(x) is very close to 1. If so, we compute x exactly and examine its argument.

EXAMPLES:

```
sage: QQbar(-sqrt(3)/2 - I/2).multiplicative_order()
12
sage: QQbar(1).multiplicative_order()
1
sage: QQbar(-I).multiplicative_order()
4
sage: QQbar(707/1000 + 707/1000*I).multiplicative_order()
+Infinity
sage: QQbar(3/5 + 4/5*I).multiplicative_order()
+Infinity
```

norm()

Returns self * self.conjugate(). This is the algebraic definition of norm, if we view QQbar as AA[I].

EXAMPLES:

```
sage: QQbar(3 + 4*I).norm()
25
sage: type(QQbar(I).norm())
<class 'sage.rings.qqbar.AlgebraicReal'>
sage: QQbar.zeta(1007).norm()
1
```

rational_argument()

Returns the argument of self, divided by 2π, as long as this result is rational. Otherwise returns None. Always triggers exact computation.

EXAMPLES:

```
sage: QQbar((1+I)*(sqrt(2)+sqrt(5))).rational_argument()
1/8
sage: QQbar(-1 + I*sqrt(3)).rational_argument()
1/3
sage: QQbar(-1 - I*sqrt(3)).rational_argument()
-1/3
sage: QQbar(3+4*I).rational_argument() is None
True
sage: (QQbar.zeta(7654321)^65536).rational_argument()
65536/7654321
sage: (QQbar.zeta(3)^65536).rational_argument()
1/3
```

real()

class AlgebraicNumber_base(*parent, x*)

This is the common base class for algebraic numbers (complex numbers which are the zero of a polynomial in $\mathbf{Z}[x]$) and algebraic reals (algebraic numbers which happen to be real).

`AlgebraicNumber` objects can be created using `QQbar` (== `AlgebraicNumberField()`), and `AlgebraicReal` objects can be created using `AA` (== `AlgebraicRealField()`). They can be created either by coercing a rational or a symbolic expression, or by using the `QQbar.polynomial_root()` or `AA.polynomial_root()` method to construct a particular root of a polynomial with algebraic coefficients. Also, `AlgebraicNumber` and `AlgebraicReal` are closed under addition, subtraction, multiplication, division (except by 0), and rational powers (including roots), except that for a negative `AlgebraicReal`, taking a power with an even denominator returns an `AlgebraicNumber` instead of an `AlgebraicReal`.

`AlgebraicNumber` and `AlgebraicReal` objects can be approximated to any desired precision. They can be compared exactly; if the two numbers are very close, or are equal, this may require exact computation, which can be extremely slow.

As long as exact computation is not triggered, computation with algebraic numbers should not be too much slower than computation with intervals. As mentioned above, exact computation is triggered when comparing two algebraic numbers which are very close together. This can be an explicit comparison in user code, but the following list of actions (not necessarily complete) can also trigger exact computation:

- Dividing by an algebraic number which is very close to 0.
- Using an algebraic number which is very close to 0 as the leading coefficient in a polynomial.
- Taking a root of an alebraic number which is very close to 0.

The exact definition of "very close" is subject to change; currently, we compute our best approximation of the two numbers using 128-bit arithmetic, and see if that's sufficient to decide the comparison. Note that comparing two algebraic numbers which are actually equal will always trigger exact computation, unless they are actually the same object.

EXAMPLES:

```
sage: sqrt(QQbar(2))
1.414213562373095?
sage: sqrt(QQbar(2))^2 == 2
True
sage: x = polygen(QQbar)
sage: phi = QQbar.polynomial_root(x^2 - x - 1, RIF(1, 2))
sage: phi
1.618033988749895?
sage: phi^2 == phi+1
True
sage: AA(sqrt(65537))
256.0019531175495?
```

as_number_field_element(*minimal=False*)

Returns a number field containing this value, a representation of this value as an element of that number field, and a homomorphism from the number field back to `AA` or `QQbar`.

This may not return the smallest such number field, unless `minimal=True` is specified.

To compute a single number field containing multiple algebraic numbers, use the function `number_field_elements_from_algebraics` instead.

EXAMPLES:

```
sage: QQbar(sqrt(8)).as_number_field_element()
(Number Field in a with defining polynomial y^2 - 2, 2*a, Ring morphism:
    From: Number Field in a with defining polynomial y^2 - 2
    To:   Algebraic Real Field
    Defn: a |--> 1.414213562373095?)
sage: x = polygen(ZZ)
sage: p = x^3 + x^2 + x + 17
sage: (rt,) = p.roots(ring=AA, multiplicities=False); rt
-2.804642726932742?
sage: (nf, elt, hom) = rt.as_number_field_element(); (nf, elt, hom)
(Number Field in a with defining polynomial y^3 - y^2 + y - 17, -a, Ring morphism:
    From: Number Field in a with defining polynomial y^3 - y^2 + y - 17
    To:   Algebraic Real Field
    Defn: a |--> 2.804642726932742?)
sage: hom(elt) == rt
True
```

We see an example where we do not get the minimal number field unless we specify `minimal=True`:

```
sage: rt2 = AA(sqrt(2))
sage: rt3 = AA(sqrt(3))
sage: rt3b = rt2 + rt3 - rt2
sage: rt3b.as_number_field_element()
(Number Field in a with defining polynomial y^4 - 4*y^2 + 1, -a^2 + 2, Ring morphism:
    From: Number Field in a with defining polynomial y^4 - 4*y^2 + 1
    To:   Algebraic Real Field
    Defn: a |--> 0.5176380902050415?)
sage: rt3b.as_number_field_element(minimal=True)
(Number Field in a with defining polynomial y^2 - 3, a, Ring morphism:
    From: Number Field in a with defining polynomial y^2 - 3
    To:   Algebraic Real Field
    Defn: a |--> 1.732050807568878?)
```

degree()

Return the degree of this algebraic number (the degree of its minimal polynomial, or equivalently, the degree of the smallest algebraic extension of the rationals containing this number).

EXAMPLES:

```
sage: QQbar(5/3).degree()
1
sage: sqrt(QQbar(2)).degree()
2
sage: QQbar(17).nth_root(5).degree()
5
sage: sqrt(3+sqrt(QQbar(8))).degree()
2
```

exactify()

Compute an exact representation for this number.

EXAMPLES:

```
sage: two = QQbar(4).nth_root(4)^2
sage: two
2.000000000000000?
sage: two.exactify()
sage: two
2
```

interval (*field*)

Given an interval field (real or complex, as appropriate) of precision p, compute an interval representation of self with `diameter()` at most 2^{-p}; then round that representation into the given field. Here `diameter()` is relative diameter for intervals not containing 0, and absolute diameter for intervals that do contain 0; thus, if the returned interval does not contain 0, it has at least $p - 1$ good bits.

EXAMPLES:

```
sage: RIF64 = RealIntervalField(64)
sage: x = AA(2).sqrt()
sage: y = x*x
sage: y = 1000 * y - 999 * y
sage: y.interval_fast(RIF64)
2.000000000000000?
sage: y.interval(RIF64)
2.0000000000000000?
sage: CIF64 = ComplexIntervalField(64)
sage: x = QQbar.zeta(11)
sage: x.interval_fast(CIF64)
0.84125353283118116897? + 0.54064081745559758?*I
sage: x.interval(CIF64)
0.84125353283118116897? + 0.54064081745559758?*I
```

interval_diameter (*diam*)

Compute an interval representation of self with `diameter()` at most `diam`. The precision of the returned value is unpredictable.

EXAMPLES:

```
sage: AA(2).sqrt().interval_diameter(1e-10)
1.4142135623730950488?
sage: AA(2).sqrt().interval_diameter(1e-30)
1.41421356237309504880168872420969807857?
sage: QQbar(2).sqrt().interval_diameter(1e-10)
1.4142135623730950488?
sage: QQbar(2).sqrt().interval_diameter(1e-30)
1.41421356237309504880168872420969807857?
```

interval_fast (*field*)

Given a `RealIntervalField`, compute the value of this number using interval arithmetic of at least the precision of the field, and return the value in that field. (More precision may be used in the computation.) The returned interval may be arbitrarily imprecise, if this number is the result of a sufficiently long computation chain.

EXAMPLES:

```
sage: x = AA(2).sqrt()
sage: x.interval_fast(RIF)
1.414213562373095?
sage: x.interval_fast(RealIntervalField(200))
1.41421356237309504880168872420969807856967187537694807317667?
sage: x = QQbar(I).sqrt()
sage: x.interval_fast(CIF)
0.7071067811865475? + 0.7071067811865475?*I
```

```
sage: x.interval_fast(RIF)
...
TypeError: Unable to convert number to real interval.
```

minpoly()

Compute the minimal polynomial of this algebraic number. The minimal polynomial is the monic polynomial of least degree having this number as a root; it is unique.

EXAMPLES:

```
sage: QQbar(4).sqrt().minpoly()
x - 2
sage: ((QQbar(2).nth_root(4))^2).minpoly()
x^2 - 2
sage: v = sqrt(QQbar(2)) + sqrt(QQbar(3)); v
3.146264369941973?
sage: p = v.minpoly(); p
x^4 - 10*x^2 + 1
sage: p(RR(v.real()))
1.31006316905768e-14
```

nth_root(*n*)

Return the n-th root of this number.

Note that for odd n and negative real numbers, `AlgebraicReal` and `AlgebraicNumber` values give different answers: `AlgebraicReal` values prefer real results, and `AlgebraicNumber` values return the principal root.

EXAMPLES:

```
sage: AA(-8).nth_root(3)
-2
sage: QQbar(-8).nth_root(3)
1.000000000000000? + 1.732050807568878?*I
sage: QQbar.zeta(12).nth_root(15)
0.9993908270190957? + 0.03489949670250097?*I
```

simplify()

Compute an exact representation for this number, in the smallest possible number field.

EXAMPLES:

```
sage: rt2 = AA(sqrt(2))
sage: rt3 = AA(sqrt(3))
sage: rt2b = rt3 + rt2 - rt3
sage: rt2b.exactify()
sage: rt2b._exact_value()
a^3 - 3*a where a^4 - 4*a^2 + 1 = 0 and a in 1.931851652578137?
sage: rt2b.simplify()
sage: rt2b._exact_value()
a where a^2 - 2 = 0 and a in 1.414213562373095?
```

sqrt()

Return the square root of this number.

EXAMPLES:

```
sage: AA(2).sqrt()
1.414213562373095?
sage: QQbar(I).sqrt()
0.7071067811865475? + 0.7071067811865475?*I
```

class **AlgebraicPolynomialTracker**(*poly*)

Keeps track of a polynomial used for algebraic numbers.

If multiple algebraic numbers are created as roots of a single polynomial, this allows the polynomial and information about the polynomial to be shared. This reduces work if the polynomial must be recomputed at higher precision, or if it must be factored.

This class is private, and should only be constructed by `AA.common_polynomial()` or `QQbar.common_polynomial()`, and should only be used as an argument to `AA.polynomial_root()` or `QQbar.polynomial_root()`. (It doesn't matter whether you create the common polynomial with `AA.common_polynomial()` or `QQbar.common_polynomial()`.)

EXAMPLES:

```
sage: x = polygen(QQbar)
sage: P = QQbar.common_polynomial(x^2 - x - 1)
sage: P
x^2 - x - 1
sage: QQbar.polynomial_root(P, RIF(1, 2))
1.618033988749895?
```

complex_roots (*prec, multiplicity*)

EXAMPLES:

```
sage: x = polygen(ZZ)
sage: cp = AA.common_polynomial(x^4 - 2)
```

Note that the precision is not guaranteed to find the tightest possible interval since complex_roots() depends on the underlying BLAS implementation.

```
sage: cp.complex_roots(30, 1)
[-1.18920711500272...?,
 1.189207115002721?,
 -1.189207115002721?*I,
 1.189207115002721?*I]
```

exactify()

Compute a common field that holds all of the algebraic coefficients of this polynomial, then factor the polynomial over that field. Store the factors for later use (ignoring multiplicity).

factors()

generator()

is_complex()

poly()

class **AlgebraicReal** (*x*)

imag()

Returns the imaginary part of this algebraic real (so it always returns 0).

EXAMPLES:

```
sage: a = AA(sqrt(2) + sqrt(3))
sage: a.imag()
0
sage: parent(a.imag())
Algebraic Real Field
```

interval_exact (*field*)

Given a `RealIntervalField`, compute the best possible approximation of this number in that field. Note that if this number is sufficiently close to some floating-point number (and, in particular, if this number is exactly representable in floating-point), then this will trigger exact computation, which may be very slow.

EXAMPLES:

```
sage: x = AA(2).sqrt()
sage: y = x*x
sage: x.interval(RIF)
1.414213562373095?
sage: x.interval_exact(RIF)
1.414213562373095?
sage: y.interval(RIF)
2.000000000000000?
sage: y.interval_exact(RIF)
2
sage: z = 1 + AA(2).sqrt() / 2^200
sage: z.interval(RIF)
1.000000000000001?
sage: z.interval_exact(RIF)
1.000000000000001?
```

real()

Returns the real part of this algebraic real (so it always returns self).

EXAMPLES:

```
sage: a = AA(sqrt(2) + sqrt(3))
sage: a.real()
3.146264369941973?
sage: a.real() is a
True
```

real_exact(*field*)

Given a `RealField`, compute the best possible approximation of this number in that field. Note that if this number is sufficiently close to the halfway point between two floating-point numbers in the field (for the default round-to-nearest mode) or if the number is sufficiently close to a floating-point number in the field (for directed rounding modes), then this will trigger exact computation, which may be very slow.

The rounding mode of the field is respected.

EXAMPLES:

```
sage: x = AA(2).sqrt()^2
sage: x.real_exact(RR)
2.00000000000000
sage: x.real_exact(RealField(53, rnd='RNDD'))
2.00000000000000
sage: x.real_exact(RealField(53, rnd='RNDU'))
2.00000000000000
sage: x.real_exact(RealField(53, rnd='RNDZ'))
2.00000000000000
sage: (-x).real_exact(RR)
-2.00000000000000
sage: (-x).real_exact(RealField(53, rnd='RNDD'))
-2.00000000000000
sage: (-x).real_exact(RealField(53, rnd='RNDU'))
-2.00000000000000
sage: (-x).real_exact(RealField(53, rnd='RNDZ'))
-2.00000000000000
sage: (x-2).real_exact(RR)
0.000000000000000
sage: (x-2).real_exact(RealField(53, rnd='RNDD'))
0.000000000000000
sage: (x-2).real_exact(RealField(53, rnd='RNDU'))
0.000000000000000
sage: (x-2).real_exact(RealField(53, rnd='RNDZ'))
```

```
0.000000000000000
sage: y = AA(2).sqrt()
sage: y.real_exact(RR)
1.41421356237310
sage: y.real_exact(RealField(53, rnd='RNDD'))
1.41421356237309
sage: y.real_exact(RealField(53, rnd='RNDU'))
1.41421356237310
sage: y.real_exact(RealField(53, rnd='RNDZ'))
1.41421356237309
```

real_number(*field*)

Given a RealField, compute a good approximation to self in that field. The approximation will be off by at most two ulp's, except for numbers which are very close to 0, which will have an absolute error at most 2**(-(field.prec()-1)). Also, the rounding mode of the field is respected.

EXAMPLES:

```
sage: x = AA(2).sqrt()^2
sage: x.real_number(RR)
2.00000000000000
sage: x.real_number(RealField(53, rnd='RNDD'))
1.99999999999999
sage: x.real_number(RealField(53, rnd='RNDU'))
2.00000000000001
sage: x.real_number(RealField(53, rnd='RNDZ'))
1.99999999999999
sage: (-x).real_number(RR)
-2.00000000000000
sage: (-x).real_number(RealField(53, rnd='RNDD'))
-2.00000000000001

sage: y.real_number(RealField(53, rnd='RNDZ'))
1.41421356237309
```

sign()

Compute the sign of this algebraic number (return -1 if negative, 0 if zero, or 1 if positive).

Computes an interval enclosing this number using 128-bit interval arithmetic; if this interval includes 0, then fall back to exact computation (which can be very slow).

EXAMPLES:

```
sage: AA(-5).nth_root(7).sign()
-1
sage: (AA(2).sqrt() - AA(2).sqrt()).sign()
0
```

class AlgebraicRealField()

The field of algebraic reals.

algebraic_closure()

EXAMPLES:

```
sage: AA.algebraic_closure()
Algebraic Field
```

completion(*p, prec, extras={}*)

EXAMPLES:

```
sage: AA.completion(infinity, 500)
Real Field with 500 bits of precision
sage: AA.completion(infinity, prec=53, extras={'type':'RDF'})
Real Double Field
sage: AA.completion(infinity, 53) is RR
True
sage: AA.completion(7, 10)
...
NotImplementedError
```

gen(*n=0*)

gens()

has_coerce_map_from_impl(*from_par*)

is_atomic_repr()

ngens()

polynomial_root(*poly, interval, multiplicity=1*)

Given a polynomial with algebraic coefficients and an interval enclosing exactly one root of the polynomial, constructs an algebraic real representation of that root.

The polynomial need not be irreducible, or even squarefree; but if the given root is a multiple root, its multiplicity must be specified. (IMPORTANT NOTE: Currently, multiplicity-k roots are handled by taking the $(k-1)$-st derivative of the polynomial. This means that the interval must enclose exactly one root of this derivative.)

The conditions on the arguments (that the interval encloses exactly one root, and that multiple roots match the given multiplicity) are not checked; if they are not satisfied, an error may be thrown (possibly later, when the algebraic number is used), or wrong answers may result.

Note that if you are constructing multiple roots of a single polynomial, it is better to use `AA.common_polynomial` (or `QQbar.common_polynomial`; the two are equivalent) to get a shared polynomial.

EXAMPLES:

```
sage: x = polygen(AA)
sage: phi = AA.polynomial_root(x^2 - x - 1, RIF(1, 2)); phi
1.618033988749895?
sage: p = (x-1)^7 * (x-2)
sage: r = AA.polynomial_root(p, RIF(9/10, 11/10), multiplicity=7)
sage: r; r == 1
1.000000000000000?
True
sage: p = (x-phi)*(x-sqrt(AA(2)))
```

```
sage: r = AA.polynomial_root(p, RIF(1, 3/2))
sage: r; r == sqrt(AA(2))
1.414213562373095?
True
```

We allow complex polynomials, as long as the particular root in question is real.

```
sage: K.<im> = QQ[I]
sage: x = polygen(K)
sage: p = (im + 1) * (x^3 - 2); p
(I + 1)*x^3 - 2*I - 2
sage: r = AA.polynomial_root(p, RIF(1, 2)); r^3
2.000000000000000?
```

an_addsub_expr(*a, b, sub*)

an_addsub_gaussian(*a, b, sub*)

an_addsub_rational(*a, b, sub*)

an_addsub_rootunity(*a, b, sub*)

an_addsub_zero(*a, b, sub*)

an_muldiv_element(*a, b, div*)

an_muldiv_expr(*a, b, div*)

an_muldiv_gaussian(*a, b, div*)

an_muldiv_rational(*a, b, div*)

an_muldiv_rootunity(*a, b, div*)

an_muldiv_zero(*a, b, div*)

clear_denominators(*poly*)

Takes a monic polynomial and rescales the variable to get a monic polynomial with "integral" coefficients. Works on any univariate polynomial whose base ring has a `denominator()` method that returns integers; for example, the base ring might be $\mathbf{Q}$ or a number field.

Returns the scale factor and the new polynomial.

(Inspired by Pari's `primitive_pol_to_monic()`.)

We assume that coefficient denominators are "small"; the algorithm factors the denominators, to give the smallest possible scale factor.

EXAMPLES:

```
sage: from sage.rings.qqbar import clear_denominators

sage: _.<x> = QQ['x']
sage: clear_denominators(x + 3/2)
(2, x + 3)
sage: clear_denominators(x^2 + x/2 + 1/4)
(2, x^2 + x + 1)
```

conjugate_expand(*v*)

If the interval `v` (which may be real or complex) includes some purely real numbers, return `v'` containing `v` such that `v' == v'.conjugate()`. Otherwise return `v` unchanged. (Note that if `v' == v'.conjugate()`,

and v' includes one non-real root of a real polynomial, then v' also includes the conjugate of that root. Also note that the diameter of the return value is at most twice the diameter of the input.)

EXAMPLES:

```
sage: from sage.rings.qqbar import conjugate_expand
sage: conjugate_expand(CIF(RIF(0, 1), RIF(1, 2))).str(style='brackets')
'[0.00000000000000000 .. 1.0000000000000000] + [1.0000000000000000 .. 2.0000000000000000]*I'
sage: conjugate_expand(CIF(RIF(0, 1), RIF(0, 1))).str(style='brackets')
'[0.00000000000000000 .. 1.0000000000000000] + [-1.0000000000000000 .. 1.0000000000000000]*I'
sage: conjugate_expand(CIF(RIF(0, 1), RIF(-2, 1))).str(style='brackets')
'[0.00000000000000000 .. 1.0000000000000000] + [-2.0000000000000000 .. 2.0000000000000000]*I'
sage: conjugate_expand(RIF(1, 2)).str(style='brackets')
'[1.0000000000000000 .. 2.0000000000000000]'
```

conjugate_shrink(*v*)

If the interval v includes some purely real numbers, return a real interval containing only those real numbers. Otherwise return v unchanged.

If v includes exactly one root of a real polynomial, and v was returned by conjugate_expand(), then conjugate_shrink(v) still includes that root, and is a RealIntervalFieldElement iff the root in question is real.

EXAMPLES:

```
sage: from sage.rings.qqbar import conjugate_shrink
sage: conjugate_shrink(RIF(3, 4)).str(style='brackets')
'[3.0000000000000000 .. 4.0000000000000000]'
sage: conjugate_shrink(CIF(RIF(1, 2), RIF(1, 2))).str(style='brackets')
'[1.0000000000000000 .. 2.0000000000000000] + [1.0000000000000000 .. 2.0000000000000000]*I'
sage: conjugate_shrink(CIF(RIF(1, 2), RIF(0, 1))).str(style='brackets')
'[1.0000000000000000 .. 2.0000000000000000]'
sage: conjugate_shrink(CIF(RIF(1, 2), RIF(-1, 2))).str(style='brackets')
'[1.0000000000000000 .. 2.0000000000000000]'
```

cyclotomic_generator(*n*)

do_polred(*poly*)

Find the polynomial of lowest discriminant that generates the same field as poly, out of those returned by the Pari polred routine. Returns a triple: (elt_fwd, elt_back, new_poly), where new_poly is the new polynomial, elt_fwd is a polynomial expression for a root of the new polynomial in terms of a root of the original polynomial, and elt_back is a polynomial expression for a root of the original polynomial in terms of a root of the new polynomial.

EXAMPLES:

```
sage: from sage.rings.qqbar import do_polred

sage: _.<x> = QQ['x']
sage: do_polred(x^2-5)
(-1/2*x + 1/2, -2*x + 1, x^2 - x - 1)
sage: do_polred(x^2-x-11)
(-1/3*x + 2/3, -3*x + 2, x^2 - x - 1)
sage: do_polred(x^3 + 123456)
(-1/4*x, -4*x, x^3 - 1929)
```

find_zero_result(*fn, l*)

l is a list of some sort. fn is a function which maps an element of l and a precision into an interval (either real or complex) of that precision, such that for sufficient precision, exactly one element of l results in an interval containing 0. Returns that one element of l.

EXAMPLES:

```
sage: from sage.rings.qqbar import find_zero_result
sage: _.<x> = QQ['x']
sage: delta = 10^(-70)
sage: p1 = x - 1
sage: p2 = x - 1 - delta
sage: p3 = x - 1 + delta
sage: p2 == find_zero_result(lambda p, prec: p(RealIntervalField(prec)(1 + delta)), [p1, p2, p3]
True
```

get_AA_golden_ratio()

is_AlgebraicField(*F*)

is_AlgebraicField_common(*F*)

is_AlgebraicNumber(*x*)

is_AlgebraicReal(*x*)

is_AlgebraicRealField(*F*)

isolating_interval(*intv_fn, pol*)

intv_fn is a function that takes a precision and returns an interval of that precision containing some particular root of pol. (It must return better approximations as the precision increases.) pol is an irreducible polynomial with rational coefficients.

Returns an interval containing at most one root of pol.

EXAMPLES:

```
sage: from sage.rings.qqbar import isolating_interval

sage: _.<x> = QQ['x']
sage: isolating_interval(lambda prec: sqrt(RealIntervalField(prec)(2)), x^2 - 2)
1.4142135623730950488?
```

And an example that requires more precision:

```
sage: delta = 10^(-70)
sage: p = (x - 1) * (x - 1 - delta) * (x - 1 + delta)
sage: isolating_interval(lambda prec: RealIntervalField(prec)(1 + delta), p)
1.000000000000000000000000000000000000000000000000000000000000000000000000000000010000000000000000000000000
```

The function also works with complex intervals and complex roots:

```
sage: p = x^2 - x + 13/36
sage: isolating_interval(lambda prec: ComplexIntervalField(prec)(1/2, 1/3), p)
0.50000000000000000000? + 0.33333333333333334?*I
```

late_import()

number_field_elements_from_algebraics(*numbers, minimal=False*)

Given a sequence of elements of either AA or QQbar (or a mixture), computes a number field containing all of these elements, these elements as members of that number field, and a homomorphism from the number field back to AA or QQbar.

This may not return the smallest such number field, unless minimal=True is specified.

Also, a single number can be passed, rather than a sequence; and any values which are not elements of AA or QQbar will automatically be coerced to QQbar

This function may be useful for efficiency reasons: doing exact computations in the corresponding number field will be faster than doing exact computations directly in `AA` or `QQbar`.

EXAMPLES:

We can use this to compute the splitting field of a polynomial. (Unfortunately this takes an unreasonably long time for non-toy examples.):

```
sage: x = polygen(QQ)
sage: p = x^3 + x^2 + x + 17
sage: rts = p.roots(ring=QQbar, multiplicities=False)
sage: splitting = number_field_elements_from_algebraics(rts)[0]; splitting
Number Field in a with defining polynomial y^6 + 169*y^4 + 7968*y^2 + 121088
sage: p.roots(ring=splitting)
[(-9/2176*a^4 - 1121/2176*a^2 - 1625/136, 1), (9/17408*a^5 + 9/4352*a^4 + 1121/17408*a^3 + 1121/

sage: rt2 = AA(sqrt(2)); rt2
1.414213562373095?
sage: rt3 = AA(sqrt(3)); rt3
1.732050807568878?
sage: qqI = QQbar.zeta(4); qqI
1*I
sage: z3 = QQbar.zeta(3); z3
-0.500000000000000? + 0.866025403784439?*I
sage: rt2b = rt3 + rt2 - rt3; rt2b
1.414213562373095?
sage: rt2c = z3 + rt2 - z3; rt2c
1.414213562373095? + 0.?e-18*I

sage: number_field_elements_from_algebraics(rt2)
(Number Field in a with defining polynomial y^2 - 2, a, Ring morphism:
    From: Number Field in a with defining polynomial y^2 - 2
    To:   Algebraic Real Field
    Defn: a |--> 1.414213562373095?)

sage: number_field_elements_from_algebraics((rt2,rt3))
(Number Field in a with defining polynomial y^4 - 4*y^2 + 1, [-a^3 + 3*a, -a^2 + 2], Ring morphi
    From: Number Field in a with defining polynomial y^4 - 4*y^2 + 1
    To:   Algebraic Real Field
    Defn: a |--> 0.5176380902050415?)
```

We've created `rt2b` in such a way that sage doesn't initially know that it's in a degree-2 extension of $\mathbf{Q}$:

```
sage: number_field_elements_from_algebraics(rt2b)
(Number Field in a with defining polynomial y^4 - 4*y^2 + 1, -a^3 + 3*a, Ring morphism:
    From: Number Field in a with defining polynomial y^4 - 4*y^2 + 1
    To:   Algebraic Real Field
    Defn: a |--> 0.5176380902050415?)
```

We can specify `minimal=True` if we want the smallest number field:

```
sage: number_field_elements_from_algebraics(rt2b, minimal=True)
(Number Field in a with defining polynomial y^2 - 2, a, Ring morphism:
    From: Number Field in a with defining polynomial y^2 - 2
    To:   Algebraic Real Field
    Defn: a |--> 1.414213562373095?)
```

Things work fine with rational numbers, too:

```
sage: number_field_elements_from_algebraics((QQbar(1/2), AA(17)))
(Rational Field, [1/2, 17], Ring morphism:
    From: Rational Field
    To:   Algebraic Real Field
    Defn: 1 |--> 1)
```

Or we can just pass in symbolic expressions, as long as they can be coerced into `QQbar`:

```
sage: number_field_elements_from_algebraics((sqrt(7), sqrt(9), sqrt(11)))
(Number Field in a with defining polynomial y^4 - 9*y^2 + 1, [-a^3 + 8*a, 3, -a^3 + 10*a], Ring
    From: Number Field in a with defining polynomial y^4 - 9*y^2 + 1
    To:   Algebraic Real Field
    Defn: a |--> 0.3354367396454047?)
```

Here we see an example of doing some computations with number field elements, and then mapping them back into `QQbar`:

```
sage: (fld,nums,hom) = number_field_elements_from_algebraics((rt2, rt3, qqI, z3))
sage: fld,nums,hom
(Number Field in a with defining polynomial y^8 - y^4 + 1, [-a^5 + a^3 + a, a^6 - 2*a^2, a^6, -a
    From: Number Field in a with defining polynomial y^8 - y^4 + 1
    To:   Algebraic Field
    Defn: a |--> -0.2588190451025208? - 0.9659258262890683?*I)
sage: (nfrt2, nfrt3, nfI, nfz3) = nums
sage: hom(nfrt2)
1.414213562373095? + 0.?e-18*I
sage: nfrt2^2
2
sage: nfrt3^2
3
sage: nfz3 + nfz3^2
-1
sage: nfI^2
-1
sage: sum = nfrt2 + nfrt3 + nfI + nfz3; sum
2*a^6 - a^5 - a^4 + a^3 - 2*a^2 + a
sage: hom(sum)
2.646264369941973? + 1.866025403784439?*I
sage: hom(sum) == rt2 + rt3 + qqI + z3
True
sage: [hom(n) for n in nums] == [rt2, rt3, qqI, z3]
True
```

TESTS:

```
sage: number_field_elements_from_algebraics(rt3)
(Number Field in a with defining polynomial y^2 - 3, a, Ring morphism:
    From: Number Field in a with defining polynomial y^2 - 3
    To:   Algebraic Real Field
    Defn: a |--> 1.732050807568878?)
sage: number_field_elements_from_algebraics((rt2,qqI))
(Number Field in a with defining polynomial y^4 + 1, [a^3 - a, -a^2], Ring morphism:
    From: Number Field in a with defining polynomial y^4 + 1
    To:   Algebraic Field
    Defn: a |--> -0.7071067811865475? + 0.7071067811865475?*I)
```

Note that for the first example, where sage doesn't realize that the number is real, we get a homomorphism to QQbar; but with minimal=True, we get a homomorphism to AA. Also note that the exact answer depends on a Pari function that gives different answers for 32-bit and 64-bit machines:

```
sage: number_field_elements_from_algebraics(rt2c)
(Number Field in a with defining polynomial y^4 + 2*y^2 + 4, 1/2*a^3, Ring morphism:
    From: Number Field in a with defining polynomial y^4 + 2*y^2 + 4
    To:   Algebraic Field
    Defn: a |--> -0.7071067811865475? + 1.224744871391589?*I) # 32-bit
    Defn: a |--> -0.7071067811865475? - 1.224744871391589?*I) # 64-bit
sage: number_field_elements_from_algebraics(rt2c, minimal=True)
(Number Field in a with defining polynomial y^2 - 2, a, Ring morphism:
    From: Number Field in a with defining polynomial y^2 - 2
    To:   Algebraic Real Field
    Defn: a |--> 1.414213562373095?)
```

prec_seq()

rational_exact_root(*r*, *d*)

Checks whether the rational r is an exact d'th power. If so, returns the d'th root of r; otherwise, returns None.

EXAMPLES:

```
sage: from sage.rings.qqbar import rational_exact_root
sage: rational_exact_root(16/81, 4)
2/3
sage: rational_exact_root(8/81, 3) is None
True
```

short_prec_seq()

tail_prec_seq()

CHAPTER

TWENTYSEVEN

P-ADICS

27.1 Introduction to the p-adics

This tutorial outlines what you need to know in order to use p-adics in Sage effectively.

Our goal is to create a rich structure of different options that will reflect the mathematical structures of the p-adics. This is very much a work in progress: some of the classes that we eventually intend to include have not yet been written, and some of the functionality for classes in existence has not yet been implemented. In addition, while we strive for perfect code, bugs (both subtle and not-so-subtle) continue to evade our clutches. As a user, you serve an important role. By writing non-trivial code that uses the p-adics, you both give us insight into what features are actually used and also expose problems in the code for us to fix.

Our design philosophy has been to create a robust, usable interface working first, with simple-minded implementations underneath. We want this interface to stabilize rapidly, so that users' code does not have to change. Once we get the framework in place, we can go back and work on the algorithms and implementations underneath. All of the current p-adic code is currently written in pure Python, which means that it does not have the speed advantage of compiled code. Thus our p-adics can be painfully slow at times when you're doing real computations. However, finding and fixing bugs in Python code is *far* easier than finding and fixing errors in the compiled alternative within Sage (Cython), and Python code is also faster and easier to write. We thus have significantly more functionality implemented and working than we would have if we had chosen to focus initially on speed. And at some point in the future, we will go back and improve the speed. Any code you have written on top of our p-adics will then get an immediate performance enhancement.

If you do find bugs, have feature requests or general comments, please email sage-support@groups.google.com or roed@math.harvard.edu.

27.1.1 Terminology and types of p-adics

To write down a general p-adic element completely would require an infinite amount of data. Since computers do not have infinite storage space, we must instead store finite approximations to elements. Thus, just as in the case of floating point numbers for representing reals, we have to store an element to a finite precision level. The different ways of doing this account for the different types of p-adics.

We can think of p-adics in two ways. First, as a projective limit of finite groups:

$$\mathbb{Z}_p = \lim_{\leftarrow n} \mathbb{Z}/p^n\mathbb{Z}.$$

Secondly, as Cauchy sequences of rationals (or integers, in the case of $\mathbb{Z}_p$) under the p-adic metric. Since we only need to consider these sequences up to equivalence, this second way of thinking of the p-adics is the same as considering power series in p with integral coefficients in the range 0 to $p-1$. If we only allow nonnegative powers of p then these power series converge to elements of $\mathbb{Z}_p$, and if we allow bounded negative powers of p then we get $\mathbb{Q}_p$.

Both of these representations give a natural way of thinking about finite approximations to a p-adic element. In

the first representation, we can just stop at some point in the projective limit, giving an element of $\mathbb{Z}/p^n\mathbb{Z}$. As $\mathbb{Z}_p/p^n\mathbb{Z}_p \cong \mathbb{Z}/p^n\mathbb{Z}$, this is equivalent to specifying our element modulo $p^n\mathbb{Z}_p$.

The *absolute precision* of a finite approximation $\bar{x} \in \mathbb{Z}/p^n\mathbb{Z}$ to $x \in \mathbb{Z}_p$ is the non-negative integer n.

In the second representation, we can achieve the same thing by truncating a series

$$a_0 + a_1 p + a_2 p^2 + \cdots$$

at p^n, yielding

$$a_0 + a_1 p + \cdots + a_{n-1} p^{n-1} + O(p^n).$$

As above, we call this n the absolute precision of our element.

Given any $x \in \mathbb{Q}_p$ with $x \neq 0$, we can write $x = p^v u$ where $v \in \mathbf{Z}$ and $u \in \mathbb{Z}_p^\times$. We could thus also store an element of $\mathbb{Q}_p$ (or $\mathbb{Z}_p$) by storing v and a finite approximation of u. This motivates the following definition: the *relative precision* of an approximation to x is defined as the absolute precision of the approximation minus the valuation of x. For example, if $x = a_k p^k + a_{k+1} p^{k+1} + \cdots + a_{n-1} p^{n-1} + O(p^n)$ then the absolute precision of x is n, the valuation of x is k and the relative precision of x is $n - k$.

There are three different representations of $\mathbb{Z}_p$ in Sage and one representation of $\mathbb{Q}_p$:

- the fixed modulus ring
- the capped absolute precision ring
- the capped relative precision ring, and
- the capped relative precision field.

Fixed Modulus Rings

The first, and simplest, type of $\mathbb{Z}_p$ is basically a wrapper around $\mathbb{Z}/p^n\mathbb{Z}$, providing a unified interface with the rest of the p-adics. You specify a precision, and all elements are stored to that absolute precision. If you perform an operation that would normally lose precision, the element does not track that it no longer has full precision.

The fixed modulus ring provides the lowest level of convenience, but it is also the one that has the lowest computational overhead. Once we have ironed out some bugs, the fixed modulus elements will be those most optimized for speed.

As with all of the implementations of $\mathbb{Z}_p$, one creates a new ring using the constructor `Zp`, and passing in `'fixed-mod'` for the `type` parameter. For example,

```
sage: R = Zp(5, prec = 10, type = 'fixed-mod', print_mode = 'series')
sage: R
5-adic Ring of fixed modulus 5^10
```

One can create elements as follows:

```
sage: a = R(375)
sage: a
3*5^3 + O(5^10)
sage: b = R(105)
sage: b
5 + 4*5^2 + O(5^10)
```

Now that we have some elements, we can do arithmetic in the ring.

```
sage: a + b
5 + 4*5^2 + 3*5^3 + O(5^10)
sage: a * b
3*5^4 + 2*5^5 + 2*5^6 + O(5^10)
```

Floor division (//) divides even though the result isn't really known to the claimed precision; note that division isn't defined:

```
sage: a // 5
3*5^2 + O(5^10)
```

```
sage: a / 5
...
ValueError: cannot invert non-unit
```

Since elements don't actually store their actual precision, one can only divide by units:

```
sage: a / 2
4*5^3 + 2*5^4 + 2*5^5 + 2*5^6 + 2*5^7 + 2*5^8 + 2*5^9 + O(5^10)
sage: a / b
...
ValueError: cannot invert non-unit
```

If you want to divide by a non-unit, do it using the `//` operator:

```
sage: a // b
3*5^2 + 3*5^3 + 2*5^5 + 5^6 + 4*5^7 + 2*5^8 + O(5^10)
```

Capped Absolute Rings

The second type of implementation of $\mathbb{Z}_p$ is similar to the fixed modulus implementation, except that individual elements track their known precision. The absolute precision of each element is limited to be less than the precision cap of the ring, even if mathematically the precision of the element would be known to greater precision (see Appendix A for the reasons for the existence of a precision cap).

Once again, use `Zp` to create a capped absolute p-adic ring.

```
sage: R = Zp(5, prec = 10, type = 'capped-abs', print_mode = 'series')
sage: R
5-adic Ring with capped absolute precision 10
```

We can do similar things as in the fixed modulus case:

```
sage: a = R(375)
sage: a
3*5^3 + O(5^10)
sage: b = R(105)
sage: b
5 + 4*5^2 + O(5^10)
sage: a + b
5 + 4*5^2 + 3*5^3 + O(5^10)
sage: a * b
3*5^4 + 2*5^5 + 2*5^6 + O(5^10)
sage: c = a // 5
```

```
sage: c
3*5^2 + O(5^9)
```

Note that when we divided by 5, the precision of c dropped. This lower precision is now reflected in arithmetic.

```
sage: c + b
5 + 2*5^2 + 5^3 + O(5^9)
```

Division is allowed: the element that results is a capped relative field element, which is discussed in the next section:

```
sage: 1 / (c + b)
5^-1 + 3 + 2*5 + 5^2 + 4*5^3 + 4*5^4 + 3*5^6 + O(5^7)
```

Capped Relative Rings and Fields

Instead of restricting the absolute precision of elements (which doesn't make much sense when elements have negative valuations), one can cap the relative precision of elements. This is analogous to floating point representations of real numbers. As in the reals, multiplication works very well: the valuations add and the relative precision of the product is the minimum of the relative precisions of the inputs. Addition, however, faces similar issues as floating point addition: relative precision is lost when lower order terms cancel.

To create a capped relative precision ring, use Zp as before. To create capped relative precision fields, use Qp.

```
sage: R = Zp(5, prec = 10, type = 'capped-rel', print_mode = 'series')
sage: R
5-adic Ring with capped relative precision 10
sage: K = Qp(5, prec = 10, type = 'capped-rel', print_mode = 'series')
sage: K
5-adic Field with capped relative precision 10
```

We can do all of the same operations as in the other two cases, but precision works a bit differently: the maximum precision of an element is limited by the precision cap of the ring.

```
sage: a = R(375)
sage: a
3*5^3 + O(5^13)
sage: b = K(105)
sage: b
5 + 4*5^2 + O(5^11)
sage: a + b
5 + 4*5^2 + 3*5^3 + O(5^11)
sage: a * b
3*5^4 + 2*5^5 + 2*5^6 + O(5^14)
sage: c = a // 5
sage: c
3*5^2 + O(5^12)
sage: c + 1
1 + 3*5^2 + O(5^10)
```

As with the capped absolute precision rings, we can divide, yielding a capped relative precision field element.

```
sage: 1 / (c + b)
5^-1 + 3 + 2*5 + 5^2 + 4*5^3 + 4*5^4 + 3*5^6 + 2*5^7 + 5^8 + O(5^9)
```

Unramified Extensions

One can create unramified extensions of $\mathbb{Z}_p$ and $\mathbb{Q}_p$ using the functions `Zq` and `Qq`.

In addition to requiring a prime power as the first argument, `Zq` also requires a name for the generator of the residue field. One can specify this name as follows:

```
sage: R.<c> = Zq(125, prec = 20); R
Unramified Extension of 5-adic Ring with capped absolute precision 20
in c defined by (1 + O(5^20))*x^3 + (3 + O(5^20))*x + (3 + O(5^20))
```

Eisenstein Extensions

It is also possible to create Eisenstein extensions of $\mathbb{Z}_p$ and $\mathbb{Q}_p$. In order to do so, create the ground field first:

```
sage: R = Zp(5, 2)
```

Then define the polynomial yielding the desired extension.:

```
sage: S.<x> = ZZ[]
sage: f = x^5 - 25*x^3 + 15*x - 5
```

Finally, use the `ext` function on the ground field to create the desired extension.:

```
sage: W.<w> = R.ext(f)
```

You can do arithmetic in this Eisenstein extension:

```
sage: (1 + w)^7
1 + 2*w + w^2 + w^5 + 3*w^6 + 3*w^7 + 3*w^8 + w^9 + O(w^10)
```

Note that the precision cap increased by a factor of 5, since the ramification index of this extension over $\mathbb{Z}_p$ is 5.

27.2 Factory.

This file contains the contructor classes and functions for p-adic rings and fields.

AUTHORS:

- David Roe

QpCR(*p, prec=20, print_mode=None, halt=40, names=None, print_pos=None, print_sep=None, print_alphabet=None, print_max_terms=None, check=True*)
A shorcut function to create capped relative p-adic fields.

Same functionality as `Qp`. See documentation for `Qp` for a description of the input paramters.

EXAMPLES:

```
sage: QpCR(5, 40)
5-adic Field with capped relative precision 40
```

class `Qp_class`()

A creation function for p-adic fields.

INPUT:

- `p` – integer: the p in $\mathbb{Q}_p$
- `prec` – integer (default: `20`) the precision cap of the field. Individual elements keep track of their own precision. See TYPES and PRECISION below.
- `type` – string (default: `'capped-rel'`) Valid types are `'capped-rel'` and `'lazy'` (though `'lazy'` currently doesn't work). See TYPES and PRECISION below
- `print_mode` – string (default: `None`). Valid modes are 'series', 'val-unit', 'terse', 'digits', and 'bars'. See PRINTING below
- `halt` – currently irrelevant (to be used for lazy fields)
- `names` – string or tuple (defaults to a string representation of p). What to use whenever p is printed.
- `ram_name` – string. Another way to specify the name; for consistency with the `Qq` and `Zq` and extension functions.
- `print_pos` – bool (default `None`) Whether to only use positive integers in the representations of elements. See PRINTING below.
- `print_sep` – string (default `None`) The separator character used in the `'bars'` mode. See PRINTING below.
- `print_alphabet` – tuple (default `None`) The encoding into digits for use in the 'digits' mode. See PRINTING below.
- `print_max_terms` – integer (default `None`) The maximum number of terms shown. See PRINTING below.
- `check` – bool (default `True`) whether to check if p is prime. Non-prime input may cause seg-faults (but can also be useful for base n expansions for example)

OUTPUT:

- The corresponding p-adic field.

TYPES AND PRECISION:

There are two types of precision for a p-adic element. The first is relative precision, which gives the number of known p-adic digits:

```
sage: R = Qp(5, 20, 'capped-rel', 'series'); a = R(675); a
2*5^2 + 5^4 + O(5^22)
sage: a.precision_relative()
20
```

The second type of precision is absolute precision, which gives the power of p that this element is defined modulo:

```
sage: a.precision_absolute()
22
```

There are two types of p-adic fields: capped relative fields and lazy fields.

In the capped relative case, the relative precision of an element is restricted to be at most a certain value, specified at the creation of the field. Individual elements also store their own precision, so the effect of various arithmetic operations on precision is tracked. When you cast an exact element into a capped relative field, it truncates it to the precision cap of the field.:

```
sage: R = Qp(5, 5, 'capped-rel', 'series'); a = R(4006); a
1 + 5 + 2*5^3 + 5^4 + O(5^5)
sage: b = R(4025); b
5^2 + 2*5^3 + 5^4 + 5^5 + O(5^7)
sage: a + b
1 + 5 + 5^2 + 4*5^3 + 2*5^4 + O(5^5)
```

The lazy case will eventually support elements that can increase their precision upon request. It is not currently implemented.

PRINTING:

There are many different ways to print p-adic elements. The way elements of a given field print is controlled by options passed in at the creation of the field. There are five basic printing modes (series, val-unit, terse, digits and bars), as well as various options that either hide some information in the print representation or sometimes make print representations more compact. Note that the printing options affect whether different p-adic fields are considered equal.

1. **series**: elements are displayed as series in p.:

```
sage: R = Qp(5, print_mode='series'); a = R(70700); a
3*5^2 + 3*5^4 + 2*5^5 + 4*5^6 + O(5^22)
sage: b = R(-70700); b
2*5^2 + 4*5^3 + 5^4 + 2*5^5 + 4*5^7 + 4*5^8 + 4*5^9 + 4*5^10 + 4*5^11 + 4*5^12 + 4*5^13 + 4*
```

print_pos controls whether negatives can be used in the coefficients of powers of p.:

```
sage: S = Qp(5, print_mode='series', print_pos=False); a = S(70700); a
-2*5^2 + 5^3 - 2*5^4 - 2*5^5 + 5^7 + O(5^22)
sage: b = S(-70700); b
2*5^2 - 5^3 + 2*5^4 + 2*5^5 - 5^7 + O(5^22)
```

print_max_terms limits the number of terms that appear.:

```
sage: T = Qp(5, print_mode='series', print_max_terms=4); b = R(-70700); repr(b)
'2*5^2 + 4*5^3 + 5^4 + 2*5^5 + ... + O(5^22)'
```

names affects how the prime is printed.:

```
sage: U.<p> = Qp(5); p
p + O(p^21)
```

print_sep and *print_alphabet* have no effect in series mode.

Note that print options affect equality:

```
sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
```

1. **val-unit**: elements are displayed as p^k*u:

```
sage: R = Qp(5, print_mode='val-unit'); a = R(70700); a
5^2 * 2828 + O(5^22)
sage: b = R(-707/5); b
5^-1 * 95367431639918 + O(5^19)
```

print_pos controls whether to use a balanced representation or not.:

```
sage: S = Qp(5, print_mode='val-unit', print_pos=False); b = S(-70700); b
5^2 * (-2828) + O(5^22)
```

names affects how the prime is printed.:

```
sage: T = Qp(5, print_mode='val-unit', names='pi'); a = T(70700); a
pi^2 * 2828 + O(pi^22)
```

print_max_terms, *print_sep* and *print_alphabet* have no effect.

Equality again depends on the printing options:

```
sage: R == S, R == T, S == T
(False, False, False)
```

1. **terse**: elements are displayed as an integer in base 10 or the quotient of an integer by a power of p (still in base 10):

   ```
   sage: R = Qp(5, print_mode='terse'); a = R(70700); a
   70700 + O(5^22)
   sage: b = R(-70700); b
   2384185790944925 + O(5^22)
   sage: c = R(-707/5); c
   95367431639918/5 + O(5^19)
   ```

The denominator, as of version 3.3, is always printed explicitly as a power of p, for predictability.:

```
sage: d = R(707/5^2); d
707/5^2 + O(5^18)
```

print_pos controls whether to use a balanced representation or not.:

```
sage: S = Qp(5, print_mode='terse', print_pos=False); b = S(-70700); b
-70700 + O(5^22)
sage: c = S(-707/5); c
-707/5 + O(5^19)
```

name affects how the name is printed.:

```
sage: T.<unif> = Qp(5, print_mode='terse'); c = T(-707/5); c
95367431639918/unif + O(unif^19)
sage: d = T(-707/5^10); d
95367431639918/unif^10 + O(unif^10)
```

print_max_terms, *print_sep* and *print_alphabet* have no effect.

Equality depends on printing options:

```
sage: R == S, R == T, S == T
(False, False, False)
```

1. **digits**: elements are displayed as a string of base p digits

Restriction: you can only use the digits printing mode for small primes. Namely, p must be less than the length of the alphabet tuple (default alphabet has length 62).:

```
sage: R = Qp(5, print_mode='digits'); a = R(70700); repr(a)
'...4230300'
sage: b = R(-70700); repr(b)
'...444444444444440214200'
sage: c = R(-707/5); repr(c)
'...444444444444443413.3'
sage: d = R(-707/5^2); repr(d)
'...44444444444444341.33'
```

Note that it's not possible to read off the precision from the representation in this mode.

print_max_terms limits the number of digits that are printed. Note that if the valuation of the element is very negative, more digits will be printed.:

```
sage: S = Qp(5, print_mode='digits', print_max_terms=4); b = S(-70700); repr(b)
'...214200'
sage: d = S(-707/5^2); repr(d)
'...41.33'
sage: e = S(-707/5^6); repr(e)
'...?.434133'
sage: f = S(-707/5^6,absprec=-2); repr(f)
'...?.??4133'
sage: g = S(-707/5^4); repr(g)
'...?.4133'
```

print_alphabet controls the symbols used to substitute for digits greater than 9.

Defaults to ('0', '1', '2', '3', '4', '5', '6', '7', '8', '9', 'A', 'B', 'C', 'D', 'E', 'F', 'G', 'H', 'I', 'J', 'K', 'L', 'M', 'N', 'O', 'P', 'Q', 'R', 'S', 'T', 'U', 'V', 'W', 'X', 'Y', 'Z', 'a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l', 'm', 'n', 'o', 'p', 'q', 'r', 's', 't', 'u', 'v', 'w', 'x', 'y', 'z'):

```
sage: T = Qp(5, print_mode='digits', print_max_terms=4, print_alphabet=('1','2','3','4','5')); b
'...325311'
```

print_pos, *name* and *print_sep* have no effect.

Equality depends on printing options:

```
sage: R == S, R == T, S == T
(False, False, False)
```

1. **bars**: elements are displayed as a string of base p digits with separators:

   ```
   sage: R = Qp(5, print_mode='bars'); a = R(70700); repr(a)
   '...4|2|3|0|3|0|0'
   sage: b = R(-70700); repr(b)
   '...4|4|4|4|4|4|4|4|4|4|4|4|4|4|4|0|2|1|4|2|0|0'
   sage: d = R(-707/5^2); repr(d)
   '...4|4|4|4|4|4|4|4|4|4|4|4|4|4|4|3|4|1|.|3|3'
   ```

Again, note that it's not possible to read of the precision from the representation in this mode.

print_pos controls whether the digits can be negative.:

```
sage: S = Qp(5, print_mode='bars',print_pos=False); b = S(-70700); repr(b)
'...-1|0|2|2|-1|2|0|0'
```

print_max_terms limits the number of digits that are printed. Note that if the valuation of the element is very negative, more digits will be printed.:

```
sage: T = Qp(5, print_mode='bars', print_max_terms=4); b = T(-70700); repr(b)
'...2|1|4|2|0|0'
sage: d = T(-707/5^2); repr(d)
'...4|1|.|3|3'
sage: e = T(-707/5^6); repr(e)
'...|.|4|3|4|1|3|3'
sage: f = T(-707/5^6,absprec=-2); repr(f)
'...|.|?|?|4|1|3|3'
sage: g = T(-707/5^4); repr(g)
'...|.|4|1|3|3'
```

print_sep controls the separation character.:

```
sage: U = Qp(5, print_mode='bars', print_sep='][', a = U(70700); repr(a)
'...4][2][3][0][3][0][0'
```

name and *print_alphabet* have no effect.

Equality depends on printing options:

```
sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
```

EXAMPLES:

```
sage: K = Qp(15, check=False); a = K(999); a
9 + 6*15 + 4*15^2 + O(15^20)
```

create_key(*p, prec=20, type='capped-rel', print_mode=None, halt=40, names=None, ram_name=None, print_pos=None, print_sep=None, print_alphabet=None, print_max_terms=None, check=True*)

Creates a key from input parameters for `Qp`.

See the documentation for `Qp` for more information.

TESTS:

```
sage: Qp.create_key(5,40)
(5, 40, 'capped-rel', 'series', '5', True, '|', ('0', '1', '2', '3', '4', '5', '6', '7', '8'
```

create_object(*version, key*)

Creates an object using a given key.

See the documentation for `Qp` for more information.

TESTS:

```
sage: Qp.create_object((3,4,2),(5, 40, 'capped-rel', 'series', '5', True, '|', ('0', '1', '2
5-adic Field with capped relative precision 40
```

Qq(*q, prec=20, type='capped-rel', modulus=None, names=None, print_mode=None, halt=40, ram_name=None, res_name=None, print_pos=None, print_sep=None, print_max_ram_terms=None, print_max_unram_terms=None, print_max_terse_terms=None, check=True*)

Given a prime power $q = p^n$, return the unique unramified extension of $\mathbb{Q}_p$ of degree n.

INPUT:

- `q` – integer: the prime power in $\mathbb{Q}_q$. OR, if check=False, a factorization object or single element list `[(p, n)]` where `p` is a prime and `n` a positive integer.
- `prec` – integer (default: `20`) the precision cap of the field. Individual elements keep track of their own precision. See TYPES and PRECISION below.
- `type` – string (default: `'capped-rel'`) Valid types are `'capped-rel'` and `'lazy'` (though `'lazy'` doesn't currently work). See TYPES and PRECISION below

- `modulus` – polynomial (default `None`) A polynomial defining an unramified extension of $\mathbb{Q}_p$. See MODULUS below.
- `names` – string or tuple (`None` is only allowed when $q = p$). The name of the generator, reducing to a generator of the residue field.
- `print_mode` – string (default: `None`). Valid modes are `'series'`, `'val-unit'`, `'terse'`, and `'bars'`. See PRINTING below.
- `halt` – currently irrelevant (to be used for lazy fields)
- `ram_name` – string (defaults to string representation of p if None). `ram_name` controls how the prime is printed. See PRINTING below.
- `res_name` – string (defaults to `None`, which corresponds to adding a `'0'` to the end of the name). Controls how elements of the reside field print.
- `print_pos` – bool (default `None`) Whether to only use positive integers in the representations of elements. See PRINTING below.
- `print_sep` – string (default `None`) The separator character used in the `'bars'` mode. See PRINTING below.
- `print_max_ram_terms` – integer (default `None`) The maximum number of powers of p shown. See PRINTING below.
- `print_max_unram_terms` – integer (default `None`) The maximum number of entries shown in a coefficient of p. See PRINTING below.
- `print_max_terse_terms` – integer (default `None`) The maximum number of terms in the polynomial representation of an element (using `'terse'`). See PRINTING below.
- `check` – bool (default `True`) whether to check inputs.

OUTPUT:

- The corresponding unramified p-adic field.

TYPES AND PRECISION:

There are two types of precision for a p-adic element. The first is relative precision, which gives the number of known p-adic digits:

```
sage: R.<a> = Qq(25, 20, 'capped-rel', print_mode='series'); b = 25*a; b
a*5^2 + O(5^22)
sage: b.precision_relative()
20
```

The second type of precision is absolute precision, which gives the power of p that this element is defined modulo:

```
sage: b.precision_absolute()
22
```

There are two types of unramified p-adic fields: capped relative fields and lazy fields.

In the capped relative case, the relative precision of an element is restricted to be at most a certain value, specified at the creation of the field. Individual elements also store their own precision, so the effect of various arithmetic operations on precision is tracked. When you cast an exact element into a capped relative field, it truncates it to the precision cap of the field.:

```
sage: R.<a> = Qq(9, 5, 'capped-rel', print_mode='series'); b = (1+2*a)^4; b
2 + (2*a + 2)*3 + (2*a + 1)*3^2 + O(3^5)
sage: c = R(3249); c
3^2 + 3^4 + 3^5 + 3^6 + O(3^7)
sage: b + c
2 + (2*a + 2)*3 + (2*a + 2)*3^2 + 3^4 + O(3^5)
```

The lazy case will eventually support elements that can increase their precision upon request. It is not currently implemented.

MODULUS:

The modulus needs to define an unramified extension of $\mathbb{Q}_p$: when it is reduced to a polynomial over $\mathbb{F}_p$ it should be irreducible.

The modulus can be given in a number of forms.

1. A **polynomial**.

The base ring can be $\mathbb{Z}$, $\mathbb{Q}$, $\mathbb{Z}_p$, $\mathbb{Q}_p$, $\mathbb{F}_p$.:

```
sage: P.<x> = ZZ[]
sage: R.<a> = Qq(27, modulus = x^3 + 2*x + 1); R.modulus()
(1 + O(3^20))*x^3 + (O(3^20))*x^2 + (2 + O(3^20))*x + (1 + O(3^20))
sage: P.<x> = QQ[]
sage: S.<a> = Qq(27, modulus = x^3 + 2*x + 1)
sage: P.<x> = Zp(3)[]
sage: T.<a> = Qq(27, modulus = x^3 + 2*x + 1)
sage: P.<x> = Qp(3)[]
sage: U.<a> = Qq(27, modulus = x^3 + 2*x + 1)
sage: P.<x> = GF(3)[]
sage: V.<a> = Qq(27, modulus = x^3 + 2*x + 1)
```

Which form the modulus is given in has no effect on the unramified extension produced:

```
sage: R == S, S == T, T == U, U == V
(True, True, True, False)
```

unless the precision of the modulus differs. In the case of V, the modulus is only given to precision 1, so the resulting field has a precision cap of 1.:

```
sage: V.precision_cap()
1
sage: U.precision_cap()
20
sage: P.<x> = Qp(3)[]
sage: modulus = x^3 + (2 + O(3^7))*x + (1 + O(3^10))
sage: modulus
(1 + O(3^20))*x^3 + (2 + O(3^7))*x + (1 + O(3^10))
sage: W.<a> = Qq(27, modulus = modulus); W.precision_cap()
7
```

1. The modulus can also be given as a **symbolic expression**.:

```
sage: x = var('x')
sage: X.<a> = Qq(27, modulus = x^3 + 2*x + 1); X.modulus()
(1 + O(3^20))*x^3 + (O(3^20))*x^2 + (2 + O(3^20))*x + (1 + O(3^20))
sage: X == R
True
```

By default, the polynomial chosen is the standard lift of the generator chosen for $\mathbb{F}_q$.:

```
sage: GF(125, 'a').modulus()
x^3 + 3*x + 3
sage: Y.<a> = Qq(125); Y.modulus()
(1 + O(5^20))*x^3 + (O(5^20))*x^2 + (3 + O(5^20))*x + (3 + O(5^20))
```

However, you can choose another polynomial if desired (as long as the reduction to $\mathbb{F}_p[x]$ is irreducible).:

```
sage: P.<x> = ZZ[]
sage: Z.<a> = Qq(125, modulus = x^3 + 3*x^2 + x + 1); Z.modulus()
(1 + O(5^20))*x^3 + (3 + O(5^20))*x^2 + (1 + O(5^20))*x + (1 + O(5^20))
sage: Y == Z
False
```

PRINTING:

There are many different ways to print p-adic elements. The way elements of a given field print is controlled by options passed in at the creation of the field. There are four basic printing modes (`'series'`, `'val-unit'`, `'terse'` and `'bars'`; `'digits'` is not available), as well as various options that either hide some information in the print representation or sometimes make print representations more compact. Note that the printing options affect whether different p-adic fields are considered equal.

1. **series**: elements are displayed as series in p.:

```
sage: R.<a> = Qq(9, 20, 'capped-rel', print_mode='series'); (1+2*a)^4
2 + (2*a + 2)*3 + (2*a + 1)*3^2 + O(3^20)
sage: -3*(1+2*a)^4
3 + a*3^2 + 3^3 + (2*a + 2)*3^4 + (2*a + 2)*3^5 + (2*a + 2)*3^6 + (2*a + 2)*3^7 + (2*a + 2)*
sage: ~(3*a+18)
(a + 2)*3^-1 + 1 + 2*3 + (a + 1)*3^2 + 3^3 + 2*3^4 + (a + 1)*3^5 + 3^6 + 2*3^7 + (a + 1)*3^8
```

print_pos controls whether negatives can be used in the coefficients of powers of p.:

```
sage: S.<b> = Qq(9, print_mode='series', print_pos=False); (1+2*b)^4
-1 - b*3 - 3^2 + (b + 1)*3^3 + O(3^20)
sage: -3*(1+2*b)^4
3 + b*3^2 + 3^3 + (-b - 1)*3^4 + O(3^21)
```

ram_name controls how the prime is printed.:

```
sage: T.<d> = Qq(9, print_mode='series', ram_name='p'); 3*(1+2*d)^4
2*p + (2*d + 2)*p^2 + (2*d + 1)*p^3 + O(p^21)
```

print_max_ram_terms limits the number of powers of p that appear.:

```
sage: U.<e> = Qq(9, print_mode='series', print_max_ram_terms=4); repr(-3*(1+2*e)^4)
'3 + e*3^2 + 3^3 + (2*e + 2)*3^4 + ... + O(3^21)'
```

print_max_unram_terms limits the number of terms that appear in a coefficient of a power of p.:

```
sage: V.<f> = Qq(128, prec = 8, print_mode='series'); repr((1+f)^9)
'(f^3 + 1) + (f^5 + f^4 + f^3 + f^2)*2 + (f^6 + f^5 + f^4 + f + 1)*2^2 + (f^5 + f^4 + f^2 + f +
sage: V.<f> = Qq(128, prec = 8, print_mode='series', print_max_unram_terms = 3); repr((1+f)^9)
'(f^3 + 1) + (f^5 + f^4 + ... + f^2)*2 + (f^6 + f^5 + ... + 1)*2^2 + (f^5 + f^4 + ... + 1)*2^3 +
sage: V.<f> = Qq(128, prec = 8, print_mode='series', print_max_unram_terms = 2); repr((1+f)^9)
'(f^3 + 1) + (f^5 + ... + f^2)*2 + (f^6 + ... + 1)*2^2 + (f^5 + ... + 1)*2^3 + (f^6 + ... + 1)*2
sage: V.<f> = Qq(128, prec = 8, print_mode='series', print_max_unram_terms = 1); repr((1+f)^9)
'(f^3 + ...) + (f^5 + ...)*2 + (f^6 + ...)*2^2 + (f^5 + ...)*2^3 + (f^6 + ...)*2^4 + (f^5 + ...)
sage: V.<f> = Qq(128, prec = 8, print_mode='series', print_max_unram_terms = 0); repr((1+f)^9 -
'(...)*2 + (...)*2^2 + (...)*2^3 + (...)*2^4 + (...)*2^5 + (...)*2^6 + (...)*2^7 + O(2^8)'
```

print_sep and *print_max_terse_terms* have no effect.

Note that print options affect equality:

```
sage: R == S, R == T, R == U, R == V, S == T, S == U, S == V, T == U, T == V, U == V
(False, False, False, False, False, False, False, False, False, False)
```

1. **val-unit**: elements are displayed as $p^k u$:

```
sage: R.<a> = Qq(9, 7, print_mode='val-unit'); b = (1+3*a)^9 - 1; b
3^3 * (15 + 64*a) + O(3^7)
sage: ~b
3^-3 * (41 + a) + O(3)
```

print_pos controls whether to use a balanced representation or not.:

```
sage: S.<a> = Qq(9, 7, print_mode='val-unit', print_pos=False); b = (1+3*a)^9 - 1; b
3^3 * (15 - 17*a) + O(3^7)
sage: ~b
3^-3 * (-40 + a) + O(3)
```

ram_name affects how the prime is printed.:

```
sage: A.<x> = Qp(next_prime(10^6), print_mode='val-unit')[]
sage: T.<a> = Qq(next_prime(10^6)^3, 4, print_mode='val-unit', ram_name='p', modulus=x^3+385831*
p^-2 * (503009563508519137754940 + 704413692798200940253892*a + 968097057817740999537581*a^2) +
sage: b * (a^2 + a - 4)
p^-2 * 1 + O(p^2)
```

print_max_terse_terms controls how many terms of the polynomial appear in the unit part.:

```
sage: U.<a> = Qq(17^4, 6, print_mode='val-unit', print_max_terse_terms=3); b = ~(17*(a^3-a+14));
17^-1 * (22110411 + 11317400*a + 20656972*a^2 + ...) + O(17^5)
sage: b*17*(a^3-a+14)
1 + O(17^6)
```

print_sep, *print_max_ram_terms* and *print_max_unram_terms* have no effect.

Equality again depends on the printing options:

```
sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
```

1. **terse**: elements are displayed as a polynomial of degree less than the degree of the extension.:

```
sage: R.<a> = Qq(125, print_mode='terse')
sage: (a+5)^177
68210977979428 + 90313850704069*a + 73948093055069*a^2 + O(5^20)
sage: (a/5+1)^177
68210977979428/5^177 + 90313850704069/5^177*a + 73948093055069/5^177*a^2 + O(5^-157)
```

As of version 3.3, if coefficients of the polynomial are non-integral, they are always printed with an explicit power of p in the denominator.:

```
sage: 5*a + a^2/25
5*a + 1/5^2*a^2 + O(5^18)
```

print_pos controls whether to use a balanced representation or not.:

```
sage: (a-5)^6
22864 + 95367431627998*a + 8349*a^2 + O(5^20)
sage: S.<a> = Qq(125, print_mode='terse', print_pos=False); b = (a-5)^6; b
22864 - 12627*a + 8349*a^2 + O(5^20)
sage: (a - 1/5)^6
-20624/5^6 + 18369/5^5*a + 1353/5^3*a^2 + O(5^14)
```

ram_name affects how the prime is printed.:

```
sage: T.<a> = Qq(125, print_mode='terse', ram_name='p'); (a - 1/5)^6
95367431620001/p^6 + 18369/p^5*a + 1353/p^3*a^2 + O(p^14)
```

print_max_terse_terms controls how many terms of the polynomial are shown.:

```
sage: U.<a> = Qq(625, print_mode='terse', print_max_terse_terms=2); (a-1/5)^6
106251/5^6 + 49994/5^5*a + ... + O(5^14)
```

print_sep, *print_max_ram_terms* and *print_max_unram_terms* have no effect.

Equality again depends on the printing options:

```
sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
```

1. **digits**: This print mode is not available when the residue field is not prime.

It might make sense to have a dictionary for small fields, but this isn't implemented.

1. **bars**: elements are displayed in a similar fashion to series, but more compactly.:

```
sage: R.<a> = Qq(125); (a+5)^6
(4*a^2 + 3*a + 4) + (3*a^2 + 2*a)*5 + (a^2 + a + 1)*5^2 + (3*a + 2)*5^3 + (3*a^2 + a + 3)*5^
sage: R.<a> = Qq(125, print_mode='bars', prec=8); repr((a+5)^6)
'...[2, 3, 2]|[3, 1, 3]|[2, 3]|[1, 1, 1]|[0, 2, 3]|[4, 3, 4]'
sage: repr((a-5)^6)
'...[0, 4]|[1, 4]|[2, 0, 2]|[1, 4, 3]|[2, 3, 1]|[4, 4, 3]|[2, 4, 4]|[4, 3, 4]'
```

Note that elements with negative valuation are shown with a decimal point at valuation 0.:

```
sage: repr((a+1/5)^6)
'...[3]|[4, 1, 3]|.|[1, 2, 3]|[3, 3]|[0, 0, 3]|[0, 1]|[0, 1]|[1]'
sage: repr((a+1/5)^2)
'...[0, 0, 1]|.|[0, 2]|[1]'
```

If not enough precision is known, `'?'` is used instead.:

```
sage: repr((a+R(1/5,relprec=3))^7)
'...|.|?|?|?|?|[0, 1, 1]|[0, 2]|[1]'
```

Note that it's not possible to read of the precision from the representation in this mode.:

```
sage: b = a + 3; repr(b)
'...[3, 1]'
sage: c = a + R(3, 4); repr(c)
'...[3, 1]'
sage: b.precision_absolute()
8
```

```
sage: c.precision_absolute()
4
```

print_pos controls whether the digits can be negative.:

```
sage: S.<a> = Qq(125, print_mode='bars', print_pos=False); repr((a-5)^6)
'...[1, -1, 1]|[2, 1, -2]|[2, 0, -2]|[-2, -1, 2]|[0, 0, -1]|[-2]|[-1, -2, -1]'
sage: repr((a-1/5)^6)
'...[0, 1, 2]|[-1, 1, 1]|.|[-2, -1, -1]|[2, 2, 1]|[0, 0, -2]|[0, -1]|[0, -1]|[1]'
```

print_max_ram_terms controls the maximum number of "digits" shown. Note that this puts a cap on the relative precision, not the absolute precision.:

```
sage: T.<a> = Qq(125, print_mode='bars', print_max_ram_terms=3, print_pos=False); repr((a-5)^6)
'...[0, 0, -1]|[-2]|[-1, -2, -1]'
sage: repr(5*(a-5)^6+50)
'...[0, 0, -1]|[]|[-1, -2, -1]|[]'
```

However, if the element has negative valuation, digits are shown up to the decimal point.:

```
sage: repr((a-1/5)^6)
'...|.|[-2, -1, -1]|[2, 2, 1]|[0, 0, -2]|[0, -1]|[0, -1]|[1]'
```

print_sep controls the separating character (`'|'` by default).:

```
sage: U.<a> = Qq(625, print_mode='bars', print_sep=''); b = (a+5)^6; repr(b)
'...[0, 1][4, 0, 2][3, 2, 2, 3][4, 2, 2, 4][0, 3][1, 1, 3][3, 1, 4, 1]'
```

print_max_unram_terms controls how many terms are shown in each "digit":

```
sage: with local_print_mode(U, {'max_unram_terms': 3}): repr(b)
'...[0, 1][4,..., 0, 2][3,..., 2, 3][4,..., 2, 4][0, 3][1,..., 1, 3][3,..., 4, 1]'
sage: with local_print_mode(U, {'max_unram_terms': 2}): repr(b)
'...[0, 1][4,..., 2][3,..., 3][4,..., 4][0, 3][1,..., 3][3,..., 1]'
sage: with local_print_mode(U, {'max_unram_terms': 1}): repr(b)
'...[..., 1][..., 2][..., 3][..., 4][..., 3][..., 3][..., 1]'
sage: with local_print_mode(U, {'max_unram_terms':0}): repr(b-75*a)
'...[...][...][...][...][][...][...]'
```

ram_name and *print_max_terse_terms* have no effect.

Equality depends on printing options:

```
sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
```

EXAMPLES

Unlike for `Qp`, you can't create `Qq(N)` when `N` is not a prime power.

However, you can use `check=False` to pass in a pair in order to not have to factor. If you do so, you need to use names explicitly rather than the `R.<a>` syntax.:

```
sage: p = next_prime(2^123)
sage: k = Qp(p)
sage: R.<x> = k[]
sage: K = Qq([(p, 5)], modulus=x^5+x+4, names='a', ram_name='p', print_pos=False, check=False)
sage: K.0^5
(-a - 4) + O(p^20)
```

In tests on sage.math.washington.edu, the creation of K as above took an average of 1.58ms, while:

```
sage: K = Qq(p^5, modulus=x^5+x+4, names='a', ram_name='p', print_pos=False, check=True)
```

took an average of 24.5ms. Of course, with smaller primes these savings disappear.

QqCR(*q, prec=20, modulus=None, names=None, print_mode=None, halt=40, ram_name=None, print_pos=None, print_sep=None, print_alphabet=None, print_max_ram_terms=None, print_max_unram_terms=None, print_max_terse_terms=None, check=True*)
A shorcut function to create capped relative unramified p-adic fields.

Same functionality as Qq. See documentation for Qq for a description of the input paramters.

EXAMPLES:

```
sage: R.<a> = QqCR(25, 40); R
Unramified Extension of 5-adic Field with capped relative precision 40 in a defined by (1 + O(5^
```

ZpCA(*p, prec=20, print_mode=None, halt=40, names=None, print_pos=None, print_sep=None, print_alphabet=None, print_max_terms=None, check=True*)
A shorcut function to create capped absolute p-adic rings.

See documentation for Zp for a description of the input paramters.

EXAMPLES:

```
sage: ZpCA(5, 40)
5-adic Ring with capped absolute precision 40
```

ZpCR(*p, prec=20, print_mode=None, halt=40, names=None, print_pos=None, print_sep=None, print_alphabet=None, print_max_terms=None, check=True*)
A shorcut function to create capped relative p-adic rings.

Same functionality as Zp. See documentation for Zp for a description of the input paramters.

EXAMPLES:

```
sage: ZpCR(5, 40)
5-adic Ring with capped relative precision 40
```

ZpFM(*p, prec=20, print_mode=None, halt=40, names=None, print_pos=None, print_sep=None, print_alphabet=None, print_max_terms=None, check=True*)
A shorcut function to create fixed modulus p-adic rings.

See documentation for Zp for a description of the input paramters.

EXAMPLES:

```
sage: ZpFM(5, 40)
5-adic Ring of fixed modulus 5^40
```

class Zp_class()
A creation function for p-adic rings.

INPUT:

- p – integer: the p in $\mathbb{Z}_p$
- prec – integer (default: 20) the precision cap of the ring. Except for the fixed modulus case, individual elements keep track of their own precision. See TYPES and PRECISION below.
- type – string (default: 'capped-rel') Valid types are 'capped-rel', 'capped-abs', 'fixed-mod' and 'lazy' (though lazy is not yet implemented). See TYPES and PRECISION below

- `print_mode` – string (default: `None`). Valid modes are `'series'`, `'val-unit'`, `'terse'`, `'digits'`, and `'bars'`. See PRINTING below
- `halt` – currently irrelevant (to be used for lazy fields)
- `names` – string or tuple (defaults to a string representation of p). What to use whenever p is printed.
- `print_pos` – bool (default `None`) Whether to only use positive integers in the representations of elements. See PRINTING below.
- `print_sep` – string (default `None`) The separator character used in the `'bars'` mode. See PRINTING below.
- `print_alphabet` – tuple (default `None`) The encoding into digits for use in the `'digits'` mode. See PRINTING below.
- `print_max_terms` – integer (default `None`) The maximum number of terms shown. See PRINTING below.
- `check` – bool (default `True`) whether to check if p is prime. Non-prime input may cause seg-faults (but can also be useful for base n expansions for example)

OUTPUT:

- The corresponding p-adic ring.

TYPES AND PRECISION:

There are two types of precision for a p-adic element. The first is relative precision, which gives the number of known p-adic digits:

```
sage: R = Zp(5, 20, 'capped-rel', 'series'); a = R(675); a
2*5^2 + 5^4 + O(5^22)
sage: a.precision_relative()
20
```

The second type of precision is absolute precision, which gives the power of p that this element is defined modulo:

```
sage: a.precision_absolute()
22
```

There are four types of p-adic rings: capped relative rings (type= `'capped-rel'`), capped absolute rings (type= `'capped-abs'`), fixed modulus ring (type= `'fixed-mod'`) and lazy rings (type= `'lazy'`).

In the capped relative case, the relative precision of an element is restricted to be at most a certain value, specified at the creation of the field. Individual elements also store their own precision, so the effect of various arithmetic operations on precision is tracked. When you cast an exact element into a capped relative field, it truncates it to the precision cap of the field.:

```
sage: R = Zp(5, 5, 'capped-rel', 'series'); a = R(4006); a
1 + 5 + 2*5^3 + 5^4 + O(5^5)
sage: b = R(4025); b
5^2 + 2*5^3 + 5^4 + 5^5 + O(5^7)
sage: a + b
1 + 5 + 5^2 + 4*5^3 + 2*5^4 + O(5^5)
```

In the capped absolute type, instead of having a cap on the relative precision of an element there is instead a cap on the absolute precision. Elements still store their own precisions, and as with the capped relative case, exact elements are truncated when cast into the ring.:

```
sage: R = Zp(5, 5, 'capped-abs', 'series'); a = R(4005); a
5 + 2*5^3 + 5^4 + O(5^5)
sage: b = R(4025); b
5^2 + 2*5^3 + 5^4 + O(5^5)
sage: a * b
5^3 + 2*5^4 + O(5^5)
sage: (a * b) // 5^3
1 + 2*5 + O(5^2)
```

The fixed modulus type is the leanest of the p-adic rings: it is basically just a wrapper around $\mathbb{Z}/p^n\mathbb{Z}$ providing a unified interface with the rest of the p-adics. This is the type you should use if your sole interest is speed. It does not track precision of elements.:

```
sage: R = Zp(5,5,'fixed-mod','series'); a = R(4005); a
5 + 2*5^3 + 5^4 + O(5^5)
sage: a // 5
1 + 2*5^2 + 5^3 + O(5^5)
```

The lazy case will eventually support elements that can increase their precision upon request. It is not currently implemented.

PRINTING

There are many different ways to print p-adic elements. The way elements of a given ring print is controlled by options passed in at the creation of the ring. There are five basic printing modes (series, val-unit, terse, digits and bars), as well as various options that either hide some information in the print representation or sometimes make print representations more compact. Note that the printing options affect whether different p-adic fields are considered equal.

1. **series**: elements are displayed as series in p.:

```
sage: R = Zp(5, print_mode='series'); a = R(70700); a
3*5^2 + 3*5^4 + 2*5^5 + 4*5^6 + O(5^22)
sage: b = R(-70700); b
2*5^2 + 4*5^3 + 5^4 + 2*5^5 + 4*5^7 + 4*5^8 + 4*5^9 + 4*5^10 + 4*5^11 + 4*5^12 + 4*5^13 + 4*
```

print_pos controls whether negatives can be used in the coefficients of powers of p.:

```
sage: S = Zp(5, print_mode='series', print_pos=False); a = S(70700); a
-2*5^2 + 5^3 - 2*5^4 - 2*5^5 + 5^7 + O(5^22)
sage: b = S(-70700); b
2*5^2 - 5^3 + 2*5^4 + 2*5^5 - 5^7 + O(5^22)
```

print_max_terms limits the number of terms that appear.:

```
sage: T = Zp(5, print_mode='series', print_max_terms=4); b = R(-70700); b
2*5^2 + 4*5^3 + 5^4 + 2*5^5 + ... + O(5^22)
```

names affects how the prime is printed.:

```
sage: U.<p> = Zp(5); p
p + O(p^21)
```

print_sep and *print_alphabet* have no effect.

Note that print options affect equality:

```
sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
```

1. **val-unit**: elements are displayed as $p^k u$:

```
sage: R = Zp(5, print_mode='val-unit'); a = R(70700); a
5^2 * 2828 + O(5^22)
sage: b = R(-707*5); b
5 * 95367431639918 + O(5^21)
```

print_pos controls whether to use a balanced representation or not.:

```
sage: S = Zp(5, print_mode='val-unit', print_pos=False); b = S(-70700); b
5^2 * (-2828) + O(5^22)
```

names affects how the prime is printed.:

```
sage: T = Zp(5, print_mode='val-unit', names='pi'); a = T(70700); a
pi^2 * 2828 + O(pi^22)
```

print_max_terms, *print_sep* and *print_alphabet* have no effect.

Equality again depends on the printing options:

```
sage: R == S, R == T, S == T
(False, False, False)
```

1. **terse**: elements are displayed as an integer in base 10:

```
sage: R = Zp(5, print_mode='terse'); a = R(70700); a
70700 + O(5^22)
sage: b = R(-70700); b
2384185790944925 + O(5^22)
```

print_pos controls whether to use a balanced representation or not.:

```
sage: S = Zp(5, print_mode='terse', print_pos=False); b = S(-70700); b
-70700 + O(5^22)
```

name affects how the name is printed. Note that this interacts with the choice of shorter string for denominators.:

```
sage: T.<unif> = Zp(5, print_mode='terse'); c = T(-707); c
95367431639918 + O(unif^20)
```

print_max_terms, *print_sep* and *print_alphabet* have no effect.

Equality depends on printing options:

```
sage: R == S, R == T, S == T
(False, False, False)
```

1. **digits**: elements are displayed as a string of base p digits

Restriction: you can only use the digits printing mode for small primes. Namely, p must be less than the length of the alphabet tuple (default alphabet has length 62).:

```
sage: R = Zp(5, print_mode='digits'); a = R(70700); repr(a)
'...4230300'
sage: b = R(-70700); repr(b)
'...444444444444440214200'
```

Note that it's not possible to read off the precision from the representation in this mode.

print_max_terms limits the number of digits that are printed.:

```
sage: S = Zp(5, print_mode='digits', print_max_terms=4); b = S(-70700); repr(b)
'...214200'
```

print_alphabet controls the symbols used to substitute for digits greater than 9. Defaults to ('0', '1', '2', '3', '4', '5', '6', '7', '8', '9', 'A', 'B', 'C', 'D', 'E', 'F', 'G', 'H', 'I', 'J', 'K', 'L', 'M', 'N', 'O', 'P', 'Q', 'R', 'S', 'T', 'U', 'V', 'W', 'X', 'Y', 'Z', 'a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l', 'm', 'n', 'o', 'p', 'q', 'r', 's', 't', 'u', 'v', 'w', 'x', 'y', 'z'):

```
sage: T = Zp(5, print_mode='digits', print_max_terms=4, print_alphabet=('1','2','3','4','5')); b
'...325311'
```

print_pos, *name* and *print_sep* have no effect.

Equality depends on printing options:

```
sage: R == S, R == T, S == T
(False, False, False)
```

1. **bars**: elements are displayed as a string of base p digits with separators

   sage: R = Zp(5, print_mode='bars'); a = R(70700); repr(a) '...4|2|3|0|3|0|0' sage: b = R(-70700); repr(b) '...4|4|4|4|4|4|4|4|4|4|4|4|4|4|4|0|2|1|4|2|0|0'

Again, note that it's not possible to read of the precision from the representation in this mode.

print_pos controls whether the digits can be negative.:

```
sage: S = Zp(5, print_mode='bars',print_pos=False); b = S(-70700); repr(b)
'...-1|0|2|2|-1|2|0|0'
```

print_max_terms limits the number of digits that are printed.:

```
sage: T = Zp(5, print_mode='bars', print_max_terms=4); b = T(-70700); repr(b)
'...2|1|4|2|0|0'
```

print_sep controls the separation character.:

```
sage: U = Zp(5, print_mode='bars', print_sep=']['); a = U(70700); repr(a)
'...4][2][3][0][3][0][0'
```

name and *print_alphabet* have no effect.

Equality depends on printing options:

```
sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
```

EXAMPLES:

We allow non-prime p, but only if `check = False`. Note that some features will not work.:

```
sage: K = Zp(15, check=False); a = K(999); a
9 + 6*15 + 4*15^2 + O(15^20)
```

We create rings with various parameters:

```
sage: Zp(7)
7-adic Ring with capped relative precision 20
sage: Zp(9)
...
ValueError: p must be prime
sage: Zp(17, 5)
17-adic Ring with capped relative precision 5
sage: Zp(17, 5)(-1)
16 + 16*17 + 16*17^2 + 16*17^3 + 16*17^4 + O(17^5)
```

It works even with a fairly huge cap:

```
sage: Zp(next_prime(10^50), 100000)
10000000000000000000000000000000000000000000000151-adic Ring with capped relative precision 100
```

We create each type of ring:

```
sage: Zp(7, 20, 'capped-rel')
7-adic Ring with capped relative precision 20
sage: Zp(7, 20, 'fixed-mod')
7-adic Ring of fixed modulus 7^20
sage: Zp(7, 20, 'capped-abs')
7-adic Ring with capped absolute precision 20
```

We create a capped relative ring with each print mode:

```
sage: k = Zp(7, 8, print_mode='series'); k
7-adic Ring with capped relative precision 8
sage: k(7*(19))
5*7 + 2*7^2 + O(7^9)
sage: k(7*(-19))
2*7 + 4*7^2 + 6*7^3 + 6*7^4 + 6*7^5 + 6*7^6 + 6*7^7 + 6*7^8 + O(7^9)
```

```
sage: k = Zp(7, print_mode='val-unit'); k
7-adic Ring with capped relative precision 20
sage: k(7*(19))
7 * 19 + O(7^21)
sage: k(7*(-19))
7 * 79792266297611982 + O(7^21)
```

```
sage: k = Zp(7, print_mode='terse'); k
7-adic Ring with capped relative precision 20
sage: k(7*(19))
133 + O(7^21)
sage: k(7*(-19))
558545864083283874 + O(7^21)
```

Note that p-adic rings are cached (via weak references):

```
sage: a = Zp(7); b = Zp(7)
sage: a is b
True
```

We create some elements in various rings:

```
sage: R = Zp(5); a = R(4); a
4 + O(5^20)
sage: S = Zp(5, 10, type = 'capped-abs'); b = S(2); b
2 + O(5^10)
sage: a + b
1 + 5 + O(5^10)
```

create_key(*p, prec=20, type='capped-rel', print_mode=None, halt=40, names=None, ram_name=None, print_pos=None, print_sep=None, print_alphabet=None, print_max_terms=None, check=True*)

Creates a key from input parameters for `Zp`.

See the documentation for `Zp` for more information.

TESTS:

```
sage: Zp.create_key(5,40)
(5, 40, 'capped-rel', 'series', '5', True, '|', ('0', '1', '2', '3', '4', '5', '6', '7', '8'
```

create_object(*version, key*)

Creates an object using a given key.

See the documentation for `Zp` for more information.

TESTS:

```
sage: Zp.create_object((3,4,2),(5, 40, 'capped-rel', 'series', '5', True, '|', ('0', '1', '2
5-adic Ring with capped relative precision 40
```

Zq(*q, prec=20, type='capped-abs', modulus=None, names=None, print_mode=None, halt=40, ram_name=None, res_name=None, print_pos=None, print_sep=None, print_max_ram_terms=None, print_max_unram_terms=None, print_max_terse_terms=None, check=True*)

Given a prime power $q = p^n$, return the unique unramified extension of $\mathbb{Z}_p$ of degree n.

INPUT:

- `q` – integer: the prime power in $\mathbb{Q}_q$. OR, if `check=False`, a factorization object or single element list `[(p, n)]` where `p` is a prime and `n` a positive integer.
- `prec` – integer (default: `20`) the precision cap of the field. Individual elements keep track of their own precision. See TYPES and PRECISION below.
- `type` – string (default: `'capped-rel'`) Valid types are `'capped-rel'` and `'lazy'` (though `'lazy'` doesn't currently work). See TYPES and PRECISION below
- modulus – polynomial (default None) A polynomial defining an unramified extension of $\mathbb{Z}_p$. See MODULUS below.
- `names` – string or tuple (`None` is only allowed when $q = p$). The name of the generator, reducing to a generator of the residue field.
- `print_mode` – string (default: `None`). Valid modes are `'series'`, `'val-unit'`, `'terse'`, and `'bars'`. See PRINTING below.
- `halt` – currently irrelevant (to be used for lazy fields)
- `ram_name` – string (defaults to string representation of p if None). `ram_name` controls how the prime is printed. See PRINTING below.
- `res_name` – string (defaults to `None`, which corresponds to adding a `'0'` to the end of the name). Controls how elements of the reside field print.
- `print_pos` – bool (default `None`) Whether to only use positive integers in the representations of elements. See PRINTING below.
- `print_sep` – string (default `None`) The separator character used in the `'bars'` mode. See PRINTING below.

- print_max_ram_terms – integer (default None) The maximum number of powers of p shown. See PRINTING below.
- print_max_unram_terms – integer (default None) The maximum number of entries shown in a coefficient of p. See PRINTING below.
- print_max_terse_terms – integer (default None) The maximum number of terms in the polynomial representation of an element (using 'terse'). See PRINTING below.
- check – bool (default True) whether to check inputs.

OUTPUT:

- The corresponding unramified p-adic ring.

TYPES AND PRECISION:

There are two types of precision for a p-adic element. The first is relative precision, which gives the number of known p-adic digits:

```
sage: R.<a> = Zq(25, 20, 'capped-rel', print_mode='series'); b = 25*a; b
a*5^2 + O(5^22)
sage: b.precision_relative()
20
```

The second type of precision is absolute precision, which gives the power of p that this element is defined modulo:

```
sage: b.precision_absolute()
22
```

There are four types of unramified p-adic rings: capped relative rings, capped absolute rings, fixed modulus rings, and lazy rings.

In the capped relative case, the relative precision of an element is restricted to be at most a certain value, specified at the creation of the field. Individual elements also store their own precision, so the effect of various arithmetic operations on precision is tracked. When you cast an exact element into a capped relative field, it truncates it to the precision cap of the field.:

```
sage: R.<a> = Zq(9, 5, 'capped-rel', print_mode='series'); b = (1+2*a)^4; b
2 + (2*a + 2)*3 + (2*a + 1)*3^2 + O(3^5)
sage: c = R(3249); c
3^2 + 3^4 + 3^5 + 3^6 + O(3^7)
sage: b + c
2 + (2*a + 2)*3 + (2*a + 2)*3^2 + 3^4 + O(3^5)
```

One can invert non-units: the result is in the fraction field.:

```
sage: d = ~(3*b+c); d
2*3^-1 + (a + 1) + (a + 1)*3 + a*3^3 + O(3^4)
sage: d.parent()
Unramified Extension of 3-adic Field with capped relative precision 5 in a defined by (1 + O(3^5
```

The capped absolute case is the same as the capped relative case, except that the cap is on the absolute precision rather than the relative precision.:

```
sage: R.<a> = Zq(9, 5, 'capped-abs', print_mode='series'); b = 3*(1+2*a)^4; b
2*3 + (2*a + 2)*3^2 + (2*a + 1)*3^3 + O(3^5)
sage: c = R(3249); c
3^2 + 3^4 + O(3^5)
sage: b*c
```

```
2*3^3 + (2*a + 2)*3^4 + O(3^5)
sage: b*c >> 1
2*3^2 + (2*a + 2)*3^3 + O(3^4)
```

The fixed modulus case is like the capped absolute, except that individual elements don't track their precision.:

```
sage: R.<a> = Zq(9, 5, 'fixed-mod', print_mode='series'); b = 3*(1+2*a)^4; b
2*3 + (2*a + 2)*3^2 + (2*a + 1)*3^3 + O(3^5)
sage: c = R(3249); c
3^2 + 3^4 + O(3^5)
sage: b*c
2*3^3 + (2*a + 2)*3^4 + O(3^5)
sage: b*c >> 1
2*3^2 + (2*a + 2)*3^3 + O(3^5)
```

The lazy case will eventually support elements that can increase their precision upon request. It is not currently implemented.

MODULUS:

The modulus needs to define an unramified extension of $\mathbb{Z}_p$: when it is reduced to a polynomial over $\mathbb{F}_p$ it should be irreducible.

The modulus can be given in a number of forms.

1. A **polynomial**.

The base ring can be $\mathbb{Z}$, $\mathbb{Q}$, $\mathbb{Z}_p$, $\mathbb{F}_p$, or anything that can be converted to $\mathbb{Z}_p$.:

```
sage: P.<x> = ZZ[]
sage: R.<a> = Zq(27, modulus = x^3 + 2*x + 1); R.modulus()
(1 + O(3^20))*x^3 + (2 + O(3^20))*x + (1 + O(3^20))
sage: P.<x> = QQ[]
sage: S.<a> = Zq(27, modulus = x^3 + 2/7*x + 1)
sage: P.<x> = Zp(3)[]
sage: T.<a> = Zq(27, modulus = x^3 + 2*x + 1)
sage: P.<x> = Qp(3)[]
sage: U.<a> = Zq(27, modulus = x^3 + 2*x + 1)
sage: P.<x> = GF(3)[]
sage: V.<a> = Zq(27, modulus = x^3 + 2*x + 1)
```

Which form the modulus is given in has no effect on the unramified extension produced:

```
sage: R == S, R == T, T == U, U == V
(False, True, True, False)
```

unless the modulus is different, or the precision of the modulus differs. In the case of `V`, the modulus is only given to precision `1`, so the resulting field has a precision cap of `1`.:

```
sage: V.precision_cap()
1
sage: U.precision_cap()
20
sage: P.<x> = Zp(3)[]
sage: modulus = x^3 + (2 + O(3^7))*x + (1 + O(3^10))
sage: modulus
(1 + O(3^20))*x^3 + (2 + O(3^7))*x + (1 + O(3^10))
sage: W.<a> = Zq(27, modulus = modulus); W.precision_cap()
7
```

1. The modulus can also be given as a **symbolic expression**.:

```
sage: x = var('x')
sage: X.<a> = Zq(27, modulus = x^3 + 2*x + 1); X.modulus()
(1 + O(3^20))*x^3 + (2 + O(3^20))*x + (1 + O(3^20))
sage: X == R
True
```

By default, the polynomial chosen is the standard lift of the generator chosen for $\mathbb{F}_q$.:

```
sage: GF(125, 'a').modulus()
x^3 + 3*x + 3
sage: Y.<a> = Zq(125); Y.modulus()
(1 + O(5^20))*x^3 + (3 + O(5^20))*x + (3 + O(5^20))
```

However, you can choose another polynomial if desired (as long as the reduction to $\mathbb{F}_p[x]$ is irreducible).:

```
sage: P.<x> = ZZ[]
sage: Z.<a> = Zq(125, modulus = x^3 + 3*x^2 + x + 1); Z.modulus()
(1 + O(5^20))*x^3 + (3 + O(5^20))*x^2 + (1 + O(5^20))*x + (1 + O(5^20))
sage: Y == Z
False
```

PRINTING:

There are many different ways to print p-adic elements. The way elements of a given field print is controlled by options passed in at the creation of the field. There are four basic printing modes (`'series'`, `'val-unit'`, `'terse'` and `'bars'`; `'digits'` is not available), as well as various options that either hide some information in the print representation or sometimes make print representations more compact. Note that the printing options affect whether different p-adic fields are considered equal.

1. **series**: elements are displayed as series in p.:

```
sage: R.<a> = Zq(9, 20, 'capped-rel', print_mode='series'); (1+2*a)^4
2 + (2*a + 2)*3 + (2*a + 1)*3^2 + O(3^20)
sage: -3*(1+2*a)^4
3 + a*3^2 + 3^3 + (2*a + 2)*3^4 + (2*a + 2)*3^5 + (2*a + 2)*3^6 + (2*a + 2)*3^7 + (2*a + 2)*
sage: b = ~(3*a+18); b
(a + 2)*3^-1 + 1 + 2*3 + (a + 1)*3^2 + 3^3 + 2*3^4 + (a + 1)*3^5 + 3^6 + 2*3^7 + (a + 1)*3^8
sage: b.parent() is R.fraction_field()
True
```

print_pos controls whether negatives can be used in the coefficients of powers of p.:

```
sage: S.<b> = Zq(9, print_mode='series', print_pos=False); (1+2*b)^4
-1 - b*3 - 3^2 + (b + 1)*3^3 + O(3^20)
sage: -3*(1+2*b)^4
3 + b*3^2 + 3^3 + (-b - 1)*3^4 + O(3^20)
```

ram_name controls how the prime is printed.:

```
sage: T.<d> = Zq(9, print_mode='series', ram_name='p'); 3*(1+2*d)^4
2*p + (2*d + 2)*p^2 + (2*d + 1)*p^3 + O(p^20)
```

print_max_ram_terms limits the number of powers of p that appear.:

```
sage: U.<e> = Zq(9, print_mode='series', print_max_ram_terms=4); repr(-3*(1+2*e)^4)
'3 + e*3^2 + 3^3 + (2*e + 2)*3^4 + ... + O(3^20)'
```

print_max_unram_terms limits the number of terms that appear in a coefficient of a power of p.:

```
sage: V.<f> = Zq(128, prec = 8, print_mode='series'); repr((1+f)^9)
'(f^3 + 1) + (f^5 + f^4 + f^3 + f^2)*2 + (f^6 + f^5 + f^4 + f + 1)*2^2 + (f^5 + f^4 + f^2 + f +
sage: V.<f> = Zq(128, prec = 8, print_mode='series', print_max_unram_terms = 3); repr((1+f)^9)
'(f^3 + 1) + (f^5 + f^4 + ... + f^2)*2 + (f^6 + f^5 + ... + 1)*2^2 + (f^5 + f^4 + ... + 1)*2^3 +
sage: V.<f> = Zq(128, prec = 8, print_mode='series', print_max_unram_terms = 2); repr((1+f)^9)
'(f^3 + 1) + (f^5 + ... + f^2)*2 + (f^6 + ... + 1)*2^2 + (f^5 + ... + 1)*2^3 + (f^6 + ... + 1)*2
sage: V.<f> = Zq(128, prec = 8, print_mode='series', print_max_unram_terms = 1); repr((1+f)^9)
'(f^3 + ...) + (f^5 + ...)*2 + (f^6 + ...)*2^2 + (f^5 + ...)*2^3 + (f^6 + ...)*2^4 + (f^5 + ...)
sage: V.<f> = Zq(128, prec = 8, print_mode='series', print_max_unram_terms = 0); repr((1+f)^9 -
'(...)*2 + (...)*2^2 + (...)*2^3 + (...)*2^4 + (...)*2^5 + (...)*2^6 + (...)*2^7 + O(2^8)'
```

print_sep and *print_max_terse_terms* have no effect.

Note that print options affect equality:

```
sage: R == S, R == T, R == U, R == V, S == T, S == U, S == V, T == U, T == V, U == V
(False, False, False, False, False, False, False, False, False, False)
```

1. **val-unit**: elements are displayed as $p^k u$:

```
sage: R.<a> = Zq(9, 7, print_mode='val-unit'); b = (1+3*a)^9 - 1; b
3^3 * (15 + 64*a) + O(3^7)
sage: ~b
3^-3 * (41 + a) + O(3)
```

print_pos controls whether to use a balanced representation or not.:

```
sage: S.<a> = Zq(9, 7, print_mode='val-unit', print_pos=False); b = (1+3*a)^9 - 1; b
3^3 * (15 - 17*a) + O(3^7)
sage: ~b
3^-3 * (-40 + a) + O(3)
```

ram_name affects how the prime is printed.:

```
sage: A.<x> = Zp(next_prime(10^6), print_mode='val-unit')[]
sage: T.<a> = Zq(next_prime(10^6)^3, 4, print_mode='val-unit', ram_name='p', modulus=x^3+385831*
p^2 * (90732455187 + 713749771767*a + 579958835561*a^2) + O(p^4)
sage: b * (a^2 + a - 4)^-4
p^2 * 1 + O(p^4)
```

print_max_terse_terms controls how many terms of the polynomial appear in the unit part.:

```
sage: U.<a> = Zq(17^4, 6, print_mode='val-unit', print_max_terse_terms=3); b = (17*(a^3-a+14)^6)
17 * (772941 + 717522*a + 870707*a^2 + ...) + O(17^6)
```

print_sep, *print_max_ram_terms* and *print_max_unram_terms* have no effect.

Equality again depends on the printing options:

```
sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
```

1. **terse**: elements are displayed as a polynomial of degree less than the degree of the extension.:

```
sage: R.<a> = Zq(125, print_mode='terse')
sage: (a+5)^177
68210977979428 + 90313850704069*a + 73948093055069*a^2 + O(5^20)
sage: (a/5+1)^177
10990518995053/5^177 + 14019905391569/5^177*a + 16727634070694/5^177*a^2 + O(5^-158)
```

Note that in this last computation, you get one fewer p-adic digit than one might expect. This is because `R` is capped absolute, and thus 5 is cast in with relative precision 19.

As of version 3.3, if coefficients of the polynomial are non-integral, they are always printed with an explicit power of p in the denominator.:

```
sage: 5*a + a^2/25
5*a + 1/5^2*a^2 + O(5^16)
```

print_pos controls whether to use a balanced representation or not.:

```
sage: (a-5)^6
22864 + 95367431627998*a + 8349*a^2 + O(5^20)
sage: S.<a> = Zq(125, print_mode='terse', print_pos=False); b = (a-5)^6; b
22864 - 12627*a + 8349*a^2 + O(5^20)
sage: (a - 1/5)^6
-20624/5^6 + 18369/5^5*a + 1353/5^3*a^2 + O(5^14)
```

ram_name affects how the prime is printed.:

```
sage: T.<a> = Zq(125, print_mode='terse', ram_name='p'); (a - 1/5)^6
95367431620001/p^6 + 18369/p^5*a + 1353/p^3*a^2 + O(p^14)
```

print_max_terse_terms controls how many terms of the polynomial are shown.:

```
sage: U.<a> = Zq(625, print_mode='terse', print_max_terse_terms=2); (a-1/5)^6
106251/5^6 + 49994/5^5*a + ... + O(5^14)
```

print_sep, *print_max_ram_terms* and *print_max_unram_terms* have no effect.

Equality again depends on the printing options:

```
sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
```

1. **digits**: This print mode is not available when the residue field is not prime. It might make sense to have a dictionary for small fields, but this isn't implemented.
2. **bars**: elements are displayed in a similar fashion to series, but more compactly.:

```
sage: R.<a> = Zq(125); (a+5)^6
(4*a^2 + 3*a + 4) + (3*a^2 + 2*a)*5 + (a^2 + a + 1)*5^2 + (3*a + 2)*5^3 + (3*a^2 + a + 3)*5^
sage: R.<a> = Zq(125, print_mode='bars', prec=8); repr((a+5)^6)
'...[2, 3, 2]|[3, 1, 3]|[2, 3]|[1, 1, 1]|[0, 2, 3]|[4, 3, 4]'
sage: repr((a-5)^6)
'...[0, 4]|[1, 4]|[2, 0, 2]|[1, 4, 3]|[2, 3, 1]|[4, 4, 3]|[2, 4, 4]|[4, 3, 4]'
```

Note that it's not possible to read of the precision from the representation in this mode.:

```
sage: b = a + 3; repr(b)
'...[3, 1]'
sage: c = a + R(3, 4); repr(c)
'...[3, 1]'
sage: b.precision_absolute()
8
sage: c.precision_absolute()
4
```

print_pos controls whether the digits can be negative.:

```
sage: S.<a> = Zq(125, print_mode='bars', print_pos=False); repr((a-5)^6)
'...[1, -1, 1]|[2, 1, -2]|[2, 0, -2]|[-2, -1, 2]|[0, 0, -1]|[-2]|[-1, -2, -1]'
sage: repr((a-1/5)^6)
'...[0, 1, 2]|[-1, 1, 1]|.|[-2, -1, -1]|[2, 2, 1]|[0, 0, -2]|[0, -1]|[0, -1]|[1]'
```

print_max_ram_terms controls the maximum number of "digits" shown. Note that this puts a cap on the relative precision, not the absolute precision.:

```
sage: T.<a> = Zq(125, print_mode='bars', print_max_ram_terms=3, print_pos=False); repr((a-5)^6)
'...[0, 0, -1]|[-2]|[-1, -2, -1]'
sage: repr(5*(a-5)^6+50)
'...[0, 0, -1]|[]|[-1, -2, -1]|[]'
```

However, if the element has negative valuation, digits are shown up to the decimal point.:

```
sage: repr((a-1/5)^6)
'...|.|[-2, -1, -1]|[2, 2, 1]|[0, 0, -2]|[0, -1]|[0, -1]|[1]'
```

print_sep controls the separating character (`'|'` by default).:

```
sage: U.<a> = Zq(625, print_mode='bars', print_sep=''); b = (a+5)^6; repr(b)
'...[0, 1][4, 0, 2][3, 2, 2, 3][4, 2, 2, 4][0, 3][1, 1, 3][3, 1, 4, 1]'
```

print_max_unram_terms controls how many terms are shown in each `'digit'`:

```
sage: with local_print_mode(U, {'max_unram_terms': 3}): repr(b)
'...[0, 1][4,..., 0, 2][3,..., 2, 3][4,..., 2, 4][0, 3][1,..., 1, 3][3,..., 4, 1]'
sage: with local_print_mode(U, {'max_unram_terms': 2}): repr(b)
'...[0, 1][4,..., 2][3,..., 3][4,..., 4][0, 3][1,..., 3][3,..., 1]'
sage: with local_print_mode(U, {'max_unram_terms': 1}): repr(b)
'...[..., 1][..., 2][..., 3][..., 4][..., 3][..., 3][..., 1]'
sage: with local_print_mode(U, {'max_unram_terms':0}): repr(b-75*a)
'...[...][...][...][...][][...][...]'
```

ram_name and *print_max_terse_terms* have no effect.

Equality depends on printing options:

```
sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
```

EXAMPLES

Unlike for `Zp`, you can't create `Zq(N)` when `N` is not a prime power.

However, you can use `check=False` to pass in a pair in order to not have to factor. If you do so, you need to use names explicitly rather than the `R.<a>` syntax.:

```
sage: p = next_prime(2^123)
sage: k = Zp(p)
sage: R.<x> = k[]
sage: K = Zq([(p, 5)], modulus=x^5+x+4, names='a', ram_name='p', print_pos=False, check=False)
sage: K.0^5
(-a - 4) + O(p^20)
```

In tests on sage.math, the creation of K as above took an average of 1.58ms, while:

```
sage: K = Zq(p^5, modulus=x^5+x+4, names='a', ram_name='p', print_pos=False, check=True)
```

took an average of 24.5ms. Of course, with smaller primes these savings disappear.

ZqCA(*q, prec=20, modulus=None, names=None, print_mode=None, halt=40, ram_name=None, print_pos=None, print_sep=None, print_alphabet=None, print_max_ram_terms=None, print_max_unram_terms=None, print_max_terse_terms=None, check=True*)
A shorcut function to create capped absolute unramified p-adic rings.

See documentation for Zq for a description of the input paramters.

EXAMPLES:

```
sage: R.<a> = ZqCA(25, 40); R
Unramified Extension of 5-adic Ring with capped absolute precision 40 in a defined by (1 + O(5^4
```

ZqCR(*q, prec=20, modulus=None, names=None, print_mode=None, halt=40, ram_name=None, print_pos=None, print_sep=None, print_alphabet=None, print_max_ram_terms=None, print_max_unram_terms=None, print_max_terse_terms=None, check=True*)
A shorcut function to create capped relative unramified p-adic rings.

Same functionality as Zq. See documentation for Zq for a description of the input paramters.

EXAMPLES:

```
sage: R.<a> = ZqCR(25, 40); R
Unramified Extension of 5-adic Ring with capped relative precision 40 in a defined by (1 + O(5^4
```

ZqFM(*q, prec=20, modulus=None, names=None, print_mode=None, halt=40, ram_name=None, print_pos=None, print_sep=None, print_alphabet=None, print_max_ram_terms=None, print_max_unram_terms=None, print_max_terse_terms=None, check=True*)
A shorcut function to create fixed modulus unramified p-adic rings.

See documentation for Zq for a description of the input paramters.

EXAMPLES:

```
sage: R.<a> = ZqFM(25, 40); R
Unramified Extension of 5-adic Ring of fixed modulus 5^40 in a defined by (1 + O(5^40))*x^2 + (4
```

is_eisenstein(*poly*)
Returns True iff this monic polynomial is Eisenstein.

A polynomial is Eisenstein if it is monic, the constant term has valuation 1 and all other terms have positive valuation.

EXAMPLES:

```
sage: R = Zp(5)
sage: S.<x> = R[]
sage: from sage.rings.padics.factory import is_eisenstein
sage: f = x^4 - 75*x + 15
sage: is_eisenstein(f)
```

```
True
sage: g = x^4 + 75
sage: is_eisenstein(g)
False
sage: h = x^7 + 27*x -15
sage: is_eisenstein(h)
False
```

is_unramified(*poly*)

Returns true iff this monic polynomial is unramified.

A polynomial is unramified if its reduction modulo the maximal ideal is irreducible.

EXAMPLES:

```
sage: R = Zp(5)
sage: S.<x> = R[]
sage: from sage.rings.padics.factory import is_unramified
sage: f = x^4 + 14*x + 9
sage: is_unramified(f)
True
sage: g = x^6 + 17*x + 6
sage: is_unramified(g)
False
```

krasner_check(*poly, prec*)

Returns True iff poly determines a unique isomorphism class of extensions at precision prec.

Currently just returns True (thus allowing extensions that are not defined to high enough precision in order to specify them up to isomorphism). This will change in the future.

EXAMPLES:

```
sage: from sage.rings.padics.factory import krasner_check
sage: krasner_check(1,2) #this is a stupid example.
True
```

class **pAdicExtension_class**()

A class for creating extensions of p-adic rings and fields.

EXAMPLES:

```
sage: R = Zp(5,3)
sage: S.<x> = ZZ[]
sage: W.<w> = pAdicExtension(R, x^4-15)
sage: W
Eisenstein Extension of 5-adic Ring with capped relative precision 3 in w defined by (1 + O(5^3)
sage: W.precision_cap()
12
```

create_key_and_extra_args(*base, premodulus, prec=None, print_mode=None, halt=None, names=None, var_name=None, res_name=None, unram_name=None, ram_name=None, print_pos=None, print_sep=None, print_alphabet=None, print_max_ram_terms=None, print_max_unram_terms=None, print_max_terse_terms=None, check=True, unram=False*)

Creates a key from input parameters for pAdicExtension.

See the documentation for `Qq` for more information.

TESTS:

```
sage: R = Zp(5,3)
sage: S.<x> = ZZ[]
sage: pAdicExtension.create_key_and_extra_args(R, x^4-15,names='w')
(('e', 5-adic Ring with capped relative precision 3, x^4 - 15, (1 + O(5^3))*x^4 + (O(5^4))*x
```

create_object(*version, key, shift_seed*)

Creates an object using a given key.

See the documentation for pAdicExtension for more information.

TESTS:

```
sage: R = Zp(5,3)
sage: S.<x> = R[]
sage: pAdicExtension.create_object(version = (3,4,2), key = ('e', R, x^4 - 15, x^4 - 15, ('w
Eisenstein Extension of 5-adic Ring with capped relative precision 3 in w defined by (1 + O(
```

truncate_to_prec(*poly, absprec*)

Truncates the unused precision off of a polynomial.

EXAMPLES:

```
sage: R = Zp(5)
sage: S.<x> = R[]
sage: from sage.rings.padics.factory import truncate_to_prec
sage: f = x^4 + (3+O(5^6))*x^3 + O(5^4)
sage: truncate_to_prec(f, 5)
(1 + O(5^5))*x^4 + (3 + O(5^5))*x^3 + (O(5^5))*x^2 + (O(5^5))*x + (O(5^4))
```

27.3 Local Generic.

Superclass for p-adic and power series rings.

AUTHORS:

- David Roe

class LocalGeneric(*base, prec, names, element_class*)

defining_polynomial(*var='x'*)

Returns the defining polynomial of this local ring, i.e. just `x`.

INPUT:

- `self` – a local ring
- `var` – string (default: `'x'`) the name of the variable

OUTPUT:

```
- polynomial -- the defining polynomial of this ring as an extension over its ground ring
```

EXAMPLES:

```
sage: R = Zp(3, 3, 'fixed-mod'); R.defining_polynomial('foo')
(1 + O(3^3))*foo
```

degree()

Returns the degree of `self` over the ground ring, i.e. 1.

INPUT:

- `self` – a local ring

OUTPUT:

- integer – the degree of this ring, i.e., 1

EXAMPLES:

```
sage: R = Zp(3, 10, 'capped-rel'); R.degree()
1
```

e(*K=None*)

Returns the ramification index over the ground ring: 1 unless overridden.

INPUT:

- `self` – a local ring
- `K` – a subring of `self` (default `None`)

OUTPUT:

- integer – the ramification index of this ring: 1 unless overridden.

EXAMPLES:

```
sage: R = Zp(3, 5, 'capped-rel'); R.e()
1
```

ext(**args, **kwds*)

Constructs an extension of self. See `extension` for more details.

EXAMPLES:

```
sage: A = Zp(7,10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2+7)
sage: B.uniformiser()
t + O(t^21)
```

f(*K=None*)

Returns the inertia degree over the ground ring: 1 unless overridden.

INPUT:

- `self` – a local ring
- `K` – a subring (default `None`)

OUTPUT:

- integer – the inertia degree of this ring: 1 unless overridden.

EXAMPLES:

```
sage: R = Zp(3, 5, 'capped-rel'); R.f()
1
```

ground_ring()

Returns `self`.

Will be overridden by extensions.

INPUT:

- `self` – a local ring

OUTPUT:

```
- the ground ring of ``self``, i.e., itself
```

EXAMPLES:

```
sage: R = Zp(3, 5, 'fixed-mod')
sage: S = Zp(3, 4, 'fixed-mod')
sage: R.ground_ring() is R
True
sage: S.ground_ring() is R
False
```

ground_ring_of_tower()

Returns `self`.

Will be overridden by extensions.

INPUT:

- `self` – a p-adic ring

OUTPUT:

- the ground ring of the tower for `self`, i.e., itself

EXAMPLES:

```
sage: R = Zp(5)
sage: R.ground_ring_of_tower()
5-adic Ring with capped relative precision 20
```

inertia_degree(*K=None*)

Returns the inertia degree over `K` (defaults to the ground ring): 1 unless overridden.

INPUT:

- `self` – a local ring
- `K` – a subring of `self` (default None)

OUTPUT:

- integer – the inertia degree of this ring: 1 unless overridden.

EXAMPLES:

```
sage: R = Zp(3, 5, 'capped-rel'); R.inertia_degree()
1
```

inertia_subring()

Returns the inertia subring, i.e. `self`.

INPUT:

- `self` – a local ring

OUTPUT:

- the inertia subring of self, i.e., itself

EXAMPLES:

```
sage: R = Zp(5)
sage: R.inertia_subring()
5-adic Ring with capped relative precision 20
```

is_atomic_repr()

Return False, since we want p-adics to be printed with parentheses around them when they are coefficients, e.g., in a polynomial.

INPUT:

- `self` – a p-adic ring

OUTPUT:

- boolean – whether `self`'s representation is atomic, i.e., `False`

EXAMPLES:

```
sage: R = Zp(5, 5, 'fixed-mod'); R.is_atomic_repr()
False
```

is_capped_absolute()

Returns whether this p-adic ring bounds precision in a capped absolute fashion.

The absolute precision of an element is the power of p modulo which that element is defined. In a capped absolute ring, the absolute precision of elements are bounded by a constant depending on the ring.

EXAMPLES:

```
sage: R = ZpCA(5, 15)
sage: R.is_capped_absolute()
True
sage: R(5^7)
5^7 + O(5^15)
sage: S = Zp(5, 15)
sage: S.is_capped_absolute()
False
sage: S(5^7)
5^7 + O(5^22)
```

is_capped_relative()

Returns whether this p-adic ring bounds precision in a capped relative fashion.

The relative precision of an element is the power of p modulo which the unit part of that element is defined. In a capped relative ring, the relative precision of elements are bounded by a constant depending on the ring.

EXAMPLES:

```
sage: R = ZpCA(5, 15)
sage: R.is_capped_relative()
False
sage: R(5^7)
5^7 + O(5^15)
sage: S = Zp(5, 15)
sage: S.is_capped_relative()
True
sage: S(5^7)
5^7 + O(5^22)
```

is_exact()

Returns whether this p-adic ring is exact, i.e. False.

INPUT: self – a p-adic rinng

OUTPUT: boolean – whether self is exact, i.e. False.

EXAMPLES: #sage: R = Zp(5, 3, 'lazy'); R.is_exact() #False sage: R = Zp(5, 3, 'fixed-mod'); R.is_exact() False

is_finite()

Returns whether this ring is finite, i.e. `False`.

INPUT:

```
- ``self`` -- a `p`-adic ring
```

OUTPUT:

```
- boolean -- whether self is finite, i.e., ``False``
```

EXAMPLES:

```
sage: R = Zp(3, 10,'fixed-mod'); R.is_finite()
False
```

is_fixed_mod()

Returns whether this p-adic ring bounds precision in a fixed modulus fashion.

The absolute precision of an element is the power of p modulo which that element is defined. In a fixed modulus ring, the absolute precision of every element is defined to be the precision cap of the parent. This means that some operations, such as division by p, don't return a well defined answer.

EXAMPLES:

```
sage: R = ZpFM(5,15)
sage: R.is_fixed_mod()
True
sage: R(5^7,absprec=9)
5^7 + O(5^15)
sage: S = ZpCA(5, 15)
sage: S.is_fixed_mod()
False
sage: S(5^7,absprec=9)
5^7 + O(5^9)
```

is_lazy()

Returns whether this p-adic ring bounds precision in a lazy fashion.

In a lazy ring, elements have mechanisms for computing themselves to greater precision.

EXAMPLES:

```
sage: R = Zp(5)
sage: R.is_lazy()
False
```

maximal_unramified_subextension()

Returns the maximal unramified subextension.

INPUT:

- `self` – a local ring

OUTPUT:

- the maximal unramified subextension of `self`

EXAMPLES:

```
sage: R = Zp(5)
sage: R.maximal_unramified_subextension()
5-adic Ring with capped relative precision 20
```

precision_cap()

Returns the precision cap for `self`.

INPUT:

- `self` – a local ring

OUTPUT:

- integer – `self`'s precision cap

EXAMPLES:

```
sage: R = Zp(3, 10,'fixed-mod'); R.precision_cap()
10
sage: R = Zp(3, 10,'capped-rel'); R.precision_cap()
10
sage: R = Zp(3, 10,'capped-abs'); R.precision_cap()
10
```

NOTES:

```
This will have different meanings depending on the type of
local ring.  For fixed modulus rings, all elements are
considered modulo ``self.prime()^self.precision_cap()``.
For rings with an absolute cap (i.e. the class
``pAdicRingCappedAbsolute``), each element has a precision
that is tracked and is bounded above by
``self.precision_cap()``.  Rings with relative caps
(e.g. the class ``pAdicRingCappedRelative``) are the same
except that the precision is the precision of the unit
part of each element.  For lazy rings, this gives the
initial precision to which elements are computed.
```

ramification_index(*K=None*)

Returns the ramification index over the ground ring: 1 unless overridden.

INPUT:

- `self` – a local ring

OUTPUT:

- integer – the ramification index of this ring: 1 unless overridden.

EXAMPLES:

```
sage: R = Zp(3, 5, 'capped-rel'); R.ramification_index()
1
```

residue_characteristic()

Returns the characteristic of `self`'s residue field.

INPUT:

- `self` – a p-adic ring.

OUTPUT:

- integer – the characteristic of the residue field.

EXAMPLES:

```
sage: R = Zp(3, 5, 'capped-rel'); R.residue_characteristic()
3
```

residue_class_degree(*K=None*)

Returns the inertia degree over the ground ring: 1 unless overridden.

INPUT:

- `self` – a local ring
- `K` – a subring (default `None`)

OUTPUT:

- integer – the inertia degree of this ring: 1 unless overridden.

EXAMPLES:

```
sage: R = Zp(3, 5, 'capped-rel'); R.residue_class_degree()
1
```

uniformiser()

Returns a uniformiser for `self`, ie a generator for the unique maximal ideal.

EXAMPLES:

```
sage: R = Zp(5)
sage: R.uniformiser()
5 + O(5^21)
sage: A = Zp(7,10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2+7)
sage: B.uniformiser()
t + O(t^21)
```

uniformiser_pow(*n*)

Returns the $n`thpowerofthe uniformiserof "self`$ (as an element of `self`).

EXAMPLES:

```
sage: R = Zp(5)
sage: R.uniformiser_pow(5)
5^5 + O(5^25)
```

27.4 p-Adic Generic.

A generic superclass for all p-adic parents.

AUTHORS:

- David Roe
- Genya Zaytman: documentation
- David Harvey: doctests

local_print_mode(*obj, print_options, pos=None, ram_name=None*)

Context manager for safely temporarily changing the print_mode of a p-adic ring/field.

EXAMPLES:

```
sage: R = Zp(5)
sage: R(45)
4*5 + 5^2 + O(5^21)
sage: with local_print_mode(R, 'val-unit'):
...       print R(45)
...
5 * 9 + O(5^21)
```

NOTES:

```
For more documentation see localvars in parent_gens.pyx
```

class pAdicGeneric(*base, p, prec, print_mode, names, element_class*)

characteristic()

Returns the characteristic of self, which is always 0.

INPUT:

```
self -- a p-adic parent
```

OUTPUT:

integer -- self's characteristic, i.e., 0

EXAMPLES:

```
sage: R = Zp(3, 10,'fixed-mod'); R.characteristic()
0
```

extension(*modulus, prec=None, names=None, print_mode=None, halt=None, **kwds*)

Create an extension of this p-adic ring.

EXAMPLES:

```
sage: k = Qp(5)
sage: R.<x> = k[]
sage: l.<w> = k.extension(x^2-5); l
Eisenstein Extension of 5-adic Field with capped relative precision 20 in w defined by (1 +

sage: F = list(Qp(19)['x'](cyclotomic_polynomial(5)).factor())[0][0]
sage: L = Qp(19).extension(F, names='a')
sage: L
Unramified Extension of 19-adic Field with capped relative precision 20 in a defined by (1 +
```

gens()

Returns a list of generators.

EXAMPLES:

```
sage: R = Zp(5); R.gens()
[5 + O(5^21)]
sage: Zq(25,names='a').gens()
[a + O(5^20)]
sage: S.<x> = ZZ[]; f = x^5 + 25*x -5; W.<w> = R.ext(f); W.gens()
[w + O(w^101)]
```

ngens()

Returns the number of generators of self.

We conventionally define this as 1: for base rings, we take a uniformizer as the generator; for extension rings, we take a root of the minimal polynomial defining the extension.

EXAMPLES:

```
sage: Zp(5).ngens()
1
sage: Zq(25,names='a').ngens()
1
```

prime()

Returns the prime, ie the characteristic of the residue field.

INPUT:

self -- a p-adic parent

OUTPUT:

integer -- the characteristic of the residue field

EXAMPLES:

```
sage: R = Zp(3,5,'fixed-mod')
sage: R.prime()
3
```

print_mode()

Returns the current print mode as a string.

INPUT:

```
self -- a p-adic field
```

OUTPUT:

```
string -- self's print mode
```

EXAMPLES:

```
sage: R = Qp(7,5, 'capped-rel')
sage: R.print_mode()
'series'
```

residue_characteristic()

Returns the prime, i.e., the characteristic of the residue field.

INPUT:

```
self -- a p-adic ring
```

OUTPUT:

```
integer -- the characteristic of the residue field
```

EXAMPLES:

```
sage: R = Zp(3,5,'fixed-mod')
sage: R.residue_characteristic()
3
```

residue_class_field()

Returns the residue class field.

INPUT:

```
self -- a p-adic ring
```

OUTPUT:

```
the residue field
```

EXAMPLES:

```
sage: R = Zp(3,5,'fixed-mod')
sage: k = R.residue_class_field()
sage: k
Finite Field of size 3
```

residue_field()

Returns the residue class field.

INPUT:

```
self -- a p-adic ring
```

OUTPUT:

```
the residue field
```

EXAMPLES:

```
sage: R = Zp(3,5,'fixed-mod')
sage: k = R.residue_field()
sage: k
Finite Field of size 3
```

residue_system()

Returns a list of elements representing all the residue classes.

INPUT:

self -- a p-adic ring

OUTPUT:

list of elementss -- a list of elements representing all the residue classes

EXAMPLES:

```
sage: R = Zp(3, 5,'fixed-mod')
sage: R.residue_system()
[O(3^5), 1 + O(3^5), 2 + O(3^5)]
```

teichmuller(*x*, *prec=None*)

Returns the teichmuller representative of x.

INPUT:

- self -- a p-adic ring
- x -- something that can be cast into self

OUTPUT:

- element -- the teichmuller lift of x

EXAMPLES:

```
sage: R = Zp(5, 10, 'capped-rel', 'series')
sage: R.teichmuller(2)
2 + 5 + 2*5^2 + 5^3 + 3*5^4 + 4*5^5 + 2*5^6 + 3*5^7 + 3*5^9 + O(5^10)
sage: R = Qp(5, 10,'capped-rel','series')
sage: R.teichmuller(2)
2 + 5 + 2*5^2 + 5^3 + 3*5^4 + 4*5^5 + 2*5^6 + 3*5^7 + 3*5^9 + O(5^10)
sage: R = Zp(5, 10, 'capped-abs', 'series')
sage: R.teichmuller(2)
2 + 5 + 2*5^2 + 5^3 + 3*5^4 + 4*5^5 + 2*5^6 + 3*5^7 + 3*5^9 + O(5^10)
sage: R = Zp(5, 10, 'fixed-mod', 'series')
sage: R.teichmuller(2)
2 + 5 + 2*5^2 + 5^3 + 3*5^4 + 4*5^5 + 2*5^6 + 3*5^7 + 3*5^9 + O(5^10)
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: y = W.teichmuller(3); y
3 + 3*w^5 + w^7 + 2*w^9 + 2*w^10 + 4*w^11 + w^12 + 2*w^13 + 3*w^15 + 2*w^16 + 3*w^17 + w^18
sage: y^5 == y
True
sage: g = x^3 + 3*x + 3
sage: A.<a> = R.ext(g)
sage: b = A.teichmuller(1 + 2*a - a^2); b
(4*a^2 + 2*a + 1) + 2*a*5 + (3*a^2 + 1)*5^2 + (a + 4)*5^3 + (a^2 + a + 1)*5^4 + O(5^5)
sage: b^125 == b
True
```

AUTHORS:

- Initial version: David Roe
- Quadratic time version: Kiran Kedlaya <kedlaya@math.mit.edu> (3/27/07)

teichmuller_system()

Returns a set of teichmuller representatives for the invertible elements of Z / pZ.

INPUT:

- self – a p-adic ring

OUTPUT:

•list of elements – a list of teichmuller representatives for the invertible elements of Z / pZ

EXAMPLES:

```
sage: R = Zp(3, 5,'fixed-mod', 'terse')
sage: R.teichmuller_system()
[1 + O(3^5), 242 + O(3^5)]
```

NOTES:

Should this return 0 as well?

uniformizer_pow(*n*)

Returns p^n, as an element of self.

If n is infinity, returns 0.

EXAMPLES:

```
sage: R = Zp(3, 5, 'fixed-mod')
sage: R.uniformizer_pow(3)
3^3 + O(3^5)
sage: R.uniformizer_pow(infinity)
O(3^5)
```

27.5 p-Adic Generic Nodes.

This file contains a bunch of intermediate classes for the p-adic parents, allowing a function to be implemented at the right level of generality.

AUTHORS:

- David Roe

class CappedAbsoluteGeneric(*base, prec, names, element_class*)

is_capped_absolute()

Returns whether this p-adic ring bounds precision in a capped absolute fashion.

The absolute precision of an element is the power of p modulo which that element is defined. In a capped absolute ring, the absolute precision of elements are bounded by a constant depending on the ring.

EXAMPLES:

```
sage: R = ZpCA(5, 15)
sage: R.is_capped_absolute()
True
sage: R(5^7)
5^7 + O(5^15)
sage: S = Zp(5, 15)
sage: S.is_capped_absolute()
False
sage: S(5^7)
5^7 + O(5^22)
```

class CappedRelativeFieldGeneric(*base, prec, names, element_class*)

class CappedRelativeGeneric(*base, prec, names, element_class*)

is_capped_relative()

Returns whether this p-adic ring bounds precision in a capped relative fashion.

The relative precision of an element is the power of p modulo which the unit part of that element is defined. In a capped relative ring, the relative precision of elements are bounded by a constant depending on the ring.

EXAMPLES:

```
sage: R = ZpCA(5, 15)
sage: R.is_capped_relative()
False
sage: R(5^7)
5^7 + O(5^15)
sage: S = Zp(5, 15)
sage: S.is_capped_relative()
True
sage: S(5^7)
5^7 + O(5^22)
```

class CappedRelativeRingGeneric(*base, prec, names, element_class*)

class FixedModGeneric(*base, prec, names, element_class*)

is_fixed_mod()

Returns whether this p-adic ring bounds precision in a fixed modulus fashion.

The absolute precision of an element is the power of p modulo which that element is defined. In a fixed modulus ring, the absolute precision of every element is defined to be the precision cap of the parent. This means that some operations, such as division by p, don't return a well defined answer.

EXAMPLES:

```
sage: R = ZpFM(5,15)
sage: R.is_fixed_mod()
True
sage: R(5^7,absprec=9)
5^7 + O(5^15)
sage: S = ZpCA(5, 15)
sage: S.is_fixed_mod()
False
sage: S(5^7,absprec=9)
5^7 + O(5^9)
```

is_pAdicField(*R*)

Returns `True` if and only if `R` is a p-adic field.

EXAMPLES:

```
sage: is_pAdicField(Zp(17))
False
sage: is_pAdicField(Qp(17))
True
```

is_pAdicRing(*R*)

Returns `True` if and only if `R` is a p-adic ring (not a field).

EXAMPLES:

```
sage: is_pAdicRing(Zp(5))
True
sage: is_pAdicRing(RR)
False
```

class **pAdicCappedAbsoluteRingGeneric**(*base, p, prec, print_mode, names, element_class*)

class **pAdicCappedRelativeFieldGeneric**(*base, p, prec, print_mode, names, element_class*)

class **pAdicCappedRelativeRingGeneric**(*base, p, prec, print_mode, names, element_class*)

class **pAdicFieldBaseGeneric**(*p, prec, print_mode, names, element_class*)

composite(*subfield1, subfield2*)

Returns the composite of two subfields of self, i.e., the largest subfield containing both

INPUT:

- `self` – a p-adic field
- `subfield1` – a subfield
- `subfield2` – a subfield

OUTPUT:

- the composite of subfield1 and subfield2

EXAMPLES:

```
sage: K = Qp(17); K.composite(K, K) is K
True
```

construction()

Returns the functorial construction of `self`, namely, completion of the rational numbers with respect a given prime.

Also preserves other information that makes this field unique (e.g. precision, rounding, print mode).

EXAMPLE:

```
sage: K = Qp(17, 8, print_mode='val-unit', print_sep='&')
sage: c, L = K.construction(); L
Rational Field
sage: c(L)
17-adic Field with capped relative precision 8
sage: K == c(L)
True
```

subfield(*list*)

Returns the subfield generated by the elements in list

INPUT:

- `self` – a p-adic field
- `list` – a list of elements of `self`

OUTPUT:

- the subfield of `self` generated by the elements of list

EXAMPLES:

```
sage: K = Qp(17); K.subfield([K(17), K(1827)]) is K
True
```

subfields_of_degree(*n*)

Returns the number of subfields of self of degree n

INPUT:

- `self` – a p-adic field
- `n` – an integer

OUTPUT:

- integer – the number of subfields of degree `n` over self.base_ring()

EXAMPLES:

```
sage: K = Qp(17)
sage: K.subfields_of_degree(1)
1
```

class pAdicFieldGeneric (*base, p, prec, print_mode, names, element_class*)

class pAdicFixedModRingGeneric (*base, p, prec, print_mode, names, element_class*)

class pAdicRingBaseGeneric (*p, prec, print_mode, names, element_class*)

construction()

Returns the functorial construction of self, namely, completion of the rational numbers with respect a given prime.

Also preserves other information that makes this field unique (e.g. precision, rounding, print mode).

EXAMPLE:

```
sage: K = Zp(17, 8, print_mode='val-unit', print_sep='&')
sage: c, L = K.construction(); L
Integer Ring
sage: c(L)
17-adic Ring with capped relative precision 8
sage: K == c(L)
True
```

random_element (*algorithm='default'*)

Returns a random element of self, optionally using the algorithm argument to decide how it generates the element. Algorithms currently implemented:

- default: Choose a_i, $i >= 0$, randomly between 0 and $p-1$ until a nonzero choice is made. Then continue choosing a_i randomly between 0 and $p-1$ until we reach precision_cap, and return $\sum a_i p^i$.

EXAMPLES:

```
sage: Zp(5,6).random_element()
3 + 3*5 + 2*5^2 + 3*5^3 + 2*5^4 + 5^5 + O(5^6)
sage: ZpCA(5,6).random_element()
4*5^2 + 5^3 + O(5^6)
sage: ZpFM(5,6).random_element()
2 + 4*5^2 + 2*5^4 + 5^5 + O(5^6)
```

class pAdicRingGeneric (*base, p, prec, print_mode, names, element_class*)

is_field()

Returns whether this ring is actually a field, ie `False`.

EXAMPLES:

```
sage: Zp(5).is_field()
False
```

krull_dimension()

Returns the Krull dimension of self, i.e. 1

INPUT:

- self – a p-adic ring

OUTPUT:

- the Krull dimension of self. Since self is a p-adic ring, this is 1.

EXAMPLES:

```
sage: Zp(5).krull_dimension()
1
```

27.6 p-Adic Base Generic.

A superclass for implementations of $\mathbb{Z}_p$ and $\mathbb{Q}_p$.

AUTHORS:

- David Roe

class pAdicBaseGeneric(*p, prec, print_mode, names, element_class*)

absolute_discriminant()
Returns the absolute discriminant of this p-adic ring
EXAMPLES:

```
sage: Zp(5).absolute_discriminant()
1
```

discriminant(*K=None*)
Returns the discriminant of this p-adic ring over `K`
INPUT:

- `self` – a p-adic ring
- `K` – a sub-ring of `self` or `None` (default: `None`)

OUTPUT:

- integer – the discriminant of this ring over `K` (or the absolute discriminant if `K` is `None`)

EXAMPLES:

```
sage: Zp(5).discriminant()
1
```

fraction_field(*print_mode=None*)
Returns the fraction field of `self`.
INPUT:

- `print_mode` - a dictionary containing print options. Defaults to the same options as this ring.

OUTPUT:

- the fraction field of `self`.

EXAMPLES:

```
sage: R = Zp(5, print_mode='digits')
sage: K = R.fraction_field(); repr(K(1/3))[3:]
'31313131313131313132'
sage: L = R.fraction_field({'max_ram_terms':4}); repr(L(1/3))[3:]
'3132'
```

gen(*n=0*)
Returns the `n`th generator of this extension. For base rings/fields, we consider the generator to be the prime.
EXAMPLES:

```
sage: R = Zp(5); R.gen()
5 + O(5^21)
```

has_pth_root()

Returns whether or not $\mathbb{Z}_p$ has a primitive p^{th} root of unity.

EXAMPLES:

```
sage: Zp(2).has_pth_root()
True
sage: Zp(17).has_pth_root()
False
```

has_root_of_unity(*n*)

Returns whether or not $\mathbb{Z}_p$ has a primitive n^{th} root of unity.

INPUT:

- `self` – a p-adic ring
- n – an integer

OUTPUT:

- `boolean` – whether `self` has primitive n^{th} root of unity

EXAMPLES:

```
sage: R=Zp(37)
sage: R.has_root_of_unity(12)
True
sage: R.has_root_of_unity(11)
False
```

integer_ring(*print_mode=None*)

Returns the integer ring of `self`, possibly with `print_mode` changed.

INPUT:

- `print_mode` - a dictionary containing print options. Defaults to the same options as this ring.

OUTPUT:

- The ring of integral elements in `self`.

EXAMPLES:

```
sage: K = Qp(5, print_mode='digits')
sage: R = K.integer_ring(); repr(R(1/3))[3:]
'31313131313131313132'
sage: S = K.integer_ring({'max_ram_terms':4}); repr(S(1/3))[3:]
'3132'
```

is_abelian()

Returns whether the Galois group is abelian, i.e. `True`. #should this be automorphism group?

EXAMPLES:

```
sage: R = Zp(3, 10,'fixed-mod'); R.is_abelian()
True
```

is_isomorphic(*ring*)

Returns whether `self` and `ring` are isomorphic, i.e. whether `ring` is an implementation of $\mathbb{Z}_p$ for the same prime as `self`.

INPUT:

- `self` – a p-adic ring
- `ring` – a ring

OUTPUT:

•boolean – whether ring is an implementation of mathbb{Z}_p‘ for the same prime as self.

EXAMPLES:

```
sage: R = Zp(5, 15, print_mode='digits'); S = Zp(5, 44, print_max_terms=4); R.is_isomorphic(
True
```

is_normal()

Returns whether or not this is a normal extension, i.e. True.

EXAMPLES:

```
sage: R = Zp(3, 10,'fixed-mod'); R.is_normal()
True
```

plot(*max_points=2500, **args*)

Creates a visualization of this p-adic ring as a fractal similar as a generalization of the the Sierpi'nski triangle. The resulting image attempts to capture the algebraic and topological characteristics of $\mathbb{Z}_p$.

INPUT:

•point_count – the maximum number or points to plot, which controls the depth of recursion (default 2500)

•**args – color, size, etc. that are passed to the underlying point graphics objects

REFERENCES:

•Cuoco, A. ''Visualizing the p-adic Integers'', The American Mathematical Monthly, Vol. 98, No. 4 (Apr., 1991), pp. 355-364

EXAMPLES:

```
sage: Zp(3).plot()
sage: Zp(5).plot(max_points=625)
sage: Zp(23).plot(rgbcolor=(1,0,0))
```

uniformizer()

Returns a uniformizer for this ring.

EXAMPLES:

```
sage: R = Zp(3,5,'fixed-mod', 'series')
sage: R.uniformizer()
3 + O(3^5)
```

uniformizer_pow(*n*)

Returns the nth power of the uniformizer of self (as an element of self).

EXAMPLES:

```
sage: R = Zp(5)
sage: R.uniformizer_pow(5)
5^5 + O(5^25)
sage: R.uniformizer_pow(infinity)
0
```

zeta(*n=None*)

Returns a generator of the group of roots of unity.

INPUT:

•self – a p-adic ring

•n – an integer or None (default: None)

OUTPUT:

•element – a generator of the n^{th} roots of unity, or a generator of the full group of roots of unity if n is None

EXAMPLES:

```
sage: R = Zp(37,5)
sage: R.zeta(12)
8 + 24*37 + 37^2 + 29*37^3 + 23*37^4 + O(37^5)
```

zeta_order()
Returns the order of the group of roots of unity.
EXAMPLES:

```
sage: R = Zp(37); R.zeta_order()
36
sage: Zp(2).zeta_order()
2
```

27.7 p-Adic Extension Generic.

A common superclass for all extensions of Qp and Zp.

AUTHORS:

- David Roe

class pAdicExtensionGeneric(*poly, prec, print_mode, names, element_class*)

defining_polynomial()
Returns the polynomial defining this extension.
EXAMPLES:

```
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: W.defining_polynomial()
(1 + O(5^5))*x^5 + (O(5^6))*x^4 + (3*5^2 + O(5^6))*x^3 + (2*5 + 4*5^2 + 4*5^3 + 4*5^4 + 4*5^
```

degree()
Returns the degree of this extension.
EXAMPLES:

```
sage: R.<a> = Zq(125); R.degree()
3
sage: R = Zp(5); S.<x> = ZZ[]; f = x^5 - 25*x^3 + 5; W.<w> = R.ext(f)
sage: W.degree()
5
```

fraction_field(*print_mode=None*)
Returns the fraction field of this extension, which is just the extension of base.fraction_field() determined by the same polynomial.
INPUT:

•print_mode – a dictionary containing print options. Defaults to the same options as this ring.

OUTPUT:

•the fraction field of self.

EXAMPLES:

```
sage: U.<a> = Zq(17^4, 6, print_mode='val-unit', print_max_terse_terms=3)
sage: U.fraction_field()
Unramified Extension of 17-adic Field with capped relative precision 6 in a defined by (1 +
sage: U.fraction_field({"pos":False}) == U.fraction_field()
False
```

ground_ring()

Returns the ring of which this ring is an extension.

EXAMPLE:

```
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: W.ground_ring()
5-adic Ring with capped relative precision 5
```

ground_ring_of_tower()

Returns the p-adic base ring of which this is ultimately an extension.

Currently this function is identical to ground_ring(), since relative extensions have not yet been implemented.

EXAMPLES:

```
sage: Qq(27,30,names='a').ground_ring_of_tower()
3-adic Field with capped relative precision 30
```

integer_ring(*print_mode=None*)

Returns the ring of integers of self, which is just the extension of base.integer_ring() determined by the same polynomial.

INPUT:

```
- print_mode -- a dictionary containing print options.
  Defaults to the same options as this ring.
```

OUTPUT:

```
- the ring of elements of self with nonnegative valuation.
```

EXAMPLES:

```
sage: U.<a> = Qq(17^4, 6, print_mode='val-unit', print_max_terse_terms=3)
sage: U.integer_ring()
Unramified Extension of 17-adic Ring with capped relative precision 6 in a defined by (1 + O
sage: U.fraction_field({"pos":False}) == U.fraction_field()
False
```

modulus()

Returns the polynomial defining this extension.

EXAMPLES:

```
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: W.modulus()
(1 + O(5^5))*x^5 + (O(5^6))*x^4 + (3*5^2 + O(5^6))*x^3 + (2*5 + 4*5^2 + 4*5^3 + 4*5^4 + 4*5^
```

polynomial_ring()

Returns the polynomial ring of which this is a quotient.

EXAMPLES:

```
sage: Qq(27,30,names='a').polynomial_ring()
Univariate Polynomial Ring in x over 3-adic Field with capped relative precision 30
```

random_element()

Returns a random element of self.

This is done by picking a random element of the ground ring self.degree() times, then treating those elements as coefficients of a polynomial in self.gen().

EXAMPLES:

```
sage: R.<a> = Zq(125, 5); R.random_element()
3*a + (2*a + 1)*5 + (4*a^2 + 3*a + 4)*5^2 + (a^2 + 2*a)*5^3 + (a + 2)*5^4 + O(5^5)
sage: R = Zp(5,3); S.<x> = ZZ[]; f = x^5 + 25*x^2 - 5; W.<w> = R.ext(f)
sage: W.random_element()
3 + 4*w + 3*w^2 + w^3 + 4*w^4 + w^5 + w^6 + 3*w^7 + w^8 + 2*w^10 + 4*w^11 + w^12 + 2*w^13 +
```

27.8 Eisenstein Extension Generic.

This file implements the shared functionality for Eisenstein extentions.

AUTHORS:

- David Roe

class EisensteinExtensionGeneric(*poly, prec, print_mode, names, element_class*)

gen(*n=0*)

Returns a generator for self as an extension of its ground ring.

EXAMPLES:

```
sage: A = Zp(7,10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2+7)
sage: B.gen()
t + O(t^21)
```

inertia_degree(*K=None*)

Returns the inertia degree of self over K, or the ground ring if K is None.

The inertia degree is the degree of the extension of residue fields induced by this extensions. Since Eisenstein extensions are totally ramified, this will be 1 for K=None.

INPUTS:

•self – an eisenstein extension

•K – a subring of self (default None -> self.ground_ring())

OUTPUTS:

•The degree of the induced extensions of residue fields.

EXAMPLES:

```
sage: A = Zp(7,10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2+7)
sage: B.inertia_degree()
1
```

inertia_subring()

Returns the inertia subring.

Since an eisenstein extension is totally ramified, this is just the ground field.

EXAMPLES:

```
sage: A = Zp(7,10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2+7)
sage: B.inertia_subring()
7-adic Ring with capped relative precision 10
```

ramification_index(*K=None*)

Returns the ramification index of self over K, or over the ground ring if K is None.

The ramification index is the index of the image of the valuation map on K in the image of the valuation map on self (both normalized so that the valuation of p is 1).

INPUTS:

- self – an eisenstein extension
- K – a subring of self (default None -> self.ground_ring())

OUTPUTS:

- The ramification index of the extension self/K

EXAMPLES:

```
sage: A = Zp(7,10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2+7)
sage: B.ramification_index()
2
```

residue_class_field()

Returns the residue class field.

INPUT:

- self – a p-adic ring

OUTPUT:

- the residue field

EXAMPLES:

```
sage: A = Zp(7,10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2+7)
sage: B.residue_class_field()
Finite Field of size 7
```

uniformizer()

Returns the uniformizer of self, ie a generator for the unique maximal ideal.

EXAMPLES:

```
sage: A = Zp(7,10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2+7)
sage: B.uniformizer()
t + O(t^21)
```

uniformizer_pow(*n*)

Returns the nth power of the uniformizer of self (as an element of self).

EXAMPLES:

```
sage: A = Zp(7,10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2+7)
sage: B.uniformizer_pow(5)
t^5 + O(t^25)
```

27.9 Unramified Extension Generic.

This file implements the shared functionality for unramified extentions.

AUTHORS:

- David Roe

class **UnramifiedExtensionGeneric**(*poly, prec, print_mode, names, element_class*)

An unramified extension of Qp or Zp.

discriminant(*K=None*)

Returns the discriminant of self over the subring K.

INPUTS:

```
- K -- a subring/subfield (defaults to the base ring).
```

EXAMPLES:

```
sage: R.<a> = Zq(125)
sage: R.discriminant()
...
NotImplementedError
```

gen(*n=0*)

Returns a generator for this unramified extension.

This is an element that satisfies the polynomial defining this extension. Such an element will reduce to a generator of the corresponding residue field extension.

EXAMPLES:

```
sage: R.<a> = Zq(125); R.gen()
a + O(5^20)
```

has_pth_root()

Returns whether or not Z_p has a primitive $p^{mbox{th}}$ root of unity.

Since adjoining a $p^{mbox{th}}$ root of unity yields a totally ramified extension, self will contain one if and only if the ground ring does.

INPUT:

```
- self -- a p-adic ring
```

OUTPUT:

```
- boolean -- whether self has primitive $p^{\mbox{th}}$
  root of unity.
```

EXAMPLES:

```
sage: R.<a> = Zq(1024); R.has_pth_root()
True
sage: R.<a> = Zq(17^5); R.has_pth_root()
False
```

has_root_of_unity(*n*)

Returns whether or not Z_p has a primitive $n^{\mbox{th}}$ root of unity.

INPUT:

```
- self -- a p-adic ring
- n -- an integer
```

OUTPUT:

```
- boolean -- whether self has primitive $n^{\mbox{th}}$
  root of unity
```

EXAMPLES:

```
sage: R.<a> = Zq(37^8)
sage: R.has_root_of_unity(144)
True
sage: R.has_root_of_unity(89)
True
sage: R.has_root_of_unity(11)
False
```

inertia_degree(*K=None*)

Returns the inertia degree of self over the subring K.

INPUTS:

```
- K -- a subring (or subfield) of self.  Defaults to the
  base.
```

EXAMPLES:

```
sage: R.<a> = Zq(125); R.inertia_degree()
3
```

is_galois(*K=None*)

Returns True if this extension is Galois.

Every unramified extension is Galois.

INPUTS:

```
- K -- a subring/subfield (defaults to the base ring).
```

EXAMPLES:

```
sage: R.<a> = Zq(125); R.is_galois()
True
```

ramification_index(*K=None*)

Returns the ramification index of self over the subring K.

INPUTS:

```
- K -- a subring (or subfield) of self.  Defaults to the
  base.
```

EXAMPLES:

```
sage: R.<a> = Zq(125); R.ramification_index()
1
```

residue_class_field()

Returns the residue class field.

EXAMPLES:

```
sage: R.<a> = Zq(125); R.residue_class_field()
Finite Field in a0 of size 5^3
```

uniformizer()

Returns a uniformizer for this extension.

Since this extension is unramified, a uniformizer for the ground ring will also be a uniformizer for this extension.

EXAMPLES:

```
sage: R.<a> = ZqCR(125)
sage: R.uniformizer()
5 + O(5^21)
```

uniformizer_pow(n)

Returns the nth power of the uniformizer of self (as an element of self).

EXAMPLES:

```
sage: R.<a> = ZqCR(125)
sage: R.uniformizer_pow(5)
5^5 + O(5^25)
```

27.10 p-Adic Base Leaves.

Implementations of $\mathbb{Z}_p$ and $\mathbb{Q}_p$

AUTHORS:

- David Roe
- Genya Zaytman: documentation
- David Harvey: doctests
- William Stein: doctest updates

EXAMPLES:

p-Adic rings and fields are examples of inexact structures, as the reals are. That means that elements cannot generally be stored exactly: to do so would take an infinite amount of storage. Instead, we store an approximation to the elements with varying precision.

There are two types of precision for a p-adic element. The first is relative precision, which gives the number of known p-adic digits:

```
sage: R = Qp(5, 20, 'capped-rel', 'series'); a = R(675); a
2*5^2 + 5^4 + O(5^22)
sage: a.precision_relative()
20
```

The second type of precision is absolute precision, which gives the power of p that this element is stored modulo:

```
sage: a.precision_absolute()
22
```

The number of times that p divides the element is called the valuation, and can be accessed with the functions `valuation()` and `ordp()`:

sage: a.valuation() 2

The following relationship holds:

`self.valuation() + self.precision_relative() == self.precision_absolute()`.

sage: a.valuation() + a.precision_relative() == a.precision_absolute() True

In the capped relative case, the relative precision of an element is restricted to be at most a certain value, specified at the creation of the field. Individual elements also store their own precision, so the effect of various arithmetic operations on precision is tracked. When you cast an exact element into a capped relative field, it truncates it to the precision cap of the field.:

```
sage: R = Qp(5, 5); a = R(4006); a
1 + 5 + 2*5^3 + 5^4 + O(5^5)
sage: b = R(17/3); b
4 + 2*5 + 3*5^2 + 5^3 + 3*5^4 + O(5^5)
sage: c = R(4025); c
5^2 + 2*5^3 + 5^4 + 5^5 + O(5^7)
sage: a + b
4*5 + 3*5^2 + 3*5^3 + 4*5^4 + O(5^5)
sage: a + b + c
4*5 + 4*5^2 + 5^4 + O(5^5)
```

```
sage: R = Zp(5, 5, 'capped-rel', 'series'); a = R(4006); a
1 + 5 + 2*5^3 + 5^4 + O(5^5)
sage: b = R(17/3); b
4 + 2*5 + 3*5^2 + 5^3 + 3*5^4 + O(5^5)
sage: c = R(4025); c
5^2 + 2*5^3 + 5^4 + 5^5 + O(5^7)
sage: a + b
4*5 + 3*5^2 + 3*5^3 + 4*5^4 + O(5^5)
sage: a + b + c
4*5 + 4*5^2 + 5^4 + O(5^5)
```

In the capped absolute type, instead of having a cap on the relative precision of an element there is instead a cap on the absolute precision. Elements still store their own precisions, and as with the capped relative case, exact elements are truncated when cast into the ring.:

```
sage: R = ZpCA(5, 5); a = R(4005); a
5 + 2*5^3 + 5^4 + O(5^5)
sage: b = R(4025); b
5^2 + 2*5^3 + 5^4 + O(5^5)
sage: a * b
5^3 + 2*5^4 + O(5^5)
sage: (a * b) // 5^3
1 + 2*5 + O(5^2)
sage: type((a * b) // 5^3)
<type 'sage.rings.padics.padic_capped_absolute_element.pAdicCappedAbsoluteElement'>
sage: (a * b) / 5^3
1 + 2*5 + O(5^2)
sage: type((a * b) / 5^3)
<type 'sage.rings.padics.padic_capped_relative_element.pAdicCappedRelativeElement'>
```

The fixed modulus type is the leanest of the p-adic rings: it is basically just a wrapper around $\mathbb{Z}/p^n\mathbb{Z}$ providing a unified interface with the rest of the p-adics. This is the type you should use if your primary interest is in speed (though it's not all that much faster than other p-adic types). It does not track precision of elements.:

```
sage: R = ZpFM(5, 5); a = R(4005); a
5 + 2*5^3 + 5^4 + O(5^5)
sage: a // 5
1 + 2*5^2 + 5^3 + O(5^5)
```

p-Adic rings and fields should be created using the creation functions `Zp` and `Qp` as above. This will ensure that there is only one instance of $\mathbb{Z}_p$ and $\mathbb{Q}_p$ of a given type, p, print mode and precision. It also saves typing very long class names.:

```
sage: Qp(17,10)
17-adic Field with capped relative precision 10
sage: R = Qp(7, prec = 20, print_mode = 'val-unit'); S = Qp(7, prec = 20, print_mode = 'val-unit'); R
True
sage: Qp(2)
2-adic Field with capped relative precision 20
```

Once one has a p-Adic ring or field, one can cast elements into it in the standard way. Integers, ints, longs, Rationals, other p-Adic types, pari p-adics and elements of $\mathbb{Z}/p^n\mathbb{Z}$ can all be cast into a p-Adic field.:

```
sage: R = Qp(5, 5, 'capped-rel','series'); a = R(16); a
1 + 3*5 + O(5^5)
sage: b = R(23/15); b
5^-1 + 3 + 3*5 + 5^2 + 3*5^3 + O(5^4)
sage: S = Zp(5, 5, 'fixed-mod','val-unit'); c = S(Mod(75,125)); c
5^2 * 3 + O(5^5)
sage: R(c)
3*5^2 + O(5^5)
```

In the previous example, since fixed-mod elements don't keep track of their precision, we assume that it has the full precision of the ring. This is why you have to cast manually here.

While you can cast explicitly as above, the chains of automatic coercion are more restricted. As always in SAGE, the following arrows are transitive and the diagram is commutative.:

```
int -> long -> Integer -> Zp capped-rel -> Zp capped_abs -> IntegerMod
Integer -> Zp fixed-mod -> IntegerMod
Integer -> Zp capped-abs -> Qp capped-rel
```

In addition, there are arrows within each type. For capped relative and capped absolute rings and fields, these arrows go from lower precision cap to higher precision cap. This works since elements track their own precision: choosing the parent with higher precision cap means that precision is less likely to be truncated unnecessarily. For fixed modulus parents, the arrow goes from higher precision cap to lower. The fact that elements do not track precision necessitates this choice in order to not produce incorrect results.

TESTS:

```
sage: R = Qp(5, 15, print_mode='bars', print_sep='&'); S = loads(dumps(R))
sage: R == S
True
sage: repr(S(2777))[3:]
'4&2&1&0&2'

sage: R = Zp(5, 15, print_mode='bars', print_sep='&'); S = loads(dumps(R))
sage: R == S
True
sage: repr(S(2777))[3:]
```

```
'4&2&1&0&2'

sage: R = ZpCA(5, 15, print_mode='bars', print_sep='&'); S = loads(dumps(R))
sage: R == S
True
sage: repr(S(2777))[3:]
'4&2&1&0&2'
```

class pAdicFieldCappedRelative (*p, prec, print_mode, names*)

An implementation of p-adic fields with capped relative precision.

EXAMPLES:

```
sage: K = Qp(17, 1000000)
sage: K = Qp(next_prime(10^60))
```

random_element (*algorithm='default'*)

Returns a random element of `self`, optionally using the `algorithm` argument to decide how it generates the element. Algorithms currently implemented:

- default: Choose an integer k using the standard distribution on the integers. Then choose an integer a uniformly in the range $0 \leq a < p^N$ where N is the precision cap of `self`. Return `self(p^k * a, absprec = k + self.precision_cap())`.

EXAMPLES:

```
sage: Qp(17,6).random_element()
15*17^-8 + 10*17^-7 + 3*17^-6 + 2*17^-5 + 11*17^-4 + 6*17^-3 + O(17^-2)
```

class pAdicRingCappedAbsolute (*p, prec, print_mode, names*)

An implementation of the p-adic integers with capped absolute precision.

class pAdicRingCappedRelative (*p, prec, print_mode, names*)

An implementation of the p-adic integers with capped relative precision.

class pAdicRingFixedMod (*p, prec, print_mode, names*)

An implementation of the p-adic integers using fixed modulus.

fraction_field (*print_mode=None*)

Would normally return $\mathbb{Q}_p$, but there is no implementation of $\mathbb{Q}_p$ matching this ring so this raises an error

If you want to be able to divide with elements of a fixed modulus p-adic ring, you must cast explicitly.

EXAMPLES:

```
sage: ZpFM(5).fraction_field()
...
TypeError: This implementation of the p-adic ring does not support fields of fractions.

sage: a = ZpFM(5)(4); b = ZpFM(5)(5)
```

27.11 p-Adic Extension Leaves.

The final classes for extensions of Zp and Qp (ie classes that are not just designed to be inherited from).

AUTHORS:

- David Roe

class EisensteinExtensionFieldCappedRelative(*prepoly, poly, prec, halt, print_mode, shift_seed, names*)

TESTS:

```
sage: R = Qp(3, 10000, print_pos=False); S.<x> = ZZ[]; f = x^3 + 9*x - 3
sage: W.<w> = R.ext(f); W == loads(dumps(W))
True
```

class EisensteinExtensionRingCappedAbsolute(*prepoly, poly, prec, halt, print_mode, shift_seed, names*)

TESTS:

```
sage: R = ZpCA(3, 10000, print_pos=False); S.<x> = ZZ[]; f = x^3 + 9*x - 3
sage: W.<w> = R.ext(f); W == loads(dumps(W))
True
```

class EisensteinExtensionRingCappedRelative(*prepoly, poly, prec, halt, print_mode, shift_seed, names*)

TESTS:

```
sage: R = Zp(3, 10000, print_pos=False); S.<x> = ZZ[]; f = x^3 + 9*x - 3
sage: W.<w> = R.ext(f); W == loads(dumps(W))
True
```

class EisensteinExtensionRingFixedMod(*prepoly, poly, prec, halt, print_mode, shift_seed, names*)

TESTS:

```
sage: R = ZpFM(3, 10000, print_pos=False); S.<x> = ZZ[]; f = x^3 + 9*x - 3
sage: W.<w> = R.ext(f); W == loads(dumps(W))
True
```

class UnramifiedExtensionFieldCappedRelative(*prepoly, poly, prec, halt, print_mode, shift_seed, names*)

TESTS:

```
sage: R.<a> = QqCR(27,10000); R == loads(dumps(R))
True
```

class UnramifiedExtensionRingCappedAbsolute(*prepoly, poly, prec, halt, print_mode, shift_seed, names*)

TESTS:

```
sage: R.<a> = ZqCA(27,10000); R == loads(dumps(R))
True
```

class UnramifiedExtensionRingCappedRelative(*prepoly, poly, prec, halt, print_mode, shift_seed, names*)

TESTS:

```
sage: R.<a> = ZqCR(27,10000); R == loads(dumps(R))
True
```

class UnramifiedExtensionRingFixedMod(*prepoly, poly, prec, halt, print_mode, shift_seed, names*)

TESTS:

```
sage: R.<a> = ZqFM(27,10000); R == loads(dumps(R))
True
```

27.12 Local Generic Element.

This file contains a common superclass for p-adic elements and power series elements.

AUTHORS:

- David Roe

class LocalGenericElement()

is_integral()

Returns whether self is an integral element.

INPUT:

•`self` – a local ring element

OUTPUT:

•boolean – whether `self` is an integral element.

EXAMPLES:

```
sage: R = Qp(3,20)
sage: a = R(7/3); a.is_integral()
False
sage: b = R(7/5); b.is_integral()
True
```

is_unit()

Returns whether self is a unit

INPUT:

•`self` – a local ring element

OUTPUT:

•boolean – whether `self` is a unit

EXAMPLES:

```
sage: R = Zp(3,20,'capped-rel'); K = Qp(3,20,'capped-rel')
sage: R(0).is_unit()
False
sage: R(1).is_unit()
True
sage: R(2).is_unit()
True
sage: R(3).is_unit()
False
```

TESTS:

```
sage: R(4).is_unit()
True
sage: R(6).is_unit()
False
sage: R(9).is_unit()
False
sage: K(0).is_unit()
False
sage: K(1).is_unit()
True
sage: K(2).is_unit()
```

```
True
sage: K(3).is_unit()
False
sage: K(4).is_unit()
True
sage: K(6).is_unit()
False
sage: K(9).is_unit()
False
sage: K(1/3).is_unit()
False
sage: K(1/9).is_unit()
False
```

normalized_valuation()

Returns the normalized valuation of this local ring element, i.e., the valuation divided by the absolute ramification index.

INPUT:

`self` – a local ring element.

OUTPUT:

rational – the normalized valuation of `self`.

EXAMPLES:

```
sage: Q7 = Qp(7)
sage: R.<x> = Q7[]
sage: F.<z> = Q7.ext(x^3+7*x+7)
sage: z.normalized_valuation()
1/3
```

slice()

Returns the sum of the $p^{i+FOO*k}$ terms of the series expansion of self, for $i + FOO * k$ between i and $j - 1$ inclusive, and FOO an arbitrary integer. Behaves analogously to the slice function for lists.

INPUT:

- `self` – a p-adic element
- `i` – an integer
- `j` – an integer
- `k` – a positive integer, default value 1

EXAMPLES: sage: R = Zp(5, 6, 'capped-rel') sage: a = R(1/2); a 3 + 2*5 + 2*5^2 + 2*5^3 + 2*5^4 + 2*5^5 + O(5^6) sage: a.slice(2, 4) 2*5^2 + 2*5^3 + O(5^4) sage: a.slice(1, 6, 2) 2*5 + 2*5^3 + 2*5^5 + O(5^6) sage: a.slice(5, 4) O(5^4)

sqrt()

TODO: document what "extend" and "all" do

INPUT:

- `self` – a local ring element

OUTPUT:

- local ring element – the square root of `self`

EXAMPLES:

```
sage: R = Zp(13, 10, 'capped-rel', 'series')
sage: a = sqrt(R(-1)); a * a
12 + 12*13 + 12*13^2 + 12*13^3 + 12*13^4 + 12*13^5 + 12*13^6 + 12*13^7 + 12*13^8 + 12*13^9 +
sage: sqrt(R(4))
2 + O(13^10)
```

```
sage: sqrt(R(4/9)) * 3
2 + O(13^10)
```

27.13 p-Adic Generic Element.

Elements of p-Adic Rings and Fields

AUTHOR:

- David Roe
- Genya Zaytman: documentation
- David Harvey: doctests

clear_mpz_globals()

gmp_randrange()

init_mpz_globals()

class **pAdicGenericElement**()

abs()

Returns the p-adic absolute value of self.

This is normalized so that the absolute value of p is 1/p.

INPUT:

```
- prec -- Integer.  The precision of the real field in
  which the answer is returned.  If None, returns a
  rational for absolutely unramified fields, or a real
  with 53 bits of precision if ramified.
```

EXAMPLES:

```
sage: a = Qp(5)(15); a.abs()
1/5
sage: a.abs(53)
0.200000000000000
```

additive_order()

Returns the additive order of self, where self is considered to be zero if it is zero modulo $p^{mbox{prec}}$.

INPUT:

```
self -- a p-adic element
prec -- an integer
```

OUTPUT:

```
integer -- the additive order of self
```

EXAMPLES:

```
sage: R = Zp(7, 4, 'capped-rel', 'series'); a = R(7^3); a.additive_order(3)
1
sage: a.additive_order(4)
+Infinity
```

```
sage: R = Zp(7, 4, 'fixed-mod', 'series'); a = R(7^5); a.additive_order(6)
1
```

algdep()

Returns a polynomial of degree at most n which is approximately satisfied by this number. Note that the returned polynomial need not be irreducible, and indeed usually won't be if this number is a good approximation to an algebraic number of degree less than n.

ALGORITHM:

```
Uses the PARI C-library algdep command.
```

INPUT:

```
- self -- a p-adic element
- n -- an integer
```

OUTPUT:

```
polynomial -- degree n polynomial aproximately satisfied by self
```

EXAMPLES:

```
sage: K = Qp(3,20,'capped-rel','series'); R = Zp(3,20,'capped-rel','series')
sage: a = K(7/19); a
1 + 2*3 + 3^2 + 3^3 + 2*3^4 + 2*3^5 + 3^8 + 2*3^9 + 3^11 + 3^12 + 2*3^15 + 2*3^16 + 3^17 + 2
sage: a.algdep(1)
19*x - 7
sage: K2 = Qp(7,20,'capped-rel')
sage: b = K2.zeta(); b.algdep(2)
x^2 - x + 1
sage: K2 = Qp(11,20,'capped-rel')
sage: b = K2.zeta(); b.algdep(4)
x^4 - x^3 + x^2 - x + 1
sage: a = R(7/19); a
1 + 2*3 + 3^2 + 3^3 + 2*3^4 + 2*3^5 + 3^8 + 2*3^9 + 3^11 + 3^12 + 2*3^15 + 2*3^16 + 3^17 + 2
sage: a.algdep(1)
19*x - 7
sage: R2 = Zp(7,20,'capped-rel')
sage: b = R2.zeta(); b.algdep(2)
x^2 - x + 1
sage: R2 = Zp(11,20,'capped-rel')
sage: b = R2.zeta(); b.algdep(4)
x^4 - x^3 + x^2 - x + 1
```

algebraic_dependency()

Returns a polynomial of degree at most n which is approximately satisfied by this number. Note that the returned polynomial need not be irreducible, and indeed usually won't be if this number is a good approximation to an algebraic number of degree less than n.

ALGORITHM:

```
Uses the PARI C-library algdep command.
```

INPUT:

```
- self -- a p-adic element
- n -- an integer
```

OUTPUT:

```
polynomial -- degree n polynomial aproximately satisfied by self
```

EXAMPLES:

```
sage: K = Qp(3,20,'capped-rel','series'); R = Zp(3,20,'capped-rel','series')
sage: a = K(7/19); a
1 + 2*3 + 3^2 + 3^3 + 2*3^4 + 2*3^5 + 3^8 + 2*3^9 + 3^11 + 3^12 + 2*3^15 + 2*3^16 + 3^17 + 2
sage: a.algebraic_dependency(1)
19*x - 7
sage: K2 = Qp(7,20,'capped-rel')
sage: b = K2.zeta(); b.algebraic_dependency(2)
x^2 - x + 1
sage: K2 = Qp(11,20,'capped-rel')
sage: b = K2.zeta(); b.algebraic_dependency(4)
x^4 - x^3 + x^2 - x + 1
sage: a = R(7/19); a
1 + 2*3 + 3^2 + 3^3 + 2*3^4 + 2*3^5 + 3^8 + 2*3^9 + 3^11 + 3^12 + 2*3^15 + 2*3^16 + 3^17 + 2
sage: a.algebraic_dependency(1)
19*x - 7
sage: R2 = Zp(7,20,'capped-rel')
sage: b = R2.zeta(); b.algebraic_dependency(2)
x^2 - x + 1
sage: R2 = Zp(11,20,'capped-rel')
sage: b = R2.zeta(); b.algebraic_dependency(4)
x^4 - x^3 + x^2 - x + 1
```

is_square()

Returns whether self is a square

INPUT:

```
self -- a p-adic element
```

OUTPUT:

```
boolean -- whether self is a square
```

EXAMPLES:

```
sage: R = Zp(3,20,'capped-rel')
sage: R(0).is_square()
True
sage: R(1).is_square()
True
sage: R(2).is_square()
False
```

TESTS:

```
sage: R(3).is_square()
False
sage: R(4).is_square()
True
sage: R(6).is_square()
False
sage: R(9).is_square()
True

sage: R2 = Zp(2,20,'capped-rel')
sage: R2(0).is_square()
True
sage: R2(1).is_square()
True
sage: R2(2).is_square()
False
```

```
sage: R2(3).is_square()
False
sage: R2(4).is_square()
True
sage: R2(5).is_square()
False
sage: R2(6).is_square()
False
sage: R2(7).is_square()
False
sage: R2(8).is_square()
False
sage: R2(9).is_square()
True

sage: K = Qp(3,20,'capped-rel')
sage: K(0).is_square()
True
sage: K(1).is_square()
True
sage: K(2).is_square()
False
sage: K(3).is_square()
False
sage: K(4).is_square()
True
sage: K(6).is_square()
False
sage: K(9).is_square()
True
sage: K(1/3).is_square()
False
sage: K(1/9).is_square()
True

sage: K2 = Qp(2,20,'capped-rel')
sage: K2(0).is_square()
True
sage: K2(1).is_square()
True
sage: K2(2).is_square()
False
sage: K2(3).is_square()
False
sage: K2(4).is_square()
True
sage: K2(5).is_square()
False
sage: K2(6).is_square()
False
sage: K2(7).is_square()
False
sage: K2(8).is_square()
False
sage: K2(9).is_square()
True
sage: K2(1/2).is_square()
False
```

```
sage: K2(1/4).is_square()
True
```

multiplicative_order()

Returns the multiplicative order of self, where self is considered to be one if it is one modulo $p^{mbox{prec}}$.

INPUT:

```
self -- a p-adic element
prec -- an integer
```

OUTPUT:

```
integer -- the multiplicative order of self
```

EXAMPLES:

```
sage: K = Qp(5,20,'capped-rel')
sage: K(-1).multiplicative_order(20)
2
sage: K(1).multiplicative_order(20)
1
sage: K(2).multiplicative_order(20)
+Infinity
sage: K(3).multiplicative_order(20)
+Infinity
sage: K(4).multiplicative_order(20)
+Infinity
sage: K(5).multiplicative_order(20)
+Infinity
sage: K(25).multiplicative_order(20)
+Infinity
sage: K(1/5).multiplicative_order(20)
+Infinity
sage: K(1/25).multiplicative_order(20)
+Infinity
sage: K.zeta().multiplicative_order(20)
4

sage: R = Zp(5,20,'capped-rel')
sage: R(-1).multiplicative_order(20)
2
sage: R(1).multiplicative_order(20)
1
sage: R(2).multiplicative_order(20)
+Infinity
sage: R(3).multiplicative_order(20)
+Infinity
sage: R(4).multiplicative_order(20)
+Infinity
sage: R(5).multiplicative_order(20)
+Infinity
sage: R(25).multiplicative_order(20)
+Infinity
sage: R.zeta().multiplicative_order(20)
4
```

ordp()

Returns the valuation of self, normalized so that the valuation of p is 1

INPUT:

self -- a p-adic element

OUTPUT:

integer -- the valuation of self, normalized so that the valuation of p is 1

EXAMPLES:

```
sage: R = Zp(5,20,'capped-rel')
sage: R(0).ordp()
+Infinity
sage: R(1).ordp()
0
sage: R(2).ordp()
0
sage: R(5).ordp()
1
sage: R(10).ordp()
1
sage: R(25).ordp()
2
sage: R(50).ordp()
2
sage: R(1/2).ordp()
0
```

rational_reconstruction()

Returns a rational approximation to this p-adic number

INPUT:

self -- a p-adic element

OUTPUT:

rational -- an approximation to self

EXAMPLES:

```
sage: R = Zp(5,20,'capped-rel')
sage: for i in range(11):
...       for j in range(1,10):
...           if j == 5:
...               continue
...           assert i/j == R(i/j).rational_reconstruction()
```

square_root()

Returns the square root of this p-adic number

INPUT:

- self -- a p-adic element
- extend -- bool (default: True); if True, return a square root in an extension if necessary; if False and no root exists in the given ring or field, raise a ValueError
- all -- bool (default: False); if True, return a list of all square roots

OUTPUT:

p-adic element -- the square root of this p-adic number

If all = False, the square root chosen is the one whose reduction mod p is in the range [0, p/2).

EXAMPLES:

```
sage: R = Zp(3,20,'capped-rel', 'val-unit')
sage: R(0).square_root()
0
sage: R(1).square_root()
1 + O(3^20)
sage: R(2).square_root(extend = False)
...
ValueError: element is not a square
sage: R(4).square_root() == R(-2)
True
sage: R(9).square_root()
3 * 1 + O(3^21)

When p = 2, the precision of the square root is one less
than the input:

sage: R2 = Zp(2,20,'capped-rel')
sage: R2(0).square_root()
0
sage: R2(1).square_root()
1 + O(2^19)
sage: R2(4).square_root()
2 + O(2^20)

sage: R2(9).square_root() == R2(3, 19) or R2(9).square_root() == R2(-3, 19)
True

sage: R2(17).square_root()
1 + 2^3 + 2^5 + 2^6 + 2^7 + 2^9 + 2^10 + 2^13 + 2^16 + 2^17 + O(2^19)

sage: R3 = Zp(5,20,'capped-rel')
sage: R3(0).square_root()
0
sage: R3(1).square_root()
1 + O(5^20)
sage: R3(-1).square_root() == R3.teichmuller(2) or R3(-1).square_root() == R3.teichmuller(3)
True
```

TESTS:

```
sage: R = Qp(3,20,'capped-rel')
sage: R(0).square_root()
0
sage: R(1).square_root()
1 + O(3^20)
sage: R(4).square_root() == R(-2)
True
sage: R(9).square_root()
3 + O(3^21)
sage: R(1/9).square_root()
3^-1 + O(3^19)

sage: R2 = Qp(2,20,'capped-rel')
sage: R2(0).square_root()
0
sage: R2(1).square_root()
1 + O(2^19)
sage: R2(4).square_root()
```

```
2 + O(2^20)
sage: R2(9).square_root() == R2(3,19) or R2(9).square_root() == R2(-3,19)
True
sage: R2(17).square_root()
1 + 2^3 + 2^5 + 2^6 + 2^7 + 2^9 + 2^10 + 2^13 + 2^16 + 2^17 + O(2^19)

sage: R3 = Qp(5,20,'capped-rel')
sage: R3(0).square_root()
0
sage: R3(1).square_root()
1 + O(5^20)
sage: R3(-1).square_root() == R3.teichmuller(2) or R3(-1).square_root() == R3.teichmuller(3)
True
```

str()

Returns a string representation of self.

EXAMPLES:

```
sage: Zp(5,5,print_mode='bars')(1/3).str()[3:]
'1|3|1|3|2'
```

val_unit()

Returns (self.valuation(), self.unit_part()).

EXAMPLES:

```
sage: Zp(5,5)(5).val_unit()
(1, 1 + O(5^5))
```

valuation()

Returns the valuation of self.

INPUT:

```
- self -- a p-adic element
```

OUTPUT:

```
- integer -- the valuation of self
```

EXAMPLES:

```
sage: R = Zp(17, 4,'capped-rel')
sage: a = R(2*17^2)
sage: a.valuation()
2
sage: R = Zp(5, 4,'capped-rel')
sage: R(0).valuation()
+Infinity
```

TESTS:

```
sage: R(1).valuation()
0
sage: R(2).valuation()
0
sage: R(5).valuation()
1
sage: R(10).valuation()
1
sage: R(25).valuation()
2
sage: R(50).valuation()
```

```
2
sage: R = Qp(17, 4)
sage: a = R(2*17^2)
sage: a.valuation()
2
sage: R = Qp(5, 4)
sage: R(0).valuation()
+Infinity
sage: R(1).valuation()
0
sage: R(2).valuation()
0
sage: R(5).valuation()
1
sage: R(10).valuation()
1
sage: R(25).valuation()
2
sage: R(50).valuation()
2
sage: R(1/2).valuation()
0
sage: R(1/5).valuation()
-1
sage: R(1/10).valuation()
-1
sage: R(1/25).valuation()
-2
sage: R(1/50).valuation()
-2
```

27.14 p-Adic Base Generic Element.

A common superclass for features shared among all elements of $\mathbb{Z}_p$ and $\mathbb{Q}_p$ (regardless of implementation).

AUTHORS:

- David Roe

class pAdicBaseGenericElement()

abs()

Returns the p-adic absolute value of `self`.

This is normalized so that the absolute value of p is $1/p$.

INPUT:

- `prec` – Integer. The precision of the real field in which the answer is returned. If `None`, returns a rational for absolutely unramified fields, or a real with 53 bits of precision if ramified.

EXAMPLES: sage: a = Qp(5)(15); a.abs() 1/5 sage: a.abs(53) 0.200000000000000

exp()

Compute the p-adic exponential of any element of $\mathbb{Z}_p$ where the series converges.

EXAMPLES:

Borrowed from log.:

```
sage: Z13 = Zp(13, 10, print_mode='series')
sage: a = Z13(13 + 6*13**2 + 2*13**3 + 5*13**4 + 10*13**6 + 13**7 + 11*13**8 + 8*13**9).add_
13 + 6*13^2 + 2*13^3 + 5*13^4 + 10*13^6 + 13^7 + 11*13^8 + 8*13^9 + O(13^10)
sage: a.exp()
1 + 13 + O(13^10)
sage: Q13 = Qp(13, 10, print_mode='series')
sage: a = Q13(13 + 6*13**2 + 2*13**3 + 5*13**4 + 10*13**6 + 13**7 + 11*13**8 + 8*13**9).add_
13 + 6*13^2 + 2*13^3 + 5*13^4 + 10*13^6 + 13^7 + 11*13^8 + 8*13^9 + O(13^10)
sage: a.exp()
1 + 13 + O(13^10)
```

The next few examples illustrate precision when computing p-adic exps. First we create a field with emph{default} precision 10.:

```
sage: R = Zp(5,10, print_mode='series')
sage: e = R(2*5 + 2*5**2 + 4*5**3 + 3*5**4 + 5**5 + 3*5**7 + 2*5**8 + 4*5**9).add_bigoh(10);
2*5 + 2*5^2 + 4*5^3 + 3*5^4 + 5^5 + 3*5^7 + 2*5^8 + 4*5^9 + O(5^10)
sage: e.exp()*R.teichmuller(4)
4 + 2*5 + 3*5^3 + O(5^10)

sage: K = Qp(5,10, print_mode='series')
sage: e = K(2*5 + 2*5**2 + 4*5**3 + 3*5**4 + 5**5 + 3*5**7 + 2*5**8 + 4*5**9).add_bigoh(10);
2*5 + 2*5^2 + 4*5^3 + 3*5^4 + 5^5 + 3*5^7 + 2*5^8 + 4*5^9 + O(5^10)
sage: e.exp()*K.teichmuller(4)
4 + 2*5 + 3*5^3 + O(5^10)
```

TESTS:

Check that results are consistent over a range of precision:

```
sage: max_prec = 40
sage: p = 3
sage: K = Zp(p, max_prec)
sage: full_exp = (K(p)).exp()
sage: for prec in range(2, max_prec):
...       ll = (K(p).add_bigoh(prec)).exp()
...       assert ll == full_exp
...       assert ll.precision_absolute() == prec
sage: K = Qp(p, max_prec)
sage: full_exp = (K(p)).exp()
sage: for prec in range(2, max_prec):
...       ll = (K(p).add_bigoh(prec)).exp()
...       assert ll == full_exp
...       assert ll.precision_absolute() == prec
```

AUTHORS:

- Genya Zaytman (2007-02-15)

log()

Compute the p-adic logarithm of any unit in $\mathbb{Z}_p$. (See below for normalization.)

The usual power series for log with values in the additive group of $\mathbb{Z}_p$ only converges for 1-units (units congruent to 1 modulo p). However, there is a unique extension of log to a homomorphism defined on all the units. If $u = a \cdot v$ is a unit with $v \equiv 1 \pmod{p}$ and a a Teichmuller representative, then we define $log(u) = log(v)$. This is the correct extension because the units U of $\mathbb{Z}_p$ split as a product $U = V \times \langle w \rangle$, where V is the subgroup of 1-units and w is a $(p-1)$'$strootofunity.The$'$\langle w \rangle$ factor is torsion, so must go to 0 under any homomorphism to the torsion free group $(\mathbb{Z}_p, +)$.

INPUTS:

- `self` – a p-adic element.
- `branch` – A choice of branch, ie a choice of logarithm of the uniformizer. This choice can be made arbitrarily.

NOTES:

What some other systems do:

•PARI: Seems to define log the same way as we do.

•MAGMA: Gives an error when unit is not a 1-unit.

ALGORITHM:

Input: Some p-adic unit u (or non-unit if `branch` is specified).

1.Check that the input p-adic number is really a unit (i.e., valuation 0), or take the unit part and multiply by `branch * self.valuation()` if not and `branch` specified.

2.Let $1 - x = u^{p-1}$, which is a 1-unit.

3.Use the series expansion

..math

```
\log(1-x) = F(x) = -x - 1/2*x^2 - 1/3*x^3 - 1/4*x^4 - 1/5*x^5 - \cdots
```

to compute the logarithm $log(u^{p-1})$. Use enough terms so that terms added on are zero

1.Then

..math

```
\log(u) = \log(u^{p-1})/(p-1) = F(1-u^{p-1})/(p-1).
```

EXAMPLES:

```
sage: Z13 = Zp(13, 10, print_mode='series')
sage: a = Z13(14); a
1 + 13 + O(13^10)
```

Note that the relative precision decreases when we take log: it is the absolute precision that is preserved.:

```
sage: a.log()
13 + 6*13^2 + 2*13^3 + 5*13^4 + 10*13^6 + 13^7 + 11*13^8 + 8*13^9 + O(13^10)
sage: Q13 = Qp(13, 10, print_mode='series')
sage: a = Q13(14); a
1 + 13 + O(13^10)
sage: a.log()
13 + 6*13^2 + 2*13^3 + 5*13^4 + 10*13^6 + 13^7 + 11*13^8 + 8*13^9 + O(13^10)
```

The next few examples illustrate precision when computing p-adic logs. First we create a field with emph{default} precision 10.:

```
sage: R = Zp(5,10, print_mode='series')
sage: e = R(389); e
4 + 2*5 + 3*5^3 + O(5^10)
sage: e.log()
2*5 + 2*5^2 + 4*5^3 + 3*5^4 + 5^5 + 3*5^7 + 2*5^8 + 4*5^9 + O(5^10)
sage: K = Qp(5,10, print_mode='series')
sage: e = K(389); e
4 + 2*5 + 3*5^3 + O(5^10)
sage: e.log()
2*5 + 2*5^2 + 4*5^3 + 3*5^4 + 5^5 + 3*5^7 + 2*5^8 + 4*5^9 + O(5^10)
```

Check that results are consistent over a range of precision:

```
sage: max_prec = 40
sage: p = 3
sage: K = Zp(p, max_prec)
sage: full_log = (K(1 + p)).log()
sage: for prec in range(2, max_prec):
...       ll = (K(1 + p).add_bigoh(prec)).log()
```

```
...       assert ll == full_log
...       assert ll.precision_absolute() == prec
```

AUTHORS:

- William Stein: initial version
- David Harvey (2006-09-13): corrected subtle precision bug (need to take denominators into account! – see trac #53)
- Genya Zaytman (2007-02-14): adapted to new p-adic class

TODO:

- Currently implemented as $O(N^2)$. This can be improved to soft-$O(N)$ using algorithm described by Dan Bernstein: `http://cr.yp.to/lineartime/multapps-20041007.pdf`

minimal_polynomial()

Returns a minimal polynomial of this p-adic element, i.e., `x - self`

INPUT:

- `self` – a p-adic element
- `name` – string: the name of the variable

OUTPUT:

- `polynomial` – a minimal polynomial of this p-adic element, i.e., `x - self`

EXAMPLES:

```
sage: Zp(5,5)(1/3).minimal_polynomial('x')
(1 + O(5^5))*x + (3 + 5 + 3*5^2 + 5^3 + 3*5^4 + O(5^5))
```

norm()

Returns the norm of this p-adic element over the ground ring.

NOTE! This is not the p-adic absolute value. This is a field theoretic norm down to a ground ring. If you want the p-adic absolute value, use the `abs()` function instead.

INPUT:

- `self` – a p-adic element
- `ground` – a subring of the ground ring (default: base ring)

OUTPUT:

- element – the norm of this p-adic element over the ground ring

EXAMPLES:

```
sage: Zp(5)(5).norm()
5 + O(5^21)
```

trace()

Returns the trace of this p-adic element over the ground ring

INPUT:

- `self` – a p-adic element
- `ground` – a subring of the ground ring (default: base ring)

OUTPUT:

- `element` – the trace of this p-adic element over the ground ring

EXAMPLES:

```
sage: Zp(5,5)(5).trace()
5 + O(5^6)
```

27.15 p-Adic Capped Relative Element.

Elements of p-Adic Rings with Capped Relative Precision

AUTHORS:

- David Roe
- Genya Zaytman: documentation
- David Harvey: doctests

TESTS:

```
sage: M = MatrixSpace(pAdicField(3,100),2)
sage: (M([1,0,0,90]) - (1+O(3^100)) * M(1)).left_kernel()
Vector space of degree 2 and dimension 1 over 3-adic Field with capped relative precision 100
Basis matrix:
[1 + O(3^100)            0]
```

clear_mpz_globals()

gmp_randrange()

init_mpz_globals()

class pAdicCappedRelativeElement()

add_bigoh()

Returns a new element with absolute precision decreased to absprec.

INPUT:

```
self -- a p-adic element
absprec -- an integer
```

OUTPUT:

```
element -- self with precision set to the minimum of
           self's precision and absprec
```

EXAMPLE:

```
sage: R = Zp(7,4,'capped-rel','series'); a = R(8); a.add_bigoh(1)
1 + O(7)
sage: b = R(0); b.add_bigoh(3)
O(7^3)
sage: R = Qp(7,4); a = R(8); a.add_bigoh(1)
1 + O(7)
sage: b = R(0); b.add_bigoh(3)
O(7^3)

The precision never increases::

sage: R(4).add_bigoh(2).add_bigoh(4)
4 + O(7^2)

Another example that illustrates that the precision does
not increase::
```

```
sage: k = Qp(3,5)
sage: a = k(1234123412/3^70); a
2*3^-70 + 3^-69 + 3^-68 + 3^-67 + O(3^-65)
sage: a.add_bigoh(2)
2*3^-70 + 3^-69 + 3^-68 + 3^-67 + O(3^-65)

sage: k = Qp(5,10)
sage: a = k(1/5^3 + 5^2); a
5^-3 + 5^2 + O(5^7)
sage: a.add_bigoh(2)
5^-3 + O(5^2)
sage: a.add_bigoh(-1)
5^-3 + O(5^-1)
```

copy()

Returns a copy of self.

EXAMPLES:

```
sage: a = Zp(5,6)(17); b = a.copy()
sage: a == b
True
sage: a is b
False
```

is_equal_to()

Returns whether self is equal to right modulo $p^{mbox{absprec}}$.

if absprec is None, returns True if self and right are equal to the minimum of their precisions.

INPUT:

```
- self -- a p-adic element
- right -- a p-addic element
- absprec -- an integer or None
```

OUTPUT:

```
- boolean -- whether self is equal to right (modulo $p^{\mbox{absprec}}$)
```

EXAMPLES:

```
sage: R = Zp(5, 10); a = R(0); b = R(0, 3); c = R(75, 5)
sage: aa = a + 625; bb = b + 625; cc = c + 625
sage: a.is_equal_to(aa), a.is_equal_to(aa, 4), a.is_equal_to(aa, 5)
(False, True, False)
sage: a.is_equal_to(aa, 15)
...
PrecisionError: Elements not known to enough precision

sage: a.is_equal_to(a, 50000)
True

sage: a.is_equal_to(b), a.is_equal_to(b, 2)
(True, True)
sage: a.is_equal_to(b, 5)
...
PrecisionError: Elements not known to enough precision

sage: b.is_equal_to(b, 5)
...
PrecisionError: Elements not known to enough precision
```

```
sage: b.is_equal_to(bb, 3)
True
sage: b.is_equal_to(bb, 4)
...
PrecisionError: Elements not known to enough precision

sage: c.is_equal_to(b, 2), c.is_equal_to(b, 3)
(True, False)
sage: c.is_equal_to(b, 4)
...
PrecisionError: Elements not known to enough precision

sage: c.is_equal_to(cc, 2), c.is_equal_to(cc, 4), c.is_equal_to(cc, 5)
(True, True, False)
```

TESTS:

```
sage: aa.is_equal_to(a), aa.is_equal_to(a, 4), aa.is_equal_to(a, 5)
(False, True, False)
sage: aa.is_equal_to(a, 15)
...
PrecisionError: Elements not known to enough precision

sage: b.is_equal_to(a), b.is_equal_to(a, 2)
(True, True)
sage: b.is_equal_to(a, 5)
...
PrecisionError: Elements not known to enough precision

sage: bb.is_equal_to(b, 3)
True
sage: bb.is_equal_to(b, 4)
...
PrecisionError: Elements not known to enough precision

sage: b.is_equal_to(c, 2), b.is_equal_to(c, 3)
(True, False)
sage: b.is_equal_to(c, 4)
...
PrecisionError: Elements not known to enough precision

sage: cc.is_equal_to(c, 2), cc.is_equal_to(c, 4), cc.is_equal_to(c, 5)
(True, True, False)
```

is_zero()

Returns whether self is zero modulo $p^{mbox{absprec}}$.

If absprec is None, returns True if this element is indistinguishable from zero.

INPUT:

```
- self -- a p-adic element
- absprec -- an integer or None
```

OUTPUT:

```
- boolean -- whether self is zero
```

EXAMPLES:

```
sage: R = Zp(5); a = R(0); b = R(0,5); c = R(75)
sage: a.is_zero(), a.is_zero(6)
```

```
(True, True)
sage: b.is_zero(), b.is_zero(5)
(True, True)
sage: c.is_zero(), c.is_zero(2), c.is_zero(3)
(False, True, False)
sage: b.is_zero(6)
...
PrecisionError: Not enough precision to determine if element is zero
```

lift()

Return an integer or rational congruent to self modulo self's precision. If a rational is returned, its denominator will eqaul p^ordp(self).

INPUT:

```
- self -- a p-adic element
```

OUTPUT:

```
- integer -- a integer congruent to self mod $p^{\mbox{prec}}$
```

EXAMPLES:

```
sage: R = Zp(7,4,'capped-rel'); a = R(8); a.lift()
8
sage: R = Qp(7,4); a = R(8); a.lift()
8
sage: R = Qp(7,4); a = R(8/7); a.lift()
8/7
```

lift_to_precision()

Returns another element of the same parent, with absolute precision at least absprec, congruent to self modulo self's precision.

If such lifting would yield an element with precision greater than allowed by the precision cap of self's parent, an error is raised.

EXAMPLES:

```
sage: R = Zp(5); a = R(0); b = R(0,5); c = R(17,3)
sage: a.lift_to_precision(5)
0
sage: b.lift_to_precision(4)
O(5^5)
sage: b.lift_to_precision(8)
O(5^8)
sage: b.lift_to_precision(40)
O(5^40)
sage: c.lift_to_precision(1)
2 + 3*5 + O(5^3)
sage: c.lift_to_precision(8)
2 + 3*5 + O(5^8)
sage: c.lift_to_precision(40)
...
PrecisionError: Precision higher than allowed by the precision cap.
```

list()

Returns a list of coefficients in a power series expansion of self in terms of p. If self is a field element, they start at p^valuation, if a ring element at p^0.

INPUT:

```
- self -- a p-adic element
- lift_mode - 'simple', 'smallest' or 'teichmuller'
```

OUTPUT:

```
- list -- the list of coeficients of self.  These will be integers if lift_mode is 'simple'
```

EXAMPLES:

```
sage: R = Zp(7,6); a = R(12837162817); a
3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6)
sage: L = a.list(); L
[3, 4, 4, 0, 4]
sage: sum([L[i] * 7^i for i in range(len(L))]) == a
True
sage: L = a.list('smallest'); L
[3, -3, -2, 1, -3, 1]
sage: sum([L[i] * 7^i for i in range(len(L))]) == a
True
sage: L = a.list('teichmuller'); L
[3 + 4*7 + 6*7^2 + 3*7^3 + 2*7^5 + O(7^6),
0,
5 + 2*7 + 3*7^3 + O(7^4),
1 + O(7^3),
3 + 4*7 + O(7^2),
5 + O(7)]
sage: sum([L[i] * 7^i for i in range(len(L))])
3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6)

sage: R = Qp(7,4); a = R(6*7+7**2); a.list()
[6, 1]
sage: a.list('smallest')
[-1, 2]
sage: a.list('teichmuller')
[6 + 6*7 + 6*7^2 + 6*7^3 + O(7^4),
2 + 4*7 + 6*7^2 + O(7^3),
3 + 4*7 + O(7^2),
3 + O(7)]
```

NOTE:

```
use slice operators to get a particular range
```

padded_list()

Returns a list of coeficiants of p starting with p^0 up to p^n exclusive (padded with zeros if needed). If a field element, starts at p^val instead.

INPUT:

```
self -- a p-adic element
n - an integer
lift_mode - 'simple', 'smallest' or 'teichmuller'
```

OUTPUT:

```
list -- the list of coeficients of self
```

EXAMPLES:

```
sage: R = Zp(7,3,'capped-rel'); a = R(2*7+7**2); a.padded_list(5)
[0, 2, 1, 0, 0]
sage: R = Qp(7,3); a = R(2*7+7**2); a.padded_list(5)
[2, 1, 0, 0]
```

```
sage: a.padded_list(3)
[2, 1]
```

NOTE:

```
the slice operators throw an error if asked for a slice above the precision
```

precision_absolute()

Returns the absolute precision of self.

This is the power of the maximal ideal modulo which this element is defined.

INPUT:

```
self -- a p-adic element
```

OUTPUT:

```
integer -- the absolute precision of self
```

EXAMPLES:

```
sage: R = Zp(7,3,'capped-rel'); a = R(7); a.precision_absolute()
4
sage: R = Qp(7,3); a = R(7); a.precision_absolute()
4
sage: R(7^-3).precision_absolute()
0
```

precision_relative()

Returns the relative precision of self.

This is the power of the maximal ideal modulo which the unit part of self is defined.

INPUT: self – a p-adic element

OUTPUT: integer – the relative precision of self

EXAMPLES: sage: R = Zp(7,3,'capped-rel'); a = R(7); a.precision_relative() 3 sage: R = Qp(7,3); a = R(7); a.precision_relative() 3 sage: a = R(7^-2, -1); a.precision_relative() 1 sage: a 7^-2 + O(7^-1)

residue()

Reduces this element modulo $p^absprec$.

INPUT:

```
- self -- a p-adic element
- absprec - an integer (defaults to 1)
```

OUTPUT:

```
- element of $Z/(p^{absprec} Z)$ -- self reduced mod p^absprec
```

EXAMPLES:

```
sage: R = Zp(7,4,'capped-rel'); a = R(8); a.residue(1)
1
sage: R = Qp(7,4,'capped-rel'); a = R(8); a.residue(1)
1
sage: a.residue(6)
...
PrecisionError: Not enough precision known in order to compute residue.
sage: b = a/7
sage: b.residue(1)
...
ValueError: Element must have non-negative valuation in order to compute residue.
```

unit_part()

Returns the unit part of self.

INPUT:

- self -- a p-adic element

OUTPUT:

- p-adic element -- the unit part of self

EXAMPLES:

```
sage: R = Zp(17,4,'capped-rel')
sage: a = R(18*17)
sage: a.unit_part()
1 + 17 + O(17^4)
sage: type(a)
<type 'sage.rings.padics.padic_capped_relative_element.pAdicCappedRelativeElement'>
sage: R = Qp(17,4,'capped-rel')
sage: a = R(18*17)
sage: a.unit_part()
1 + 17 + O(17^4)
sage: type(a)
<type 'sage.rings.padics.padic_capped_relative_element.pAdicCappedRelativeElement'>
sage: a = R(2*17^2); a
2*17^2 + O(17^6)
sage: a.unit_part()
2 + O(17^4)
sage: b=1/a; b
9*17^-2 + 8*17^-1 + 8 + 8*17 + O(17^2)
sage: b.unit_part()
9 + 8*17 + 8*17^2 + 8*17^3 + O(17^4)
sage: Zp(5)(75).unit_part()
3 + O(5^20)
```

val_unit()

Returns a pair (self.valuation(), self.unit_part()).

EXAMPLES:

```
sage: R = Zp(5); a = R(75, 20); a
3*5^2 + O(5^20)
sage: a.val_unit()
(2, 3 + O(5^18))
sage: R(0).val_unit()
(+Infinity, O(5^0))
sage: R(0, 10).val_unit()
(10, O(5^0))
```

unpickle_pcre_v1()

Unpickles a capped relative element.

EXAMPLES:

```
sage: from sage.rings.padics.padic_capped_relative_element import unpickle_pcre_v1
sage: R = Zp(5)
sage: a = unpickle_pcre_v1(R, 17, 2, 5); a
2*5^2 + 3*5^3 + O(5^7)
```

27.16 p-Adic Capped Absolute Element.

Elements of p-Adic Rings with Absolute Precision Cap

AUTHORS:

- David Roe
- Genya Zaytman: documentation
- David Harvey: doctests

clear_mpz_globals()

gmp_randrange()

init_mpz_globals()

make_pAdicCappedAbsoluteElement()

Unpickles a capped absolute element.

EXAMPLES:

```
sage: from sage.rings.padics.padic_capped_absolute_element import make_pAdicCappedAbsoluteElemen
sage: R = ZpCA(5)
sage: a = make_pAdicCappedAbsoluteElement(R, 17*25, 5); a
2*5^2 + 3*5^3 + O(5^5)
```

class **pAdicCappedAbsoluteElement**()

add_bigoh()

Returns a new element with absolute precision decreased to `prec`. The precision never increases.

INPUT:

- `self` – a p-adic element
- `prec` – an integer

OUTPUT:

- `element` – `self` with precision set to the minimum of `self`'s precision and `prec`

EXAMPLES:

```
sage: R = Zp(7,4,'capped-abs','series'); a = R(8); a.add_bigoh(1)
1 + O(7)

sage: k = ZpCA(3,5)
sage: a = k(41); a
2 + 3 + 3^2 + 3^3 + O(3^5)
sage: a.add_bigoh(7)
2 + 3 + 3^2 + 3^3 + O(3^5)
sage: a.add_bigoh(3)
2 + 3 + 3^2 + O(3^3)
```

copy()

Returns a copy of `self`.

EXAMPLES:

```
sage: a = ZpCA(5,6)(17); b = a.copy()
sage: a == b
True
sage: a is b
False
```

is_equal_to()

Returns whether `self` is equal to `right` modulo `p^absprec`.

INPUT:

- self – a p-adic element
- right – a p-adic element with the same parent
- absprec – an integer

OUTPUT:

- boolean – whether self is equal to right

EXAMPLES:

```
sage: R = ZpCA(2, 6)
sage: R(13).is_equal_to(R(13))
True
sage: R(13).is_equal_to(R(13+2^10))
True
sage: R(13).is_equal_to(R(17), 2)
True
sage: R(13).is_equal_to(R(17), 5)
False
```

is_zero()

Returns whether self is zero modulo p^absprec.

INPUT:

- self – a p-adic element
- prec – an integer

OUTPUT:

- boolean – whether self is zero

EXAMPLES:

```
sage: R = ZpCA(17, 6)
sage: R(0).is_zero()
True
sage: R(17^6).is_zero()
True
sage: R(17^2).is_zero(absprec=2)
True
```

lift()

Returns an integer congruent to this p-adic element modulo p^self.absprec().

EXAMPLES:

```
sage: R = ZpCA(3)
sage: R(10).lift()
10
sage: R(-1).lift()
3486784400
```

lift_to_precision()

Returns a p-adic integer congruent to this p-adic element modulo p^absprec with precision at least absprec.

If such lifting would yield an element with precision greater than allowed by the precision cap of self's parent, an error is raised.

EXAMPLES:

```
sage: R = ZpCA(17)
sage: R(-1,2).lift_to_precision(10)
16 + 16*17 + O(17^10)
sage: R(1,15).lift_to_precision(10)
```

```
1 + O(17^15)
sage: R(1,15).lift_to_precision(30)
...
PrecisionError: Precision higher than allowed by the precision cap.
```

list()

Returns a list of coefficients of p starting with p^0

INPUT:

- `self` – a p-adic element
- `lift_mode` – `'simple'`, `'smallest'` or `'teichmuller'` (default `'simple'`)

OUTPUT:

- `list` – the list of coeficients of `self`

NOTES:

- Returns a list $[a_0, a_1, \ldots, a_n]$ so that:
  - If `lift_mode = 'simple'`, a_i is an integer with $0 \leq a_i < p$.
  - If `lift_mode = 'smallest'`, a_i is an integer with $-p/2 < a_i \leq p/2$.
  - If `lift_mode = 'teichmuller'`, a_i has the same parent as $self$ and $a_i^p \equiv a_i$ modulo `p^(self.precision_absolute() - i)`
- $\sum_{i=0}^{n} a_i \cdot p^i =$ `self`, modulo the precision of `self`.

EXAMPLES:

```
sage: R = ZpCA(7,6); a = R(12837162817); a
3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6)
sage: L = a.list(); L
[3, 4, 4, 0, 4]
sage: sum([L[i] * 7^i for i in range(len(L))]) == a
True
sage: L = a.list('smallest'); L
[3, -3, -2, 1, -3, 1]
sage: sum([L[i] * 7^i for i in range(len(L))]) == a
True
sage: L = a.list('teichmuller'); L
[3 + 4*7 + 6*7^2 + 3*7^3 + 2*7^5 + O(7^6),
O(7^5),
5 + 2*7 + 3*7^3 + O(7^4),
1 + O(7^3),
3 + 4*7 + O(7^2),
5 + O(7)]
sage: sum([L[i] * 7^i for i in range(len(L))])
3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6)
```

multiplicative_order()

Returns the minimum possible multiplicative order of `self`.

INPUT:

- `self` – a p-adic element

OUTPUT:

- the multiplicative order of self. This is the minimum multiplicative order of all elements of $\mathbb{Z}_p$ lifting `self` to infinite precision.

EXAMPLES:

```
sage: R = ZpCA(7, 6)
sage: R(1/3)
5 + 4*7 + 4*7^2 + 4*7^3 + 4*7^4 + 4*7^5 + O(7^6)
```

```
sage: R(1/3).multiplicative_order()
+Infinity
sage: R(7).multiplicative_order()
+Infinity
sage: R(1).multiplicative_order()
1
sage: R(-1).multiplicative_order()
2
sage: R.teichmuller(3).multiplicative_order()
6
```

padded_list()

Returns a list of coefficients of p starting with p^0 up to p^n exclusive (padded with zeros if needed)

INPUT:

- self – a p-adic element
- n - an integer

OUTPUT:

- list – the list of coeficients of self

EXAMPLES:

```
sage: R = Zp(7,4,'capped-abs'); a = R(2*7+7**2); a.padded_list(5)
[0, 2, 1, 0, 0]
```

NOTE:

this differs from the padded_list method of padic_field_element

the slice operators throw an error if asked for a slice above the precision, while this function works

precision_absolute()

Returns the absolute precision of self.

This is the power of the maximal ideal modulo which this element is defined.

INPUT:

- self – a p-adic element

OUTPUT:

- integer – the absolute precision of self

EXAMPLES:

```
sage: R = Zp(7,4,'capped-abs'); a = R(7); a.precision_absolute()
4
```

precision_relative()

Returns the relative precision of self.

This is the power of the maximal ideal modulo which the unit part of self is defined.

INPUT:

- self – a p-adic element

OUTPUT:

- integer – the relative precision of self

EXAMPLES:

```
sage: R = Zp(7,4,'capped-abs'); a = R(7); a.precision_relative()
3
```

residue()

Reduces self modulo p^absprec

INPUT:

- `self` – a p-adic element
- `absprec` - an integer

OUTPUT:

- element of $\mathbb{Z}/p^{\text{absprec}}\mathbb{Z}$ – `self` reduced modulo `p^absprec`.

EXAMPLES:

```
sage: R = Zp(7,4,'capped-abs'); a = R(8); a.residue(1)
1
```

unit_part()

Returns the unit part of `self`.

INPUT:

- `self` – a p-adic element

OUTPUT:

- p-adic element – the unit part of `self`

EXAMPLES:

```
sage: R = Zp(17,4,'capped-abs', 'val-unit')
sage: a = R(18*17)
sage: a.unit_part()
18 + O(17^3)
sage: type(a)
<type 'sage.rings.padics.padic_capped_absolute_element.pAdicCappedAbsoluteElement'>
```

val_unit()

Returns a 2-tuple, the first element set to the valuation of `self`, and the second to the unit part of `self`.

If `self = 0`, then the unit part is `O(p^0)`.

EXAMPLES:

```
sage: R = ZpCA(5)
sage: a = R(75, 6); b = a - a
sage: a.val_unit()
(2, 3 + O(5^4))
sage: b.val_unit()
(6, O(5^0))
```

valuation()

Returns the valuation of `self`, ie the largest power of p dividing `self`.

EXAMPLES:

```
sage: R = ZpCA(5)
sage: R(5^5*1827).valuation()
5
```

TESTS:

```
sage: R(1).valuation()
0
sage: R(2).valuation()
0
sage: R(5).valuation()
1
sage: R(10).valuation()
1
sage: R(25).valuation()
2
sage: R(50).valuation()
```

```
2
sage: R(0).valuation()
20
```

27.17 p-Adic Fixed-Mod Element.

Elements of p-Adic Rings with Fixed Modulus

AUTHORS:

- David Roe
- Genya Zaytman: documentation
- David Harvey: doctests

clear_mpz_globals()

gmp_randrange()

init_mpz_globals()

make_pAdicFixedModElement()

Unpickles a capped relative element.

EXAMPLES:

```
sage: from sage.rings.padics.padic_fixed_mod_element import make_pAdicFixedModElement
sage: R = ZpFM(5)
sage: a = make_pAdicFixedModElement(R, 17*25); a
2*5^2 + 3*5^3 + O(5^20)
```

class **pAdicFixedModElement**()

add_bigoh()

Returns a new element truncated modulo p^absprec.

INPUT:

```
- self -- a p-adic element
- absprec -- an integer
```

OUTPUT:

```
- element -- a new element truncated modulo p^absprec.
```

EXAMPLES:

```
sage: R = Zp(7,4,'fixed-mod','series'); a = R(8); a.add_bigoh(1)
1 + O(7^4)
```

copy()

Returns a copy of self.

EXAMPLES:

```
sage: a = ZpFM(5,6)(17); b = a.copy()
sage: a == b
True
sage: a is b
False
```

is_equal_to()

Returns whether self is equal to right modulo $p^{mbox{absprec}}$.

If absprec is None, returns if self == 0.

INPUT:

```
- self -- a p-adic element
- right -- a p-addic element with the same parent
- absprec -- a positive integer (or None)
```

OUTPUT:

```
boolean -- whether self is equal to right
```

EXAMPLES:

```
sage: R = ZpFM(2, 6)
sage: R(13).is_equal_to(R(13))
True
sage: R(13).is_equal_to(R(13+2^10))
True
sage: R(13).is_equal_to(R(17), 2)
True
sage: R(13).is_equal_to(R(17), 5)
False
```

is_zero()

Returns whether self is zero modulo $p^{mbox{absprec}}$.

INPUT:

```
- self -- a p-adic element
- absprec -- an integer
```

OUTPUT:

```
boolean -- whether self is zero
```

EXAMPLES:

```
sage: R = ZpFM(17, 6)
sage: R(0).is_zero()
True
sage: R(17^6).is_zero()
True
sage: R(17^2).is_zero(absprec=2)
True
```

lift()

Return an integer congruent to self modulo self's precision.

INPUT:

```
- self -- a p-adic element
```

OUTPUT:

```
- integer -- a integer congruent to self mod $p^{\mbox{prec}}$
```

EXAMPLES:

```
sage: R = Zp(7,4,'fixed-mod'); a = R(8); a.lift()
8
sage: type(a.lift())
<type 'sage.rings.integer.Integer'>
```

lift_to_precision()

Returns self.

For compatibility with other p-adic types.

EXAMPLES:

```
sage: R = ZpFM(5); a = R(5); a.lift_to_precision(7)
5 + O(5^20)
```

list()

Returns a list of coefficients of p starting with p^0.

INPUT:

```
- self -- a p-adic element
- lift_mode -- 'simple', 'smallest' or 'teichmuller' (default 'simple')
```

OUTPUT:

```
- list -- the list of coeficients of self
```

NOTES:

```
Returns a list [a_0, a_1, \ldots, a_n] so that each a_i is an integer
and \sum_{i = 0}^n a_i * p^i = self, modulo the precision cap.
If lift_mode = 'simple', 0 <= a_i < p.
If lift_mode = 'smallest', -p/2 < a_i <= p/2.
If lift_mode = 'teichmuller', a_i^p = a_i, modulo the precision cap.
```

EXAMPLES:

```
sage: R = ZpFM(7,6); a = R(12837162817); a
3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6)
sage: L = a.list(); L
[3, 4, 4, 0, 4]
sage: sum([L[i] * 7^i for i in range(len(L))]) == a
True
sage: L = a.list('smallest'); L
[3, -3, -2, 1, -3, 1]
sage: sum([L[i] * 7^i for i in range(len(L))]) == a
True
sage: L = a.list('teichmuller'); L
[3 + 4*7 + 6*7^2 + 3*7^3 + 2*7^5 + O(7^6),
O(7^6),
5 + 2*7 + 3*7^3 + 6*7^4 + 4*7^5 + O(7^6),
1 + O(7^6),
3 + 4*7 + 6*7^2 + 3*7^3 + 2*7^5 + O(7^6),
5 + 2*7 + 3*7^3 + 6*7^4 + 4*7^5 + O(7^6)]
sage: sum([L[i] * 7^i for i in range(len(L))])
3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6)
```

multiplicative_order()

Returns the minimum possible multiplicative order of self.

INPUT:

```
- self -- a p-adic element
```

OUTPUT:

```
- integer -- the multiplicative order of self.  This is
  the minimum multiplicative order of all elements of Z_p
  lifting self to infinite precision.
```

EXAMPLES:

```
sage: R = ZpFM(7, 6)
sage: R(1/3)
5 + 4*7 + 4*7^2 + 4*7^3 + 4*7^4 + 4*7^5 + O(7^6)
sage: R(1/3).multiplicative_order()
+Infinity
sage: R(7).multiplicative_order()
+Infinity
sage: R(1).multiplicative_order()
1
sage: R(-1).multiplicative_order()
2
sage: R.teichmuller(3).multiplicative_order()
6
```

padded_list()

Returns a list of coefficients of p starting with p^0 up to p^n exclusive (padded with zeros if needed)

INPUT:

```
- self -- a p-adic element
- n -- an integer
```

OUTPUT:

```
- list -- the list of coeficients of self
```

EXAMPLES:

```
sage: R = Zp(7,4,'fixed-mod'); a = R(2*7+7**2); a.padded_list(5)
[0, 2, 1, 0, 0]
```

NOTE:

```
For elements with positive valuation, this function will
return a list with leading 0s, unlike for field elements.

The slice operators throw an error if asked for a slice
above the precision, while this function works
```

precision_absolute()

Returns the absolute precision of self.

INPUT:

```
- self -- a p-adic element
```

OUTPUT:

```
- integer -- the absolute precision of self
```

EXAMPLES:

```
sage: R = Zp(7,4,'fixed-mod'); a = R(7); a.precision_absolute()
4
```

precision_relative()

Returns the relative precision of self

INPUT:

```
- self -- a p-adic element
```

OUTPUT:

```
- integer -- the relative precision of self
```

EXAMPLES:

```
sage: R = Zp(7,4,'fixed-mod'); a = R(7); a.precision_relative()
3
sage: a = R(0); a.precision_relative()
0
```

residue()

Reduces this mod p^prec

INPUT:

```
- self -- a p-adic element
- absprec - an integer (default 1)
```

OUTPUT:

```
- element of Z/(p^prec Z) -- self reduced mod p^prec
```

EXAMPLES:

```
sage: R = Zp(7,4,'fixed-mod'); a = R(8); a.residue(1)
1
```

unit_part()

Returns the unit part of self.

If the valuation of self is positive, then the high digits of the result will be zero.

INPUT:

```
- self -- a p-adic element
```

OUTPUT:

```
- p-adic element -- the unit part of self
```

EXAMPLES:

```
sage: R = Zp(17, 4, 'fixed-mod')
sage: R(5).unit_part()
5 + O(17^4)
sage: R(18*17).unit_part()
1 + 17 + O(17^4)
sage: R(0).unit_part()
O(17^4)
sage: type(R(5).unit_part())
<type 'sage.rings.padics.padic_fixed_mod_element.pAdicFixedModElement'>
sage: R = ZpFM(5, 5); a = R(75); a.unit_part()
3 + O(5^5)
```

val_unit()

Returns a 2-tuple, the first element set to the valuation of self, and the second to the unit part of self.

If self == 0, then the unit part is O(p^self.parent().precision_cap()).

EXAMPLES:

```
sage: R = ZpFM(5,5)
sage: a = R(75); b = a - a
sage: a.val_unit()
(2, 3 + O(5^5))
sage: b.val_unit()
(5, O(5^5))
```

valuation()

Returns the valuation of self.

If self is zero, the valuation returned is the precision of the ring.

INPUT:

- self -- a p-adic element

OUTPUT:

- integer -- the valuation of self.

EXAMPLES:

```
sage: R = Zp(17, 4,'fixed-mod')
sage: a = R(2*17^2)
sage: a.valuation()
2
sage: R = Zp(5, 4,'fixed-mod')
sage: R(0).valuation()
4
sage: R(1).valuation()
0
sage: R(2).valuation()
0
sage: R(5).valuation()
1
sage: R(10).valuation()
1
sage: R(25).valuation()
2
sage: R(50).valuation()
2
```

27.18 p-Adic Extension Element.

A common superclass for all elements of extension rings and field of Zp and Qp.

AUTHORS:

- David Roe

class pAdicExtElement()

abs()

Returns the p-adic absolute value of self.

This is normalized so that the absolute value of p is 1/p.

INPUT – prec - Integer. The precision of the real field in which the answer is returned. If None, returns a rational for absolutely unramified fields, or a real with 53 bits of precision if ramified.

EXAMPLES: sage: R = Zp(5,5) sage: S.<x> = ZZ[] sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5 sage: W.<w> = R.ext(f) sage: w.abs() 0.724779663677696

27.19 p-Adic ZZ_pX Element.

A common superclass implementing features shared by all elements that use NTL's ZZ_pX as the fundamental data type.

AUTHORS:

- David Roe

class pAdicZZpXElement()

norm()

Return the absolute or relative norm of this element.

NOTE! This is not the p-adic absolute value. This is a field theoretic norm down to a ground ring. If you want the p-adic absolute value, use the `abs()` function instead.

If `base` is given then `base` must be a subfield of the parent L of `self`, in which case the norm is the relative norm from L to `base`.

In all other cases, the norm is the absolute norm down to $\mathbb{Q}_p$ or $\mathbb{Z}_p$.

EXAMPLES:

```
sage: R = ZpCR(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: ((1+2*w)^5).norm()
1 + 5^2 + O(5^5)
sage: ((1+2*w)).norm()^5
1 + 5^2 + O(5^5)
```

TESTS:

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: ((1+2*w)^5).norm()
1 + 5^2 + O(5^5)
sage: ((1+2*w)).norm()^5
1 + 5^2 + O(5^5)
sage: R = ZpFM(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: ((1+2*w)^5).norm()
1 + 5^2 + O(5^5)
sage: ((1+2*w)).norm()^5
1 + 5^2 + O(5^5)
```

trace()

Return the absolute or relative trace of this element.

If `base` is given then `base` must be a subfield of the parent L of `self`, in which case the norm is the relative norm from L to `base`.

In all other cases, the norm is the absolute norm down to $\mathbb{Q}_p$ or $\mathbb{Z}_p$.

EXAMPLES:

```
sage: R = ZpCR(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = (2+3*w)^7
sage: b = (6+w^3)^5
sage: a.trace()
3*5 + 2*5^2 + 3*5^3 + 2*5^4 + O(5^5)
sage: a.trace() + b.trace()
```

```
4*5 + 5^2 + 5^3 + 2*5^4 + O(5^5)
sage: (a+b).trace()
4*5 + 5^2 + 5^3 + 2*5^4 + O(5^5)
```

TESTS:

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = (2+3*w)^7
sage: b = (6+w^3)^5
sage: a.trace()
3*5 + 2*5^2 + 3*5^3 + 2*5^4 + O(5^5)
sage: a.trace() + b.trace()
4*5 + 5^2 + 5^3 + 2*5^4 + O(5^5)
sage: (a+b).trace()
4*5 + 5^2 + 5^3 + 2*5^4 + O(5^5)
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = (2+3*w)^7
sage: b = (6+w^3)^5
sage: a.trace()
3*5 + 2*5^2 + 3*5^3 + 2*5^4 + O(5^5)
sage: a.trace() + b.trace()
4*5 + 5^2 + 5^3 + 2*5^4 + O(5^5)
sage: (a+b).trace()
4*5 + 5^2 + 5^3 + 2*5^4 + O(5^5)
```

27.20 p-Adic `ZZ_pX` CR Element.

This file implements elements of eisenstein and unramified extensions of $\mathbb{Z}_p$ and $\mathbb{Q}_p$ with capped relative precision.

For the parent class see padic_extension_leaves.pyx.

The underlying implementation is through NTL's `ZZ_pX` class. Each element contains the following data:

- `ordp` (`long`) – A power of the uniformizer to scale the unit by. For unramified extensions this uniformizer is p, for eisenstein extensions it is not. A value equal to the maximum value of a long indicates that the element is an exact zero.

- `relprec` (`long`) – A signed integer giving the precision to which this element is defined. For nonzero `relprec`, the absolute value gives the power of the uniformizer modulo which the unit is defined. A positive value indicates that the element is normalized (ie `unit` is actually a unit: in the case of eisenstein extensions the constant term is not divisible by p, in the case of unramified extensions that there is at least one coefficient that is not divisible by p). A negative value indicates that the element may or may not be normalized. A zero value indicates that the element is zero to some precision. If so, `ordp` gives the absolute precision of the element. If `ordp` is greater than `maxordp`, then the element is an exact zero.

- `unit` (`ZZ_pX_c`) – An ntl `ZZ_pX` storing the unit part. The varible x is the uniformizer in the case of eisenstein extensions. If the element is not normalized, the `unit` may or may not actually be a unit. This `ZZ_pX` is created with global ntl modulus determined by the absolute value of `relprec`. If `relprec` is 0, `unit` **is not initialized**, or destructed if normalized and found to be zero. Otherwise, let r be relprec and e be the ramification index over $\mathbb{Q}_p$ or $\mathbb{Z}_p$. Then the modulus of unit is given by $p^{ceil(r/e)}$. Note that all kinds of problems arise if you

try to mix moduli. ZZ_pX_conv_modulus gives a semi-safe way to convert between different moduli without having to pass through ZZX (see sage/libs/ntl/decl.pxi and c_lib/src/ntl_wrap.cpp)

- prime_pow (some subclass of PowComputer_ZZ_pX) – a class, identical among all elements with the same parent, holding common data.
  - prime_pow.deg – The degree of the extension
  - prime_pow.e – The ramification index
  - prime_pow.f – The inertia degree
  - prime_pow.prec_cap – the unramified precision cap. For eisenstein extensions this is the smallest power of p that is zero.
  - prime_pow.ram_prec_cap – the ramified precision cap. For eisenstein extensions this will be the smallest power of x that is indistinugishable from zero.
  - prime_pow.pow_ZZ_tmp, prime_pow.pow_mpz_t_tmp‘‘, prime_pow.pow_Integer – functions for accessing powers of p. The first two return pointers. See sage/rings/padics/pow_computer_ext for examples and important warnings.
  - prime_pow.get_context, prime_pow.get_context_capdiv, prime_pow.get_top_context – obtain an ntl_ZZ_pContext_class corresponding to p^n. The capdiv version divides by prime_pow.e as appropriate. top_context corresponds to p^{prec_cap}.
  - prime_pow.restore_context, prime_pow.restore_context_capdiv, prime_pow.restore_top_context – restores the given context.
  - prime_pow.get_modulus, get_modulus_capdiv, get_top_modulus – Returns a ZZ_pX_Modulus_c* pointing to a polynomial modulus defined modulo p^n (appropriately divided by prime_pow.e in the capdiv case).

EXAMPLES:

An eisenstein extension:

```
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f); W
Eisenstein Extension of 5-adic Ring with capped relative precision 5 in w defined by (1 + O(5^5))*x^5
sage: z = (1+w)^5; z
1 + w^5 + w^6 + 2*w^7 + 4*w^8 + 3*w^10 + w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + 4*w^17 + 4*w^20 +
sage: y = z >> 1; y
w^4 + w^5 + 2*w^6 + 4*w^7 + 3*w^9 + w^11 + 4*w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + 4*w^19 + w^20
sage: y.valuation()
4
sage: y.precision_relative()
20
sage: y.precision_absolute()
24
sage: z - (y << 1)
1 + O(w^25)
sage: (1/w)^12+w
w^-12 + w + O(w^13)
sage: (1/w).parent()
Eisenstein Extension of 5-adic Field with capped relative precision 5 in w defined by (1 + O(5^5))*x^
```

An unramified extension:

```
sage: g = x^3 + 3*x + 3
sage: A.<a> = R.ext(g)
sage: z = (1+a)^5; z
(2*a^2 + 4*a) + (3*a^2 + 3*a + 1)*5 + (4*a^2 + 3*a + 4)*5^2 + (4*a^2 + 4*a + 4)*5^3 + (4*a^2 + 4*a +
sage: z - 1 - 5*a - 10*a^2 - 10*a^3 - 5*a^4 - a^5
O(5^5)
sage: y = z >> 1; y
(3*a^2 + 3*a + 1) + (4*a^2 + 3*a + 4)*5 + (4*a^2 + 4*a + 4)*5^2 + (4*a^2 + 4*a + 4)*5^3 + O(5^4)
sage: 1/a
(3*a^2 + 4) + (a^2 + 4)*5 + (3*a^2 + 4)*5^2 + (a^2 + 4)*5^3 + (3*a^2 + 4)*5^4 + O(5^5)
```

Different printing modes:

```
sage: R = Zp(5, print_mode='digits'); S.<x> = R[]; f = x^5 + 75*x^3 - 15*x^2 + 125*x -5; W.<w> = R.ex
sage: z = (1+w)^5; repr(z)
'...411040311321031044222131124200011101120110200202330321433201121440323201314400140044441030421100
sage: R = Zp(5, print_mode='bars'); S.<x> = R[]; g = x^3 + 3*x + 3; A.<a> = R.ext(g)
sage: z = (1+a)^5; repr(z)
'...[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4,
sage: R = Zp(5, print_mode='terse'); S.<x> = R[]; f = x^5 + 75*x^3 - 15*x^2 + 125*x -5; W.<w> = R.ext
sage: z = (1+w)^5; z
6 + 95367431640505*w + 25*w^2 + 95367431640560*w^3 + 5*w^4 + O(w^100)
sage: R = Zp(5, print_mode='val-unit'); S.<x> = R[]; f = x^5 + 75*x^3 - 15*x^2 + 125*x -5; W.<w> = R
sage: y = (1+w)^5 - 1; y
w^5 * (2090041 + 19073486126901*w + 1258902*w^2 + 674*w^3 + 16785*w^4) + O(w^100)
```

You can get at the underlying ntl unit:

```
sage: z._ntl_rep()
[6 95367431640505 25 95367431640560 5]
sage: y._ntl_rep()
[2090041 19073486126901 1258902 674 16785]
sage: y._ntl_rep_abs()
([5 95367431640505 25 95367431640560 5], 0)
```

NOTES:

```
If you get an error ``internal error: can't grow this
_ntl_gbigint,`` it indicates that moduli are being mixed
inappropriately somewhere.  For example, when calling a function
with a ``ZZ_pX_c`` as an argument, it copies.  If the modulus is not
set to the modulus of the ``ZZ_pX_c``, you can get errors.
```

AUTHORS:

- David Roe (2008-01-01) initial version

make_ZZpXCRElement()

Unpickling.

EXAMPLES:

```
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
```

```
sage: y = W(775, 19); y
w^10 + 4*w^12 + 2*w^14 + w^15 + 2*w^16 + 4*w^17 + w^18 + O(w^19)
sage: loads(dumps(y)) #indirect doctest
w^10 + 4*w^12 + 2*w^14 + w^15 + 2*w^16 + 4*w^17 + w^18 + O(w^19)
```

class pAdicZZpXCRElement()

copy()

Returns a copy of `self`.

EXAMPLES:

```
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: b = W(45, 17); b
4*w^5 + 3*w^7 + w^9 + w^10 + 2*w^11 + w^12 + w^13 + 3*w^14 + w^16 + O(w^17)
sage: c = b.copy(); c
4*w^5 + 3*w^7 + w^9 + w^10 + 2*w^11 + w^12 + w^13 + 3*w^14 + w^16 + O(w^17)
sage: c is b
False
```

is_equal_to()

Returns whether `self` is equal to `right` modulo `self.uniformizer()^absprec`.

If `absprec` is `None`, returns if `self` is equal to `right` modulo the lower of their two precisions.

EXAMPLES:

```
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(47); b = W(47 + 25)
sage: a.is_equal_to(b)
False
sage: a.is_equal_to(b, 7)
True
```

is_zero()

Returns whether the valuation of `self` is at least `absprec`. If `absprec` is `None`, returns if `self` is indistinugishable from zero.

If `self` is an inexact zero of valuation less than `absprec`, raises a PrecisionError.

EXAMPLES:

```
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: O(w^189).is_zero()
True
sage: W(0).is_zero()
True
sage: a = W(675)
sage: a.is_zero()
False
sage: a.is_zero(7)
True
sage: a.is_zero(21)
```

```
False
```

lift_to_precision()

Returns a pAdicZZpXCRElement congruent to self but with absolute precision at least absprec. If setting absprec that high would violate the precision cap, raises a precision error. If self is an inexact zero and absprec is greater than the maximum allowed valuation, raises an error.

Note that the new digits will not necessarily be zero.

EXAMPLES:

```
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(345, 17); a
4*w^5 + 3*w^7 + w^9 + 3*w^10 + 2*w^11 + 4*w^12 + w^13 + 2*w^14 + 2*w^15 + O(w^17)
sage: b = a.lift_to_precision(19); b
4*w^5 + 3*w^7 + w^9 + 3*w^10 + 2*w^11 + 4*w^12 + w^13 + 2*w^14 + 2*w^15 + w^17 + 2*w^18 + O(
sage: c = a.lift_to_precision(24); c
4*w^5 + 3*w^7 + w^9 + 3*w^10 + 2*w^11 + 4*w^12 + w^13 + 2*w^14 + 2*w^15 + w^17 + 2*w^18 + 4*
sage: a._ntl_rep()
[19 35 118 60 121]
sage: b._ntl_rep()
[19 35 118 60 121]
sage: c._ntl_rep()
[19 35 118 60 121]
```

list()

Returns a list giving a series representation of self.

- If lift_mode == 'simple' or 'smallest', the returned list will consist of integers (in the eisenstein case) or a list of lists of integers (in the unramified case). self can be reconstructed as a sum of elements of the list times powers of the uniformiser (in the eisenstein case), or as a sum of powers of the p times polynomials in the generator (in the unramified case).
  - If lift_mode == 'simple', all integers will be in the interval $[0, p-1]$.
  - If lift_mode == 'smallest' they will be in the interval $[(1-p)/2, p/2]$.
- If lift_mode == 'teichmuller', returns a list of pAdicZZpXCRElements, all of which are Teichmuller representatives and such that self is the sum of that list times powers of the uniformizer.

Note that zeros are truncated from the returned list if self.parent() is a field, so you must use the valuation function to fully reconstruct self.

EXAMPLES:

```
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: y = W(775, 19); y
w^10 + 4*w^12 + 2*w^14 + w^15 + 2*w^16 + 4*w^17 + w^18 + O(w^19)
sage: (y>>9).list()
[0, 1, 0, 4, 0, 2, 1, 2, 4, 1]
sage: (y>>9).list('smallest')
[0, 1, 0, -1, 0, 2, 1, 2, 0, 1]
sage: w^10 - w^12 + 2*w^14 + w^15 + 2*w^16 + w^18 + O(w^19)
w^10 + 4*w^12 + 2*w^14 + w^15 + 2*w^16 + 4*w^17 + w^18 + O(w^19)
sage: g = x^3 + 3*x + 3
sage: A.<a> = R.ext(g)
sage: y = 75 + 45*a + 1200*a^2; y
```

```
4*a*5 + (3*a^2 + a + 3)*5^2 + 4*a^2*5^3 + a^2*5^4 + O(5^6)
sage: y.list()
[[], [0, 4], [3, 1, 3], [0, 0, 4], [0, 0, 1]]
sage: y.list('smallest')
[[], [0, -1], [-2, 2, -2], [1], [0, 0, 2]]
sage: 5*((-2*5 + 25) + (-1 + 2*5)*a + (-2*5 + 2*125)*a^2)
4*a*5 + (3*a^2 + a + 3)*5^2 + 4*a^2*5^3 + a^2*5^4 + O(5^6)
sage: W(0).list()
[]
sage: W(0,4).list()
[0]
sage: A(0,4).list()
[[]]
```

log()

Compute the p-adic logarithm of any unit. (See below for normalization.)

INPUT:

- branch – pAdicZZpXFMElement (default None). The log of the uniformizer. If None, then an error is raised if self is not a unit.
- same_ring – bool or pAdicGeneric (default True). When $e > p$ it is possible (even common) that the image of the log map is not contained in the ring of integers. If same_ring is True, then this function will return a value in self.parent() or raise an error if the answer would have negative valuation. If same_ring is False, then this function will raise an error (this behavior is for consistency with other p-adic types). If same_ring is a p-adic field into which this fixed mod ring can be successfully cast, then self is cast into that field and the log is taken there. Note that this casting will assume that self has the full precision possible.

OUTPUT:

- The p-adic log of self.

Let K be the parent of self, π be a uniformizer of K and w be a generator for the group of roots of unity in K. The usual power series for log with values in the additive group of K only converges for 1-units (units congruent to 1 modulo π). However, there is a unique extension of log to a homomorphism defined on all the units. If $u = av$ is a unit with $v \equiv 1 \pmod{p}$, then we define $log(u) = log(v)$. This is the correct extension because the units U of K split as a product $U = V \times < w >$, where V is the subgroup of 1-units. The $< w >$ factor is torsion, so must go to 0 under any homomorphism to the torsion free group $(K, +)$.

NOTES:

What some other systems do with regard to non-1-units:

- PARI: Seems to define log the same way as we do.
- MAGMA: Gives an error when unit is not a 1-unit.

In addition, if branch is specified, then the log map will work on non-units.

..math

```
log(pi^k \cdot u) = k \cdot branch + log(u)
```

ALGORITHM:

Input: Some unit u.

1. Check that the input is really a unit (i.e., valuation 0), or that branch is specified.
2. Let $1 - x = u^{q-1}$, which is a 1-unit, where q is the order of the residue field of K.
3. Use the series expansion

..math

```
\log(1-x) = F(x) = -x - 1/2*x^2 - 1/3*x^3 - 1/4*x^4 - 1/5*x^5 - \cdots
```

to compute the logarithm $log(u^{q-1})$.
Add on terms until x^k is zero modulo the precision cap, and then determine if there are further terms that contribute to the sum (those where k is slightly above the precision cap but divisible by p).

1.Then

..math

```
\log(u) = log(u^{q-1})/(q-1) = F(1-u^{q-1})/(q-1).``
```

EXAMPLES:
First, the Eisenstein case.:

```
sage: R = ZpCR(5,5)
sage: S.<x> = R[]
sage: f = x^4 + 15*x^2 + 625*x - 5
sage: W.<w> = R.ext(f)
sage: z = 1 + w^2 + 4*w^7; z
1 + w^2 + 4*w^7 + O(w^20)
```

Log is actually not implemented completely yet in this case!:

```
sage: z.log()   # not tested -- what we wish would happen
4*w^2 + 3*w^4 + w^6 + w^7 + w^8 + 4*w^9 + 3*w^10 + w^12 + w^13 + 3*w^14 + w^15 + 4*w^16 + 4*
sage: z.log()   # what does happen
...
NotImplementedError: log is not quite working yet
```

Check that log is multiplicative:

```
sage: y = 1 + 3*w^4 + w^5
sage: y.log() + z.log() - (y*z).log()  # not tested -- what we wish would happen
O(w^20)
sage: y.log() + z.log() - (y*z).log()  # what does happen
...
NotImplementedError: log is not quite working yet
```

Now an unramified example.:

```
sage: g = x^3 + 3*x + 3
sage: A.<a> = R.ext(g)
sage: b = 1 + 5*(1 + a^2) + 5^3*(3 + 2*a)
sage: b.log()          # not tested -- what should happen
(4*a^2 + 4)*5 + (a^2 + a + 2)*5^2 + (a^2 + 2*a + 4)*5^3 + (a^2 + 2*a + 2)*5^4 + O(5^5)
sage: b.log()          # what does happen
...
NotImplementedError: log is not quite working yet
```

Check that log is multiplicative:

```
sage: c = 3 + 5^2*(2 + 4*a)
sage: b.log() + c.log() - (b*c).log()   # not tested -- what should happen
O(5^5)
sage: b.log() + c.log() - (b*c).log()   # what *actually* does happen
...
NotImplementedError: log is not quite working yet
```

AUTHORS:

•David Roe: initial version

TODO:

•Currently implemented as $O(N^2)$. This can be improved to soft-$O(N)$ using algorithm described by Dan Bernstein: http://cr.yp.to/lineartime/multapps-20041007.pdf

matrix_mod_pn()

Returns the matrix of right multiplication by the element on the power basis $1, x, x^2, \ldots, x^{d-1}$ for this extension field. Thus the *rows* of this matrix give the images of each of the x^i. The entries of the matrices are IntegerMod elements, defined modulo p^(self.absprec() / e).

Raises an error if self has negative valuation.

EXAMPLES:

```
sage: R = ZpCR(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = (3+w)^7
sage: a.matrix_mod_pn()
[2757  333 1068  725 2510]
[  50 1507  483  318  725]
[ 500   50 3007 2358  318]
[1590 1375 1695 1032 2358]
[2415  590 2370 2970 1032]
```

precision_absolute()

Returns the absolute precision of self, ie the power of the uniformizer modulo which this element is defined.

EXAMPLES:

```
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(75, 19); a
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + O(w^19)
sage: a.valuation()
10
sage: a.precision_absolute()
19
sage: a.precision_relative()
9
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + O(w^9)
sage: (a.unit_part() - 3).precision_absolute()
9
```

precision_relative()

Returns the relative precision of self, ie the power of the uniformizer modulo which the unit part of self is defined.

EXAMPLES:

```
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(75, 19); a
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + O(w^19)
sage: a.valuation()
10
sage: a.precision_absolute()
19
```

```
sage: a.precision_relative()
9
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + O(w^9)
```

unit_part()
Returns the unit part of `self`, ie `self / uniformizer^(self.valuation())`
EXAMPLES:

```
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(75, 19); a
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + O(w^19)
sage: a.valuation()
10
sage: a.precision_absolute()
19
sage: a.precision_relative()
9
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + O(w^9)
```

27.21 p-Adic `ZZ_pX` CA Element.

This file implements elements of eisenstein and unramified extensions of `Zp` with capped absolute precision.

For the parent class see padic_extension_leaves.pyx.

The underlying implementation is through NTL's `ZZ_pX` class. Each element contains the following data:

- `absprec` (long) – An integer giving the precision to which this element is defined. This is the power of the uniformizer modulo which the element is well defined.
- `value` (`ZZ_pX_c`) – An ntl `ZZ_pX` storing the value. The varible x is the uniformizer in the case of eisenstein extensions. This ZZ_pX is created with global ntl modulus determined by absprec. Let a be absprec and e be the ramification index over $\mathbb{Q}_p$ or $\mathbb{Z}_p$. Then the modulus is given by $p^{ceil(a/e)}$. Note that all kinds of problems arise if you try to mix moduli. `ZZ_pX_conv_modulus` gives a semi-safe way to convert between different moduli without having to pass through ZZX (see `sage/libs/ntl/decl.pxi` and `c_lib/src/ntl_wrap.cpp`)
- `prime_pow` (some subclass of `PowComputer_ZZ_pX`) – a class, identical among all elements with the same parent, holding common data.
  - `prime_pow.deg` – The degree of the extension
  - `prime_pow.e` – The ramification index
  - `prime_pow.f` – The inertia degree
  - `prime_pow.prec_cap` – the unramified precision cap. For eisenstein extensions this is the smallest power of p that is zero.
  - `prime_pow.ram_prec_cap` – the ramified precision cap. For eisenstein extensions this will be the smallest power of x that is indistinugishable from zero.
  - `prime_pow.pow_ZZ_tmp`, prime_pow.pow_mpz_t_tmp‘‘, `prime_pow.pow_Integer` – functions for accessing powers of p. The first two return pointers. See `sage/rings/padics/pow_computer_ext` for examples and important warnings.

- prime_pow.get_context, prime_pow.get_context_capdiv, prime_pow.get_top_context – obtain an ntl_ZZ_pContext_class corresponding to p^n. The capdiv version divides by prime_pow.e as appropriate. top_context corresponds to p^{prec_cap}.
- prime_pow.restore_context, prime_pow.restore_context_capdiv, prime_pow.restore_top_context – restores the given context.
- prime_pow.get_modulus, get_modulus_capdiv, get_top_modulus – Returns a ZZ_pX_Modulus_c* pointing to a polynomial modulus defined modulo p^n (appropriately divided by prime_pow.e in the capdiv case).

EXAMPLES:

An eisenstein extension:

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f); W
Eisenstein Extension of 5-adic Ring with capped absolute precision 5 in w defined by (1 + O(5^5))*x^5
sage: z = (1+w)^5; z
1 + w^5 + w^6 + 2*w^7 + 4*w^8 + 3*w^10 + w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + 4*w^17 + 4*w^20 +
sage: y = z >> 1; y
w^4 + w^5 + 2*w^6 + 4*w^7 + 3*w^9 + w^11 + 4*w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + 4*w^19 + w^20
sage: y.valuation()
4
sage: y.precision_relative()
20
sage: y.precision_absolute()
24
sage: z - (y << 1)
1 + O(w^25)
sage: (1/w)^12+w
w^-12 + w + O(w^12)
sage: (1/w).parent()
Eisenstein Extension of 5-adic Field with capped relative precision 5 in w defined by (1 + O(5^5))*x^
```

An unramified extension:

```
sage: g = x^3 + 3*x + 3
sage: A.<a> = R.ext(g)
sage: z = (1+a)^5; z
(2*a^2 + 4*a) + (3*a^2 + 3*a + 1)*5 + (4*a^2 + 3*a + 4)*5^2 + (4*a^2 + 4*a + 4)*5^3 + (4*a^2 + 4*a +
sage: z - 1 - 5*a - 10*a^2 - 10*a^3 - 5*a^4 - a^5
O(5^5)
sage: y = z >> 1; y
(3*a^2 + 3*a + 1) + (4*a^2 + 3*a + 4)*5 + (4*a^2 + 4*a + 4)*5^2 + (4*a^2 + 4*a + 4)*5^3 + O(5^4)
sage: 1/a
(3*a^2 + 4) + (a^2 + 4)*5 + (3*a^2 + 4)*5^2 + (a^2 + 4)*5^3 + (3*a^2 + 4)*5^4 + O(5^5)
```

Different printing modes:

```
sage: R = ZpCA(5, print_mode='digits'); S.<x> = ZZ[]; f = x^5 + 75*x^3 - 15*x^2 + 125*x -5; W.<w> = R
sage: z = (1+w)^5; repr(z)
'...411040311321031044222131124200011101120110200202330321433201121440323201314400140044441030421100
sage: R = ZpCA(5, print_mode='bars'); S.<x> = ZZ[]; g = x^3 + 3*x + 3; A.<a> = R.ext(g)
sage: z = (1+a)^5; repr(z)
```

```
'...[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4,
sage: R = ZpCA(5, print_mode='terse'); S.<x> = ZZ[]; f = x^5 + 75*x^3 - 15*x^2 + 125*x -5; W.<w> = R
sage: z = (1+w)^5; z
6 + 95367431640505*w + 25*w^2 + 95367431640560*w^3 + 5*w^4 + O(w^100)
sage: R = ZpCA(5, print_mode='val-unit'); S.<x> = ZZ[]; f = x^5 + 75*x^3 - 15*x^2 + 125*x -5; W.<w> =
sage: y = (1+w)^5 - 1; y
w^5 * (2090041 + 19073486126901*w + 1258902*w^2 + 674*w^3 + 16785*w^4) + O(w^100)
```

You can get at the underlying ntl representation:

```
sage: z._ntl_rep()
[6 95367431640505 25 95367431640560 5]
sage: y._ntl_rep()
[5 95367431640505 25 95367431640560 5]
sage: y._ntl_rep_abs()
([5 95367431640505 25 95367431640560 5], 0)
```

NOTES:

```
If you get an error 'internal error: can't grow this
_ntl_gbigint,' it indicates that moduli are being mixed
inappropriately somewhere.

For example, when calling a function with a ZZ_pX_c as an
argument, it copies.  If the modulus is not set to the modulus of
the ZZ_pX_c, you can get errors.
```

AUTHORS:

- David Roe (2008-01-01) initial version

make_ZZpXCAElement()

For pickling. Makes a `pAdicZZpXCAElement` with given `parent`, `value`, `absprec`.

EXAMPLES:

```
sage: from sage.rings.padics.padic_ZZ_pX_CA_element import make_ZZpXCAElement
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: make_ZZpXCAElement(W, ntl.ZZ_pX([3,2,4],5^3),13,0)
3 + 2*w + 4*w^2 + O(w^13)
```

class pAdicZZpXCAElement()

copy()

Returns a copy of `self`.

EXAMPLES:

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: b = W(45, 17); b
4*w^5 + 3*w^7 + w^9 + w^10 + 2*w^11 + w^12 + w^13 + 3*w^14 + w^16 + O(w^17)
```

```
sage: c = b.copy(); c
4*w^5 + 3*w^7 + w^9 + w^10 + 2*w^11 + w^12 + w^13 + 3*w^14 + w^16 + O(w^17)
sage: c is b
False
```

is_equal_to()

Returns whether `self` is equal to `right` modulo `self.uniformizer()^absprec`.

If `absprec` is `None`, returns if `self` is equal to `right` modulo the lower of their two precisions.

EXAMPLES:

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(47); b = W(47 + 25)
sage: a.is_equal_to(b)
False
sage: a.is_equal_to(b, 7)
True
```

is_zero()

Returns whether the valuation of `self` is at least `absprec`. If `absprec` is `None`, returns if `self` is indistinugishable from zero.

If `self` is an inexact zero of valuation less than `absprec`, raises a PrecisionError.

EXAMPLES:

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: O(w^189).is_zero()
True
sage: W(0).is_zero()
True
sage: a = W(675)
sage: a.is_zero()
False
sage: a.is_zero(7)
True
sage: a.is_zero(21)
False
```

lift_to_precision()

Returns a `pAdicZZpXCAElement` congruent to `self` but with absolute precision at least `absprec`. If setting `absprec` that high would violate the precision cap, raises a precision error.

Note that the new digits will not necessarily be zero.

EXAMPLES:

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(345, 17); a
4*w^5 + 3*w^7 + w^9 + 3*w^10 + 2*w^11 + 4*w^12 + w^13 + 2*w^14 + 2*w^15 + O(w^17)
sage: b = a.lift_to_precision(19); b # indirect doctest
4*w^5 + 3*w^7 + w^9 + 3*w^10 + 2*w^11 + 4*w^12 + w^13 + 2*w^14 + 2*w^15 + w^17 + 2*w^18 + O(
sage: c = a.lift_to_precision(24); c
4*w^5 + 3*w^7 + w^9 + 3*w^10 + 2*w^11 + 4*w^12 + w^13 + 2*w^14 + 2*w^15 + w^17 + 2*w^18 + 4*
```

```
sage: a._ntl_rep()
[345]
sage: b._ntl_rep()
[345]
sage: c._ntl_rep()
[345]
```

list()

Returns a list giving a series representation of `self`.

- If `lift_mode == 'simple'` or `'smallest'`, the returned list will consist of integers (in the eisenstein case) or a list of lists of integers (in the unramified case). `self` can be reconstructed as a sum of elements of the list times powers of the uniformiser (in the eisenstein case), or as a sum of powers of p times polynomials in the generator (in the unramified case).
  - If `lift_mode == 'simple'`, all integers will be in the interval $[0, p-1]$
  - If `lift_mod == 'smallest'` they will be in the interval $[(1-p)/2, p/2]$.
- If `lift_mode == 'teichmuller'`, returns a list of `pAdicZZpXCAElements`, all of which are Teichmuller representatives and such that `self` is the sum of that list times powers of the uniformizer.

EXAMPLES:

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: y = W(775, 19); y
w^10 + 4*w^12 + 2*w^14 + w^15 + 2*w^16 + 4*w^17 + w^18 + O(w^19)
sage: (y>>9).list()
[0, 1, 0, 4, 0, 2, 1, 2, 4, 1]
sage: (y>>9).list('smallest')
[0, 1, 0, -1, 0, 2, 1, 2, 0, 1]
sage: w^10 - w^12 + 2*w^14 + w^15 + 2*w^16 + w^18 + O(w^19)
w^10 + 4*w^12 + 2*w^14 + w^15 + 2*w^16 + 4*w^17 + w^18 + O(w^19)
sage: g = x^3 + 3*x + 3
sage: A.<a> = R.ext(g)
sage: y = 75 + 45*a + 1200*a^2; y
4*a*5 + (3*a^2 + a + 3)*5^2 + 4*a^2*5^3 + a^2*5^4 + O(5^5)
sage: y.list()
[[], [0, 4], [3, 1, 3], [0, 0, 4], [0, 0, 1]]
sage: y.list('smallest')
[[], [0, -1], [-2, 2, -2], [1], [0, 0, 2]]
sage: 5*((-2*5 + 25) + (-1 + 2*5)*a + (-2*5 + 2*125)*a^2)
4*a*5 + (3*a^2 + a + 3)*5^2 + 4*a^2*5^3 + a^2*5^4 + O(5^5)
sage: W(0).list()
[0]
sage: A(0,4).list()
[[]]
```

matrix_mod_pn()

Returns the matrix of right multiplication by the element on the power basis $1, x, x^2, \ldots, x^{d-1}$ for this extension field. Thus the *rows* of this matrix give the images of each of the x^i. The entries of the matrices are `IntegerMod` elements, defined modulo `p^(self.absprec() / e)`.

EXAMPLES:

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
```

```
sage: W.<w> = R.ext(f)
sage: a = (3+w)^7
sage: a.matrix_mod_pn()
[2757  333 1068  725 2510]
[  50 1507  483  318  725]
[ 500   50 3007 2358  318]
[1590 1375 1695 1032 2358]
[2415  590 2370 2970 1032]
```

precision_absolute()

Returns the absolute precision of `self`, ie the power of the uniformizer modulo which this element is defined.

EXAMPLES:

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(75, 19); a
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + O(w^19)
sage: a.valuation()
10
sage: a.precision_absolute()
19
sage: a.precision_relative()
9
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + O(w^9)
```

precision_relative()

Returns the relative precision of `self`, ie the power of the uniformizer modulo which the unit part of `self` is defined.

EXAMPLES:

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(75, 19); a
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + O(w^19)
sage: a.valuation()
10
sage: a.precision_absolute()
19
sage: a.precision_relative()
9
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + O(w^9)
```

to_fraction_field()

Returns `self` cast into the fraction field of `self.parent()`.

EXAMPLES:

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: z = (1 + w)^5; z
```

```
1 + w^5 + w^6 + 2*w^7 + 4*w^8 + 3*w^10 + w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + 4*w^17 +
sage: y = z.to_fraction_field(); y #indirect doctest
1 + w^5 + w^6 + 2*w^7 + 4*w^8 + 3*w^10 + w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + 4*w^17 +
sage: y.parent()
Eisenstein Extension of 5-adic Field with capped relative precision 5 in w defined by (1 + C
```

unit_part()

Returns the unit part of `self`, ie `self / uniformizer^(self.valuation())`

EXAMPLES:

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(75, 19); a
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + O(w^19)
sage: a.valuation()
10
sage: a.precision_absolute()
19
sage: a.precision_relative()
9
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + O(w^9)
```

27.22 p-Adic `ZZ_pX` FM Element.

This file implements elements of eisenstein and unramified extensions of $\mathbb{Z}_p$ with fixed modulus precision.

For the parent class see `padic_extension_leaves.pyx`.

The underlying implementation is through NTL's `ZZ_pX` class. Each element contains the following data:

- `value` (`ZZ_pX_c`) – An ntl `ZZ_pX` storing the value. The varible x is the uniformizer in the case of eisenstein extensions. This `ZZ_pX` is created with global ntl modulus determined by the parent's precision cap and shared among all elements.
- `prime_pow` (some subclass of `PowComputer_ZZ_pX`) – a class, identical among all elements with the same parent, holding common data.
  - `prime_pow.deg` – The degree of the extension
  - `prime_pow.e` – The ramification index
  - `prime_pow.f` – The inertia degree
  - `prime_pow.prec_cap` – the unramified precision cap. For eisenstein extensions this is the smallest power of p that is zero.
  - `prime_pow.ram_prec_cap` – the ramified precision cap. For eisenstein extensions this will be the smallest power of x that is indistinugishable from zero.
  - `prime_pow.pow_ZZ_tmp`, prime_pow.pow_mpz_t_tmp'', `prime_pow.pow_Integer` – functions for accessing powers of p. The first two return pointers. See `sage/rings/padics/pow_computer_ext` for examples and important warnings.
  - `prime_pow.get_context`, `prime_pow.get_context_capdiv`, `prime_pow.get_top_context` – obtain an `ntl_ZZ_pContext_class` corresponding to p^n. The capdiv version divides by `prime_pow.e` as appropriate. `top_context` corresponds to p^{prec_cap}.

- prime_pow.restore_context, prime_pow.restore_context_capdiv, prime_pow.restore_top_context – restores the given context.
- prime_pow.get_modulus, get_modulus_capdiv, get_top_modulus – Returns a ZZ_pX_Modulus_c* pointing to a polynomial modulus defined modulo p^n (appropriately divided by prime_pow.e in the capdiv case).

EXAMPLES:

An eisenstein extension:

```
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f); W
Eisenstein Extension of 5-adic Ring of fixed modulus 5^5 in w defined by (1 + O(5^5))*x^5 + (3*5^2 +
sage: z = (1+w)^5; z
1 + w^5 + w^6 + 2*w^7 + 4*w^8 + 3*w^10 + w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + 4*w^17 + 4*w^20 +
sage: y = z >> 1; y
w^4 + w^5 + 2*w^6 + 4*w^7 + 3*w^9 + w^11 + 4*w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + 4*w^19 + w^20
sage: y.valuation()
4
sage: y.precision_relative()
21
sage: y.precision_absolute()
25
sage: z - (y << 1)
1 + O(w^25)
```

An unramified extension:

```
sage: g = x^3 + 3*x + 3
sage: A.<a> = R.ext(g)
sage: z = (1+a)^5; z

```

AUTHORS:

- David Roe (2008-01-01) initial version

make_ZZpXFMElement()

Creates a new pAdicZZpXFMElement out of an ntl_ZZ_pX f, with parent parent. For use with pickling.

EXAMPLES:

```
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: z = (1 + w)^5 - 1
sage: loads(dumps(z)) == z # indirect doctest
True
```

class **pAdicZZpXFMElement**()

copy()

Returns a copy of self.

EXAMPLES:

```
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: b = W(45); b
4*w^5 + 3*w^7 + w^9 + w^10 + 2*w^11 + w^12 + w^13 + 3*w^14 + w^16 + 2*w^17 + w^19 + 4*w^20 +
sage: c = b.copy(); c
4*w^5 + 3*w^7 + w^9 + w^10 + 2*w^11 + w^12 + w^13 + 3*w^14 + w^16 + 2*w^17 + w^19 + 4*w^20 +
sage: c is b
False
```

is_equal_to()

Returns whether self is equal to right modulo self.uniformizer()^absprec.

If absprec is None, returns if self is equal to right modulo the precision cap.

EXAMPLES:

```
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(47); b = W(47 + 25)
sage: a.is_equal_to(b)
False
sage: a.is_equal_to(b, 7)
True
```

is_zero()

Returns whether the valuation of self is at least absprec. If absprec is None, returns whether self is indistinugishable from zero.

EXAMPLES:

```
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: O(w^189).is_zero()
True
```

```
sage: W(0).is_zero()
True
sage: a = W(675)
sage: a.is_zero()
False
sage: a.is_zero(7)
True
sage: a.is_zero(21)
False
```

lift_to_precision()

Returns `self`.

EXAMPLES:

```
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: w.lift_to_precision(10000)
w + O(w^25)
```

list()

Returns a list giving a series representation of `self`.

- If `lift_mode == 'simple' or 'smallest'`, the returned list will consist of
  - integers (in the eisenstein case) or
  - lists of integers (in the unramified case).
- `self` can be reconstructed as
  - a sum of elements of the list times powers of the uniformiser (in the eisenstein case), or
  - as a sum of powers of the p times polynomials in the generator (in the unramified case).
- If `lift_mode == 'simple'`, all integers will be in the range $[0, p-1]$,
- If `lift_mode == 'smallest'` they will be in the range $[(1-p)/2, p/2]$.
- If `lift_mode == 'teichmuller'`, returns a list of `pAdicZZpXCRElements`, all of which are Teichmuller representatives and such that `self` is the sum of that list times powers of the uniformizer.

EXAMPLES:

```
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: y = W(775); y
w^10 + 4*w^12 + 2*w^14 + w^15 + 2*w^16 + 4*w^17 + w^18 + w^20 + 2*w^21 + 3*w^22 + w^23 + w^2
sage: (y>>9).list()
[0, 1, 0, 4, 0, 2, 1, 2, 4, 1, 0, 1, 2, 3, 1, 1, 4, 1, 2, 4, 1, 0, 4, 3]
sage: (y>>9).list('smallest')
[0, 1, 0, -1, 0, 2, 1, 2, 0, 1, 2, 1, 1, -1, -1, 2, -2, 0, -2, -2, -2, 0, 2, -2, 2]
sage: w^10 - w^12 + 2*w^14 + w^15 + 2*w^16 + w^18 + 2*w^19 + w^20 + w^21 - w^22 - w^23 + 2*w
w^10 + 4*w^12 + 2*w^14 + w^15 + 2*w^16 + 4*w^17 + w^18 + w^20 + 2*w^21 + 3*w^22 + w^23 + w^2
sage: g = x^3 + 3*x + 3
sage: A.<a> = R.ext(g)
sage: y = 75 + 45*a + 1200*a^2; y
4*a*5 + (3*a^2 + a + 3)*5^2 + 4*a^2*5^3 + a^2*5^4 + O(5^5)
sage: y.list()
[[], [0, 4], [3, 1, 3], [0, 0, 4], [0, 0, 1]]
sage: y.list('smallest')
[[], [0, -1], [-2, 2, -2], [1], [0, 0, 2]]
```

```
sage: 5*((-2*5 + 25) + (-1 + 2*5)*a + (-2*5 + 2*125)*a^2)
4*a*5 + (3*a^2 + a + 3)*5^2 + 4*a^2*5^3 + a^2*5^4 + O(5^5)
sage: W(0).list()
[0]
sage: A(0,4).list()
[[]]
```

log()

Compute the p-adic logarithm of any unit.

See below for normalization.

INPUT:

- branch – pAdicZZpXFMElement (default None). The log of the uniformizer. If None, then an error is raised if self is not a unit.
- same_ring – bool or pAdicGeneric (default True). When $e > p$ it is possible (even common) that the image of the log map is not contained in the ring of integers. If same_ring is True, then this function will return a value in self.parent() or raise an error if the answer would have negative valuation. If same_ring is False, then this function will raise an error (this behavior is for consistency with other p-adic types). If same_ring is a p-adic field into which this fixed mod ring can be successfully cast, then self is cast into that field and the log is taken there. Note that this casting will assume that self has the full precision possible.

OUTPUT:

The p-adic log of self.

Let K be the parent of self, π be a uniformizer of K and w be a generator for the group of roots of unity in K. The usual power series for log with values in the additive group of K only converges for 1-units (units congruent to 1 modulo π). However, there is a unique extension of log to a homomorphism defined on all the units. If $u = a \cdot v$ is a unit with $v = 1 \pmod{p}$, then we define $\log(u) = \log(v)$. This is the correct extension because the units U of K split as a product $U = V \times \langle w \rangle$, where V is the subgroup of 1-units. The $\langle w \rangle$ factor is torsion, so must go to 0 under any homomorphism to the torsion free group $(K, +)$.

NOTES:

What some other systems do with regard to non-1-units:

- PARI: Seems to define log the same way as we do.
- MAGMA: Gives an error when unit is not a 1-unit.

In addition, if branch is specified, then the log map will work on non-units

..math

```
\log(\pi^k \cdot u) = k \cdot branch + \log(u)
```

ALGORITHM:

Input: Some unit u.

1. Check that the input is really a unit (i.e., valuation 0), or that branch is specified.
2. Let $1 - x = u^{q-1}$, which is a 1-unit, where q is the order of the residue field of K.
3. Use the series expansion

..math

```
\log(1-x) = F(x) = -x - 1/2*x^2 - 1/3*x^3 - 1/4*x^4 - 1/5*x^5 - ...
```

to compute the logarithm $log(u^{q-1})$.

Add on terms until x^k is zero modulo the precision cap, and then determine if there are further terms that contribute to the sum (those where k is slightly above the precision cap but divisible by p).

1. Then

..math

```
\log(u) = \log(u^{q-1})/(q-1) = F(1-u^{q-1})/(q-1).
```

EXAMPLES:

First, the Eisenstein case.:

```
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^4 + 15*x^2 + 625*x - 5
sage: W.<w> = R.ext(f)
sage: z = 1 + w^2 + 4*w^7; z
1 + w^2 + 4*w^7 + O(w^20)
sage: z.log()
4*w^2 + 3*w^4 + w^6 + w^7 + w^8 + 4*w^9 + 3*w^10 + w^12 + w^13 + 3*w^14 + w^15 + 4*w^16 + 4*
```

Check that log is multiplicative:

```
sage: y = 1 + 3*w^4 + w^5
sage: y.log() + z.log() - (y*z).log()
O(w^20)
```

Now an unramified example.:

```
sage: g = x^3 + 3*x + 3
sage: A.<a> = R.ext(g)
sage: b = 1 + 5*(1 + a^2) + 5^3*(3 + 2*a)
sage: b.log()
(4*a^2 + 4)*5 + (a^2 + a + 2)*5^2 + (a^2 + 2*a + 4)*5^3 + (a^2 + 2*a + 2)*5^4 + O(5^5)
```

Check that log is multiplicative:

```
sage: c = 3 + 5^2*(2 + 4*a)
sage: b.log() + c.log() - (b*c).log()
O(5^5)
```

AUTHORS:

- David Roe: initial version

TODO:

- Currently implemented as $O(N^2)$. This can be improved to soft-$O(N)$ using algorithm described by Dan Bernstein: http://cr.yp.to/lineartime/multapps-20041007.pdf

matrix_mod_pn()

Returns the matrix of right multiplication by the element on the power basis $1, x, x^2, \ldots, x^{d-1}$ for this extension field. Thus the emph{rows} of this matrix give the images of each of the x^i. The entries of the matrices are `IntegerMod` elements, defined modulo `p^(self.absprec() / e)`.

Raises an error if self has negative valuation.

EXAMPLES:

```
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = (3+w)^7
sage: a.matrix_mod_pn()
[2757  333 1068  725 2510]
[  50 1507  483  318  725]
[ 500   50 3007 2358  318]
[1590 1375 1695 1032 2358]
[2415  590 2370 2970 1032]
```

norm()

Return the absolute or relative norm of this element.

NOTE! This is not the p-adic absolute value. This is a field theoretic norm down to a ground ring.

If you want the p-adic absolute value, use the `abs()` function instead.

If K is given then K must be a subfield of the parent L of `self`, in which case the norm is the relative norm from L to K. In all other cases, the norm is the absolute norm down to $\mathbb{Q}_p$ or $\mathbb{Z}_p$.

EXAMPLES:

```
sage: R = ZpCR(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: ((1+2*w)^5).norm()
1 + 5^2 + O(5^5)
sage: ((1+2*w)).norm()^5
1 + 5^2 + O(5^5)
```

precision_absolute()

Returns the absolute precision of `self`, ie the precision cap of `self.parent()`.

EXAMPLES:

```
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(75); a
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + 3*w^19 + 2*w^21 + 3*w^22 + 3*w^23 + O(w^25)
sage: a.valuation()
10
sage: a.precision_absolute()
25
sage: a.precision_relative()
15
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + 3*w^9 + 2*w^11 + 3*w^12 + 3*w^13 + w^15 + 4*w^16 + 2*w
```

precision_relative()

Returns the relative precision of `self`, ie the precision cap of `self.parent()` minus the `valuation of self`.

EXAMPLES:

```
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(75); a
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + 3*w^19 + 2*w^21 + 3*w^22 + 3*w^23 + O(w^25)
sage: a.valuation()
10
sage: a.precision_absolute()
25
sage: a.precision_relative()
15
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + 3*w^9 + 2*w^11 + 3*w^12 + 3*w^13 + w^15 + 4*w^16 + 2*w
```

trace()

Return the absolute or relative trace of this element.

If K is given then K must be a subfield of the parent L of `self`, in which case the norm is the relative norm from L to K. In all other cases, the norm is the absolute norm down to $\mathbb{Q}_p$ or $\mathbb{Z}_p$.

EXAMPLES:

```
sage: R = ZpCR(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = (2+3*w)^7
sage: b = (6+w^3)^5
sage: a.trace()
3*5 + 2*5^2 + 3*5^3 + 2*5^4 + O(5^5)
sage: a.trace() + b.trace()
4*5 + 5^2 + 5^3 + 2*5^4 + O(5^5)
sage: (a+b).trace()
4*5 + 5^2 + 5^3 + 2*5^4 + O(5^5)
```

unit_part()

Returns the unit part of `self`, ie `self / uniformizer^(self.valuation())`

EXAMPLES:

```
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(75); a
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + 3*w^19 + 2*w^21 + 3*w^22 + 3*w^23 + O(w^25)
sage: a.valuation()
10
sage: a.precision_absolute()
25
sage: a.precision_relative()
15
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + 3*w^9 + 2*w^11 + 3*w^12 + 3*w^13 + w^15 + 4*w^16 + 2*w
```

27.23 PowComputer.

A class for computing and caching powers of the same integer.

This class is designed to be used as a field of p-adic rings and fields. Since elements of p-adic rings and fields need to use powers of p over and over, this class precomputes and stores powers of p. There is no reason that the base has to be prime however.

EXAMPLES:

```
sage: X = PowComputer(3, 4, 10)
sage: X(3)
27
sage: X(10) == 3^10
True
```

AUTHORS:

- David Roe

PowComputer()

Returns a PowComputer that caches the values $1, m, m^2, ldots, m^cache_limit$.

Once you create a PowComputer, merely call it to get values out.

You can input any integer, even if it's outside of the precomputed range.

INPUT:

```
* m -- An integer, the base that you want to exponentiate.
* cache_limit -- A positive integer that you want to cache powers up to.
```

EXAMPLES:

```
sage: PC = PowComputer(3, 5, 10)
sage: PC
PowComputer for 3
sage: PC(4)
81
sage: PC(6)
729
sage: PC(-1)
1/3
```

class **PowComputer_base**()

class **PowComputer_class**()

pow_Integer_Integer()

Tests the pow_Integer function.

EXAMPLES:

```
sage: PC = PowComputer(3, 5, 10)
sage: PC.pow_Integer_Integer(4)
81
sage: PC.pow_Integer_Integer(6)
729
sage: PC.pow_Integer_Integer(0)
1
sage: PC.pow_Integer_Integer(10)
59049
sage: PC = PowComputer_ext_maker(3, 5, 10, 20, False, ntl.ZZ_pX([-3,0,1], 3^10), 'big','e',r
sage: PC.pow_Integer_Integer(4)
81
sage: PC.pow_Integer_Integer(6)
729
sage: PC.pow_Integer_Integer(0)
1
sage: PC.pow_Integer_Integer(10)
59049
```

clear_mpz_globals()

gmp_randrange()

init_mpz_globals()

27.24 PowComputer_ext.

The classes in this file are designed to be attached to p-adic parents and elements for cython access to properties of the parent.

In addition to storing the defining polynomial (as an NTL polynomial) at different precisions, they also cache powers of p and data to speed right shifting of elements.

The heirarchy of PowComputers splits first at whether it's for a base ring (Qp or Zp) or an extension.

Among the extension classes (those in this file), they are first split by the type of NTL polynomial (ntl_ZZ_pX or ntl_ZZ_pEX), then by the amount and style of caching (see below). Finally, there are subclasses of the ntl_ZZ_pX PowComputers that cache additional information for Eisenstein extensions.

There are three styles of caching:

- FM: caches powers of p up to the cache_limit, only caches the polynomial modulus and the ntl_ZZ_pContext of precision prec_cap.
- small: Requires cache_limit = prec_cap. Caches p^k for every k up to the cache_limit and caches a polynomial modulus and a ntl_ZZ_pContext for each such power of p.
- big: Caches as the small does up to cache_limit and caches prec_cap. Also has a dictionary that caches values above the cache_limit when they are computed (rather than at ring creation time).

AUTHORS:

- David Roe (2008-01-01) initial version

class PowComputer_ZZ_pX()

polynomial()

Returns the polynomial (with coefficient precision prec_cap) associated to this PowComputer.

The polynomial is output as an ntl_ZZ_pX.

EXAMPLES:

```
sage: PC = PowComputer_ext_maker(5, 5, 10, 20, False, ntl.ZZ_pX([-5,0,1],5^10), 'FM', 'e',nt
sage: PC.polynomial()
[9765620 0 1]
```

speed_test()

Runs a speed test.

INPUT:

```
n -- input to a function to be tested (the function needs to be set in the source code).
runs -- The number of runs of that function
```

OUTPUT:

```
The time in seconds that it takes to call the function on n, runs times.

sage: PC = PowComputer_ext_maker(5, 10, 10, 20, False, ntl.ZZ_pX([-5, 0, 1], 5^10), 'small',
sage: PC.speed_test(10, 10^6) # random
0.0090679999999991878
```

class PowComputer_ZZ_pX_FM()

This class only caches a context and modulus for p^prec_cap.

Designed for use with fixed modulus p-adic rings, in Eisenstein and unramified extensions of $mathbb{Z}_p$.

class PowComputer_ZZ_pX_FM_Eis()

This class computes and stores low_shifter and high_shifter, which aid in right shifting elements.

class PowComputer_ZZ_pX_big()

This class caches all contexts and moduli between 1 and cache_limit, and also caches for prec_cap. In addition, it stores a dictionary of contexts and moduli of

reset_dictionaries()

Resets the dictionaries. Note that if there are elements lying around that need access to these dictionaries, calling this function and then doing arithmetic with those elements could cause trouble (if the context object gets garbage collected for example. The bugs introduced could be very subtle, because NTL will generate a new context object and use it, but there's the potential for the object to be incompatible with the different context object).

EXAMPLES:

```
sage: A = PowComputer_ext_maker(5, 6, 10, 20, False, ntl.ZZ_pX([-5,0,1],5^10), 'big','e',ntl
sage: P = A._get_context_test(8)
sage: A._context_dict()
{8: NTL modulus 390625}
sage: A.reset_dictionaries()
sage: A._context_dict()
{}
```

class PowComputer_ZZ_pX_big_Eis()

This class computes and stores low_shifter and high_shifter, which aid in right shifting elements. These are only stored at maximal precision: in order to get lower precision versions just reduce mod p^n.

class PowComputer_ZZ_pX_small()

This class caches contexts and moduli densely between 1 and cache_limit. It requires cache_limit == prec_cap.

It is intended for use with capped relative and capped absolute rings and fields, in Eisenstein and unramified extensions of the base p-adic fields.

class PowComputer_ZZ_pX_small_Eis()

This class computes and stores low_shifter and high_shifter, which aid in right shifting elements. These are only stored at maximal precision: in order to get lower precision versions just reduce mod p^n.

class PowComputer_ext()

PowComputer_ext_maker()

Returns a PowComputer that caches the values $1, prime, prime^2, ldots, prime^cache_limit$.

Once you create a PowComputer, merely call it to get values out. You can input any integer, even if it's outside of the precomputed range.

INPUT:

```
- prime -- An integer, the base that you want to exponentiate.

- cache_limit -- A positive integer that you want to cache
  powers up to.

- prec_cap -- The cap on precisions of elements.  For ramified
  extensions, p^((prec_cap - 1) // e) will be the largest
  power of p distinguishable from zero

- in_field -- Boolean indicating whether this PowComputer is
  attached to a field or not.

- poly -- An ntl_ZZ_pX or ntl_ZZ_pEX defining the extension.
  It should be defined modulo p^((prec_cap - 1) // e + 1)

- prec_type -- 'FM', 'small', or 'big', defining how caching
  is done.
```

```
- ext_type -- 'u' = unramified, 'e' = eisenstein, 't' =
  two-step

- shift_seed -- (required only for eisenstein and two-step)
  For eisenstein and two-step extensions, if f = a_n x^n - p
  a_{n-1} x^{n-1} - ... - p a_0 with a_n a unit, then
  shift_seed should be 1/a_n (a_{n-1} x^{n-1} + ... + a_0)
```

EXAMPLES:

```
sage: PC = PowComputer_ext_maker(5, 10, 10, 20, False, ntl.ZZ_pX([-5, 0, 1], 5^10), 'small','e',
sage: PC
PowComputer_ext for 5, with polynomial [9765620 0 1]
```

ZZ_pX_eis_shift_test()

Shifts _a right _n x-adic digits, where x is considered modulo the polynomial in _shifter.

EXAMPLES:

```
sage: from sage.rings.padics.pow_computer_ext import ZZ_pX_eis_shift_test
sage: A = PowComputer_ext_maker(5, 3, 10, 40, False, ntl.ZZ_pX([-5,75,15,0,1],5^10), 'big', 'e',
sage: ZZ_pX_eis_shift_test(A, [0, 1], 1, 5)
[1]
sage: ZZ_pX_eis_shift_test(A, [0, 0, 1], 1, 5)
[0 1]
sage: ZZ_pX_eis_shift_test(A, [5], 1, 5)
[75 15 0 1]
sage: ZZ_pX_eis_shift_test(A, [1], 1, 5)
[]
sage: ZZ_pX_eis_shift_test(A, [17, 91, 8, -2], 1, 5)
[316 53 3123 3]
sage: ZZ_pX_eis_shift_test(A, [316, 53, 3123, 3], -1, 5)
[15 91 8 3123]
sage: ZZ_pX_eis_shift_test(A, [15, 91, 8, 3123], 1, 5)
[316 53 3123 3]
```

clear_mpz_globals()

gmp_randrange()

init_mpz_globals()

27.25 p-Adic Printing.

This file contains code for printing p-adic elements.

It has been moved here to prevent code duplication and make finding the relevant code easier.

AUTHORS:

- David Roe

clear_mpz_globals()

gmp_randrange()

init_mpz_globals()

pAdicPrinter()
Creates a pAdicPrinter.

INPUT:

```
- ring -- a p-adic ring or field.

- options -- a dictionary, with keys in 'mode', 'pos',
  'ram_name', 'unram_name', 'var_name', 'max_ram_terms',
  'max_unram_terms', 'max_terse_terms', 'sep', 'alphabet'; see
  pAdicPrinter_class for the meanings of these keywords.
```

EXAMPLES:

```
sage: from sage.rings.padics.padic_printing import pAdicPrinter
sage: R = Zp(5)
sage: pAdicPrinter(R, {'sep': '&'})
series printer for 5-adic Ring with capped relative precision 20
```

class **pAdicPrinterDefaults**()
This class stores global defaults for p-adic printing.

allow_negatives()
Controls whether or not to display a balanced representation.

neg=None returns the current value.

EXAMPLES:

```
sage: padic_printing.allow_negatives(True)
sage: padic_printing.allow_negatives()
True
sage: Qp(29)(-1)
-1 + O(29^20)
sage: Qp(29)(-1000)
-14 - 5*29 - 29^2 + O(29^20)
sage: padic_printing.allow_negatives(False)
```

alphabet()
Controls the alphbet used to translate p-adic digits into strings (so that no separator need be used in 'digits' mode).

alphabet should be passed in as a list or tuple.

alphabet=None returns the current value.

EXAMPLES:

```
sage: padic_printing.alphabet("abc")
sage: padic_printing.mode('digits')
sage: repr(Qp(3)(1234))
'...bcaacab'

sage: padic_printing.mode('series')
sage: padic_printing.alphabet(('0','1','2','3','4','5','6','7','8','9','A','B','C','D','E','
```

max_poly_terms()
Controls the number of terms appearing when printing polynomial representations in 'terse' or 'val-unit' modes.

max=None returns the current value.

max=-1 encodes 'no limit.'

EXAMPLES:

```
sage: padic_printing.max_poly_terms(3)
sage: padic_printing.max_poly_terms()
3
sage: padic_printing.mode('terse')
sage: Zq(7^5, 5, names='a')([2,3,4])^8
2570 + 15808*a + 9018*a^2 + ... + O(7^5)

sage: padic_printing.max_poly_terms(-1)
sage: padic_printing.mode('series')
```

max_series_terms()

Controls the maximum number of terms shown when printing in 'series', 'digits' or 'bars' mode.

max=None returns the current value.

max=-1 encodes 'no limit.'

EXAMPLES:

```
sage: padic_printing.max_series_terms(2)
sage: padic_printing.max_series_terms()
2
sage: Qp(31)(1000)
8 + 31 + ... + O(31^20)
sage: padic_printing.max_series_terms(-1)
sage: Qp(37)(100000)
26 + 37 + 36*37^2 + 37^3 + O(37^20)
```

max_unram_terms()

For rings with non-prime residue fields, controls how many terms appear in the coefficient of each pi^n when printing in 'series' or 'bar' modes.

max=None returns the current value.

max=-1 encodes 'no limit.'

EXAMPLES:

```
sage: padic_printing.max_unram_terms(2)
sage: padic_printing.max_unram_terms()
2
sage: Zq(5^6, 5, names='a')([1,2,3,-1])^17
(3*a^4 + ... + 3) + (a^5 + ... + a)*5 + (3*a^3 + ... + 2)*5^2 + (3*a^5 + ... + 2)*5^3 + (4*a

sage: padic_printing.max_unram_terms(-1)
```

mode()

Set the default printing mode.

mode=None returns the current value.

The allowed values for mode are: 'val-unit', 'series', 'terse', 'digits' and 'bars'.

EXAMPLES:

```
sage: padic_printing.mode('terse')
sage: padic_printing.mode()
'terse'
sage: Qp(7)(100)
100 + O(7^20)
sage: padic_printing.mode('series')
sage: Qp(11)(100)
1 + 9*11 + O(11^20)
sage: padic_printing.mode('val-unit')
sage: Qp(13)(130)
13 * 10 + O(13^21)
```

```
sage: padic_printing.mode('digits')
sage: repr(Qp(17)(100))
'...5F'
sage: repr(Qp(17)(1000))
'...37E'
sage: padic_printing.mode('bars')
sage: repr(Qp(19)(1000))
'...2|14|12'

sage: padic_printing.mode('series')
```

sep()

Controls the separator used in 'bars' mode.

sep=None returns the current value.

EXAMPLES:

```
sage: padic_printing.sep('][')
sage: padic_printing.sep()
']['
sage: padic_printing.mode('bars')
sage: repr(Qp(61)(-1))
'...60][60][60][60][60][60][60][60][60][60][60][60][60][60][60][60][60][60][60][60'

sage: padic_printing.sep('|')
sage: padic_printing.mode('series')
```

class **pAdicPrinter_class**()

This class stores the printing options for a specific p-adic ring or field, and uses these to compute the representations of elements.

cmp_modes()

Returns a comparison of the printing modes of self and other.

Returns 0 if and only if all relevant modes are equal (max_unram_terms is irrelevant if the ring is totally ramified over the base for example). Does not check if the rings are equal (to prevent infinite recursion in the comparison functions of p-adic rings), but it does check if the primes are the same (since the prime affects whether pos is relevant).

EXAMPLES:

```
sage: R = Qp(7, print_mode='digits', print_pos=True)
sage: S = Qp(7, print_mode='digits', print_pos=False)
sage: R._printer.cmp_modes(S._printer)
0
sage: R = Qp(7)
sage: S = Qp(7,print_mode='val-unit')
sage: R == S
False
sage: R._printer.cmp_modes(S._printer)
-1
```

dict()

Returns a dictionary storing all of self's printing options.

EXAMPLES:

```
sage: D = Zp(5)._printer.dict(); D['sep']
'|'
```

repr_gen()

The entry point for printing an element.

INPUT:

- elt -- a p-adic element of the appropriate ring to print.

- do_latex -- whether to return a latex representation or a normal one.

EXAMPLES:

```
sage: R = Zp(5,5); P = R._printer; a = R(-5); a
4*5 + 4*5^2 + 4*5^3 + 4*5^4 + 4*5^5 + O(5^6)
sage: P.repr_gen(a, False, pos=False)
'-5 + O(5^6)'
sage: P.repr_gen(a, False, ram_name='p')
'4*p + 4*p^2 + 4*p^3 + 4*p^4 + 4*p^5 + O(p^6)'
```

27.26 Precision Error.

The errors in this file indicate various styles of precision problems that can go wrong for p-adics and power series.

AUTHORS:

- David Roe

exception HaltingError

exception PrecisionError

exception PrecisionLimitError

27.27 Miscellaneous Functions.

This file contains some miscellaneous functions used by p-adics.

- min – a version of min that returns ∞ on empty input.
- max – a version of max that returns $-\infty$ on empty input.

AUTHORS:

- David Roe

max(*L)

Returns the maximum of the inputs, where the maximum of the empty list is -infinity.

EXAMPLES:

```
sage: from sage.rings.padics.misc import max
sage: max()
-Infinity
sage: max(2,3)
3
```

min(*L)

Returns the minimum of the inputs, where the minimum of the empty list is infinity.

EXAMPLES:

```
sage: from sage.rings.padics.misc import min
sage: min()
+Infinity
sage: min(2,3)
2
```

CHAPTER

TWENTYEIGHT

POLYNOMIAL RINGS

28.1 Univariate Polynomial Rings

Sage implements sparse and dense polynomials over commutative and non-commutative rings. In the non-commutative case, the polynomial variable commutes with the elements of the base ring.

AUTHOR:

- William Stein
- Kiran Kedlaya (2006-02-13): added macaulay2 option
- Martin Albrecht (2006-08-25): removed it again as it isn't needed anymore

EXAMPLES: Creating a polynomial ring injects the variable into the interpreter namespace:

```
sage: z = QQ['z'].0
sage: (z^3 + z - 1)^3
z^9 + 3*z^7 - 3*z^6 + 3*z^5 - 6*z^4 + 4*z^3 - 3*z^2 + 3*z - 1
```

Saving and loading of polynomial rings works:

```
sage: loads(dumps(QQ['x'])) == QQ['x']
True
sage: k = PolynomialRing(QQ['x'],'y'); loads(dumps(k))==k
True
sage: k = PolynomialRing(ZZ,'y'); loads(dumps(k)) == k
True
sage: k = PolynomialRing(ZZ,'y', sparse=True); loads(dumps(k))
Sparse Univariate Polynomial Ring in y over Integer Ring
```

The rings of sparse and dense polynomials in the same variable are canonically isomorphic:

```
sage: PolynomialRing(ZZ,'y', sparse=True) == PolynomialRing(ZZ,'y')
True

sage: QQ['y'] < QQ['x']
False
sage: QQ['y'] < QQ['z']
True
```

We create a polynomial ring over a quaternion algebra:

```
sage: A.<i,j,k> = QuaternionAlgebra(QQ, -1,-1)
sage: R.<w> = PolynomialRing(A,sparse=True)
sage: f = w^3 + (i+j)*w + 1
sage: f
w^3 + (i + j)*w + 1
sage: f^2
w^6 + (2*i + 2*j)*w^4 + 2*w^3 - 2*w^2 + (2*i + 2*j)*w + 1
sage: f = w + i ; g = w + j
sage: f * g
w^2 + (i + j)*w + k
sage: g * f
w^2 + (i + j)*w - k
```

TESTS:

```
sage: K.<x>=FractionField(QQ['x'])
sage: V.<z> = K[]
sage: x+z
z + x
```

These may change over time:

```
sage: type(ZZ['x'].0)
<type 'sage.rings.polynomial.polynomial_integer_dense_flint.Polynomial_integer_dense_flint'>
sage: type(QQ['x'].0)
<class 'sage.rings.polynomial.polynomial_element_generic.Polynomial_rational_dense'>
sage: type(RR['x'].0)
<type 'sage.rings.polynomial.polynomial_real_mpfr_dense.PolynomialRealDense'>
sage: type(Integers(4)['x'].0)
<type 'sage.rings.polynomial.polynomial_zmod_flint.Polynomial_zmod_flint'>
sage: type(Integers(5*2^100)['x'].0)
<type 'sage.rings.polynomial.polynomial_modn_dense_ntl.Polynomial_dense_modn_ntl_ZZ'>
sage: type(CC['x'].0)
<class 'sage.rings.polynomial.polynomial_element_generic.Polynomial_generic_dense_field'>
sage: type(CC['t']['x'].0)
<type 'sage.rings.polynomial.polynomial_element.Polynomial_generic_dense'>
```

class **PolynomialRing_commutative** (*base_ring, name=None, sparse=False, element_class=None*)

Univariate polynomial ring over a commutative ring.

quotient_by_principal_ideal (*f, names=None*)

Return the quotient of this polynomial ring by the principal ideal generated by f.

EXAMPLES:

class **PolynomialRing_dense_mod_n** (*base_ring, name=None, element_class=None, implementation=None*)

modulus ()

EXAMPLES:

```
sage: R.<x> = Zmod(15)[]
sage: R.modulus()
15
```

class **PolynomialRing_dense_mod_p** (*base_ring, name='x', implementation=None*)

class **PolynomialRing_dense_padic_field_capped_relative** (*base_ring, name=None, element_class=None*)

class PolynomialRing_dense_padic_field_generic(*base_ring, name='x', sparse=False, element_class=None*)

class PolynomialRing_dense_padic_field_lazy(*base_ring, name=None, element_class=None*)

class PolynomialRing_dense_padic_ring_capped_absolute(*base_ring, name=None, element_class=None*)

class PolynomialRing_dense_padic_ring_capped_relative(*base_ring, name=None, element_class=None*)

class PolynomialRing_dense_padic_ring_fixed_mod(*base_ring, name=None, element_class=None*)

class PolynomialRing_dense_padic_ring_generic(*base_ring, name='x', sparse=False, implementation=None, element_class=None*)

class PolynomialRing_dense_padic_ring_lazy(*base_ring, name=None, element_class=None*)

class PolynomialRing_field(*base_ring, name='x', sparse=False, element_class=None*)

divided_difference(*points, full_table=False*)

Return the Newton divided-difference coefficients of the n-th Lagrange interpolation polynomial of `points`.

If `points` are $n+1$ distinct points $(x_0, f(x_0)), (x_1, f(x_1)), \ldots, (x_n, f(x_n))$, then $P_n(x)$ is the n-th Lagrange interpolation polynomial of $f(x)$ that passes through the points $(x_i, f(x_i))$. This method returns the coefficients $F_{i,i}$ such that

$$P_n(x) = \sum_{i=0}^{n} F_{i,i} \prod_{j=0}^{i-1} (x - x_j)$$

INPUT:

- `points` – a list of tuples $(x_0, f(x_0)), (x_1, f(x_1)), \ldots, (x_n, f(x_n))$ where each $x_i \neq x_j$ for $i \neq j$
- `full_table` – (default: `False`) if `True` then return the full divided-difference table; if `False` then only return entries along the main diagonal. The entries along the main diagonal are the Newton divided-difference coefficients $F_{i,i}$.

OUTPUT:

- The Newton divided-difference coefficients of the n-th Lagrange interpolation polynomial that passes through the points in `points`.

EXAMPLES:

Only return the divided-difference coefficients $F_{i,i}$. This example is taken from Example 1, p.121 of [BF05]:

```
sage: points = [(1.0, 0.7651977), (1.3, 0.6200860), (1.6, 0.4554022), (1.9, 0.2818186), (2.2
sage: R = PolynomialRing(QQ, "x")
sage: R.divided_difference(points)
<BLANKLINE>
[0.765197700000000,
-0.483705666666666,
-0.108733888888889,
0.0658783950617283,
0.00182510288066044]
```

Now return the full divided-difference table:

```
sage: points = [(1.0, 0.7651977), (1.3, 0.6200860), (1.6, 0.4554022), (1.9, 0.2818186), (2.2
sage: R = PolynomialRing(QQ, "x")
sage: R.divided_difference(points, full_table=True)
<BLANKLINE>
[[0.765197700000000],
```

```
[0.620086000000000, -0.483705666666666],
[0.455402200000000, -0.548946000000000, -0.108733888888889],
[0.281818600000000,
-0.578612000000000,
-0.0494433333333339,
0.0658783950617283],
[0.110362300000000,

0.0680685185185209,
0.00182510288066044]]
```

The following example is taken from Example 4.12, p.225 of [MF99]:

```
sage: points = [(1, -3), (2, 0), (3, 15), (4, 48), (5, 105), (6, 192)]
sage: R = PolynomialRing(RR, "x")
sage: R.divided_difference(points)
[-3, 3, 6, 1, 0, 0]
sage: R.divided_difference(points, full_table=True)
<BLANKLINE>
[[-3],
[0, 3],
[15, 15, 6],
[48, 33, 9, 1],
[105, 57, 12, 1, 0],
[192, 87, 15, 1, 0, 0]]
```

REFERENCES:

lagrange_polynomial(*points, algorithm='divided_difference', previous_row=None*)

Return the Lagrange interpolation polynomial in self associated to the given list of points.

Given a list of points, i.e. tuples of elements of self's base ring, this function returns the interpolation polynomial in the Lagrange form.

INPUT:

- `points` – a list of tuples representing points through which the polynomial returned by this function must pass.
- `algorithm` – (default: `'divided_difference'`) the available values for this option are `'divided_difference'` and `neville`.
  - If `algorithm='divided_difference'` then use the method of divided difference.
  - If `algorithm='neville'` then adapt Neville's method as described on page 144 of [BF05] to recursively generate the Lagrange interpolation polynomilal. Neville's method generates a table of approximating polynomials, where the last row of that table contains the n-th Lagrange interpolation polynomial. The adaptation implemented by this method is to only generate the last row of this table, instead of the full table itself. Generating the full table can be memory inefficient.
- `previous_row` – (default: `None`) This option is only relevant if used together with `algorithm='neville'`. If provided, this should be the last row of the table resulting from a previous use of Neville's method. If such a row is passed in, then `points` should consist of both previous and new interpolating points. Neville's method will then use that last row and the interpolating points to generate a new row which contains a better Lagrange interpolation polynomial.

EXAMPLE:

By default, we use the method of divided-difference:

```
sage: R = PolynomialRing(QQ, 'x')
sage: f = R.lagrange_polynomial([(0,1),(2,2),(3,-2),(-4,9)]); f
-23/84*x^3 - 11/84*x^2 + 13/7*x + 1
```

```
sage: f(0)
1
sage: f(2)
2
sage: f(3)
-2
sage: f(-4)
9
sage: R = PolynomialRing(GF(2**3,'a'), 'x')
sage: a = R.base_ring().gen()
sage: f = R.lagrange_polynomial([(a^2+a,a),(a,1),(a^2,a^2+a+1)]); f
a^2*x^2 + a^2*x + a^2
sage: f(a^2+a)
a
sage: f(a)
1
sage: f(a^2)
a^2 + a + 1
```

Now use a memory efficient version of Neville's method:

```
sage: R = PolynomialRing(QQ, 'x')
sage: R.lagrange_polynomial([(0,1),(2,2),(3,-2),(-4,9)], algorithm="neville")
<BLANKLINE>
[9,
-11/7*x + 19/7,
-17/42*x^2 - 83/42*x + 53/7,
-23/84*x^3 - 11/84*x^2 + 13/7*x + 1]
sage: R = PolynomialRing(GF(2**3,'a'), 'x')
sage: a = R.base_ring().gen()
sage: R.lagrange_polynomial([(a^2+a,a),(a,1),(a^2,a^2+a+1)], algorithm="neville")
[a^2 + a + 1, x + a + 1, a^2*x^2 + a^2*x + a^2]
```

Repeated use of Neville's method to get better Lagrange interpolation polynomials:

```
sage: R = PolynomialRing(QQ, 'x')
sage: p = R.lagrange_polynomial([(0,1),(2,2)], algorithm="neville")
sage: R.lagrange_polynomial([(0,1),(2,2),(3,-2),(-4,9)], algorithm="neville", previous_row=p
-23/84*x^3 - 11/84*x^2 + 13/7*x + 1
sage: R = PolynomialRing(GF(2**3,'a'), 'x')
sage: a = R.base_ring().gen()
sage: p = R.lagrange_polynomial([(a^2+a,a),(a,1)], algorithm="neville")
sage: R.lagrange_polynomial([(a^2+a,a),(a,1),(a^2,a^2+a+1)], algorithm="neville", previous_r
a^2*x^2 + a^2*x + a^2
```

TESTS:

The value for `algorithm` must be either `'divided_difference'` (by default it is), or `'neville'`:

```
sage: R = PolynomialRing(QQ, "x")
sage: R.lagrange_polynomial([(0,1),(2,2),(3,-2),(-4,9)], algorithm="abc")
...
ValueError: algorithm must be one of 'divided_difference' or 'neville'
sage: R.lagrange_polynomial([(0,1),(2,2),(3,-2),(-4,9)], algorithm="divided difference")
...
ValueError: algorithm must be one of 'divided_difference' or 'neville'
sage: R.lagrange_polynomial([(0,1),(2,2),(3,-2),(-4,9)], algorithm="")
...
ValueError: algorithm must be one of 'divided_difference' or 'neville'
```

REFERENCES:

class **PolynomialRing_general**(*base_ring, name=None, sparse=False, element_class=None*)

Univariate polynomial ring over a ring.

base_extend(*R*)

Return the base extension of this polynomial ring to R.

EXAMPLES:

```
sage: R.<x> = RR[]; R
Univariate Polynomial Ring in x over Real Field with 53 bits of precision
sage: R.base_extend(CC)
Univariate Polynomial Ring in x over Complex Field with 53 bits of precision
sage: R.base_extend(QQ)
...
TypeError: no such base extension
sage: R.change_ring(QQ)
Univariate Polynomial Ring in x over Rational Field
```

change_ring(*R*)

Return the polynomial ring in the same variable as self over R.

EXAMPLES:

```
sage: R.<ZZZ> = RealIntervalField() []; R
Univariate Polynomial Ring in ZZZ over Real Interval Field with 53 bits of precision
sage: R.change_ring(GF(19^2,'b'))
Univariate Polynomial Ring in ZZZ over Finite Field in b of size 19^2
```

change_var(*var*)

Return the polynomial ring in variable var over the same base ring.

EXAMPLES:

```
sage: R.<x> = ZZ[]; R
Univariate Polynomial Ring in x over Integer Ring
sage: R.change_var('y')
Univariate Polynomial Ring in y over Integer Ring
```

characteristic()

Return the characteristic of this polynomial ring, which is the same as that of its base ring.

EXAMPLES:

```
sage: R.<ZZZ> = RealIntervalField() []; R
Univariate Polynomial Ring in ZZZ over Real Interval Field with 53 bits of precision
sage: R.characteristic()
0
sage: S = R.change_ring(GF(19^2,'b')); S
Univariate Polynomial Ring in ZZZ over Finite Field in b of size 19^2
sage: S.characteristic()
19
```

completion(*p, prec=20, extras=None*)

Return the completion of self with respect to the irreducible polynomial p. Currently only implemented for p=self.gen(), i.e. you can only complete R[x] with respect to x, the result being a ring of power series in x. The prec variable controls the precision used in the power series ring.

EXAMPLES:

```
sage: P.<x>=PolynomialRing(QQ)
sage: P
Univariate Polynomial Ring in x over Rational Field
sage: PP=P.completion(x)
sage: PP
Power Series Ring in x over Rational Field
```

```
sage: f=1-x
sage: PP(f)
1 - x
sage: 1/f
1/(-x + 1)
sage: 1/PP(f)
1 + x + x^2 + x^3 + x^4 + x^5 + x^6 + x^7 + x^8 + x^9 + x^10 + x^11 + x^12 + x^13 + x^14 + x
```

construction()

cyclotomic_polynomial(*n*)

Return the nth cyclotomic polynomial as a polynomial in this polynomial ring.

EXAMPLES:

```
sage: R = ZZ['x']
sage: R.cyclotomic_polynomial(8)
x^4 + 1
sage: R.cyclotomic_polynomial(12)
x^4 - x^2 + 1
sage: S = PolynomialRing(FiniteField(7), 'x')
sage: S.cyclotomic_polynomial(12)
x^4 + 6*x^2 + 1
sage: S.cyclotomic_polynomial(1)
x + 6
```

TESTS:

Make sure it agrees with other systems for the trivial case:

```
sage: ZZ['x'].cyclotomic_polynomial(1)
x - 1
sage: gp('polcyclo(1)')
x - 1
```

extend_variables(*added_names, order='degrevlex'*)

Returns a multivariate polynomial ring with the same base ring but with added_names as additional variables.

EXAMPLES:

```
sage: R.<x> = ZZ[]; R
Univariate Polynomial Ring in x over Integer Ring
sage: R.extend_variables('y, z')
Multivariate Polynomial Ring in x, y, z over Integer Ring
sage: R.extend_variables(('y', 'z'))
Multivariate Polynomial Ring in x, y, z over Integer Ring
```

gen(*n=0*)

Return the indeterminate generator of this polynomial ring.

EXAMPLES:

```
sage: R.<abc> = Integers(8)[]; R
Univariate Polynomial Ring in abc over Ring of integers modulo 8
sage: t = R.gen(); t
abc
sage: t.is_gen()
True
```

An identical generator is always returned.

```
sage: t is R.gen()
True
```

gens_dict()
Returns a dictionary whose keys are the variable names of this ring as strings and whose values are the corresponding generators.

EXAMPLES:

```
sage: R.<x> = RR[]
sage: R.gens_dict()
{'x': 1.00000000000000*x}
```

is_exact()

is_field()
Return False, since polynomial rings are never fields.

EXAMPLES:

```
sage: R.<z> = Integers(2)[]; R
Univariate Polynomial Ring in z over Ring of integers modulo 2 (using NTL)
sage: R.is_field()
False
```

is_finite()
Return False since polynomial rings are not finite (unless the base ring is 0.)

EXAMPLES:

```
sage: R = Integers(1)['x']
sage: R.is_finite()
True
sage: R = GF(7)['x']
sage: R.is_finite()
False
sage: R['x']['y'].is_finite()
False
```

is_integral_domain()
EXAMPLES:

```
sage: ZZ['x'].is_integral_domain()
True
sage: Integers(8)['x'].is_integral_domain()
False
```

is_noetherian()

is_sparse()
Return true if elements of this polynomial ring have a sparse representation.

EXAMPLES:

```
sage: R.<z> = Integers(8)[]; R
Univariate Polynomial Ring in z over Ring of integers modulo 8
sage: R.is_sparse()
False
sage: R.<W> = PolynomialRing(QQ, sparse=True); R
Sparse Univariate Polynomial Ring in W over Rational Field
sage: R.is_sparse()
True
```

krull_dimension()
Return the Krull dimension of this polynomial ring, which is one more than the Krull dimension of the base ring.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: R.krull_dimension()
1
sage: R.<z> = GF(9,'a')[]; R
Univariate Polynomial Ring in z over Finite Field in a of size 3^2
sage: R.krull_dimension()
1
sage: S.<t> = R[]
sage: S.krull_dimension()
2
sage: for n in range(10):
...       S = PolynomialRing(S,'w')
sage: S.krull_dimension()
12
```

monics(*of_degree=None, max_degree=None*)

Return an iterator over the monic polynomials of specified degree.

INPUT: Pass exactly one of:

- `max_degree` - an int; the iterator will generate all monic polynomials which have degree less than or equal to max_degree
- `of_degree` - an int; the iterator will generate all monic polynomials which have degree of_degree

OUTPUT: an iterator

EXAMPLES:

```
sage: P = PolynomialRing(GF(4,'a'),'y')
sage: for p in P.monics( of_degree = 2 ): print p
y^2
y^2 + a
y^2 + a + 1
y^2 + 1
y^2 + a*y
y^2 + a*y + a
y^2 + a*y + a + 1
y^2 + a*y + 1
y^2 + (a + 1)*y
y^2 + (a + 1)*y + a
y^2 + (a + 1)*y + a + 1
y^2 + (a + 1)*y + 1
y^2 + y
y^2 + y + a
y^2 + y + a + 1
y^2 + y + 1
sage: for p in P.monics( max_degree = 1 ): print p
1
y
y + a
y + a + 1
y + 1
sage: for p in P.monics( max_degree = 1, of_degree = 3 ): print p
...
ValueError: you should pass exactly one of of_degree and max_degree
```

AUTHORS:

- Joel B. Mohler

ngens()

Return the number of generators of this polynomial ring, which is 1 since it is a univariate polynomial ring.

EXAMPLES:

```
sage: R.<z> = Integers(8)[]; R
Univariate Polynomial Ring in z over Ring of integers modulo 8
sage: R.ngens()
1
```

parameter()

Return the generator of this polynomial ring.

This is the same as `self.gen()`.

polynomials(*of_degree=None, max_degree=None*)

Return an iterator over the polynomials of specified degree.

INPUT: Pass exactly one of:

- `max_degree` - an int; the iterator will generate all polynomials which have degree less than or equal to max_degree
- `of_degree` - an int; the iterator will generate all polynomials which have degree of_degree

OUTPUT: an iterator

EXAMPLES:

```
sage: P = PolynomialRing(GF(3),'y')
sage: for p in P.polynomials( of_degree = 2 ): print p
y^2
y^2 + 1
y^2 + 2
y^2 + y
y^2 + y + 1
y^2 + y + 2
y^2 + 2*y
y^2 + 2*y + 1
y^2 + 2*y + 2
2*y^2
2*y^2 + 1
2*y^2 + 2
2*y^2 + y
2*y^2 + y + 1
2*y^2 + y + 2
2*y^2 + 2*y
2*y^2 + 2*y + 1
2*y^2 + 2*y + 2
sage: for p in P.polynomials( max_degree = 1 ): print p
0
1
2
y
y + 1
y + 2
2*y
2*y + 1
2*y + 2
sage: for p in P.polynomials( max_degree = 1, of_degree = 3 ): print p
...
ValueError: you should pass exactly one of of_degree and max_degree
```

AUTHORS:

- Joel B. Mohler

random_element(*degree=2, *args, **kwds*)

Return a random polynomial.

INPUT:

- `degree` - an integer
- `*args, **kwds` - passed on to the `random_element` method for the base ring.

OUTPUT:

- `Polynomial` - A polynomial such that the coefficient of x^i, for i up to `degree`, are coercions to the base ring of random integers between -`bound` and `bound`.

EXAMPLES:

```
sage: R.<x> = ZZ[]
sage: R.random_element(10, 5,10)
9*x^10 + 8*x^9 + 6*x^8 + 8*x^7 + 8*x^6 + 9*x^5 + 8*x^4 + 8*x^3 + 6*x^2 + 8*x + 8
sage: R.random_element(6)
x^6 - 3*x^5 - x^4 + x^3 - x^2 + x + 1
sage: R.random_element(6)
-2*x^5 + 2*x^4 - 3*x^3 + 1
sage: R.random_element(6)
x^4 - x^3 + x - 2
```

variable_names_recursive(*depth=+Infinity*)

Returns the list of variable names of this and its base rings, as if it were a single multi-variate polynomial.

EXAMPLES:

```
sage: R = QQ['x']['y']['z']
sage: R.variable_names_recursive()
('x', 'y', 'z')
sage: R.variable_names_recursive(2)
('y', 'z')
```

class **PolynomialRing_integral_domain**(*base_ring, name='x', sparse=False, implementation=None, element_class=None*)

is_PolynomialRing(*x*)

Return True if x is a *univariate* polynomial ring (and not a sparse multivariate polynomial ring in one variable).

EXAMPLES:

```
sage: from sage.rings.polynomial.polynomial_ring import is_PolynomialRing
sage: from sage.rings.polynomial.multi_polynomial_ring import is_MPolynomialRing
sage: is_PolynomialRing(2)
False
```

This polynomial ring is not univariate.

```
sage: is_PolynomialRing(ZZ['x,y,z'])
False
sage: is_MPolynomialRing(ZZ['x,y,z'])
True
```

```
sage: is_PolynomialRing(ZZ['w'])
True
```

Univariate means not only in one variable, but is a specific data type. There is a multivariate (sparse) polynomial ring data type, which supports a single variable as a special case.

```
sage: is_PolynomialRing(PolynomialRing(ZZ,1,'w'))
False
sage: R = PolynomialRing(ZZ,1,'w'); R
Multivariate Polynomial Ring in w over Integer Ring
sage: is_PolynomialRing(R)
```

```
False
sage: type(R)
<type 'sage.rings.polynomial.multi_polynomial_libsingular.MPolynomialRing_libsingular'>
```

polygen(*ring_or_element, name='x'*)

Return a polynomial indeterminate.

INPUT:

- polygen(base_ring, name="x")
- polygen(ring_element, name="x")

If the first input is a ring, return a polynomial generator over that ring. If it is a ring element, return a polynomial generator over the parent of the element.

EXAMPLES:

```
sage: z = polygen(QQ,'z')
sage: z^3 + z +1
z^3 + z + 1
sage: parent(z)
Univariate Polynomial Ring in z over Rational Field
```

Note: If you give a list or comma separated string to polygen, you'll get a tuple of indeterminates, exactly as if you called polygens.

polygens(*base_ring, names='x'*)

Return indeterminates over the given base ring with the given names.

EXAMPLES:

```
sage: x,y,z = polygens(QQ,'x,y,z')
sage: (x+y+z)^2
x^2 + 2*x*y + y^2 + 2*x*z + 2*y*z + z^2
sage: parent(x)
Multivariate Polynomial Ring in x, y, z over Rational Field
sage: t = polygens(QQ,['x','yz','abc'])
sage: t
(x, yz, abc)
```

28.2 Univariate Polynomial Base Class

AUTHORS:

- William Stein: first version
- Martin Albrecht: Added singular coercion.
- Robert Bradshaw: Move Polynomial_generic_dense to Cython

TESTS:

```
sage: R.<x> = ZZ[]
sage: f = x^5 + 2*x^2 + (-1)
sage: f == loads(dumps(f))
True
```

class ConstantPolynomialSection()

This class is used for conversion from a polynomial ring to its base ring.

It calls the constant_coefficient method, which can be optimized for a particular polynomial type.

class Polynomial()

A polynomial.

EXAMPLE:

```
sage: R.<y> = QQ['y']
sage: S.<x> = R['x']
sage: f = x*y; f
y*x
sage: type(f)
<type 'sage.rings.polynomial.polynomial_element.Polynomial_generic_dense'>
sage: p = (y+1)^10; p(1)
1024
```

args()

Returns the generator of this polynomial ring, which is the (only) argument used when calling self.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: x.args()
(x,)
```

A constant polynomial has no variables, but still takes a single argument.

```
sage: R(2).args()
(x,)
```

base_extend()

Return a copy of this polynomial but with coefficients in R, if there is a natural map from coefficient ring of self to R.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: f = x^3 - 17*x + 3
sage: f.base_extend(GF(7))
...
TypeError: no such base extension
sage: f.change_ring(GF(7))
x^3 + 4*x + 3
```

base_ring()

Return the base ring of the parent of self.

EXAMPLES:

```
sage: R.<x> = ZZ[]
sage: x.base_ring()
Integer Ring
sage: (2*x+3).base_ring()
Integer Ring
```

change_ring()

Return a copy of this polynomial but with coefficients in R, if at all possible.

EXAMPLES:

```
sage: K.<z> = CyclotomicField(3)
sage: f = K.defining_polynomial()
```

```
sage: f.change_ring(GF(7))
x^2 + x + 1
```

change_variable_name()

Return a new polynomial over the same base ring but in a different variable.

EXAMPLES:

```
sage: x = polygen(QQ,'x')
sage: f = -2/7*x^3 + (2/3)*x - 19/993; f
-2/7*x^3 + 2/3*x - 19/993
sage: f.change_variable_name('theta')
-2/7*theta^3 + 2/3*theta - 19/993
```

coefficients()

Return the coefficients of the monomials appearing in self.

EXAMPLES:

```
sage: _.<x> = PolynomialRing(ZZ)
sage: f = x^4+2*x^2+1
sage: f.coefficients()
[1, 2, 1]
```

coeffs()

Returns `self.list()`.

(It is potentially slightly faster to use `self.list()` directly.)

EXAMPLES:

```
sage: x = QQ['x'].0
sage: f = 10*x^3 + 5*x + 2/17
sage: f.coeffs()
[2/17, 5, 0, 10]
```

complex_roots()

Return the complex roots of this polynomial, without multiplicities.

Calls self.roots(ring=CC), unless this is a polynomial with floating-point coefficients, in which case it is uses the appropriate precision from the input coefficients.

EXAMPLES:

```
sage: x = polygen(ZZ)
sage: (x^3 - 1).complex_roots()   # note: low order bits slightly different on ppc.
[1.00000000000000, -0.500000000000000 - 0.86602540378443...*I, -0.500000000000000 + 0.866025
```

TESTS:

```
sage: x = polygen(RR)
sage: (x^3 - 1).complex_roots()[0].parent()
Complex Field with 53 bits of precision
sage: x = polygen(RDF)
sage: (x^3 - 1).complex_roots()[0].parent()
Complex Double Field
sage: x = polygen(RealField(200))
sage: (x^3 - 1).complex_roots()[0].parent()
Complex Field with 200 bits of precision
sage: x = polygen(CDF)
sage: (x^3 - 1).complex_roots()[0].parent()
Complex Double Field
sage: x = polygen(ComplexField(200))
sage: (x^3 - 1).complex_roots()[0].parent()
Complex Field with 200 bits of precision
```

constant_coefficient()

Return the constant coefficient of this polynomial.

OUTPUT: element of base ring

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: f = -2*x^3 + 2*x - 1/3
sage: f.constant_coefficient()
-1/3
```

degree()

Return the degree of this polynomial. The zero polynomial has degree -1.

EXAMPLES:

```
sage: x = ZZ['x'].0
sage: f = x^93 + 2*x + 1
sage: f.degree()
93
sage: x = PolynomialRing(QQ, 'x', sparse=True).0
sage: f = x^100000
sage: f.degree()
100000

sage: x = QQ['x'].0
sage: f = 2006*x^2006 - x^2 + 3
sage: f.degree()
2006
sage: f = 0*x
sage: f.degree()
-1
sage: f = x + 33
sage: f.degree()
1
```

AUTHORS:

- Naqi Jaffery (2006-01-24): examples

denominator()

Return the least common multiple of the denominators of the entries of self, when this makes sense, i.e., when the coefficients have a denominator function.

Warning: This is not the denominator of the rational function defined by self, which would always be 1 since self is a polynomial.

EXAMPLES:

First we compute the denominator of a polynomial with integer coefficients, which is of course 1.

```
sage: R.<x> = ZZ[]
sage: f = x^3 + 17*x + 1
sage: f.denominator()
1
```

Next we compute the denominator of a polynomial with rational coefficients.

```
sage: R.<x> = PolynomialRing(QQ)
sage: f = (1/17)*x^19 - (2/3)*x + 1/3; f
1/17*x^19 - 2/3*x + 1/3
sage: f.denominator()
51
```

Finally, we try to compute the denominator of a polynomial with coefficients in the real numbers, which is a ring whose elements do not have a denominator method.

```
sage: R.<x> = RR[]
sage: f = x + RR('0.3'); f
1.00000000000000*x + 0.300000000000000
sage: f.denominator()
...
AttributeError: 'sage.rings.real_mpfr.RealNumber' object has no attribute 'denominator'
```

derivative()

The formal derivative of this polynomial, with respect to variables supplied in args.

Multiple variables and iteration counts may be supplied; see documentation for the global derivative() function for more details.

See Also:

_derivative()

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: g = -x^4 + x^2/2 - x
sage: g.derivative()
-4*x^3 + x - 1
sage: g.derivative(x)
-4*x^3 + x - 1
sage: g.derivative(x, x)
-12*x^2 + 1
sage: g.derivative(x, 2)
-12*x^2 + 1

sage: R.<t> = PolynomialRing(ZZ)
sage: S.<x> = PolynomialRing(R)
sage: f = t^3*x^2 + t^4*x^3
sage: f.derivative()
3*t^4*x^2 + 2*t^3*x
sage: f.derivative(x)
3*t^4*x^2 + 2*t^3*x
sage: f.derivative(t)
4*t^3*x^3 + 3*t^2*x^2
```

dict()

Return a sparse dictionary representation of this univariate polynomial.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: f = x^3 + -1/7*x + 13
sage: f.dict()
{0: 13, 1: -1/7, 3: 1}
```

discriminant()

Returns the discriminant of self.

The discriminant is

$$R_n := a_n^{2n-2} \prod_{1<i<j<n} (r_i - r_j)^2,$$

where n is the degree of self, a_n is the leading coefficient of self and the roots of self are $r_1, \ldots, r_n$.

OUTPUT: An element of the base ring of the polynomial ring.

Note: Uses the identity $R_n(f) := (-1)^{(}n(n-1)/2)R(f,f')a_n^{(}n-k-2)$, where n is the degree of self, a_n is the leading coefficient of self, f' is the derivative of f, and k is the degree of f'. Calls `resultant()`.

EXAMPLES:

In the case of elliptic curves in special form, the discriminant is easy to calculate:

```
sage: R.<x> = QQ[]
sage: f = x^3 + x + 1
sage: d = f.discriminant(); d
-31
sage: d.parent() is QQ
True
sage: EllipticCurve([1, 1]).discriminant()/16
-31

sage: R.<x> = QQ[]
sage: f = 2*x^3 + x + 1
sage: d = f.discriminant(); d
-116
```

We can also compute discriminants over univariate and multivariate polynomial rings, provided that PARI's variable ordering requirements are respected. Usually, your discriminants will work if you always ask for them in the variable `x`:

```
sage: R.<a> = QQ[]
sage: S.<x> = R[]
sage: f = a*x + x + a + 1
sage: d = f.discriminant(); d
1
sage: d.parent() is R
True

sage: R.<a, b> = QQ[]
sage: S.<x> = R[]
sage: f = x^2 + a + b
sage: d = f.discriminant(); d
-4*a - 4*b
sage: d.parent() is R
True
```

Unfortunately Sage does not handle PARI's variable ordering requirements gracefully, so the following fails:

```
sage: R.<x, y> = QQ[]
sage: S.<a> = R[]
sage: f = x^2 + a
sage: f.discriminant()
...
PariError: (8)
```

exponents()

Return the exponents of the monomials appearing in self.

EXAMPLES:

```
sage: _.<x> = PolynomialRing(ZZ)
sage: f = x^4+2*x^2+1
sage: f.exponents()
[0, 2, 4]
```

factor()

Return the factorization of self over the base ring of this polynomial. Factoring polynomials over $\mathbf{Z}/n\mathbf{Z}$ for n composite is at the moment not implemented.

INPUT: a polynomial

OUTPUT:

- `Factorization` - the factorization of self, which is a product of a unit with a product of powers of irreducible factors.

Over a field the irreducible factors are all monic.

EXAMPLES:

We factor some polynomials over $\mathbf{Q}$.

```
sage: x = QQ['x'].0
sage: f = (x^3 - 1)^2
sage: f.factor()
(x - 1)^2 * (x^2 + x + 1)^2
```

Notice that over the field $\mathbf{Q}$ the irreducible factors are monic.

```
sage: f = 10*x^5 - 1
sage: f.factor()
(10) * (x^5 - 1/10)
sage: f = 10*x^5 - 10
sage: f.factor()
(10) * (x - 1) * (x^4 + x^3 + x^2 + x + 1)
```

Over $\mathbf{Z}$ the irreducible factors need not be monic:

```
sage: x = ZZ['x'].0
sage: f = 10*x^5 - 1
sage: f.factor()
10*x^5 - 1
```

We factor a non-monic polynomial over the finite field F_{25}.

```
sage: k.<a> = GF(25)
sage: R.<x> = k[]
sage: f = 2*x^10 + 2*x + 2*a
sage: F = f.factor(); F
(2) * (x + a + 2) * (x^2 + 3*x + 4*a + 4) * (x^2 + (a + 1)*x + a + 2) * (x^5 + (3*a + 4)*x^4
```

Notice that the unit factor is included when we multiply F back out.

```
sage: expand(F)
2*x^10 + 2*x + 2*a
```

Factorization also works even if the variable of the finite field is nefariously labeled "x".

```
sage: x = GF(3^2, 'a')['x'].0
sage: f = x^10 +7*x -13
sage: G = f.factor(); G
(x + a) * (x + 2*a + 1) * (x^4 + (a + 2)*x^3 + (2*a + 2)*x + 2) * (x^4 + 2*a*x^3 + (a + 1)*x
sage: prod(G) == f
True

sage: f.parent().base_ring()._assign_names(['a'])
sage: f.factor()
(x + a) * (x + 2*a + 1) * (x^4 + (a + 2)*x^3 + (2*a + 2)*x + 2) * (x^4 + 2*a*x^3 + (a + 1)*x

sage: k = GF(9,'x')    # purposely calling it x to test robustness
sage: x = PolynomialRing(k,'x0').gen()
sage: f = x^3 + x + 1
sage: f.factor()
```

```
(x0 + 2) * (x0 + x) * (x0 + 2*x + 1)
sage: f = 0*x
sage: f.factor()
...
ValueError: factorization of 0 not defined

sage: f = x^0
sage: f.factor()
1
```

Arbitrary precision real and complex factorization:

```
sage: R.<x> = RealField(100)[]
sage: F = factor(x^2-3); F
(1.0000000000000000000000000000*x - 1.7320508075688772935274463415) * (1.0000000000000000000
sage: expand(F)
1.0000000000000000000000000000*x^2 - 3.0000000000000000000000000000
sage: factor(x^2 + 1)
1.0000000000000000000000000000*x^2 + 1.0000000000000000000000000000
sage: C = ComplexField(100)
sage: R.<x> = C[]
sage: F = factor(x^2+3); F
(1.0000000000000000000000000000*x - 1.7320508075688772935274463415*I) * (1.0000000000000000
sage: expand(F)
1.0000000000000000000000000000*x^2 + 3.0000000000000000000000000000
sage: factor(x^2+1)
(1.0000000000000000000000000000*x - 1.0000000000000000000000000000*I) * (1.0000000000000000
sage: f = C.0 * (x^2 + 1) ; f
1.0000000000000000000000000000*I*x^2 + 1.0000000000000000000000000000*I
sage: F = factor(f); F
(1.0000000000000000000000000000*I) * (1.0000000000000000000000000000*x - 1.0000000000000000
sage: expand(F)
1.0000000000000000000000000000*I*x^2 + 1.0000000000000000000000000000*I
```

Over a complicated number field:

```
sage: x = polygen(QQ, 'x')
sage: f = x^6 + 10/7*x^5 - 867/49*x^4 - 76/245*x^3 + 3148/35*x^2 - 25944/245*x + 48771/1225
sage: K.<a> = NumberField(f)
sage: S.<T> = K[]
sage: ff = S(f); ff
T^6 + 10/7*T^5 - 867/49*T^4 - 76/245*T^3 + 3148/35*T^2 - 25944/245*T + 48771/1225
sage: F = ff.factor()
sage: len(F)
4
sage: F[:2]
[(T - a, 1), (T - 40085763200/924556084127*a^5 - 145475769880/924556084127*a^4 + 5276170964
sage: expand(F)
T^6 + 10/7*T^5 - 867/49*T^4 - 76/245*T^3 + 3148/35*T^2 - 25944/245*T + 48771/1225

sage: f = x^2 - 1/3 ; K.<a> = NumberField(f) ; A.<T> = K[] ; g = A(x^2-1)
sage: g.factor()
(T - 1) * (T + 1)

sage: h = A(3*x^2-1) ; h.factor()
(3) * (T - a) * (T + a)

sage: h = A(x^2-1/3) ; h.factor()
(T - a) * (T + a)
```

Over the real double field:

```
sage: x = polygen(RDF)
sage: f = (x-1)^3
sage: f.factor() # random output (unfortunately)
(1.0*x - 1.00000859959) * (1.0*x^2 - 1.99999140041*x + 0.999991400484)
sage: (-2*x^2 - 1).factor()
(-2.0) * (1.0*x^2 + 0.5)
sage: (-2*x^2 - 1).factor().expand()
-2.0*x^2 - 1.0
```

Note that this factorization suffers from the roots function:

```
sage: f.roots() # random output (unfortunately)
[1.00000859959, 0.999995700205 + 7.44736245561e-06*I, 0.999995700205 - 7.44736245561e-06*I]
```

Over the complex double field. Because this is approximate, all factors will occur with multiplicity 1.

```
sage: x = CDF['x'].0; i = CDF.0
sage: f = (x^2 + 2*i)^3
sage: f.factor()    # random low order bits
(1.0*x + -0.999994409957 + 1.00001040378*I) * (1.0*x + -0.999993785062 + 0.999989956987*I) *
sage: f(-f.factor()[0][0][0])   # random low order bits
-2.38358052913e-14 - 2.57571741713e-14*I
```

Over a relative number field:

```
sage: x = QQ['x'].0
sage: L.<a> = CyclotomicField(3).extension(x^3 - 2)
sage: x = L['x'].0
sage: f = (x^3 + x + a)*(x^5 + x + L.1); f
x^8 + x^6 + a*x^5 + x^4 + zeta3*x^3 + x^2 + (a + zeta3)*x + zeta3*a
sage: f.factor()
(x^3 + x + a) * (x^5 + x + zeta3)
```

Factoring polynomials over $\mathbf{Z}/n\mathbf{Z}$ for composite n is not implemented:

```
sage: R.<x> = PolynomialRing(Integers(35))
sage: f = (x^2+2*x+2)*(x^2+3*x+9)
sage: f.factor()
...
NotImplementedError: factorization of polynomials over rings with composite characteristic i
```

hamming_weight()

Returns the number of non-zero coefficients of self.

EXAMPLES:

```
sage: R.<x> = ZZ[]
sage: f = x^3 - x
sage: f.hamming_weight()
2
sage: R(0).hamming_weight()
0
sage: f = (x+1)^100
sage: f.hamming_weight()
101
sage: S = GF(5)['y']
sage: S(f).hamming_weight()
5
sage: cyclotomic_polynomial(105).hamming_weight()
33
```

integral()

Return the integral of this polynomial.

Note: The integral is always chosen so the constant term is 0.

EXAMPLES:

```
sage: R.<x> = ZZ[]
sage: R(0).integral()
0
sage: f = R(2).integral(); f
2*x
```

Note that since the integral is defined over the same base ring the integral is actually in the base ring.

```
sage: f.parent()
Univariate Polynomial Ring in x over Integer Ring
```

If the integral isn't defined over the same base ring, then the base ring is extended:

```
sage: f = x^3 + x - 2
sage: g = f.integral(); g
1/4*x^4 + 1/2*x^2 - 2*x
sage: g.parent()
Univariate Polynomial Ring in x over Rational Field
```

inverse_mod()

Inverts the polynomial a with respect to m, or raises a ValueError if no such inverse exists. The parameter m may be either a single polynomial or an ideal (for consistency with inverse_mod in other rings).

EXAMPLES:

```
sage: S.<t> = QQ[]
sage: f = inverse_mod(t^2 + 1, t^3 + 1); f
-1/2*t^2 - 1/2*t + 1/2
sage: f * (t^2 + 1) % (t^3 + 1)
1
sage: f = t.inverse_mod((t+1)^7); f
-t^6 - 7*t^5 - 21*t^4 - 35*t^3 - 35*t^2 - 21*t - 7
sage: (f * t) + (t+1)^7
1
sage: t.inverse_mod(S.ideal((t + 1)^7)) == f
True
```

It also works over in-exact rings, but note that due to rounding error the product is only guaranteed to be within epsilon of the constant polynomial 1.

```
sage: R.<x> = RDF[]
sage: f = inverse_mod(x^2 + 1, x^5 + x + 1); f
0.4*x^4 - 0.2*x^3 - 0.4*x^2 + 0.2*x + 0.8
sage: f * (x^2 + 1) % (x^5 + x + 1)
2.22044604925e-16*x^2 + 1.11022302463e-16*x + 1.0
sage: f = inverse_mod(x^3 - x + 1, x - 2); f
0.142857142857
sage: f * (x^3 - x + 1) % (x - 2)
1.0
```

ALGORITHM: Solve the system as + mt = 1, returning s as the inverse of a mod m.

Uses the Euclidean algorithm for exact rings, and solves a linear system for the coefficients of s and t for inexact rings (as the Euclidean algorithm may not converge in that case).

AUTHORS:

- Robert Bradshaw (2007-05-31)

inverse_of_unit()

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: f = x - 90283
sage: f.inverse_of_unit()
...
ValueError: self is not a unit.
sage: f = R(-90283); g = f.inverse_of_unit(); g
-1/90283
sage: parent(g)
Univariate Polynomial Ring in x over Rational Field
```

is_constant()

Return True if this is a constant polynomial.

OUTPUT:

- bool - True if and only if this polynomial is constant

EXAMPLES:

```
sage: R.<x> = ZZ[]
sage: x.is_constant()
False
sage: R(2).is_constant()
True
sage: R(0).is_constant()
True
```

is_gen()

Return True if this polynomial is the distinguished generator of the parent polynomial ring.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: R(1).is_gen()
False
sage: R(x).is_gen()
True
```

Important - this function doesn't return True if self equals the generator; it returns True if self *is* the generator.

```
sage: f = R([0,1]); f
x
sage: f.is_gen()
False
sage: f is x
False
sage: f == x
True
```

is_irreducible()

Return True precisely if this polynomial is irreducible over its base ring. Testing irreducibility over $\mathbf{Z}/n\mathbf{Z}$ for composite n is not implemented.

The function returns False for polynomials which are units, and raises an exception for the zero polynomial.

EXAMPLES:

```
sage: R.<x> = ZZ[]
sage: (x^3 + 1).is_irreducible()
False
sage: (x^2 - 1).is_irreducible()
False
sage: (x^3 + 2).is_irreducible()
```

```
True
sage: R(0).is_irreducible()
...
ValueError: self must be nonzero
```

See #5140: sage: R(1).is_irreducible() False sage: R(4).is_irreducible() False sage: R(5).is_irreducible() True

The base ring does matter: for example, 2x is irreducible as a polynomial in QQ[x], but not in ZZ[x]:

sage: R.<x> = ZZ[] sage: R(2*x).is_irreducible() False sage: R.<x> = QQ[] sage: R(2*x).is_irreducible() True

TESTS:

```
sage: F.<t> = NumberField(x^2-5)
sage: Fx.<xF> = PolynomialRing(F)
sage: f = Fx([2*t - 5, 5*t - 10, 3*t - 6, -t, -t + 2, 1])
sage: f.is_irreducible()
False
sage: f = Fx([2*t - 3, 5*t - 10, 3*t - 6, -t, -t + 2, 1])
sage: f.is_irreducible()
True
```

is_monic()

Returns True if this polynomial is monic. The zero polynomial is by definition not monic.

EXAMPLES:

```
sage: x = QQ['x'].0
sage: f = x + 33
sage: f.is_monic()
True
sage: f = 0*x
sage: f.is_monic()
False
sage: f = 3*x^3 + x^4 + x^2
sage: f.is_monic()
True
sage: f = 2*x^2 + x^3 + 56*x^5
sage: f.is_monic()
False
```

AUTHORS:

- Naqi Jaffery (2006-01-24): examples

is_monomial()

Returns True if this is a monomial.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: x.is_monomial()
True
sage: (x+1).is_monomial()
False
sage: (x^2).is_monomial()
True
```

is_nilpotent()

Return True if this polynomial is nilpotent.

EXAMPLES:

```
sage: R = Integers(12)
sage: S.<x> = R[]
sage: f = 5 + 6*x
sage: f.is_nilpotent()
False
sage: f = 6 + 6*x^2
sage: f.is_nilpotent()
True
sage: f^2
0
```

EXERCISE (Atiyah-McDonald, Ch 1): Let $A[x]$ be a polynomial ring in one variable. Then $f = \sum a_i x^i \in A[x]$ is nilpotent if and only if every a_i is nilpotent.

is_primitive()

Returns `True` if the polynomial is primitive. The semantics of "primitive" depend on the polynomial coefficients.

- (field theory) A polynomial of degree m over a finite field $\mathbf{F}_q$ is primitive if it is irreducible and its root in $\mathbf{F}_{q^m}$ generates the multiplicative group $\mathbf{F}_{q^m}^*$.
- (ring theory) A polynomial over a ring is primitive if its coefficients generate the unit ideal.

Calling $is_primitive$ on a polynomial over an infinite field will raise an error.

The additional inputs to this function are to speed up computation for field semantics (see note).

INPUTS:

- `n` (default: `None`) - if provided, should equal $q - 1$ where `self.parent()` is the field with q elements; otherwise it will be computed.
- `n_prime_divs` (default: `None`) - if provided, should be a list of the prime divisors of `n`; otherwise it will be computed.

Note: Computation of the prime divisors of `n` can dominate the running time of this method, so performing this computation externally (e.g. `pdivs=n.prime_divisors()`) is a good idea for repeated calls to is_primitive for polynomials of the same degree.

Results may be incorrect if the wrong `n` and/or factorization are provided.

EXAMPLES:

Field semantics examples.

::

```
sage: R.<x> = GF(2)['x']
sage: f = x^4+x^3+x^2+x+1
sage: f.is_irreducible(), f.is_primitive()
(True, False)
sage: f = x^3+x+1
sage: f.is_irreducible(), f.is_primitive()
(True, True)
sage: R.<x> = GF(3)[]
sage: f = x^3-x+1
sage: f.is_irreducible(), f.is_primitive()
(True, True)
sage: f = x^2+1
sage: f.is_irreducible(), f.is_primitive()
(True, False)
sage: R.<x> = GF(5)[]
sage: f = x^2+x+1
sage: f.is_primitive()
False
```

  sage: a=R.gen(1)
  sage: a^2
  -5
  sage: f=a*x+2
  sage: f.is_primitive()
  True
  sage: f=(1+a)*x+2
  sage: f.is_primitive()
  False

  sage: x=polygen(Integers(10));
  sage: f=5*x^2+2
  sage: #f.is_primitive()  #BUG:: elsewhere in Sage, should return True
  sage: f=4*x^2+2
  sage: #f.is_primitive()  #BUG:: elsewhere in Sage, should return False
```

TESTS:

```
sage: R.<x> = GF(2)['x']
sage: f = x^4+x^3+x^2+x+1
sage: f.is_primitive(15)
False
sage: f.is_primitive(15, [3,5])
False
sage: f.is_primitive(n_prime_divs=[3,5])
False
sage: f = x^3+x+1
sage: f.is_primitive(7, [7])
True
sage: R.<x> = GF(3)[]
sage: f = x^3-x+1
sage: f.is_primitive(26, [2,13])
True
sage: f = x^2+1
sage: f.is_primitive(8, [2])
False
```

```
sage: R.<x> = GF(5)[]
sage: f = x^2+x+1
sage: f.is_primitive(24, [2,3])
False
sage: f = x^2-x+2
sage: f.is_primitive(24, [2,3])
True
sage: x=polygen(Integers(103)); f=x^2+1
sage: f.is_primitive()
False
```

is_square()

Returns whether or not polynomial is square. If the optional argument root is True, then also returns the square root (or None, if the polynomial is not square).

INPUT:

- `root` - whether or not to also return a square root (default: False)

OUTPUT:

- `bool` - whether or not a square
- `object` - (optional) an actual square root if found, and None otherwise.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: f = 12*(x+1)^2 * (x+3)^2
sage: S.<y> = PolynomialRing(RR)
sage: g = 12*(y+1)^2 * (y+3)^2
sage: f.is_square()
False
sage: f.is_square(root=True)
(False, None)
sage: g.is_square()
True
sage: h = f/3; h
4*x^4 + 32*x^3 + 88*x^2 + 96*x + 36
sage: h.is_square(root=True)
(True, 2*x^2 + 8*x + 6)
```

is_squarefree()

Return True if this polynomial is square free.

EXAMPLES:

```
sage: x = polygen(QQ)
sage: f = (x-1)*(x-2)*(x^2-5)*(x^17-3); f
x^21 - 3*x^20 - 3*x^19 + 15*x^18 - 10*x^17 - 3*x^4 + 9*x^3 + 9*x^2 - 45*x + 30
sage: f.is_squarefree()
True
sage: (f*(x^2-5)).is_squarefree()
False
```

is_unit()

Return True if this polynomial is a unit.

EXAMPLES:

```
sage: a = Integers(90384098234^3)
sage: b = a(2*191*236607587)
sage: b.is_nilpotent()
True
sage: R.<x> = a[]
```

```
sage: f = 3 + b*x + b^2*x^2
sage: f.is_unit()
True
sage: f = 3 + b*x + b^2*x^2 + 17*x^3
sage: f.is_unit()
False
```

EXERCISE (Atiyah-McDonald, Ch 1): Let $A[x]$ be a polynomial ring in one variable. Then $f = \sum a_i x^i \in A[x]$ is a unit if and only if a_0 is a unit and $a_1, \ldots, a_n$ are nilpotent.

lcm()

Let f and g be two polynomials. Then this function returns the monic least common multiple of f and g.

leading_coefficient()

Return the leading coefficient of this polynomial.

OUTPUT: element of the base ring

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: f = (-2/5)*x^3 + 2*x - 1/3
sage: f.leading_coefficient()
-2/5
```

list()

Return a new copy of the list of the underlying elements of self.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: f = (-2/5)*x^3 + 2*x - 1/3
sage: v = f.list(); v
[-1/3, 2, 0, -2/5]
```

Note that v is a list, it is mutable, and each call to the list method returns a new list:

```
sage: type(v)
<type 'list'>
sage: v[0] = 5
sage: f.list()
[-1/3, 2, 0, -2/5]
```

Here is an example with a generic polynomial ring:

```
sage: R.<x> = QQ[]
sage: S.<y> = R[]
sage: f = y^3 + x*y -3*x; f
y^3 + x*y - 3*x
sage: type(f)
<type 'sage.rings.polynomial.polynomial_element.Polynomial_generic_dense'>
sage: v = f.list(); v
[-3*x, x, 0, 1]
sage: v[0] = 10
sage: f.list()
[-3*x, x, 0, 1]
```

monic()

Return this polynomial divided by its leading coefficient. Does not change this polynomial.

EXAMPLES:

```
sage: x = QQ['x'].0
sage: f = 2*x^2 + x^3 + 56*x^5
sage: f.monic()
```

```
x^5 + 1/56*x^3 + 1/28*x^2
sage: f = (1/4)*x^2 + 3*x + 1
sage: f.monic()
x^2 + 12*x + 4
```

The following happens because $f = 0$ cannot be made into a monic polynomial

```
sage: f = 0*x
sage: f.monic()
...
ZeroDivisionError: rational division by zero
```

Notice that the monic version of a polynomial over the integers is defined over the rationals.

```
sage: x = ZZ['x'].0
sage: f = 3*x^19 + x^2 - 37
sage: g = f.monic(); g
x^19 + 1/3*x^2 - 37/3
sage: g.parent()
Univariate Polynomial Ring in x over Rational Field
```

AUTHORS:

- Naqi Jaffery (2006-01-24): examples

name()

Note: This function is deprecated. It will be removed in a future release of Sage. Please use the .variable_name() function instead.

Return the string variable name of the indeterminate of this polynomial.

EXAMPLES:

```
sage: R.<theta> = ZZ[];
sage: f = (2-theta)^3; f
-theta^3 + 6*theta^2 - 12*theta + 8
sage: f.name()
doctest:...: DeprecationWarning: This function is deprecated. It will be removed in a future
'theta'
```

newton_raphson()

Return a list of n iterative approximations to a root of this polynomial, computed using the Newton-Raphson method.

The Newton-Raphson method is an iterative root-finding algorithm. For f(x) a polynomial, as is the case here, this is essentially the same as Horner's method.

INPUT:

- `n` - an integer (=the number of iterations),
- `x0` - an initial guess x0.

OUTPUT: A list of numbers hopefully approximating a root of f(x)=0.

If one of the iterates is a critical point of f then a ZeroDivisionError exception is raised.

EXAMPLES:

```
sage: x = PolynomialRing(RealField(), 'x').gen()
sage: f = x^2 - 2
sage: f.newton_raphson(4, 1)
[1.50000000000000, 1.41666666666667, 1.41421568627451, 1.41421356237469]
```

AUTHORS:

- David Joyner and William Stein (2005-11-28)

newton_slopes()

Return the p-adic slopes of the Newton polygon of self, when this makes sense.

OUTPUT: list of rational numbers

EXAMPLES:

```
sage: x = QQ['x'].0
sage: f = x^3 + 2
sage: f.newton_slopes(2)
[1/3, 1/3, 1/3]
```

ALGORITHM: Uses PARI.

norm()

Return the p-norm of this polynomial.

DEFINITION: For integer p, the p-norm of a polynomial is the pth root of the sum of the pth powers of the absolute values of the coefficients of the polynomial.

INPUT:

- p - (positive integer or +infinity) the degree of the norm

EXAMPLES:

```
sage: R.<x> =RR[]
sage: f = x^6 + x^2 + -x^4 - 2*x^3
sage: f.norm(2)
2.64575131106459
sage: (sqrt(1^2 + 1^2 + (-1)^2 + (-2)^2)).n()
2.64575131106459

sage: f.norm(1)
5.00000000000000
sage: f.norm(infinity)
2.00000000000000

sage: f.norm(-1)
...
ValueError: The degree of the norm must be positive
```

TESTS:

```
sage: R.<x> = RR[]
sage: f = x^6 + x^2 + -x^4 -x^3
sage: f.norm(int(2))
2.00000000000000
```

AUTHORS:

- Didier Deshommes
- William Stein: fix bugs, add definition, etc.

ord()

This is the same as the valuation of self at p. See the documentation for `self.valuation`.

EXAMPLES:

```
sage: P,x=PolynomialRing(ZZ,'x').objgen()
sage: (x^2+x).ord(x+1)
1
```

padded_list()

Return list of coefficients of self up to (but not including) q^n.

Includes 0's in the list on the right so that the list has length n.

INPUT:

- n - (default: None); if given, an integer that is at least 0

EXAMPLES:

```
sage: x = polygen(QQ)
sage: f = 1 + x^3 + 23*x^5
sage: f.padded_list()
[1, 0, 0, 1, 0, 23]
sage: f.padded_list(10)
[1, 0, 0, 1, 0, 23, 0, 0, 0, 0]
sage: len(f.padded_list(10))
10
sage: f.padded_list(3)
[1, 0, 0]
sage: f.padded_list(0)
[]
sage: f.padded_list(-1)
...
ValueError: n must be at least 0
```

plot()

Return a plot of this polynomial.

INPUT:

- `xmin` - float
- `xmax` - float
- `*args, **kwds` - passed to either plot or point

OUTPUT: returns a graphic object.

EXAMPLES:

```
sage: x = polygen(GF(389))
sage: plot(x^2 + 1, rgbcolor=(0,0,1))
sage: x = polygen(QQ)
sage: plot(x^2 + 1, rgbcolor=(1,0,0))
```

polynomial()

Let var be one of the variables of the parent of self. This returns self viewed as a univariate polynomial in var over the polynomial ring generated by all the other variables of the parent.

For univariate polynomials, if var is the generator of the parent ring, we return this polynomial, otherwise raise an error.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: (x+1).polynomial(x)
x + 1
```

TESTS:

```
sage: x.polynomial(1)
...
ValueError: given variable is not the generator of parent.
```

prec()

Return the precision of this polynomial. This is always infinity, since polynomials are of infinite precision by definition (there is no big-oh).

EXAMPLES:

```
sage: x = polygen(ZZ)
sage: (x^5 + x + 1).prec()
+Infinity
sage: x.prec()
+Infinity
```

radical()

Returns the radical of self; over a field, this is the product of the distinct irreducible factors of self. (This is also sometimes called the "square-free part" of self, but that term is ambiguous; it is sometimes used to mean the quotient of self by its maximal square factor.)

EXAMPLES:

```
sage: P.<x> = ZZ[]
sage: t = (x^2-x+1)^3 * (3*x-1)^2
sage: t.radical()
3*x^3 - 4*x^2 + 4*x - 1
```

real_roots()

Return the real roots of this polynomial, without multiplicities.

Calls self.roots(ring=RR), unless this is a polynomial with floating-point real coefficients, in which case it calls self.roots().

EXAMPLES:

```
sage: x = polygen(ZZ)
sage: (x^2 - x - 1).real_roots()
[-0.618033988749895, 1.61803398874989]
```

TESTS:

```
sage: x = polygen(RealField(100))
sage: (x^2 - x - 1).real_roots()[0].parent()
    Real Field with 100 bits of precision
sage: x = polygen(RDF)
sage: (x^2 - x - 1).real_roots()[0].parent()
Real Double Field
```

resultant()

Returns the resultant of self and other.

INPUT:

- `other` - a polynomial

OUTPUT: an element of the base ring of the polynomial ring

Note: Implemented using PARI's `polresultant` function.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: f = x^3 + x + 1;  g = x^3 - x - 1
sage: r = f.resultant(g); r
-8
sage: r.parent() is QQ
True
```

We can also compute resultants over univariate and multivariate polynomial rings, provided that PARI's variable ordering requirements are respected. Usually, your resultants will work if you always ask for them in the variable `x`:

```
sage: R.<a> = QQ[]
sage: S.<x> = R[]
sage: f = x^2 + a; g = x^3 + a
sage: r = f.resultant(g); r
a^3 + a^2
sage: r.parent() is R
True
```

```
sage: R.<a, b> = QQ[]
sage: S.<x> = R[]
sage: f = x^2 + a; g = x^3 + b
sage: r = f.resultant(g); r
a^3 + b^2
sage: r.parent() is R
True
```

Unfortunately Sage does not handle PARI's variable ordering requirements gracefully, so the following fails:

```
sage: R.<x, y> = QQ[]
sage: S.<a> = R[]
sage: f = x^2 + a; g = y^3 + a
sage: f.resultant(g)
...
PariError: (8)
```

reverse()

Return polynomial but with the coefficients reversed.

EXAMPLES:

```
sage: R.<x> = ZZ[]; S.<y> = R[]
sage: f = y^3 + x*y -3*x; f
y^3 + x*y - 3*x
sage: f.reverse()
-3*x*y^3 + x*y^2 + 1
```

root_field()

Return the field generated by the roots of the irreducible polynomial self. The output is either a number field, relative number field, a quotient of a polynomial ring over a field, or the fraction field of the base ring.

EXAMPLES:

```
sage: R.<x> = QQ['x']
sage: f = x^3 + x + 17
sage: f.root_field('a')
Number Field in a with defining polynomial x^3 + x + 17

sage: R.<x> = QQ['x']
sage: f = x - 3
sage: f.root_field('b')
Rational Field

sage: R.<x> = ZZ['x']
sage: f = x^3 + x + 17
sage: f.root_field('b')
Number Field in b with defining polynomial x^3 + x + 17

sage: y = QQ['x'].0
sage: L.<a> = NumberField(y^3-2)
sage: R.<x> = L['x']
sage: f = x^3 + x + 17
sage: f.root_field('c')
Number Field in c with defining polynomial x^3 + x + 17 over its base field

sage: R.<x> = PolynomialRing(GF(9,'a'))
sage: f = x^3 + x^2 + 8
sage: K.<alpha> = f.root_field(); K
```

```
Univariate Quotient Polynomial Ring in alpha over Finite Field in a of size 3^2 with modulus
sage: alpha^2 + 1
alpha^2 + 1
sage: alpha^3 + alpha^2
1

sage: R.<x> = QQ[]
sage: f = x^2
sage: K.<alpha> = f.root_field()
...
ValueError: polynomial must be irreducible
```

TESTS:

```
sage: (PolynomialRing(Integers(31),name='x').0+5).root_field('a')
Ring of integers modulo 31
```

roots()

Return the roots of this polynomial (by default, in the base ring of this polynomial).

INPUT:

- `ring` - the ring to find roots in
- `multiplicities` - bool (default: True) if True return list of pairs (r, n), where r is the root and n is the multiplicity. If False, just return the unique roots, with no information about multiplicities.
- `algorithm` - the root-finding algorithm to use. We attempt to select a reasonable algorithm by default, but this lets the caller override our choice.

By default, this finds all the roots that lie in the base ring of the polynomial. However, the ring parameter can be used to specify a ring to look for roots in.

If the polynomial and the output ring are both exact (integers, rationals, finite fields, etc.), then the output should always be correct (or raise an exception, if that case is not yet handled).

If the output ring is approximate (floating-point real or complex numbers), then the answer will be estimated numerically, using floating-point arithmetic of at least the precision of the output ring. If the polynomial is ill-conditioned, meaning that a small change in the coefficients of the polynomial will lead to a relatively large change in the location of the roots, this may give poor results. Distinct roots may be returned as multiple roots, multiple roots may be returned as distinct roots, real roots may be lost entirely (because the numerical estimate thinks they are complex roots). Note that polynomials with multiple roots are always ill-conditioned; there's a footnote at the end of the docstring about this.

If the output ring is a RealIntervalField or ComplexIntervalField of a given precision, then the answer will always be correct (or an exception will be raised, if a case is not implemented). Each root will be contained in one of the returned intervals, and the intervals will be disjoint. (The returned intervals may be of higher precision than the specified output ring.)

At the end of this docstring (after the examples) is a description of all the cases implemented in this function, and the algorithms used. That section also describes the possibilities for "algorithm=", for the cases where multiple algorithms exist.

EXAMPLES:

```
sage: x = QQ['x'].0
sage: f = x^3 - 1
sage: f.roots()
[(1, 1)]
sage: f.roots(ring=CC)    # note -- low order bits slightly different on ppc.
[(1.00000000000000, 1), (-0.500000000000000 - 0.86602540378443...*I, 1), (-0.500000000000000
sage: f = (x^3 - 1)^2
sage: f.roots()
[(1, 2)]
```

```
sage: f = -19*x + 884736
sage: f.roots()
[(884736/19, 1)]
sage: (f^20).roots()
[(884736/19, 20)]

sage: K.<z> = CyclotomicField(3)
sage: f = K.defining_polynomial()
sage: f.roots(ring=GF(7))
[(4, 1), (2, 1)]
sage: g = f.change_ring(GF(7))
sage: g.roots()
[(4, 1), (2, 1)]
sage: g.roots(multiplicities=False)
[4, 2]
```

An example over RR, which illustrates that only the roots in RR are returned:

```
sage: x = RR['x'].0
sage: f = x^3 -2
sage: f.roots()
[(1.25992104989487, 1)]
sage: f.factor()
(1.00000000000000*x - 1.25992104989487) * (1.00000000000000*x^2 + 1.25992104989487*x + 1.587
sage: x = RealField(100)['x'].0
sage: f = x^3 -2
sage: f.roots()
[(1.2599210498948731647672106073, 1)]

sage: x = CC['x'].0
sage: f = x^3 -2
sage: f.roots()
[(1.25992104989487, 1), (-0.62996052494743... - 1.09112363597172*I, 1), (-0.62996052494743..
sage: f.roots(algorithm='pari')
[(1.25992104989487, 1), (-0.629960524947437 - 1.09112363597172*I, 1), (-0.629960524947437 +
```

Another example showing that only roots in the base ring are returned:

```
sage: x = polygen(ZZ)
sage: f = (2*x-3) * (x-1) * (x+1)
sage: f.roots()
[(1, 1), (-1, 1)]
sage: f.roots(ring=QQ)
[(3/2, 1), (1, 1), (-1, 1)]
```

An example involving large numbers:

```
sage: x = RR['x'].0
sage: f = x^2 - 1e100
sage: f.roots()
[(-1.00000000000000e50, 1), (1.00000000000000e50, 1)]
sage: f = x^10 - 2*(5*x-1)^2
sage: f.roots(multiplicities=False)
[-1.6772670339941..., 0.19995479628..., 0.20004530611..., 1.5763035161844...]

sage: x = CC['x'].0
sage: i = CC.0
sage: f = (x - 1)*(x - i)
sage: f.roots(multiplicities=False) #random - this example is numerically rather unstable
[2.22044604925031e-16 + 1.00000000000000*I, 1.00000000000000 + 8.32667268468867e-17*I]
```

```
sage: g=(x-1.33+1.33*i)*(x-2.66-2.66*i)
sage: g.roots(multiplicities=False)
[1.33000000000000 - 1.33000000000000*I, 2.66000000000000 + 2.66000000000000*I]
```

A purely symbolic roots example:

```
sage: X = var('X')
sage: f = expand((X-1)*(X-I)^3*(X^2 - sqrt(2))); f
-sqrt(2)*X^4 + I*sqrt(2) + X^6 - (3*I - 1)*X^5 + (3*I - 3)*X^4 + (3*I + 1)*sqrt(2)*X^3 + (I
sage: print f.roots()
[(I, 3), (-2^(1/4), 1), (2^(1/4), 1), (1, 1)]
```

A couple of examples where the base ring doesn't have a factorization algorithm (yet). Note that this is currently done via naive enumeration, so could be very slow:

```
sage: R = Integers(6)
sage: S.<x> = R['x']
sage: p = x^2-1
sage: p.roots()
...
NotImplementedError: root finding with multiplicities for this polynomial not implemented (t
sage: p.roots(multiplicities=False)
[1, 5]
sage: R = Integers(9)
sage: A = PolynomialRing(R, 'y')
sage: y = A.gen()
sage: f = 10*y^2 - y^3 - 9
sage: f.roots(multiplicities=False)
[0, 1, 3, 6]
```

An example over the complex double field (where root finding is fast, thanks to numpy):

```
sage: R.<x> = CDF[]
sage: f = R.cyclotomic_polynomial(5); f
1.0*x^4 + 1.0*x^3 + 1.0*x^2 + 1.0*x + 1.0
sage: f.roots(multiplicities=False)   # slightly random
[0.309016994375 + 0.951056516295*I, 0.309016994375 - 0.951056516295*I, -0.809016994375 + 0.5
sage: [z^5 for z in f.roots(multiplicities=False)]     # slightly random
[1.0 - 2.44929359829e-16*I, 1.0 + 2.44929359829e-16*I, 1.0 - 4.89858719659e-16*I, 1.0 + 4.89
sage: f = CDF['x']([1,2,3,4]); f
4.0*x^3 + 3.0*x^2 + 2.0*x + 1.0
sage: r = f.roots(multiplicities=False)
sage: [f(a) for a in r]    # slightly random
[2.55351295664e-15, -4.4408920985e-16 - 2.08166817117e-16*I, -4.4408920985e-16 + 2.081668171
```

Another example over RDF:

```
sage: x = RDF['x'].0
sage: ((x^3 -1)).roots()
[(1.0, 1)]
sage: ((x^3 -1)).roots(multiplicities=False)
[1.0]
```

Another examples involving the complex double field:

```
sage: x = CDF['x'].0
sage: i = CDF.0
sage: f = x^3 + 2*i; f
1.0*x^3 + 2.0*I
sage: f.roots()
[(-1.09112363597 - 0.629960524947*I, 1),
 (... + 1.25992104989*I, 1),
```

```
 (1.09112363597 - 0.629960524947*I, 1)]
sage: f.roots(multiplicities=False)
[-1.09112363597 - 0.629960524947*I,
 ... + 1.25992104989r*I,
 1.09112363597 - 0.629960524947*I]
sage: [f(z) for z in f.roots(multiplicities=False)] # random, too close to 0
[-2.56337823492e-15 - 6.66133814775e-15*I,
 3.96533069372e-16 + 1.99840144433e-15*I,
 4.19092485179e-17 - 8.881784197e-16*I]
sage: f = i*x^3 + 2; f
1.0*I*x^3 + 2.0
sage: f.roots()
[(-1.09112363597 + 0.629960524947*I, 1),
 (... - 1.25992104989*I, 1),
 (1.09112363597 + 0.629960524947*I, 1)]
sage: f(f.roots()[0][0]) # random, too close to 0
-2.56337823492e-15 - 6.66133814775e-15*I
```

Examples using real root isolation:

```
sage: x = polygen(ZZ)
sage: f = x^2 - x - 1
sage: f.roots()
[]
sage: f.roots(ring=RIF)
[(-0.618033988749894848204586834365638117720309179805762862135448622?, 1), (1.618033988749894848204586834365638117720309179805762862135448622?, 1)]
sage: f.roots(ring=RIF, multiplicities=False)
[-0.618033988749894848204586834365638117720309179805762862135448622?, 1.618033988749894848204586834365638117720309179805762862135448622?]
sage: f.roots(ring=RealIntervalField(150))
[(-0.618033988749894848204586834365638117720309179805762862135448622?, 1), (1.6180339887498
sage: f.roots(ring=AA)
[(-0.6180339887498950?, 1), (1.6180339887498950?, 1)]
sage: f = f^2 * (x - 1)
sage: f.roots(ring=RIF)
[(-0.618033988749894848204586834365638117720309179805762862135448622?, 2), (1.000000000000000000000000000000000?, 1), (1.61803
sage: f.roots(ring=RIF, multiplicities=False)
[-0.618033988749894848204586834365638117720309179805762862135448622?, 1.000000000000000000000000000000000?, 1.6180339887498948
```

Examples using complex root isolation:

```
sage: x = polygen(ZZ)
sage: p = x^5 - x - 1
sage: p.roots()
[]
sage: p.roots(ring=CIF)
[(1.167303978261419?, 1), (-0.764884433600585? - 0.352471546031727?*I, 1), (-0.764884433600
sage: p.roots(ring=ComplexIntervalField(200))
[(1.16730397826141868425604589985484218072056037152548903914000 82?, 1), (-0.7648844336005847
sage: rts = p.roots(ring=QQbar); rts
[(1.167303978261419?, 1), (-0.7648844336005847? - 0.352471546031726 3?*I, 1), (-0.764884433600
sage: p.roots(ring=AA)
[(1.167303978261419?, 1)]
sage: p = (x - rts[4][0])^2 * (3*x^2 + x + 1)
sage: p.roots(ring=QQbar)
[(-0.1666666666666667? - 0.552770798392567?*I, 1), (-0.1666666666666667? + 0.552770798392567
sage: p.roots(ring=CIF)
[(-0.1666666666666667? - 0.552770798392567?*I, 1), (-0.1666666666666667? + 0.552770798392567
```

Note that coefficients in a number field with defining polynomial $x^2 + 1$ are considered to be Gaussian rationals (with the generator mapping to +I), if you ask for complex roots.

```
sage: K.<im> = NumberField(x^2 + 1)
sage: y = polygen(K)
sage: p = y^4 - 2 - im
sage: p.roots(ring=CC)
[(-1.2146389322441... - 0.14142505258239...*I, 1), (-0.14142505258239... + 1.2146389322441...
sage: p = p^2 * (y^2 - 2)
sage: p.roots(ring=CIF)
[(-1.414213562373095?, 1), (1.414213562373095?, 1), (-1.214638932244183? - 0.14142505258239
```

There are many combinations of floating-point input and output types that work. (Note that some of them are quite pointless... there's no reason to use high-precision input and output, and still use numpy to find the roots.)

```
sage: rflds = (RR, RDF, RealField(100))
sage: cflds = (CC, CDF, ComplexField(100))
sage: def cross(a, b):
...       return list(cartesian_product_iterator([a, b]))
sage: flds = cross(rflds, rflds) + cross(rflds, cflds) + cross(cflds, cflds)
sage: for (fld_in, fld_out) in flds:
...       x = polygen(fld_in)
...       f = x^3 - fld_in(2)
...       x2 = polygen(fld_out)
...       f2 = x2^3 - fld_out(2)
...       for algo in (None, 'pari', 'numpy'):
...           rts = f.roots(ring=fld_out, multiplicities=False)
...           if fld_in == fld_out and algo is None:
...               print fld_in, rts
...           for rt in rts:
...               assert(abs(f2(rt)) <= 1e-10)
...               assert(rt.parent() == fld_out)
Real Field with 53 bits of precision [1.25992104989487]

Complex Field with 100 bits of precision [1.2599210498948731647672106073, -0.629960524947436
```

Note that we can find the roots of a polynomial with algebraic coefficients:

```
sage: rt2 = sqrt(AA(2))
sage: rt3 = sqrt(AA(3))
sage: x = polygen(AA)
sage: f = (x - rt2) * (x - rt3); f
    x^2 - 3.146264369941973?*x + 2.449489742783178?
sage: rts = f.roots(); rts
[(1.414213562373095?, 1), (1.732050807568878?, 1)]
sage: rts[0][0] == rt2
True
sage: f.roots(ring=RealIntervalField(150))
[(1.41421356237309504880168872420969807856967187537694807317667973 8?, 1), (1.732050807568877
```

We can handle polynomials with huge coefficients.

This number doesn't even fit in an IEEE double-precision float, but RR and CC allow a much larger range of floating-point numbers:

```
sage: bigc = 2^1500
sage: CDF(bigc)
+infinity
sage: CC(bigc)
3.50746621104340e451
```

Polynomials using such large coefficients can't be handled by numpy, but pari can deal with them:

```
sage: x = polygen(QQ)
sage: p = x + bigc
sage: p.roots(ring=RR, algorithm='numpy')
...
ValueError: array must not contain infs or NaNs
sage: p.roots(ring=RR, algorithm='pari')
[(-3.50746621104340e451, 1)]
sage: p.roots(ring=AA)
[(-3.5074662110434039?e451, 1)]
sage: p.roots(ring=QQbar)
[(-3.5074662110434039?e451, 1)]
sage: p = bigc*x + 1
sage: p.roots(ring=RR)
[(0.000000000000000, 1)]
sage: p.roots(ring=AA)
[(-2.8510609648967059?e-452, 1)]
sage: p.roots(ring=QQbar)
[(-2.8510609648967059?e-452, 1)]
sage: p = x^2 - bigc
sage: p.roots(ring=RR)
[(-5.92238652153286e225, 1), (5.92238652153286e225, 1)]
sage: p.roots(ring=QQbar)
[(-5.9223865215328558?e225, 1), (5.9223865215328558?e225, 1)]
```

Algorithms used:

For brevity, we will use RR to mean any RealField of any precision; similarly for RIF, CC, and CIF. Since Sage has no specific implementation of Gaussian rationals (or of number fields with embedding, at all), when we refer to Gaussian rationals below we will accept any number field with defining polynomial $x^2 + 1$, mapping the field generator to +I.

We call the base ring of the polynomial K, and the ring given by the ring= argument L. (If ring= is not specified, then L is the same as K.)

If K and L are floating-point (RDF, CDF, RR, or CC), then a floating-point root-finder is used. If L has precision 53 bits or less (RDF and CDF both have precision exactly 53 bits, as do the default RR=RealField() and CC=ComplexField()) then we default to using numpy's roots(); otherwise, we use Pari's polroots(). This choice can be overridden with algorithm='pari' or algorithm='numpy'. If the algorithm is unspecified and numpy's roots() algorithm fails, then we fall back to pari (numpy will fail if some coefficient is infinite, for instance).

If L is AA or RIF, and K is ZZ, QQ, or AA, then the root isolation algorithm sage.rings.polynomial.real_roots.real_roots() is used. (You can call real_roots() directly to get more control than this method gives.)

If L is QQbar or CIF, and K is ZZ, QQ, AA, QQbar, or the Gaussian rationals, then the root isolation algorithm sage.rings.polynomial.complex_roots.complex_roots() is used. (You can call complex_roots() directly to get more control than this method gives.)

If L is AA and K is QQbar or the Gaussian rationals, then complex_roots() is used (as above) to find roots in QQbar, then these roots are filtered to select only the real roots.

If L is floating-point and K is not, then we attempt to change the polynomial ring to L (using .change_ring()) (or, if L is complex and K is not, to the corresponding real field). Then we use either Pari or numpy as specified above.

For all other cases where K is different than L, we just use .change_ring(L) and proceed as below.

The next method, which is used if K is an integral domain, is to attempt to factor the polynomial. If this succeeds, then for every degree-one factor a*x+b, we add -b/a as a root (as long as this quotient is actually in the desired ring).

If factoring over K is not implemented (or K is not an integral domain), and K is finite, then we find the

roots by enumerating all elements of K and checking whether the polynomial evaluates to zero at that value.

Note: We mentioned above that polynomials with multiple roots are always ill-conditioned; if your input is given to n bits of precision, you should not expect more than n/k good bits for a k-fold root. (You can get solutions that make the polynomial evaluate to a number very close to zero; basically the problem is that with a multiple root, there are many such numbers, and it's difficult to choose between them.)

To see why this is true, consider the naive floating-point error analysis model where you just pretend that all floating-point numbers are somewhat imprecise - a little 'fuzzy', if you will. Then the graph of a floating-point polynomial will be a fuzzy line. Consider the graph of $(x-1)^3$; this will be a fuzzy line with a horizontal tangent at $x = 1$, $y = 0$. If the fuzziness extends up and down by about j, then it will extend left and right by about cube_root(j).

TESTS:

```
sage: K.<zeta> = CyclotomicField(2)
sage: R.<x> = K[]
sage: factor(x^3-1)
(x - 1) * (x^2 + x + 1)
```

shift()

Returns this polynomial multiplied by the power x^n. If n is negative, terms below x^n will be discarded. Does not change this polynomial (since polynomials are immutable).

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: p = x^2 + 2*x + 4
sage: p.shift(0)
 x^2 + 2*x + 4
sage: p.shift(-1)
 x + 2
sage: p.shift(-5)
 0
sage: p.shift(2)
 x^4 + 2*x^3 + 4*x^2
```

One can also use the infix shift operator:

```
sage: f = x^3 + x
sage: f >> 2
x
sage: f << 2
x^5 + x^3
```

TESTS:

```
sage: p = R(0)
sage: p.shift(3).is_zero()
True
sage: p.shift(-3).is_zero()
True
```

AUTHORS:

- David Harvey (2006-08-06)
- Robert Bradshaw (2007-04-18): Added support for infix operator.

square()

Returns the square of this polynomial.

TODO:

- This is just a placeholder; for now it just uses ordinary multiplication. But generally speaking, squaring is faster than ordinary multiplication, and it's frequently used, so subclasses may choose to provide a specialised squaring routine.

•Perhaps this even belongs at a lower level? ring_element or something?

AUTHORS:

•David Harvey (2006-09-09)

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: f = x^3 + 1
sage: f.square()
x^6 + 2*x^3 + 1
sage: f*f
x^6 + 2*x^3 + 1
```

squarefree_decomposition()

Return the square-free decomposition of self. This is a partial factorization of self into square-free, relatively prime polynomials.

This is the straightforward algorithm, using only polynomial GCD and polynomial division. Faster algorithms exist. The algorithm comes from the Wikipedia article, "Square-free polynomial".

EXAMPLES:

```
sage: x = polygen(QQ)
sage: p = 37 * (x-1)^3 * (x-2)^3 * (x-1/3)^7 * (x-3/7)
sage: p.squarefree_decomposition()
(37*x - 111/7) * (x^2 - 3*x + 2)^3 * (x - 1/3)^7
sage: p = 37 * (x-2/3)^2
sage: p.squarefree_decomposition()
(37) * (x - 2/3)^2
sage: x = polygen(GF(3))
sage: x.squarefree_decomposition()
...
NotImplementedError: Squarefree decomposition not implemented for Univariate Polynomial Ring
```

subs()

Identical to self(*x).

See the docstring for `self.__call__`.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: f = x^3 + x - 3
sage: f.subs(x=5)
127
sage: f.subs(5)
127
sage: f.subs({x:2})
7
sage: f.subs({})
x^3 + x - 3
sage: f.subs({'x':2})
...
TypeError: keys do not match self's parent
```

substitute()

Identical to self(*x).

See the docstring for `self.__call__`.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: f = x^3 + x - 3
```

```
sage: f.subs(x=5)
127
sage: f.subs(5)
127
sage: f.subs({x:2})
7
sage: f.subs({})
x^3 + x - 3
sage: f.subs({'x':2})
...
TypeError: keys do not match self's parent
```

truncate()

Returns the polynomial of degree ' < n' which is equivalent to self modulo x^n.

EXAMPLES:

```
sage: R.<x> = ZZ[]; S.<y> = R[]
sage: f = y^3 + x*y -3*x; f
y^3 + x*y - 3*x
sage: f.truncate(2)
x*y - 3*x
sage: f.truncate(1)
-3*x
sage: f.truncate(0)
0
```

valuation()

If $f = a_r x^r + a_{r+1} x^{r+1} + \cdots$, with a_r nonzero, then the valuation of f is r. The valuation of the zero polynomial is ∞.

If a prime (or non-prime) p is given, then the valuation is the largest power of p which divides self.

The valuation at ∞ is -self.degree().

EXAMPLES:

```
sage: P,x=PolynomialRing(ZZ,'x').objgen()
sage: (x^2+x).valuation()
1
sage: (x^2+x).valuation(x+1)
1
sage: (x^2+1).valuation()
0
sage: (x^3+1).valuation(infinity)
-3
sage: P(0).valuation()
+Infinity
```

variable_name()

Return name of variable used in this polynomial as a string.

OUTPUT: string

EXAMPLES:

```
sage: R.<t> = QQ[]
sage: f = t^3 + 3/2*t + 5
sage: f.variable_name()
't'
```

variables()

Returns the list of variables occurring in this polynomial.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: x.variables()
(x,)
```

A constant polynomial has no variables.

```
sage: R(2).variables()
()
```

class PolynomialBaseringInjection()

This class is used for conversion from a ring to a polynomial over that ring.

It calls the _new_constant_poly method on the generator, which should be optimized for a particular polynomial type. Technically, it should be a method of the polynomial ring, but few polynomial rings are cython classes.

section()

TESTS:

```
sage: from sage.rings.polynomial.polynomial_element import PolynomialBaseringInjection
sage: m = PolynomialBaseringInjection(RDF, RDF['x'])
sage: m.section()
Generic map:
  From: Univariate Polynomial Ring in x over Real Double Field
  To:   Real Double Field
sage: type(m.section())
<type 'sage.rings.polynomial.polynomial_element.ConstantPolynomialSection'>
```

class Polynomial_generic_dense()

A generic dense polynomial.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(PolynomialRing(QQ,'y'))
sage: f = x^3 - x + 17
sage: type(f)
<type 'sage.rings.polynomial.polynomial_element.Polynomial_generic_dense'>
sage: loads(f.dumps()) == f
True
```

constant_coefficient()

Return the constant coefficient of this polynomial.

OUTPUT: element of base ring

EXAMPLES: sage: R.<t> = QQ[] sage: S.<x> = R[] sage: f = x*t + x + t sage: f.constant_coefficient() t

degree()

EXAMPLES:

```
sage: R.<x> = RDF[]
sage: f = (1+2*x^7)^5
sage: f.degree()
35
```

list()

Return a new copy of the list of the underlying elements of self.

EXAMPLES:

```
sage: R.<x> = GF(17)[]
sage: f = (1+2*x)^3 + 3*x; f
8*x^3 + 12*x^2 + 9*x + 1
sage: f.list()
[1, 9, 12, 8]
```

shift()

Returns this polynomial multiplied by the power x^n. If n is negative, terms below x^n will be discarded. Does not change this polynomial.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(PolynomialRing(QQ,'y'), 'x')
sage: p = x^2 + 2*x + 4
sage: type(p)
<type 'sage.rings.polynomial.polynomial_element.Polynomial_generic_dense'>
sage: p.shift(0)
 x^2 + 2*x + 4
sage: p.shift(-1)
 x + 2
sage: p.shift(2)
 x^4 + 2*x^3 + 4*x^2
```

TESTS:

```
sage: p = R(0)
sage: p.shift(3).is_zero()
True
sage: p.shift(-3).is_zero()
True
```

AUTHORS:

- David Harvey (2006-08-06)

truncate()

Returns the polynomial of degree ' < n' which is equivalent to self modulo x^n.

EXAMPLES:

```
sage: S.<q> = QQ['t']['q']
sage: f = (1+q^10+q^11+q^12).truncate(11); f
q^10 + 1
sage: f = (1+q^10+q^100).truncate(50); f
q^10 + 1
sage: f.degree()
10
sage: f = (1+q^10+q^100).truncate(500); f
q^100 + q^10 + 1
```

TESTS:

Make sure we're not actually testing a specialized implementation.

```
sage: type(f)
<type 'sage.rings.polynomial.polynomial_element.Polynomial_generic_dense'>
```

is_Polynomial()

Return True if f is of type univariate polynomial.

INPUT:

- f - an object

EXAMPLES:

```
sage: from sage.rings.polynomial.polynomial_element import is_Polynomial
sage: R.<x> = ZZ[]
sage: is_Polynomial(x^3 + x + 1)
True
sage: S.<y> = R[]
```

```
sage: f = y^3 + x*y -3*x; f
y^3 + x*y - 3*x
sage: is_Polynomial(f)
True
```

However this function does not return True for genuine multivariate polynomial type objects or symbolic polynomials, since those are not of the same data type as univariate polynomials:

```
sage: R.<x,y> = QQ[]
sage: f = y^3 + x*y -3*x; f
y^3 + x*y - 3*x
sage: is_Polynomial(f)
False
sage: var('x,y')
(x, y)
sage: f = y^3 + x*y -3*x; f
y^3 + x*y - 3*x
sage: is_Polynomial(f)
False
```

make_generic_polynomial()

28.3 Quotients of Univariate Polynomial Rings

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: S = R.quotient(x**3-3*x+1, 'alpha')
sage: S.gen()**2 in S
True
sage: x in S
True
sage: S.gen() in R
False
sage: 1 in S
True
```

PolynomialQuotientRing(*ring, polynomial, names=None*)

Create a quotient of a polynomial ring.

INPUT:

- `ring` - a univariate polynomial ring in one variable.
- `polynomial` - element
- `names` - (optional) name for the variable

OUTPUT: Creates the quotient ring R/I, where R is the ring and I is the principal ideal generated by the polynomial.

EXAMPLES:

We create the quotient ring $\mathbf{Z}[x]/(x^3+7)$, and demonstrate many basic functions with it:

```
sage: Z = IntegerRing()
sage: R = PolynomialRing(Z,'x'); x = R.gen()
sage: S = R.quotient(x^3 + 7, 'a'); a = S.gen()
sage: S
```

```
Univariate Quotient Polynomial Ring in a over Integer Ring with modulus x^3 + 7
sage: a^3
-7
sage: S.is_field()
False
sage: a in S
True
sage: x in S
True
sage: a in R
False
sage: S.polynomial_ring()
Univariate Polynomial Ring in x over Integer Ring
sage: S.modulus()
x^3 + 7
sage: S.degree()
3
```

We create the "iterated" polynomial ring quotient

$$R = (\mathbf{F}_2[y]/(y^2+y+1))[x]/(x^3-5).$$

```
sage: A.<y> = PolynomialRing(GF(2)); A
Univariate Polynomial Ring in y over Finite Field of size 2 (using NTL)
sage: B = A.quotient(y^2 + y + 1, 'y2'); print B
Univariate Quotient Polynomial Ring in y2 over Finite Field of size 2 with modulus y^2 + y + 1
sage: C = PolynomialRing(B, 'x'); x=C.gen(); print C
Univariate Polynomial Ring in x over Univariate Quotient Polynomial Ring in y2 over Finite Field
sage: R = C.quotient(x^3 - 5); print R
Univariate Quotient Polynomial Ring in xbar over Univariate Quotient Polynomial Ring in y2 over
```

Next we create a number field, but viewed as a quotient of a polynomial ring over $\mathbf{Q}$:

```
sage: R = PolynomialRing(RationalField(), 'x'); x = R.gen()
sage: S = R.quotient(x^3 + 2*x - 5, 'a')
sage: S
Univariate Quotient Polynomial Ring in a over Rational Field with modulus x^3 + 2*x - 5
sage: S.is_field()
True
sage: S.degree()
3
```

There are conversion functions for easily going back and forth between quotients of polynomial rings over $\mathbf{Q}$ and number fields:

```
sage: K = S.number_field(); K
Number Field in a with defining polynomial x^3 + 2*x - 5
sage: K.polynomial_quotient_ring()
Univariate Quotient Polynomial Ring in a over Rational Field with modulus x^3 + 2*x - 5
```

The leading coefficient must be a unit (but need not be 1).

```
sage: R = PolynomialRing(Integers(9), 'x'); x = R.gen()
sage: S = R.quotient(2*x^4 + 2*x^3 + x + 2, 'a')
sage: S = R.quotient(3*x^4 + 2*x^3 + x + 2, 'a')
...
TypeError: polynomial must have unit leading coefficient
```

Another example:

```
sage: R.<x> = PolynomialRing(IntegerRing())
sage: f = x^2 + 1
sage: R.quotient(f)
Univariate Quotient Polynomial Ring in xbar over Integer Ring with modulus x^2 + 1
```

class **PolynomialQuotientRing_domain**(*ring, polynomial, name=None*)

EXAMPLES:

```
sage: R.<x> = PolynomialRing(ZZ)
sage: S.<xbar> = R.quotient(x^2 + 1)
sage: S
Univariate Quotient Polynomial Ring in xbar over Integer Ring with modulus x^2 + 1
sage: loads(S.dumps()) == S
True
sage: loads(xbar.dumps()) == xbar
True
```

field_extension(*names*)

Takes a polynomial quotient ring, and returns a tuple with three elements: the NumberField defined by the same polynomial quotient ring, a homomorphism from its parent to the NumberField sending the generators to one another, and the inverse isomorphism.

OUTPUT:

- field
- homomorphism from self to field
- homomorphism from field to self

EXAMPLES:

```
sage: R.<x> = PolynomialRing(Rationals())
sage: S.<alpha> = R.quotient(x^3-2)
sage: F.<b>, f, g = S.field_extension()
sage: F
Number Field in b with defining polynomial x^3 - 2
sage: a = F.gen()
sage: f(alpha)
b
sage: g(a)
alpha
```

Note that the parent ring must be an integral domain:

```
sage: R.<x> = GF(25,'f25')['x']
sage: S.<a> = R.quo(x^3 - 2)
sage: F, g, h = S.field_extension('b')
...
AttributeError: 'PolynomialQuotientRing_generic' object has no attribute 'field_extension'
```

Over a finite field, the corresponding field extension is not a number field:

```
sage: R.<x> = GF(25, 'a')['x']
sage: S.<a> = R.quo(x^3 + 2*x + 1)
sage: F, g, h = S.field_extension('b')
sage: h(F.0^2 + 3)
a^2 + 3
sage: g(x^2 + 2)
b^2 + 2
```

We do an example involving a relative number field:

```
sage: R.<x> = QQ['x']
sage: K.<a> = NumberField(x^3 - 2)
sage: S.<X> = K['X']
sage: Q.<b> = S.quo(X^3 + 2*X + 1)
sage: Q.field_extension('b')
(Number Field in b with defining polynomial X^3 + 2*X + 1 over its base field, ...
  Defn: b |--> b, Relative number field morphism:
  From: Number Field in b with defining polynomial X^3 + 2*X + 1 over its base field
  To:   Univariate Quotient Polynomial Ring in b over Number Field in a with defining polync
  Defn: b |--> b
        a |--> a)
```

We slightly change the example above so it works.

```
sage: R.<x> = QQ['x']
sage: K.<a> = NumberField(x^3 - 2)
sage: S.<X> = K['X']
sage: f = (X+a)^3 + 2*(X+a) + 1
sage: f
X^3 + 3*a*X^2 + (3*a^2 + 2)*X + 2*a + 3
sage: Q.<z> = S.quo(f)
sage: F.<w>, g, h = Q.field_extension()
sage: c = g(z)
sage: f(c)
0
sage: h(g(z))
z
sage: g(h(w))
w
```

AUTHORS:

- Craig Citro (2006-08-07)
- William Stein (2006-08-06)

is_finite()

Return whether or not this quotient ring is finite.

EXAMPLES:

```
sage: R.<x> = ZZ[]
sage: R.quo(1).is_finite()
True
sage: R.quo(x^3-2).is_finite()
False

sage: R.<x> = GF(9,'a')[]
sage: R.quo(2*x^3+x+1).is_finite()
True
sage: R.quo(2).is_finite()
True
```

class PolynomialQuotientRing_field(*ring, polynomial, name=None*)

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: S.<xbar> = R.quotient(x^2 + 1)
sage: S
Univariate Quotient Polynomial Ring in xbar over Rational Field with modulus x^2 + 1
sage: loads(S.dumps()) == S
True
```

```
sage: loads(xbar.dumps()) == xbar
True
```

base_field()
Alias for base_ring, when we're defined over a field.

complex_embeddings(*prec=53*)
Return all homomorphisms of this ring into the approximate complex field with precision prec.
EXAMPLES:

```
sage: R.<x> = QQ[]
sage: f = x^5 + x + 17
sage: k = R.quotient(f)
sage: v = k.complex_embeddings(100)
sage: [phi(k.0^2) for phi in v]
[2.9757207403766761469671194565, -2.4088994371613850098316292196 + 1.9025410530350528612407
```

class **PolynomialQuotientRing_generic**(*ring, polynomial, name=None*)
Quotient of a univariate polynomial ring by an ideal.
EXAMPLES:

```
sage: R.<x> = PolynomialRing(Integers(8)); R
Univariate Polynomial Ring in x over Ring of integers modulo 8
sage: S.<xbar> = R.quotient(x^2 + 1); S
Univariate Quotient Polynomial Ring in xbar over Ring of integers modulo 8 with modulus x^2 + 1
```

We demonstrate object persistence.

```
sage: loads(S.dumps()) == S
True
sage: loads(xbar.dumps()) == xbar
True
```

We create some sample homomorphisms;

```
sage: R.<x> = PolynomialRing(ZZ)
sage: S = R.quo(x^2-4)
sage: f = S.hom([2])
sage: f
Ring morphism:
  From: Univariate Quotient Polynomial Ring in xbar over Integer Ring with modulus x^2 - 4
  To:   Integer Ring
  Defn: xbar |--> 2
sage: f(x)
2
sage: f(x^2 - 4)
0
sage: f(x^2)
4
```

base_ring()
Return the base ring of the polynomial ring, of which this ring is a quotient.
EXAMPLES:
The base ring of $\mathbf{Z}[z]/(z^3+z^2+z+1)$ is $\mathbf{Z}$.

```
sage: R.<z> = PolynomialRing(ZZ)
sage: S.<beta> = R.quo(z^3 + z^2 + z + 1)
```

```
sage: S.base_ring()
Integer Ring
```

Next we make a polynomial quotient ring over S and ask for its basering.

```
sage: T.<t> = PolynomialRing(S)
sage: W = T.quotient(t^99 + 99)
sage: W.base_ring()
Univariate Quotient Polynomial Ring in beta over Integer Ring with modulus z^3 + z^2 + z + 1
```

characteristic()

Return the characteristic of this quotient ring.

This is always the same as the characteristic of the base ring.

EXAMPLES:

```
sage: R.<z> = PolynomialRing(ZZ)
sage: S.<a> = R.quo(z - 19)
sage: S.characteristic()
0
sage: R.<x> = PolynomialRing(GF(9,'a'))
sage: S = R.quotient(x^3 + 1)
sage: S.characteristic()
3
```

degree()

Return the degree of this quotient ring. The degree is the degree of the polynomial that we quotiented out by.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(GF(3))
sage: S = R.quotient(x^2005 + 1)
sage: S.degree()
2005
```

discriminant(*v=None*)

Return the discriminant of this ring over the base ring. This is by definition the discriminant of the polynomial that we quotiented out by.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: S = R.quotient(x^3 + x^2 + x + 1)
sage: S.discriminant()
-16
sage: S = R.quotient((x + 1) * (x + 1))
sage: S.discriminant()
0
```

The discriminant of the quotient polynomial ring need not equal the discriminant of the corresponding number field, since the discriminant of a number field is by definition the discriminant of the ring of integers of the number field:

```
sage: S = R.quotient(x^2 - 8)
sage: S.number_field().discriminant()
8
sage: S.discriminant()
32
```

gen(*n=0*)

Return the generator of this quotient ring. This is the equivalence class of the image of the generator of the polynomial ring.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: S = R.quotient(x^2 - 8, 'gamma')
sage: S.gen()
gamma
```

is_field()

Return whether or not this quotient ring is a field.

EXAMPLES:

```
sage: R.<z> = PolynomialRing(ZZ)
sage: S = R.quo(z^2-2)
sage: S.is_field()
False
sage: R.<x> = PolynomialRing(QQ)
sage: S = R.quotient(x^2 - 2)
sage: S.is_field()
True
```

krull_dimension()

modulus()

Return the polynomial modulus of this quotient ring.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(GF(3))
sage: S = R.quotient(x^2 - 2)
sage: S.modulus()
x^2 + 1
```

ngens()

Return the number of generators of this quotient ring over the base ring. This function always returns 1.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: S.<y> = PolynomialRing(R)
sage: T.<z> = S.quotient(y + x)
sage: T
Univariate Quotient Polynomial Ring in z over Univariate Polynomial Ring in x over Rational
sage: T.ngens()
1
```

number_field()

Return the number field isomorphic to this quotient polynomial ring, if possible.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: S.<alpha> = R.quotient(x^29 - 17*x - 1)
sage: K = S.number_field()
sage: K
Number Field in alpha with defining polynomial x^29 - 17*x - 1
sage: alpha = K.gen()
sage: alpha^29
17*alpha + 1
```

order()

Return the number of elements of this quotient ring.

EXAMPLES:

```
sage: F1.<a> = GF(2^7)
sage: P1.<x> = F1[]
sage: F2 = F1.extension(x^2+x+1, 'u')
sage: F2.order()
16384

sage: F1 = QQ
sage: P1.<x> = F1[]
sage: F2 = F1.extension(x^2+x+1, 'u')
sage: F2.order()
+Infinity
```

polynomial_ring()

Return the polynomial ring of which this ring is the quotient.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: S = R.quotient(x^2-2)
sage: S.polynomial_ring()
Univariate Polynomial Ring in x over Rational Field
```

random_element()

Return a random element of this quotient ring.

EXAMPLES:

```
sage: F1.<a> = GF(2^7)
sage: P1.<x> = F1[]
sage: F2 = F1.extension(x^2+x+1, 'u')
sage: F2.random_element()
(a^6 + 1)*u + a^5 + a^4 + a^3 + 1
```

is_PolynomialQuotientRing(x)

28.4 Elements of Quotients of Univariate Polynomial Rings

EXAMPLES: We create a quotient of a univariate polynomial ring over $\mathbf{Z}$.

```
sage: R.<x> = ZZ[]
sage: S.<a> = R.quotient(x^3 + 3*x -1)
sage: 2 * a^3
-6*a + 2
```

Next we make a univeriate polynomial ring over $\mathbf{Z}[x]/(x^3 + 3x - 1)$.

```
sage: S.<y> = S[]
```

And, we quotient out that by $y^2 + a$.

```
sage: T.<z> = S.quotient(y^2+a)
```

In the quotient z^2 is $-a$.

```
sage: z^2
-a
```

And since $a^3 = -3x + 1$, we have:

```
sage: z^6
3*a - 1
```

```
sage: R.<x> = PolynomialRing(Integers(9))
sage: S.<a> = R.quotient(x^4 + 2*x^3 + x + 2)
sage: a^100
7*a^3 + 8*a + 7
```

```
sage: R.<x> = PolynomialRing(QQ)
sage: S.<a> = R.quotient(x^3-2)
sage: a
a
sage: a^3
2
```

For the purposes of comparison in Sage the quotient element a^3 is equal to x^3. This is because when the comparison is performed, the right element is coerced into the parent of the left element, and x^3 coerces to a^3.

```
sage: a == x
True
sage: a^3 == x^3
True
sage: x^3
x^3
sage: S(x^3)
2
```

AUTHORS:

- William Stein

class **PolynomialQuotientRingElement** (*parent, polynomial, check=True*)

Element of a quotient of a polynomial ring.

charpoly (*var*)

The characteristic polynomial of this element, which is by definition the characteristic polynomial of right multiplication by this element.

INPUT:

•`var` - string - the variable name

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: S.<a> = R.quo(x^3 -389*x^2 + 2*x - 5)
sage: a.charpoly('X')
X^3 - 389*X^2 + 2*X - 5
```

fcp (*var='x'*)

Return the factorization of the characteristic polynomial of this element.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: S.<a> = R.quotient(x^3 -389*x^2 + 2*x - 5)
sage: a.fcp('x')
x^3 - 389*x^2 + 2*x - 5
```

```
sage: S(1).fcp('y')
(y - 1)^3
```

field_extension(*names*)

Given a polynomial with base ring a quotient ring, return a 3-tuple: a number field defined by the same polynomial, a homomorphism from its parent to the number field sending the generators to one another, and the inverse isomorphism.

INPUT:

- names - name of generator of output field

OUTPUT:

- field
- homomorphism from self to field
- homomorphism from field to self

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: S.<alpha> = R.quotient(x^3-2)
sage: F.<a>, f, g = alpha.field_extension()
sage: F
Number Field in a with defining polynomial x^3 - 2
sage: a = F.gen()
sage: f(alpha)
a
sage: g(a)
alpha
```

Over a finite field, the corresponding field extension is not a number field:

```
sage: R.<x> = GF(25,'b')['x']
sage: S.<a> = R.quo(x^3 + 2*x + 1)
sage: F.<b>, g, h = a.field_extension()
sage: h(b^2 + 3)
a^2 + 3
sage: g(x^2 + 2)
b^2 + 2
```

We do an example involving a relative number field:

```
sage: R.<x> = QQ['x']
sage: K.<a> = NumberField(x^3-2)
sage: S.<X> = K['X']
sage: Q.<b> = S.quo(X^3 + 2*X + 1)
sage: F, g, h = b.field_extension('c')
```

Another more awkward example:

```
sage: R.<x> = QQ['x']
sage: K.<a> = NumberField(x^3-2)
sage: S.<X> = K['X']
sage: f = (X+a)^3 + 2*(X+a) + 1
sage: f
X^3 + 3*a*X^2 + (3*a^2 + 2)*X + 2*a + 3
sage: Q.<z> = S.quo(f)
sage: F.<w>, g, h = z.field_extension()
sage: c = g(z)
sage: f(c)
0
sage: h(g(z))
```

```
z
sage: g(h(w))
w
```

AUTHORS:

- Craig Citro (2006-08-06)
- William Stein (2006-08-06)

lift()

Return lift of this polynomial quotient ring element to the unique equivalent polynomial of degree less than the modulus.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: S.<a> = R.quotient(x^3-2)
sage: b = a^2 - 3
sage: b
a^2 - 3
sage: b.lift()
x^2 - 3
```

list()

Return list of the elements of self, of length the same as the degree of the quotient polynomial ring.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: S.<a> = R.quotient(x^3 + 2*x - 5)
sage: a^10
-134*a^2 - 35*a + 300
sage: (a^10).list()
[300, -35, -134]
```

matrix()

The matrix of right multiplication by this element on the power basis for the quotient ring.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: S.<a> = R.quotient(x^3 + 2*x - 5)
sage: a.matrix()
[ 0  1  0]
[ 0  0  1]
[ 5 -2  0]
```

minpoly()

The minimal polynomial of this element, which is by definition the minimal polynomial of right multiplication by this element.

norm()

The norm of this element, which is the norm of the matrix of right multiplication by this element.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: S.<a> = R.quotient(x^3 -389*x^2 + 2*x - 5)
sage: a.norm()
5
```

trace()

The trace of this element, which is the trace of the matrix of right multiplication by this element.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: S.<a> = R.quotient(x^3 -389*x^2 + 2*x - 5)
sage: a.trace()
389
```

28.5 Term Orderings

Sage supports the following term orderings:

Lexicographic (*lex*) $x^a < x^b \Leftrightarrow \exists\, 0 \leq i < n : a_0 = b_0, \ldots, a_{i-1} = b_{i-1}, a_i < b_i$

EXAMPLES:

```
sage: P.<x,y,z> = PolynomialRing(QQ, 3, order='lex')
sage: x > y
True
sage: x > y^2
True
sage: x > 1
True
sage: x^1*y^2 > y^3*z^4
True
sage: x^3*y^2*z^4 < x^3*y^2*z^1
False
```

This term ordering is called 'lp' in Singular.

Degree reverse lexicographic (*degrevlex*) Let $deg(x^a) = a_0 + \cdots + a_{n-1}$, then $x^a < x^b \Leftrightarrow deg(x^a) < deg(x^b)$ or $deg(x^a) = deg(x^b)$ and $\exists\, 0 \leq i < n : a_{n-1} = b_{n-1}, \ldots, a_{i+1} = b_{i+1}, a_i > b_i$.

EXAMPLES:

```
sage: P.<x,y,z> = PolynomialRing(QQ, 3, order='degrevlex')
sage: x > y
True
sage: x > y^2*z
False
sage: x > 1
True
sage: x^1*y^5*z^2 > x^4*y^1*z^3
True
sage: x^2*y*z^2 > x*y^3*z
False
```

This term ordering is called 'dp' in Singular.

Degree lexicographic (*deglex*) Let $deg(x^a) = a_0 + \cdots + a_{n-1}$, then $x^a < x^b \Leftrightarrow deg(x^a) < deg(x^b)$ or $deg(x^a) = deg(x^b)$ and $\exists\, 0 \leq i < n : a_0 = b_0, \ldots, a_{i-1} = b_{i-1}, a_i < b_i$.

EXAMPLES:

```
sage: P.<x,y,z> = PolynomialRing(QQ, 3, order='deglex')
sage: x > y
True
sage: x > y^2*z
False
sage: x > 1
True
```

```
sage: x^1*y^2*z^3 > x^3*y^2*z^0
True
sage: x^2*y*z^2 > x*y^3*z
True
```

This term order is called 'Dp' in Singular.

Inverse lexicographic (*invlex*) $x^a < x^b \Leftrightarrow \exists\ 0 \leq i < n : a_{n-1} = b_{n-1}, \ldots, a_{i+1} = b_{i+1}, a_i < b_i$.

EXAMPLES:

```
sage: P.<x,y,z> = PolynomialRing(QQ, 3, order='invlex')
sage: x > y
False
sage: y > x^2
True
sage: x > 1
True
sage: x*y > z
False
```

This term ordering only makes sense in a non-commutative setting because if P is the ring $k[x_1, \ldots, x_n]$ and term ordering 'invlex' then it is equivalent to the ring $k[x_n, \ldots, x_1]$ with term ordering 'lex'.

This ordering is called 'rp' in Singular.

Negative lexicographic (*neglex*) $x^a < x^b \Leftrightarrow \exists\ 0 \leq i < n : a_0 = b_0, \ldots, a_{i-1} = b_{i-1}, a_i > b_i$

EXAMPLES:

```
sage: P.<x,y,z> = PolynomialRing(QQ, 3, order='neglex')
sage: x > y
False
sage: x > 1
False
sage: x^1*y^2 > y^3*z^4
False
sage: x^3*y^2*z^4 < x^3*y^2*z^1
True
sage: x*y > z
False
```

This term ordering is called 'ls' in Singular.

Negative degree reverse lexicographic (*negdegrevlex*) Let $deg(x^a) = a_0 + \cdots + a_{n-1}$, then $x^a < x^b \Leftrightarrow deg(x^a) > deg(x^b)$ or $deg(x^a) = deg(x^b)$ and $\exists\ 0 \leq i < n : a_{n-1} = b_{n-1}, \ldots, a_{i+1} = b_{i+1}, a_i > b_i$.

EXAMPLES:

```
sage: P.<x,y,z> = PolynomialRing(QQ, 3, order='negdegrevlex')
sage: x > y
True
sage: x > x^2
True
sage: x > 1
False
sage: x^1*y^2 > y^3*z^4
True
sage: x^2*y*z^2 > x*y^3*z
False
```

This term ordering is called 'ds' in Singular.

Negative degree lexicographic (*negdeglex*) Let $deg(x^a) = a_0 + \cdots + a_{n-1}$, then $x^a < x^b \Leftrightarrow deg(x^a) > deg(x^b)$ or $deg(x^a) = deg(x^b)$ and $\exists\ 0 \leq i < n : a_0 = b_0, \ldots, a_{i-1} = b_{i-1}, a_i < b_i$.

EXAMPLES:

```
sage: P.<x,y,z> = PolynomialRing(QQ, 3, order='negdeglex')
sage: x > y
True
sage: x > x^2
True
sage: x > 1
False
sage: x^1*y^2 > y^3*z^4
True
sage: x^2*y*z^2 > x*y^3*z
True
```

This term ordering is called 'Ds' in Singular.

Of these, only 'degrevlex', 'deglex', 'invlex' and 'lex' are global orderings.

Additionally all these monomial orderings may be combined to product or block orderings, defined as:

Let $x = (x_0, \ldots, x_{n-1})$ and $y = (y_0, \ldots, y_{m-1})$ be two ordered sets of variables, $<_1$ a monomial ordering on $k[x]$ and $<_2$ a monomial ordering on $k[y]$.

The product ordering (or block ordering) $< := (<_1, <_2)$ on $k[x, y]$ is defined as: $x^a y^b < x^A y^B \Leftrightarrow x^a <_1 x^A$ or $(x^a = x^A$ and $y^b <_2 y^B)$.

These block orderings are constructed in Sage by giving a comma separated list of monomial orderings with the length of each block attached to them.

EXAMPLE:

As an example, consider constructing a block ordering where the first four variables are compared using the degree reverse lexicographical ordering while the last two variables in the second block are compared using negative lexicographical ordering.

```
sage: P.<a,b,c,d,e,f> = PolynomialRing(QQ, 6,order='degrevlex(4),neglex(2)')
sage: a > c^4
False
sage: a > e^4
True
sage: e > f^2
False
```

The same result can be achieved by:

```
sage: T1 = TermOrder('degrevlex',4)
sage: T2 = TermOrder('neglex',2)
sage: T = T1 + T2
sage: P.<a,b,c,d,e,f> = PolynomialRing(QQ, 6, order=T)
sage: a > c^4
False
sage: a > e^4
True
```

If any other unsupported term ordering is given the provided string is passed through as is to Singular, Macaulay2, and Magma. This ensures that it is for example possible to calculate a Groebner basis with respect to some term ordering

Singular supports but Sage doesn't. However a warning is issued to make the user aware of the situation and potential typos:

```
sage: T = TermOrder("royalorder")
verbose 0 (...: term_order.py, __init__) Term ordering 'royalorder' unknown.
```

AUTHORS:

- David Joyner and William Stein: initial version multi_polynomial_ring
- Kiran S. Kedlaya: added macaulay2 interface
- Martin Albrecht: implemented native term orderings, refactoring

class TermOrder (*name='lex', n=0, blocks=True*)

A term order.

See `sage.rings.polynomial.term_order` for details on supported term orderings.

compare_tuples_Dp (*f, g*)

Compares two exponent tuples with respect to the degree lexicographical term order.

INPUT:

- `f` - exponent tuple
- `g` - exponent tuple

EXAMPLE:

```
sage: P.<x,y> = PolynomialRing(QQbar, 2, order='deglex')
sage: x > y^2 # indirect doctest
False
sage: x > 1
True
```

compare_tuples_Ds (*f, g*)

Compares two exponent tuples with respect to the negative degree lexicographical term order.

INPUT:

- `f` - exponent tuple
- `g` - exponent tuple

EXAMPLE:

```
sage: P.<x,y> = PolynomialRing(QQbar, 2, order='negdeglex')
sage: x > y^2 # indirect doctest
True
sage: x > 1
False
```

compare_tuples_block (*f, g*)

Compares two exponent tuples with respect to the block ordering as specified when constructing this element.

INPUT:

- `f` - exponent tuple
- `g` - exponent tuple

EXAMPLE:

```
sage: P.<a,b,c,d,e,f>=PolynomialRing(QQbar, 6, order='degrevlex(3),degrevlex(3)')
sage: a > c^4 # indirect doctest
False
sage: a > e^4
True
```

compare_tuples_dp(*f*, *g*)

Compares two exponent tuples with respect to the degree reversed lexicographical term order.

INPUT:

- f - exponent tuple
- g - exponent tuple

EXAMPLE:

```
sage: P.<x,y> = PolynomialRing(QQbar, 2, order='degrevlex')
sage: x > y^2 # indirect doctest
False
sage: x > 1
True
```

compare_tuples_ds(*f*, *g*)

Compares two exponent tuples with respect to the negative degree reverse lexicographical term order.

INPUT:

- f - exponent tuple
- g - exponent tuple

EXAMPLE:

```
sage: P.<x,y> = PolynomialRing(QQbar, 2, order='negdegrevlex')
sage: x > y^2 # indirect doctest
True
sage: x > 1
False
```

compare_tuples_lp(*f*, *g*)

Compares two exponent tuples with respect to the lexicographical term order.

INPUT:

- f - exponent tuple
- g - exponent tuple

EXAMPLE:

```
sage: P.<x,y> = PolynomialRing(QQbar, 2, order='lex')
sage: x > y^2 # indirect doctest
True
sage: x > 1
True
```

compare_tuples_ls(*f*, *g*)

Compares two exponent tuples with respect to the negative lexicographical term order.

INPUT:

- f - exponent tuple
- g - exponent tuple

EXAMPLE:

```
sage: P.<x,y> = PolynomialRing(QQbar, 2, order='neglex')
sage: x > y^2 # indirect doctest
False
sage: x > 1
False
```

compare_tuples_rp(*f*, *g*)

Compares two exponent tuples with respect to the inversed lexicographical term order.

INPUT:

- f - exponent tuple
- g - exponent tuple

EXAMPLE:

```
sage: P.<x,y> = PolynomialRing(QQbar, 2, order='invlex')
sage: x > y^2 # indirect doctest
False
sage: x > 1
True
```

greater_tuple_Dp (*f*, *g*)

Returns the greater exponent tuple with respect to the total degree lexicographical term order.

INPUT:

- f - exponent tuple
- g - exponent tuple

EXAMPLE:

```
sage: P.<x,y,z> = PolynomialRing(QQbar, 3, order='deglex')
sage: f = x + y; f.lm() # indirect doctest
x
sage: f = x + y^2*z; f.lm()
y^2*z
```

This method is called by the lm/lc/lt methods of `MPolynomial_polydict`.

greater_tuple_Ds (*f*, *g*)

Returns the greater exponent tuple with respect to the negative degree lexicographical term order.

INPUT:

- f - exponent tuple
- g - exponent tuple

EXAMPLE:

```
sage: P.<x,y,z> = PolynomialRing(QQbar, 3, order='negdeglex')
sage: f = x + y; f.lm() # indirect doctest
x
sage: f = x + x^2; f.lm()
x
sage: f = x^2*y*z^2 + x*y^3*z; f.lm()
x^2*y*z^2
```

This method is called by the lm/lc/lt methods of `MPolynomial_polydict`.

greater_tuple_block (*f*, *g*)

Returns the greater exponent tuple with respect to the block ordering as specified when constructing this element.

This method is called by the lm/lc/lt methods of `MPolynomial_polydict`.

INPUT:

- f - exponent tuple
- g - exponent tuple

EXAMPLE:

```
sage: P.<a,b,c,d,e,f>=PolynomialRing(QQbar, 6, order='degrevlex(3),degrevlex(3)')
sage: f = a + c^4; f.lm() # indirect doctest
c^4
sage: g = a + e^4; g.lm()
a
```

greater_tuple_dp(*f*, *g*)

Returns the greater exponent tuple with respect to the total degree reversed lexicographical term order.

INPUT:

- f - exponent tuple
- g - exponent tuple

EXAMPLES:

```
sage: P.<x,y,z> = PolynomialRing(QQbar, 3, order='degrevlex')
sage: f = x + y; f.lm() # indirect doctest
x
sage: f = x + y^2*z; f.lm()
y^2*z
```

This method is called by the lm/lc/lt methods of MPolynomial_polydict.

greater_tuple_ds(*f*, *g*)

Returns the greater exponent tuple with respect to the negative degree reverse lexicographical term order.

INPUT:

- f - exponent tuple
- g - exponent tuple

EXAMPLE:

```
sage: P.<x,y,z> = PolynomialRing(QQbar, 3, order='negdegrevlex')
sage: f = x + y; f.lm() # indirect doctest
x
sage: f = x + x^2; f.lm()
x
sage: f = x^2*y*z^2 + x*y^3*z; f.lm()
x*y^3*z
```

This method is called by the lm/lc/lt methods of MPolynomial_polydict.

greater_tuple_lp(*f*, *g*)

Returns the greater exponent tuple with respect to the lexicographical term order.

INPUT:

- f - exponent tuple
- g - exponent tuple

EXAMPLES:

```
sage: P.<x,y,z> = PolynomialRing(QQbar, 3, order='lex')
sage: f = x + y^2; f.lm() # indirect doctest
x
```

This method is called by the lm/lc/lt methods of MPolynomial_polydict.

greater_tuple_ls(*f*, *g*)

Returns the greater exponent tuple with respect to the negative lexicographical term order.

This method is called by the lm/lc/lt methods of MPolynomial_polydict.

INPUT:

- f - exponent tuple
- g - exponent tuple

EXAMPLE:

```
sage: P.<a,b,c,d,e,f>=PolynomialRing(QQbar, 6, order='degrevlex(3),degrevlex(3)')
sage: f = a + c^4; f.lm() # indirect doctest
c^4
sage: g = a + e^4; g.lm()
a
```

greater_tuple_rp(*f*, *g*)

Returns the greater exponent tuple with respect to the inversed lexicographical term order.

INPUT:

- f - exponent tuple
- g - exponent tuple

EXAMPLE:

```
sage: P.<x,y,z> = PolynomialRing(QQbar, 3, order='invlex')
sage: f = x + y; f.lm() # indirect doctest
y
sage: f = y + x^2; f.lm()
y
```

This method is called by the lm/lc/lt methods of MPolynomial_polydict.

is_global()

Return True if this term ordering is definitely global. Return False otherwise, which includes unknown term orderings.

EXAMPLE:

```
sage: T = TermOrder('lex')
sage: T.is_global()
True
sage: T = TermOrder('degrevlex', 3) + TermOrder('degrevlex', 3)
sage: T.is_global()
True
sage: T = TermOrder('degrevlex', 3) + TermOrder('negdegrevlex', 3)
sage: T.is_global()
False
```

is_local()

Return True if this term ordering is definitely local. Return False otherwise, which includes unknown term orderings.

EXAMPLE:

```
sage: T = TermOrder('lex')
sage: T.is_local()
False
sage: T = TermOrder('negdeglex', 3) + TermOrder('negdegrevlex', 3)
sage: T.is_local()
True
sage: T = TermOrder('degrevlex', 3) + TermOrder('negdegrevlex', 3)
sage: T.is_local()
False
```

macaulay2_str()

Return a Macaulay2 representation of self.

Used to convert polynomial rings to their Macaulay2 representation.

EXAMPLE:

```
sage: P = PolynomialRing(GF(127), 8,names='x',order='degrevlex(3),lex(5)')
sage: T = P.term_order()
sage: T.macaulay2_str()
'(GRevLex => 3,Lex => 5)'
sage: P._macaulay2_() # optional - macaulay2
ZZ/127 [x0, x1, x2, x3, x4, x5, x6, x7, MonomialOrder => {GRevLex => 3, Lex => 5}, MonomialS
```

magma_str()

Return a MAGMA representation of self.

Used to convert polynomial rings to their MAGMA representation.

EXAMPLE:

```
sage: P = PolynomialRing(GF(127), 10,names='x',order='degrevlex')
sage: magma(P)                                                    # optional - magma
Polynomial ring of rank 10 over GF(127)
Graded Reverse Lexicographical Order
Variables: x0, x1, x2, x3, x4, x5, x6, x7, x8, x9

sage: T = P.term_order()
sage: T.magma_str()
'"grevlex"'
```

name()

EXAMPLE:

```
sage: TermOrder('lex').name()
'lex'
```

singular_str()

Return a SINGULAR representation of self.

Used to convert polynomial rings to their SINGULAR representation.

EXAMPLE:

```
sage: P = PolynomialRing(GF(127),10,names='x',order='lex(3),deglex(5),lex(2)')
sage: T = P.term_order()
sage: T.singular_str()
'(lp(3),Dp(5),lp(2))'
sage: P._singular_()
//   characteristic : 127
//   number of vars : 10
//        block   1 : ordering lp
//                  : names    x0 x1 x2
//        block   2 : ordering Dp
//                  : names    x3 x4 x5 x6 x7
//        block   3 : ordering lp
//                  : names    x8 x9
//        block   4 : ordering C
```

28.6 Multivariate Polynomial Rings

Sage implements multivariate polynomial rings through several backends. The generic implementation used the classes `PolyDict` and `ETuple` to construct a dictionary with exponent tuples as keys and coefficients as values.

Additionally, specialized and optimized implementations are provided for multivariate polynomials over $\mathbf{Q}$ and $\mathbf{F}_p$. These are implemented in the classes `MPolynomialRing_libsingular` and `MPolynomial_libsingular`

AUTHORS:

- David Joyner and William Stein
- Kiran S. Kedlaya (2006-02-12): added Macaulay2 analogues of Singular features
- Martin Albrecht (2006-04-21): reorganize class hiearchy for singular rep
- Martin Albrecht (2007-04-20): reorganized class hierarchy to support Pyrex implementations
- Robert Bradshaw (2007-08-15): Coercions from rings in a subset of the variables.

EXAMPLES:

We construct the Frobenius morphism on $\mathrm{F}_5[x, y, z]$ over $\mathbf{F}_5$:

```
sage: R, (x,y,z) = PolynomialRing(GF(5), 3, 'xyz').objgens()
sage: frob = R.hom([x^5, y^5, z^5])
sage: frob(x^2 + 2*y - z^4)
-z^20 + x^10 + 2*y^5
sage: frob((x + 2*y)^3)
x^15 + x^10*y^5 + 2*x^5*y^10 - 2*y^15
sage: (x^5 + 2*y^5)^3
x^15 + x^10*y^5 + 2*x^5*y^10 - 2*y^15
```

We make a polynomial ring in one variable over a polynomial ring in two variables:

```
sage: R.<x, y> = PolynomialRing(QQ, 2)
sage: S.<t> = PowerSeriesRing(R)
sage: t*(x+y)
(x + y)*t
```

class MPolynomialRing_macaulay2_repr()

is_exact()

class MPolynomialRing_polydict(*base_ring, n, names, order*)

Multivariable polynomial ring.

EXAMPLES:

```
sage: R = PolynomialRing(Integers(12), 'x', 5); R
Multivariate Polynomial Ring in x0, x1, x2, x3, x4 over Ring of integers modulo 12
sage: loads(R.dumps()) == R
True
```

class MPolynomialRing_polydict_domain(*base_ring, n, names, order*)

ideal(**gens, **kwds*)

Create an ideal in this polynomial ring.

is_field()

is_integral_domain()

monomial_all_divisors(*t*)

Return a list of all monomials that divide t, coefficients are ignored.

INPUT:

- t - a monomial

OUTPUT: a list of monomials

EXAMPLE:

```
sage: from sage.rings.polynomial.multi_polynomial_ring import MPolynomialRing_polydict_domai
sage: P.<x,y,z>=MPolynomialRing_polydict_domain(QQ,3, order='degrevlex')
sage: P.monomial_all_divisors(x^2*z^3)
[x, x^2, z, x*z, x^2*z, z^2, x*z^2, x^2*z^2, z^3, x*z^3, x^2*z^3]
```

ALGORITHM: addwithcarry idea by Toon Segers

monomial_divides(*a, b*)

Return False if a does not divide b and True otherwise.

INPUT:

- a - monomial
- b - monomial

EXAMPLES:

```
sage: P.<x,y,z>=MPolynomialRing(ZZ,3, order='degrevlex')
doctest:1: DeprecationWarning: MPolynomialRing is deprecated, use PolynomialRing instead!
sage: P.monomial_divides(x*y*z, x^3*y^2*z^4)
True
sage: P.monomial_divides(x^3*y^2*z^4, x*y*z)
False
```

TESTS:

```
sage: P.<x,y,z>=MPolynomialRing(ZZ,3, order='degrevlex')
sage: P.monomial_divides(P(1), P(0))
True
sage: P.monomial_divides(P(1), x)
True
```

monomial_lcm(*f*, *g*)

LCM for monomials. Coefficients are ignored.

INPUT:

- f - monomial
- g - monomial

EXAMPLE:

```
sage: from sage.rings.polynomial.multi_polynomial_ring import MPolynomialRing_polydict_domai
sage: P.<x,y,z>=MPolynomialRing_polydict_domain(QQ,3, order='degrevlex')
sage: P.monomial_lcm(3/2*x*y,x)
x*y
```

TESTS:

```
sage: from sage.rings.polynomial.multi_polynomial_ring import MPolynomialRing_polydict_domai
sage: R.<x,y,z>=MPolynomialRing_polydict_domain(QQ,3, order='degrevlex')
sage: P.<x,y,z>=MPolynomialRing_polydict_domain(QQ,3, order='degrevlex')
sage: P.monomial_lcm(x*y,R.gen())
x*y

sage: P.monomial_lcm(P(3/2),P(2/3))
1

sage: P.monomial_lcm(x,P(1))
x
```

monomial_pairwise_prime(*h*, *g*)

Return True if h and g are pairwise prime. Both are treated as monomials.

INPUT:

- h - monomial
- g - monomial

EXAMPLES:

```
sage: from sage.rings.polynomial.multi_polynomial_ring import MPolynomialRing_polydict_domai
sage: P.<x,y,z>=MPolynomialRing_polydict_domain(QQ,3, order='degrevlex')
sage: P.monomial_pairwise_prime(x^2*z^3, y^4)
True
```

```
sage: P.monomial_pairwise_prime(1/2*x^3*y^2, 3/4*y^3)
False
```

TESTS:

```
sage: from sage.rings.polynomial.multi_polynomial_ring import MPolynomialRing_polydict_domai
sage: P.<x,y,z>=MPolynomialRing_polydict_domain(QQ,3, order='degrevlex')
sage: Q.<x,y,z>=MPolynomialRing_polydict_domain(QQ,3, order='degrevlex')
sage: P.monomial_pairwise_prime(x^2*z^3, Q('y^4'))
True

sage: P.monomial_pairwise_prime(1/2*x^3*y^2, Q(0))
True

sage: P.monomial_pairwise_prime(P(1/2),x)
False
```

monomial_quotient (*f, g, coeff=False*)

Return f/g, where both f and g are treated as monomials. Coefficients are ignored by default.

INPUT:

- `f` - monomial
- `g` - monomial
- `coeff` - divide coefficents as well (default: False)

EXAMPLE:

```
sage: from sage.rings.polynomial.multi_polynomial_ring import MPolynomialRing_polydict_domai
sage: P.<x,y,z>=MPolynomialRing_polydict_domain(QQ, 3, order='degrevlex')
sage: P.monomial_quotient(3/2*x*y,x)
y

sage: P.monomial_quotient(3/2*x*y,2*x,coeff=True)
3/4*y
```

TESTS:

```
sage: from sage.rings.polynomial.multi_polynomial_ring import MPolynomialRing_polydict_domai
sage: R.<x,y,z>=MPolynomialRing_polydict_domain(QQ,3, order='degrevlex')
sage: P.<x,y,z>=MPolynomialRing_polydict_domain(QQ,3, order='degrevlex')
sage: P.monomial_quotient(x*y,x)
y

sage: P.monomial_quotient(x*y,R.gen())
y

sage: P.monomial_quotient(P(0),P(1))
0

sage: P.monomial_quotient(P(1),P(0))
...
ZeroDivisionError

sage: P.monomial_quotient(P(3/2),P(2/3), coeff=True)
9/4

sage: P.monomial_quotient(x,y) # Note the wrong result
x*y^-1
```

```
sage: P.monomial_quotient(x,P(1))
x
```

Note: Assumes that the head term of f is a multiple of the head term of g and return the multiplicant m. If this rule is violated, funny things may happen.

monomial_reduce (*f, G*)

Try to find a g in G where g.lm() divides f. If found (g,flt) is returned, (0,0) otherwise, where flt is f/g.lm(). It is assumed that G is iterable and contains ONLY elements in self.

INPUT:

- f - monomial
- G - list/set of mpolynomials

EXAMPLES:

```
sage: from sage.rings.polynomial.multi_polynomial_ring import MPolynomialRing_polydict_domai
sage: P.<x,y,z>=MPolynomialRing_polydict_domain(QQ,3, order='degrevlex')
sage: f = x*y^2
sage: G = [ 3/2*x^3 + y^2 + 1/2, 1/4*x*y + 2/7, P(1/2)  ]
sage: P.monomial_reduce(f,G)
(y, 1/4*x*y + 2/7)
```

TESTS:

```
sage: from sage.rings.polynomial.multi_polynomial_ring import MPolynomialRing_polydict_domai
sage: P.<x,y,z>=MPolynomialRing_polydict_domain(QQ,3, order='degrevlex')
sage: f = x*y^2
sage: G = [ 3/2*x^3 + y^2 + 1/2, 1/4*x*y + 2/7, P(1/2)  ]

sage: P.monomial_reduce(P(0),G)
(0, 0)

sage: P.monomial_reduce(f,[P(0)])
(0, 0)
```

28.7 Multivariate Polynomials

AUTHORS:

- David Joyner: first version
- William Stein: use dict's instead of lists
- Martin Albrecht malb@informatik.uni-bremen.de: some functions added
- William Stein (2006-02-11): added better __div__ behavior.
- Kiran S. Kedlaya (2006-02-12): added Macaulay2 analogues of some Singular features
- William Stein (2006-04-19): added e.g., `f[1,3]` to get coeff of xy^3; added examples of the new `R.x,y = PolynomialRing(QQ,2)` notation.
- Martin Albrecht: improved singular coercions (restructured class hierarchy) and added ETuples
- Robert Bradshaw (2007-08-14): added support for coercion of polynomials in a subset of variables (including multi-level univariate rings)
- Joel B. Mohler (2008-03): Refactored interactions with ETuples.

EXAMPLES:

We verify Lagrange's four squares identity:

```
sage: R.<a0,a1,a2,a3,b0,b1,b2,b3> = QQbar[]
sage: (a0^2 + a1^2 + a2^2 + a3^2)*(b0^2 + b1^2 + b2^2 + b3^2) == (a0*b0 - a1*b1 - a2*b2 - a3*b3)^2 +
True
```

class MPolynomial_element (*parent, x*)

change_ring (*R*)

element ()

class MPolynomial_polydict (*parent, x*)

Multivariate polynomials implemented in pure python using polydicts.

coefficient (*degrees*)

Return the coefficient of the variables with the degrees specified in the python dictionary `degrees`. Mathematically, this is the coefficient in the base ring adjoined by the variables of this ring not listed in `degrees`. However, the result has the same parent as this polynomial.

This function contrasts with the function `monomial_coefficient` which returns the coefficient in the base ring of a monomial.

INPUT:

- `degrees` - Can be any of:
  - a dictionary of degree restrictions
  - a list of degree restrictions (with None in the unrestricted variables)
  - a monomial (very fast, but not as flexible)

OUTPUT: element of the parent of self

See Also:

For coefficients of specific monomials, look at `monomial_coefficient()`.

EXAMPLES:

```
sage: R.<x, y> = QQbar[]
sage: f = 2 * x * y
sage: c = f.coefficient({x:1,y:1}); c
2
sage: c.parent()
Multivariate Polynomial Ring in x, y over Algebraic Field
sage: c in PolynomialRing(QQbar, 2, names = ['x','y'])
True
sage: f = y^2 - x^9 - 7*x + 5*x*y
sage: f.coefficient({y:1})
5*x
sage: f.coefficient({y:0})
-x^9 + (-7)*x
sage: f.coefficient({x:0,y:0})
0
sage: f=(1+y+y^2)*(1+x+x^2)
sage: f.coefficient({x:0})
y^2 + y + 1
sage: f.coefficient([0,None])
y^2 + y + 1
sage: f.coefficient(x)
y^2 + y + 1
sage: # Be aware that this may not be what you think!
sage: # The physical appearance of the variable x is deceiving -- particularly if the expone
```

```
sage: f.coefficient(x^0) # outputs the full polynomial
x^2*y^2 + x^2*y + x*y^2 + x^2 + x*y + y^2 + x + y + 1

sage: R.<x,y> = RR[]
sage: f=x*y+5
sage: c=f.coefficient({x:0,y:0}); c
5.00000000000000
sage: parent(c)
Multivariate Polynomial Ring in x, y over Real Field with 53 bits of precision
```

AUTHORS:

- Joel B. Mohler (2007-10-31)

constant_coefficient()

Return the constant coefficient of this multivariate polynomial.

EXAMPLES:

```
sage: R.<x,y> = QQbar[]
sage: f = 3*x^2 - 2*y + 7*x^2*y^2 + 5
sage: f.constant_coefficient()
5
sage: f = 3*x^2
sage: f.constant_coefficient()
0
```

degree(*x=None*)

Return the degree of self in x, where x must be one of the generators for the parent of self.

INPUT:

- x - multivariate polynomial (a generator of the parent of self) If x is not specified (or is None), return the total degree, which is the maximum degree of any monomial.

OUTPUT: integer

EXAMPLE:

```
sage: R.<x,y> = RR[]
sage: f = y^2 - x^9 - x
sage: f.degree(x)
9
sage: f.degree(y)
2
sage: (y^10*x - 7*x^2*y^5 + 5*x^3).degree(x)
3
sage: (y^10*x - 7*x^2*y^5 + 5*x^3).degree(y)
10
```

degrees()

Returns a tuple (precisely - an ETuple) with the degree of each variable in this polynomial. The list of degrees is, of course, ordered by the order of the generators.

EXAMPLES:

```
sage: R.<x,y,z>=PolynomialRing(QQbar)
sage: f = 3*x^2 - 2*y + 7*x^2*y^2 + 5
sage: f.degrees()
(2, 2, 0)
sage: f = x^2+z^2
sage: f.degrees()
(2, 0, 2)
sage: f.total_degree()  # this simply illustrates that total degree is not the sum of the de
2
```

```
sage: R.<x,y,z,u>=PolynomialRing(QQbar)
sage: f=(1-x)*(1+y+z+x^3)^5
sage: f.degrees()
(16, 5, 5, 0)
sage: R(0).degrees()
(0, 0, 0, 0)
```

dict()
Return underlying dictioniary with keys the exponents and values the coefficients of this polynomial.

exponents()
Return the exponents of the monomials appearing in self.
EXAMPLES:

```
sage: R.<a,b,c> = PolynomialRing(QQbar, 3)
sage: f = a^3 + b + 2*b^2
sage: f.exponents()
[(3, 0, 0), (0, 2, 0), (0, 1, 0)]
```

factor()
Compute the irreducible factorization of this polynomial if it is univariate.
ALGORITHM: Use univariate factorization code.
If a polynomial is univariate, the appropriate univariate factorization code is called.

```
sage: R.<z> = PolynomialRing(CC,1)
sage: f = z^4 - 6*z + 3
sage: f.factor()
(z - 1.60443920904349) * (z - 0.511399619393097) * (z + 1.05791941421830 - 1.59281852704435*
```

inverse_of_unit()

is_constant()
True if polynomial is constant, and False otherwise.
EXAMPLES:

```
sage: R.<x,y> = QQbar[]
sage: f = 3*x^2 - 2*y + 7*x^2*y^2 + 5
sage: f.is_constant()
False
sage: g = 10*x^0
sage: g.is_constant()
True
```

is_generator()
Returns True if self is a generator of it's parent.
EXAMPLES:

```
sage: R.<x,y>=QQbar[]
sage: x.is_generator()
True
sage: (x+y-y).is_generator()
True
sage: (x*y).is_generator()
False
```

is_homogeneous()
Return True if self is a homogeneous polynomial.
EXAMPLES:

```
sage: R.<x,y> = QQbar[]
sage: (x+y).is_homogeneous()
True
sage: (x.parent()(0)).is_homogeneous()
True
sage: (x+y^2).is_homogeneous()
False
sage: (x^2 + y^2).is_homogeneous()
True
sage: (x^2 + y^2*x).is_homogeneous()
False
sage: (x^2*y + y^2*x).is_homogeneous()
True
```

is_monomial()

Returns True if self is a monomial. A monomial is defined to be a product of generators with coefficient 1.

EXAMPLES:

```
sage: R.<x,y>=QQbar[]
sage: x.is_monomial()
True
sage: (x+2*y).is_monomial()
False
sage: (2*x).is_monomial()
False
sage: (x*y).is_monomial()
True
```

is_unit()

Return True if self is a unit.

EXAMPLES:

```
sage: R.<x,y> = QQbar[]
sage: (x+y).is_unit()
False
sage: R(0).is_unit()
False
sage: R(-1).is_unit()
True
sage: R(-1 + x).is_unit()
False
sage: R(2).is_unit()
True
```

is_univariate()

Returns True if this multivariate polynomial is univariate and False otherwise.

EXAMPLES:

```
sage: R.<x,y> = QQbar[]
sage: f = 3*x^2 - 2*y + 7*x^2*y^2 + 5
sage: f.is_univariate()
False
sage: g = f.subs({x:10}); g
700*y^2 + (-2)*y + 305
sage: g.is_univariate()
True
sage: f = x^0
sage: f.is_univariate()
True
```

lc()

Returns the leading coefficent of self i.e., self.coefficient(self.lm())

EXAMPLES:

```
sage: R.<x,y,z>=QQbar[]
sage: f=3*x^2-y^2-x*y
sage: f.lc()
3
```

lift(*I*)

given an ideal I = (f_1,...,f_r) and some g (== self) in I, find s_1,...,s_r such that g = s_1 f_1 + ... + s_r f_r

ALGORITHM: Use Singular.

EXAMPLE:

```
sage: A.<x,y> = PolynomialRing(CC,2,order='degrevlex')
sage: I = A.ideal([x^10 + x^9*y^2, y^8 - x^2*y^7 ])
sage: f = x*y^13 + y^12
sage: M = f.lift(I)
sage: M
[y^7, x^7*y^2 + x^8 + x^5*y^3 + x^6*y + x^3*y^4 + x^4*y^2 + x*y^5 + x^2*y^3 + y^4]
sage: sum( map( mul , zip( M, I.gens() ) ) ) == f
True
```

lm()

Returns the lead monomial of self with respect to the term order of self.parent().

EXAMPLES:

```
sage: R.<x,y,z>=PolynomialRing(GF(7),3,order='lex')
sage: (x^1*y^2 + y^3*z^4).lm()
x*y^2
sage: (x^3*y^2*z^4 + x^3*y^2*z^1).lm()
x^3*y^2*z^4

sage: R.<x,y,z>=PolynomialRing(CC,3,order='deglex')
sage: (x^1*y^2*z^3 + x^3*y^2*z^0).lm()
x*y^2*z^3
sage: (x^1*y^2*z^4 + x^1*y^1*z^5).lm()
x*y^2*z^4

sage: R.<x,y,z>=PolynomialRing(QQbar,3,order='degrevlex')
sage: (x^1*y^5*z^2 + x^4*y^1*z^3).lm()
x*y^5*z^2
sage: (x^4*y^7*z^1 + x^4*y^2*z^3).lm()
x^4*y^7*z
```

lt()

Returns the leading term of self i.e., self.lc()*self.lm(). The notion of "leading term" depends on the ordering defined in the parent ring.

EXAMPLES:

```
sage: R.<x,y,z>=PolynomialRing(QQbar)
sage: f=3*x^2-y^2-x*y
sage: f.lt()
3*x^2
sage: R.<x,y,z>=PolynomialRing(QQbar,order="invlex")
sage: f=3*x^2-y^2-x*y
sage: f.lt()
-y^2
```

monomial_coefficient(*mon*)

Return the coefficient in the base ring of the monomial mon in self, where mon must have the same parent as self.

This function contrasts with the function `coefficient` which returns the coefficient of a monomial viewing this polynomial in a polynomial ring over a base ring having fewer variables.

INPUT:

- `mon` - a monomial

OUTPUT: coefficient in base ring

See Also:

For coefficients in a base ring of fewer variables, look at `coefficient()`.

EXAMPLES:

The parent of the return is a member of the base ring.

```
sage: R.<x,y>=QQbar[]
```

The parent of the return is a member of the base ring.

```
sage: f = 2 * x * y
sage: c = f.monomial_coefficient(x*y); c
2
sage: c.parent()
Algebraic Field

sage: f = y^2 + y^2*x - x^9 - 7*x + 5*x*y
sage: f.monomial_coefficient(y^2)
1
sage: f.monomial_coefficient(x*y)
5
sage: f.monomial_coefficient(x^9)
-1
sage: f.monomial_coefficient(x^10)
0

sage: var('a')
a
sage: K.<a> = NumberField(a^2+a+1)
sage: P.<x,y> = K[]
sage: f=(a*x-1)*((a+1)*y-1); f
-x*y + (-a)*x + (-a - 1)*y + 1
sage: f.monomial_coefficient(x)
-a
```

monomials()

Returns the list of monomials in self. The returned list is decreasingly ordered by the term ordering of self.parent().

OUTPUT: list of MPolynomials representing Monomials

EXAMPLES:

```
sage: R.<x,y> = QQbar[]
sage: f = 3*x^2 - 2*y + 7*x^2*y^2 + 5
sage: f.monomials()
[x^2*y^2, x^2, y, 1]

sage: R.<fx,fy,gx,gy> = QQbar[]
sage: F = ((fx*gy - fy*gx)^3)
sage: F
-fy^3*gx^3 + 3*fx*fy^2*gx^2*gy + (-3)*fx^2*fy*gx*gy^2 + fx^3*gy^3
```

```
sage: F.monomials()
[fy^3*gx^3, fx*fy^2*gx^2*gy, fx^2*fy*gx*gy^2, fx^3*gy^3]
sage: F.coefficients()
[-1, 3, -3, 1]
sage: sum(map(mul,zip(F.coefficients(),F.monomials()))) == F
True
```

nvariables()

Number of variables in this polynomial

EXAMPLES:

```
sage: R.<x,y> = QQbar[]
sage: f = 3*x^2 - 2*y + 7*x^2*y^2 + 5
sage: f.nvariables ()
2
sage: g = f.subs({x:10}); g
700*y^2 + (-2)*y + 305
sage: g.nvariables ()
1
```

quo_rem(*right*)

Returns quotient and remainder of self and right.

EXAMPLE:

```
sage: R.<x,y> = CC[]
sage: f = y*x^2 + x + 1
sage: f.quo_rem(x)
(x*y + 1.00000000000000, 1.00000000000000)
```

ALGORITHM: Use Singular.

reduce(*I*)

Reduce this polynomial by the the polynomials in I.

INPUT:

- `I` - a list of polynomials or an ideal

EXAMPLE:

```
sage: P.<x,y,z> = QQbar[]
sage: f1 = -2 * x^2 + x^3
sage: f2 = -2 * y + x* y
sage: f3 = -x^2 + y^2
sage: F = Ideal([f1,f2,f3])
sage: g = x*y - 3*x*y^2
sage: g.reduce(F)
(-6)*y^2 + 2*y
sage: g.reduce(F.gens())
(-6)*y^2 + 2*y

sage: f = 3*x
sage: f.reduce([2*x,y])
0

sage: k.<w> = CyclotomicField(3)
sage: A.<y9,y12,y13,y15> = PolynomialRing(k)
sage: J = [ y9 + y12]
sage: f = y9 - y12; f.reduce(J)
-2*y12
sage: f = y13*y15; f.reduce(J)
y13*y15
```

```
sage: f = y13*y15 + y9 - y12; f.reduce(J)
y13*y15 - 2*y12
```

subs (*fixed=None, **kw*)

Fixes some given variables in a given multivariate polynomial and returns the changed multivariate polynomials. The polynomial itself is not affected. The variable,value pairs for fixing are to be provided as a dictionary of the form {variable:value}.

This is a special case of evaluating the polynomial with some of the variables constants and the others the original variables.

INPUT:

- `fixed` - (optional) dictionary of inputs
- `**kw` - named parameters

OUTPUT: new MPolynomial

EXAMPLES:

```
sage: R.<x,y> = QQbar[]
sage: f = x^2 + y + x^2*y^2 + 5
sage: f((5,y))
25*y^2 + y + 30
sage: f.subs({x:5})
25*y^2 + y + 30
```

total_degree()

Return the total degree of self, which is the maximum degree of any monomial in self.

EXAMPLES:

```
sage: R.<x,y,z> = QQbar[]
sage: f=2*x*y^3*z^2
sage: f.total_degree()
6
sage: f=4*x^2*y^2*z^3
sage: f.total_degree()
7
sage: f=99*x^6*y^3*z^9
sage: f.total_degree()
18
sage: f=x*y^3*z^6+3*x^2
sage: f.total_degree()
10
sage: f=z^3+8*x^4*y^5*z
sage: f.total_degree()
10
sage: f=z^9+10*x^4+y^8*x^2
sage: f.total_degree()
10
```

univariate_polynomial (*R=None*)

Returns a univariate polynomial associated to this multivariate polynomial.

INPUT:

- `R` - (default: None) PolynomialRing

If this polynomial is not in at most one variable, then a ValueError exception is raised. This is checked using the is_univariate() method. The new Polynomial is over the same base ring as the given MPolynomial.

EXAMPLES:

```
sage: R.<x,y> = QQbar[]
sage: f = 3*x^2 - 2*y + 7*x^2*y^2 + 5
sage: f.univariate_polynomial()
...
TypeError: polynomial must involve at most one variable
sage: g = f.subs({x:10}); g
700*y^2 + (-2)*y + 305
sage: g.univariate_polynomial ()
700*y^2 - 2*y + 305
sage: g.univariate_polynomial(PolynomialRing(QQ,'z'))
700*z^2 - 2*z + 305
```

variable(*i*)

Returns i-th variable occuring in this polynomial.

EXAMPLES:

```
sage: R.<x,y> = QQbar[]
sage: f = 3*x^2 - 2*y + 7*x^2*y^2 + 5
sage: f.variable(0)
x
sage: f.variable(1)
y
```

variables()

Returns the list of variables occuring in this polynomial.

EXAMPLES:

```
sage: R.<x,y> = QQbar[]
sage: f = 3*x^2 - 2*y + 7*x^2*y^2 + 5
sage: f.variables()
[x, y]
sage: g = f.subs({x:10}); g
700*y^2 + (-2)*y + 305
sage: g.variables()
[y]
```

degree_lowest_rational_function(*r*, *x*)

INPUT:

- r - a multivariate rational function
- x - a multivariate polynomial ring generator x

OUTPUT:

- integer - the degree of r in x and its "leading" (in the x-adic sense) coefficient.

Note: This function is dependent on the ordering of a python dict. Thus, it isn't really mathematically well-defined. I think that it should made a method of the FractionFieldElement class and rewritten.

EXAMPLES:

```
sage: R1 = PolynomialRing(FiniteField(5), 3, names = ["a","b","c"])
sage: F = FractionField(R1)
sage: a,b,c = R1.gens()
sage: f = 3*a*b^2*c^3+4*a*b*c
sage: g = a^2*b*c^2+2*a^2*b^4*c^7
```

Consider the quotient $f/g = \frac{4+3bc^2}{ac+2ab^3c^6}$ (note the cancellation).

```
sage: r = f/g; r
(-2*b*c^2 - 1)/(2*a*b^3*c^6 + a*c)
sage: degree_lowest_rational_function(r,a)
(-1, 3)
sage: degree_lowest_rational_function(r,b)
(0, 4)
sage: degree_lowest_rational_function(r,c)
(-1, 4)
```

is_MPolynomial(x)

28.8 Infinite Polynomial Rings

By Infinite Polynomial Rings, we mean polynomial rings in a countably infinite number of variables. The implementation consists of a wrapper around the current *finite* polynomial rings in Sage.

AUTHORS:

- Simon King <simon.king@uni-jena.de>
- Mike Hansen <mhansen@gmail.com>

An Infinite Polynomial Ring has finitely many generators $x_*, y_*, ...$ and infinitely many variables of the form $x_0, x_1, x_2, ..., y_0, y_1, y_2, ..., ...$ We refer to the natural number n as the *index* of the variable x_n.

INPUT:

- `R`, the base ring, which must in fact be a *field*
- `names`, a list of generator names. Generator names must be pairwise different. We only allow generator names that are single characters.
- `order` (optional string). The default order is `'lex'` (lexicographic). `'deglex'` is degree lexicographic, and `'degrevlex'` (degree reverse lexicographic) is possible but discouraged.

Each generator `x` produces an infinite sequence of variables `x[1], x[2], ...` which are printed on screen as `x1, x2, ...` and are latex typeset as x_1, x_2. Then, the Infinite Polynomial Ring is formed by polynomials in these variables.

By default, the monomials are ordered lexicographically. Alternatively, degree (reverse) lexicographic ordering is possible as well. However, we do not guarantee that the computation of Groebner bases will terminate in this case.

In either case, the variables of a Infinite Polynomial Ring X are ordered according to the following rule:

`X.gen(i)[m] < X.gen(j)[n]` if and only if `i<j or (i==j and m<n)`

We provide a 'dense' and a 'sparse' implementation. In the dense implementation, the Infinite Polynomial Ring carries a finite polynomial ring that comprises *all* variables up to the maximal index that has been used so far. This is potentially a very big ring and may also comprise many variables that are not used.

In the sparse implementation, we try to keep the underlying finite polynomial rings small, using only those variables that are really needed. By default, we use the dense implementation, since it usually is much faster.

We provide coercion from an Infinite Polynomial Ring `X` over a field `F_X` to an Infinite Polynomial ring `Y` over a field `F_Y` (regardless of dense or sparse implementation and of monomial ordering) if and only if there is a coercion from

F_X to F_Y, and the set of generator names of X is a subset of the set of generator names of Y. The coercion map is name preserving. We also allow coercion from a *classical* polynomial ring to X if base rings and variable names fit.

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ, implementation='sparse')
sage: A.<a,b> = InfinitePolynomialRing(QQ, order='deglex')

sage: f = x[5] + 2; f
x5 + 2
sage: g = 3*y[1]; g
3*y1
sage: g._p.parent()
Univariate Polynomial Ring in y1 over Rational Field

sage: f2 = a[5] + 2; f2
a5 + 2
sage: g2 = 3*b[1]; g2
3*b1
sage: A.polynomial_ring()
Multivariate Polynomial Ring in b5, b4, b3, b2, b1, b0, a5, a4, a3, a2, a1, a0 over Rational Field
```

Of course, we provide the usual polynomial arithmetic:

```
sage: f+g
3*y1 + x5 + 2
sage: p = x[10]^2*(f+g); p
3*y1*x10^2 + x10^2*x5 + 2*x10^2
```

There is a permutation action on the variables, by permuting positive variable indices:

```
sage: P = Permutation(((10,1)))
sage: p^P
3*y10*x1^2 + x5*x1^2 + 2*x1^2
```

Note that $x_0^P = x_0$, since the permutations only change *positive* variable indices.

We also implemented ideals of Infinite Polynomial Rings. Here, it is thoroughly assumed that the ideals are set-wise invariant under the permutation action. We therefore refer to these ideals as *Symmetric Ideals*. Symmetric Ideals are finitely generated modulo addition, multiplication by ring elements and permutation of variables, and (at least in the default case of a lexicographic order), one can compute Groebner bases:

```
sage: I = (x[1]*y[2])*X
sage: I.groebner_basis()
[y1*x2, y2*x1]
sage: J = A*(a[1]*b[2])
sage: J.groebner_basis()
[b1*a2, b2*a1]
```

For more details, see SymmetricIdeal.

class InfinitePolynomialGen (*parent, name*)

This class provides the object which is responsible for returning variables in an infinite polynomial ring (implemented in __getitem__()).

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(RR)
sage: x
Generator for the x's in Infinite polynomial ring in x, y over Real Field with 53 bits of precis
sage: x[5]
x5
sage: x == loads(dumps(x))
True
```

class InfinitePolynomialRingFactory()

A factory for creating infinite polynomial ring elements. It handles making sure that they are unique as well as handling pickling. For more details, see `UniqueFactory` and `infinite_polynomial_ring`.

EXAMPLES:

```
sage: X.<x> = InfinitePolynomialRing(QQ)
sage: X2.<x> = InfinitePolynomialRing(QQ)
sage: X is X2
True
sage: X3.<x> = InfinitePolynomialRing(QQ, implementation='sparse')
sage: X is X3
False

sage: X is loads(dumps(X))
True
```

create_key(*R, names=('x',), order='lex', implementation='dense'*)

Creates a key which uniquely defines the infinite polynomial ring.

TESTS:

```
sage: InfinitePolynomialRing.create_key(QQ)
(Rational Field, ('x',), 'lex', 'dense')
sage: InfinitePolynomialRing.create_key(QQ, 'y')
(Rational Field, 'y', 'lex', 'dense')
sage: InfinitePolynomialRing.create_key(QQ, names='y', order='deglex', implementation='spars
(Rational Field, 'y', 'deglex', 'sparse')
sage: InfinitePolynomialRing.create_key(QQ, names=['x','y'], implementation='dense')
(Rational Field, ('x', 'y'), 'lex', 'dense')
```

create_object(*version, key*)

Returns the infinite polynomial ring corresponding to the key `key`.

TESTS:

```
sage: InfinitePolynomialRing.create_object('1.0', (QQ, 'x', 'deglex', 'sparse'))
Infinite polynomial ring in x over Rational Field
```

class InfinitePolynomialRing_dense(*R, names, order*)

Dense implementation of Infinite Polynomial Rings

Compared with `InfinitePolynomialRing_sparse`, from which this class inherits, it keeps a polynomial ring that comprises all elements that have been created so far.

polynomial_ring()

Returns the underlying *finite* polynomial ring.

Note: This ring returned can change over time as more variables are used.

EXAMPLES:

```
sage: X.<x, y> = InfinitePolynomialRing(QQ)
sage: X.polynomial_ring()
Multivariate Polynomial Ring in y0, x0 over Rational Field
```

```
sage: a = y[3]
sage: X.polynomial_ring()
Multivariate Polynomial Ring in y3, y2, y1, y0, x3, x2, x1, x0 over Rational Field
```

class InfinitePolynomialRing_sparse(*R, names, order*)

Sparse implementation of Infinite Polynomial Rings.

An Infinite Polynomial Ring with generators $x_*, y_*, ...$ over a field F is a free commutative F-algebra generated by $x_0, x_1, x_2, ..., y_0, y_1, y_2, ..., ...$ and is equipped with a permutation action on the generators, namely $x_n^P = x_{P(n)}, y_n^P = y_{P(n)}, ...$ for any permutation P (note that variables of index zero are invariant under such permutation).

It is known that any permutation invariant ideal in an Infinite Polynomial Ring is finitely generated modulo the permutation action – see `SymmetricIdeal` for more details.

Usually, an instance of this class is created using `InfinitePolynomialRing` with the optional parameter `implementation='sparse'`. This takes care of uniqueness of parent structures. However, a direct construction is possible, in principle:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ, implementation='sparse')
sage: Y.<x,y> = InfinitePolynomialRing(QQ, implementation='sparse')
sage: X is Y
True
sage: from sage.rings.polynomial.infinite_polynomial_ring import InfinitePolynomialRing_sparse
sage: Z = InfinitePolynomialRing_sparse(QQ, ['x','y'], 'lex')
sage: Z == X
True
sage: Z is X
False
```

The last parameter ('lex' in the above example) can also be 'deglex' or 'degrevlex'; this would result in an Infinite Polynomial Ring in degree lexicographic or degree reverse lexicographic order.

See `infinite_polynomial_ring` for more details.

characteristic()

Return the characteristic of the base field.

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(GF(25,'a'))
sage: X
Infinite polynomial ring in x, y over Finite Field in a of size 5^2
sage: X.characteristic()
5
```

gen()

Returns the i^{th} 'generator' (see the description in `ngens()`) of this infinite polynomial ring.

EXAMPLES:

```
sage: X = InfinitePolynomialRing(QQ)
sage: x = X.gen()
sage: x[1]
x1
sage: X.gen() is X.gen(0)
True
sage: XX = InfinitePolynomialRing(GF(5))
sage: XX.gen(0) is XX.gen()
True
```

ngens()

Returns the number of generators for this ring. Since there are countably infinitely many variables

in this polynomial ring, by 'generators' we mean the number of infinite families of variables. See `infinite_polynomial_ring` for more details.

EXAMPLES:

```
sage: X.<x> = InfinitePolynomialRing(QQ)
sage: X.ngens()
1

sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: X.ngens()
2
```

varname_cmp(*x, y*)

Comparison of two variable names

INPUT:

- `x, y` should both be strings of the form `a+str(n)`, where a is a single character appearing in the list of generator names, and n is an integer

RETURN:

-1,0,1 if x<y, x==y, x>y, respectively, where the order is defined as follows: x<y $\iff$ the letter `x[0]` is earlier in the list of generator names of self than `y[0]`, or (`x[0]==y[0]` and `int(x[1:])<int(y[1:])`)

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: X.varname_cmp('x1','y10')
-1
sage: X.varname_cmp('y1','x10')
1
sage: X.varname_cmp('y1','y10')
-1
```

28.9 Elements of Infinite Polynomial Rings

AUTHORS:

- Simon King <simon.king@uni-jena.de>
- Mike Hansen <mhansen@gmail.com>

An Infinite Polynomial Ring has generators $x_*, y_*, ...$, so that the variables are of the form $x_0, x_1, x_2, ..., y_0, y_1, y_2, ..., ...$ (see `infinite_polynomial_ring`). Using the generators, we can create elements as follows:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: a = x[3]
sage: b = y[4]
sage: a
x3
sage: b
y4
sage: c = a*b+a^3-2*b^4
sage: c
-2*y4^4 + y4*x3 + x3^3
```

Any Infinite Polynomial Ring `X` is equiped with a monomial ordering. We only consider monomial orderings in which:

`X.gen(i)[m] < X.gen(j)[n]` $\iff$ `i<j`, or `i==j` and `m<n`

Under this restriction, the monomial ordering can be lexicographic (default), degree lexicographic, or degree reverse lexicographic. Here, the ordering is lexicographic, and elements can be compared as usual:

```
sage: X._order
'lex'
sage: a < b
True
```

Note that, when a method is called that is not directly implemented for 'InfinitePolynomial', it is tried to call this method for the underlying *classical* polynomial. This holds, e.g., when applying the `latex` function:

```
sage: latex(c)
-2 y_{4}^{4} + y_{4} x_{3} + x_{3}^{3}
```

There is a permutation action on Infinite Polynomial Rings by permuting the indices of the variables:

```
sage: P = Permutation(((4,5),(2,3)))
sage: c^P
-2*y5^4 + y5*x2 + x2^3
```

Note that `P(0)==0`, and thus variables of index zero are invariant under the permutation action. More generally, if `P` is any callable object that accepts non-negative integers as input and returns non-negative integers, then `c^P` means to apply `P` to the variable indices occuring in `c`.

InfinitePolynomial(*A, p, is_good_poly=False*)

Create an element of a Polynomial Ring with a Countably Infinite Number of Variables

Usually, an InfinitePolynomial is obtained by using the generators of an Infinite Polynomial Ring (see `infinite_polynomial_ring`). But a direct construction is possible as well.

INPUT:

- `A`, an Infinite Polynomial Ring
- `p`, which is either an Infinite Polynomial, a *classical* polynomial, a string, or anything else that can be interpreted in `A`.

If the optional parameter `is_good_poly` is given, then it is assumed that `p` is a *classical* polynomial that can be interpreted in `A`. Otherwise, the input is checked.

EXAMPLES:

```
sage: from sage.rings.polynomial.infinite_polynomial_element import InfinitePolynomial
sage: X.<x> = InfinitePolynomialRing(QQ)
sage: a = InfinitePolynomial(X, '(x1+x2)^2')
sage: a
x2^2 + 2*x2*x1 + x1^2
sage: p = a.polynomial()
sage: b = InfinitePolynomial(X, p)
sage: a==b
True
sage: InfinitePolynomial(X, int(1))
1
sage: InfinitePolynomial(X, 1)
1
```

```
sage: Y.<x,y> = InfinitePolynomialRing(GF(2), implementation='sparse')
sage: InfinitePolynomial(Y, a)
x2^2 + x1^2
```

If it is sure that p is a polynomial that fits well to X then the optional parameter is_good_poly can be used to speed up the element creation. However, this option should be used with care:

```
sage: R.<z0> = QQ[]
sage: InfinitePolynomial(Y, z0, is_good_poly=True)
z0
```

The preceding answer means that it was assumed that z0 fits into an Infinite Polynomial Ring generated by x and y – and in the sparse implementation of Infinite Polynomial Rings this is not tested. In the default implementation, it is somehow indirectly tested: The dense implementation of Infinite Polynomial Rings has an underlying ring, and if is_good_poly is granted, then that underlying ring will not be changed, resulting in a traceback.

```
sage: InfinitePolynomial(X, z0, is_good_poly=True)
...
TypeError: not a constant polynomial
sage: S.<x4> = QQ[]
sage: X.polynomial_ring()
Multivariate Polynomial Ring in x2, x1, x0 over Rational Field
sage: InfinitePolynomial(X, x4, is_good_poly=True)
...
TypeError: not a constant polynomial
```

Without the optional parameter, the underlying ring is appropriately changed:

```
sage: InfinitePolynomial(X, x4)
x4
sage: X.polynomial_ring()
Multivariate Polynomial Ring in x4, x3, x2, x1, x0 over Rational Field
```

class InfinitePolynomial_dense(*A, p, is_good_poly=False*)
Element of a dense Polynomial Ring with a Countably Infinite Number of Variables

INPUT:

- X, an Infinite Polynomial Ring in dense implementation
- p, which is either an Infinite Polynomial, a *classical* polynomial, a string, or anything else that can be interpreted in X.

If the optional parameter is_good_poly is given, then it is assumed that p is a *classical* polynomial that can be interpreted in X. Otherwise, the input is checked.

This class inherits from InfinitePolynomial_sparse. See there for a description of the methods.

class InfinitePolynomial_sparse(*A, p, is_good_poly=False*)
Element of a sparse Polynomial Ring with a Countably Infinite Number of Variables

INPUT:

- A, an Infinite Polynomial Ring in sparse implementation
- p, which is either an Infinite Polynomial, a *classical* polynomial, a string, or anything else that can be interpreted in A.

If the optional parameter is_good_poly is given, then it is assumed that p is a *classical* polynomial that can be interpreted in A. Otherwise, the input is checked.

coefficient(*monomial*)

Returns the coefficient of a monomial in this polynomial.

INPUT:

- A monomial (element of the parent of self) or
- **a dictionary that describes a monomial (the keys** are variables of the parent of self, the values are the corresponding exponents)

EXAMPLES:

We can get the coefficient in front of monomials:

```
sage: X.<x> = InfinitePolynomialRing(QQ)
sage: a = 2*x[0]*x[1] + x[1] + x[2]
sage: a.coefficient(x[0])
2*x1
sage: a.coefficient(x[1])
2*x0 + 1
sage: a.coefficient(x[2])
1
sage: a.coefficient(x[0]*x[1])
2
```

We can also pass in a dictionary:

```
sage: a.coefficient({x[0]:1, x[1]:1})
2
```

footprint()

Leading exponents in increasing order sorted by generator names

OUTPUT: `D` – a dictionary whose keys are the occuring variable indices. `D[s]` is a list `[i_1,...,i_n]`, where `i_j` gives the exponent of `self.parent().gen(j)[s]` in the leading term of self.

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: p = x[30]*y[1]^3*x[1]^2+2*x[10]*y[30]
sage: p.footprint()
{10: [1, 0], 30: [0, 1]}
```

lc()

The coefficient of the leading term of self

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: p = 2*x[10]*y[30]+3*x[10]*y[1]^3*x[1]^2
sage: p.lc()
2
```

lm()

The leading monomial of self

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: p = 2*x[10]*y[30]+x[10]*y[1]^3*x[1]^2
sage: p.lm()
y30*x10
```

lt()

The leading term (= product of coefficient and monomial) of self

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: p = 2*x[10]*y[30]+3*x[10]*y[1]^3*x[1]^2
sage: p.lt()
2*y30*x10
```

max_index()

Return the maximal index of a variable occuring in self, or -1 if self is scalar

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: p=x[1]^2+y[2]^2+x[1]*x[2]*y[3]+x[1]*y[4]
sage: p.max_index()
4
sage: x[0].max_index()
0
sage: X(10).max_index()
-1
```

polynomial()

Return the underlying polynomial

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(GF(7))
sage: p=x[2]*y[1]+3*y[0]
sage: p
y1*x2 + 3*y0
sage: p.polynomial()
y1*x2 + 3*y0
sage: p.polynomial().parent()
Multivariate Polynomial Ring in y2, y1, y0, x2, x1, x0 over Finite Field of size 7
sage: p.parent()
Infinite polynomial ring in x, y over Finite Field of size 7
```

reduce(*I, tailreduce=False, report=None*)

Symmetrical reduction of self with respect to a symmetric ideal (or list of Infinite Polynomials)

Reducing an element p of an Infinite Polynomial Ring X by some other element q means the following:

1. Let M and N be the leading terms of p and q.
2. Test whether there is a permutation P that does not does not diminish the variable indices occuring in N and preserves their order, so that there is some term $T \in X$ with $TN^P = M$. If there is no such permutation, return p
3. Replace p by $p - Tq^P$ and continue with step 1.

INPUT:

- I – a `SymmetricIdeal` or a list of Infinite Polynomials
- Sometimes it is useful to reduce not only the leading term of p. This *tail reduction* is performed if the optional parameter `tailreduce` is True.
- If the optional parameter `report` is not None, some information on the progress of computation is given, since reduction of huge polynomials may be expensive.

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: p = y[1]^2*y[3]+y[1]*x[3]
sage: p.reduce([y[2]^2*y[1]])
y3*y1^2 + y1*x3
```

The preceding is correct, since any permutation that turns `y[2]^2*y[1]` into a factor of `y[1]^2*y[3]` interchanges the variable indices 1 and 2 – which is not allowed. However, reduction by `y[1]^2*y[2]` works, since one can change variable index 1 into 2 and 2 into 3:

```
sage: p.reduce([y[1]^2*y[2]])
y1*x3
```

The next example shows that tail reduction is not done, unless it is explicitly adviced. The input can also be a Symmetric Ideal:

```
sage: I = (x[2])*X
sage: p.reduce(I)
y3*y1^2 + y1*x3
sage: p.reduce(I, tailreduce=True)
y3*y1^2
```

Last, we demonstrate the `report` option:

```
sage: p=x[1]^2+y[2]^2+x[1]*x[2]*y[3]+x[1]*y[4]
sage: p.reduce(I, tailreduce=True, report=True)
T[3]:>
>
y4*x1 + y2^2 + x1^2
```

The output 'T[3]' means that tail reduction is performed on a polynomial with three terms. ':' means that there was one reduction of the leading monomial. At '>', one round of the reduction process is finished.

ring()

The ring which self belongs to. This is the same as `self.parent()`.

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ,implementation='sparse')
sage: p = x[100]*y[1]^3*x[1]^2+2*x[10]*y[30]
sage: p.ring()
Infinite polynomial ring in x, y over Rational Field
```

squeezed()

Reduce the variable indices occuring in self

OUTPUT: Apply a permutation to self that does not change the order of the variable indices of self but squeezes them into the range 1,2,...

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ,implementation='sparse')
sage: p = x[1]*y[100] + x[50]*y[1000]
sage: p.squeezed()
y4*x2 + y3*x1
```

stretch(k)

Replace v_n with $v_{n \cdot k}$ for all generators v_* occuring in self.

EXAMPLES:

```
sage: X.<x> = InfinitePolynomialRing(QQ)
sage: a = x[0] + x[1] + x[2]
sage: a.stretch(2)
x4 + x2 + x0

sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: a = x[0] + x[1] + y[0]*y[1]; a
y1*y0 + x1 + x0
sage: a.stretch(2)
y2*y0 + x2 + x0
```

TESTS:

```
sage: X.<x> = InfinitePolynomialRing(QQ, implementation='sparse')
sage: a = x[2] + x[3]
sage: a.stretch(2000)
x6000 + x4000
```

symmetric_cancellation_order(*other*)

Comparison of leading terms by Symmetric Cancellation Order, $<_{sc}$

INPUT: self, other – two Infinite Polynomials

ASSUMPTION: Both Infintie Polynomials are non-zero

OUTPUT: `(c, sigma, w)`, where

- c = -1,0,1, or None if the leading monomial of `self` is smaller, equal, greater, or incomparable with respect to `other` in the monomial ordering of the Infinite Polynomial Ring
- sigma is a permutation witnessing `self` $<_{sc}$ `other` (resp. `self` $>_{sc}$ `other`) or is 1 if `self.lm()==other.lm()`
- w is 1 or is a term so that `w*self.lt()^sigma == other.lt()` if $c \leq 0$, and `w*other.lt()^sigma == self.lt()` if $c = 1$

THEORY: If the Symmetric Cancellation Order is a well-quasi-ordering then computation of Groebner bases always terminates. This is the case, e.g., if the monomial order is lexicographic. For that reason, lexicographic order is our default order.

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: (x[2]*x[1]).symmetric_cancellation_order(x[2]^2)
(None, 1, 1)
sage: (x[2]*x[1]).symmetric_cancellation_order(x[2]*x[3]*y[1])
(-1, [2, 3, 1], y1)
sage: (x[2]*x[1]*y[1]).symmetric_cancellation_order(x[2]*x[3]*y[1])
(None, 1, 1)
sage: (x[2]*x[1]*y[1]).symmetric_cancellation_order(x[2]*x[3]*y[2])
(-1, [2, 3, 1], 1)
```

tail()

The tail of self (this is self minus its leading term)

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: p = 2*x[10]*y[30]+3*x[10]*y[1]^3*x[1]^2
sage: p.tail()
3*y1^3*x10*x1^2
```

variables()

Return the variables occuring in self (list of elements of some polynomial ring)

EXAMPLES:

```
sage: X.<x> = InfinitePolynomialRing(QQ)
sage: p = x[1] + x[2] - 2*x[1]*x[3]
sage: p.variables()
[x3, x2, x1]
sage: x[1].variables()
[x1]
sage: X(1).variables()
[]
```

28.10 Ideals in multivariate polynomial rings.

Sage has a powerful system to compute with multivariate polynomial rings. Most algorithms dealing with these ideals are centered the computation of *Groebner bases*. Sage makes use of Singular to implement this functionality. Singular is widely regarded as the best open-source system for Groebner basis calculation in multivariate polynomial rings over fields.

AUTHORS:

- William Stein
- Kiran S. Kedlaya (2006-02-12): added Macaulay2 analogues of some Singular features
- Martin Albrecht (2008,2007): refactoring, many Singular related functions

EXAMPLES:

We compute a Groebner basis for some given ideal. The type returned by the `groebner_basis` method is `Sequence`, i.e. it is not an `MPolynomialIdeal`.

```
sage: x,y,z = QQ['x,y,z'].gens()
sage: I = ideal(x^5 + y^4 + z^3 - 1,  x^3 + y^3 + z^2 - 1)
sage: B = I.groebner_basis()
sage: type(B)
<class 'sage.structure.sequence.Sequence'>
```

Groebner bases can be used to solve the ideal membership problem.

```
sage: f,g,h = B
sage: (2*x*f + g).reduce(B)
0

sage: (2*x*f + g) in I
True

sage: (2*x*f + 2*z*h + y^3).reduce(B)
y^3

sage: (2*x*f + 2*z*h + y^3) in I
False
```

We compute a Groebner basis for cyclic 6, which is a standard benchmark and test ideal.

```
sage: R.<x,y,z,t,u,v> = QQ['x,y,z,t,u,v']
sage: I = sage.rings.ideal.Cyclic(R,6)
sage: B = I.groebner_basis()
sage: len(B)
45
```

We compute in a quotient of a polynomial ring over $\mathbf{Z}/17\mathbf{Z}$:

```
sage: R.<x,y> = ZZ[]
sage: S.<a,b> = R.quotient((x^2 + y^2, 17))      # optional -- macaulay2
...
verbose 0 ... Warning: falling back to very slow toy implementation.
sage: S                                          # optional -- macaulay2
Quotient of Multivariate Polynomial Ring in x, y over Integer Ring
by the ideal (x^2 + y^2, 17)

sage: a^2 + b^2 == 0                             # optional -- macaulay2
```

```
True
sage: a^3 - b^2                                    # optional -- macaulay2
a*b^2 - b^2
sage: (a+b)^17                                     # optional -- macaulay2
a*b^16 + b^17
sage: S(17) == 0                                   # optional -- macaulay2
True
```

Working with a polynomial ring over $\mathbf{Z}$:

```
sage: R.<x,y,z,w> = ZZ['x,y,z,w']
sage: i = ideal(x^2 + y^2 - z^2 - w^2, x-y)
sage: j = i^2
sage: j.groebner_basis('macaulay2')           # optional - macaulay2
[4*y^4 - 4*y^2*z^2 + z^4 - 4*y^2*w^2 + 2*z^2*w^2 + w^4,
 2*x*y^2 - 2*y^3 - x*z^2 + y*z^2 - x*w^2 + y*w^2,
 x^2 - 2*x*y + y^2]

sage: y^2 - 2*x*y + x^2 in j                  # optional - macaulay2
True
sage: 0 in j                                  # optional - macaulay2
True
```

We do a Groebner basis computation over a number field:

```
sage: K.<zeta> = CyclotomicField(3)
sage: R.<x,y,z> = K[]; R
Multivariate Polynomial Ring in x, y, z over Cyclotomic Field of order 3 and degree 2

sage: i = ideal(x - zeta*y + 1, x^3 - zeta*y^3); i
Ideal (x + (-zeta)*y + 1, x^3 + (-zeta)*y^3) of Multivariate
Polynomial Ring in x, y, z over Cyclotomic Field of order 3 and degree 2

sage: i.groebner_basis()
[y^3 + (2*zeta + 1)*y^2 + (zeta - 1)*y + (-1/3*zeta - 2/3), x + (-zeta)*y + 1]

sage: S = R.quotient(i); S
Quotient of Multivariate Polynomial Ring in x, y, z over
Cyclotomic Field of order 3 and degree 2 by the ideal (x +
(-zeta)*y + 1, x^3 + (-zeta)*y^3)

sage: S.0  - zeta*S.1
-1
sage: S.0^3 - zeta*S.1^3
0
```

Two examples from the Mathematica documentation (done in Sage):

We compute a Groebner basis:

```
sage: R.<x,y> = PolynomialRing(QQ, order='lex')
sage: ideal(x^2 - 2*y^2, x*y - 3).groebner_basis()
 [x - 2/3*y^3, y^4 - 9/2]
```

We show that three polynomials have no common root:

```
sage: R.<x,y> = QQ[]
sage: ideal(x+y, x^2 - 1, y^2 - 2*x).groebner_basis()
[1]
```

The next example shows how we can use Groebner bases over $\mathbf{Z}$ to find the primes modulo which a system of equations has a solution, when the system has no solutions over the rationals.

We first form a certain ideal I in $\mathbf{Z}[x, y, z]$, and note that the Groebner basis of I over $\mathbf{Q}$ contains 1, so there are no solutions over $\mathbf{Q}$ or an algebraic closure of it (this is not surprising as there are 4 equations in 3 unknowns).

```
sage: P.<x,y,z> = PolynomialRing(ZZ,order='lex')
sage: I = ideal(-y^2 - 3*y + z^2 + 3, -2*y*z + z^2 + 2*z + 1, \
                x*z + y*z + z^2, -3*x*y + 2*y*z + 6*z^2)
sage: I.change_ring(P.change_ring(QQ)).groebner_basis()
[1]
```

However, when we compute the Groebner basis of I (defined over \$ZZ\$), we note that there is a certain integer in the ideal which is not 1.

```
sage: I.groebner_basis()          # optional -- macaulay2
...
verbose 0 ... Warning: falling back to very slow toy implementation.
[x + y + z, y^2 + y + 23234, y*z + y + 26532, 2*y + 158864, z^2 + 17223, 2*z + 41856, 164878]
```

Now for each prime p dividing this integer 164878, the Groebner basis of I modulo p will be non-trivial and will thus give a solution of the original system modulo p.

```
sage: factor(164878)
2 * 7 * 11777

sage: I.change_ring(P.change_ring( GF(2) )).groebner_basis()
[x + y + z, y^2 + y, y*z + y, z^2 + 1]
sage: I.change_ring(P.change_ring( GF(7) )).groebner_basis()
[x - 1, y + 3, z - 2]
sage: I.change_ring(P.change_ring( GF(11777 ))).groebner_basis()
[x + 5633, y - 3007, z - 2626]
```

The Groebner basis modulo any product of the prime factors is also non-trivial.

```
sage: I.change_ring(P.change_ring( IntegerModRing(2*7) )).groebner_basis()   # optional -- macau
verbose 0 (...: multi_polynomial_ideal.py, groebner_basis) Warning: falling back to very slow to
[x + y + z, y^2 + y + 8, y*z + y + 2, 2*y + 6, z^2 + 3, 2*z + 10]
```

Modulo any other prime the Groebner basis is trivial so there are no other solutions. For example:

```
sage: I.change_ring( P.change_ring( GF(3) ) ).groebner_basis()
[1]
```

TESTS:

```
sage: x,y,z = QQ['x,y,z'].gens()
sage: I = ideal(x^5 + y^4 + z^3 - 1,  x^3 + y^3 + z^2 - 1)
sage: I == loads(dumps(I))
True
```

class MPolynomialIdeal (*ring, gens, coerce=True*)

change_ring(*P*)

Return the ideal `I` in `P` spanned by the generators $g_1, ..., g_n$ of self as returned by `self.gens()`.

INPUT:

- `P` - a multivariate polynomial ring

EXAMPLE:

```
sage: P.<x,y,z> = PolynomialRing(QQ,3,order='lex')
sage: I = sage.rings.ideal.Cyclic(P)
sage: I
Ideal (x + y + z, x*y + x*z + y*z, x*y*z - 1) of
Multivariate Polynomial Ring in x, y, z over Rational Field

sage: I.groebner_basis()
[x + y + z, y^2 + y*z + z^2, z^3 - 1]

sage: Q.<x,y,z> = P.change_ring(order='degrevlex'); Q
Multivariate Polynomial Ring in x, y, z over Rational Field
sage: Q.term_order()
Degree reverse lexicographic term order

sage: J = I.change_ring(Q); J
Ideal (x + y + z, x*y + x*z + y*z, x*y*z - 1) of
Multivariate Polynomial Ring in x, y, z over Rational Field

sage: J.groebner_basis()
[z^3 - 1, y^2 + y*z + z^2, x + y + z]
```

groebner_basis()

Return the reduced Groebner basis of this ideal. A Groebner basis $g_1, ..., g_n$ for an ideal I is a basis such that $< LM(g_i) >= LM(I)$, i.e., the leading monomial ideal of I is spanned by the leading terms of $g_1, ..., g_n$. Groebner bases are the key concept in computational ideal theory in multivariate polynomial rings which allows a variety of problems to be solved. Additionally, a *reduced* Groebner basis G is a unique representation for the ideal $< G >$ with respect to the chosen monomial ordering.

INPUT:

- `algorithm` - determines the algorithm to use, see below for available algorithms.
- `*args` - additional parameters passed to the respective implementations
- `**kwds` - additional keyword parameters passed to the respective implementations

ALGORITHMS:

'' autoselect (default)
'singular:groebner' Singular's `groebner` command
'singular:std' Singular's `std` command
'singular:stdhilb' Singular's `stdhib` command
'singular:stdfglm' Singular's `stdfglm` command
'singular:slimgb' Singular's `slimgb` command
'libsingular:std' libSingular's `std` command
'libsingular:slimgb' libSingular's `slimgb` command
'toy:buchberger' Sage's toy/educational buchberger without Buchberger criteria
'toy:buchberger2' Sage's toy/educational buchberger with Buchberger criteria
'toy:d_basis' Sage's toy/educational algorithm for computation over PIDs
'macaulay2:gb' Macaulay2's `gb` command (if available)

'magma:GroebnerBasis' Magma's `Groebnerbasis` command (if available)

If only a system is given - e.g. 'magma' - the default algorithm is chosen for that system.

Note: The Singular and libSingular versions of the respective algorithms are identical, but the former calls an external Singular process while the later calls a C function, i.e. the calling overhead is smaller.

EXAMPLES:

Consider Katsura-3 over QQ with lexicographical term ordering. We compute the reduced Groebner basis using every available implementation and check their equality.

```
sage: P.<a,b,c> = PolynomialRing(QQ,3, order='lex')
sage: I = sage.rings.ideal.Katsura(P,3) # regenerate to prevent caching
sage: I.groebner_basis()
[a - 60*c^3 + 158/7*c^2 + 8/7*c - 1, b + 30*c^3 - 79/7*c^2 + 3/7*c, c^4 - 10/21*c^3 + 1/84*c

sage: I = sage.rings.ideal.Katsura(P,3) # regenerate to prevent caching
sage: I.groebner_basis('singular:groebner')
[a - 60*c^3 + 158/7*c^2 + 8/7*c - 1, b + 30*c^3 - 79/7*c^2 + 3/7*c, c^4 - 10/21*c^3 + 1/84*c

sage: I = sage.rings.ideal.Katsura(P,3) # regenerate to prevent caching
sage: I.groebner_basis('singular:std')
[a - 60*c^3 + 158/7*c^2 + 8/7*c - 1, b + 30*c^3 - 79/7*c^2 + 3/7*c, c^4 - 10/21*c^3 + 1/84*c

sage: I = sage.rings.ideal.Katsura(P,3) # regenerate to prevent caching
sage: I.groebner_basis('singular:stdhilb')
[a - 60*c^3 + 158/7*c^2 + 8/7*c - 1, b + 30*c^3 - 79/7*c^2 + 3/7*c, c^4 - 10/21*c^3 + 1/84*c

sage: I = sage.rings.ideal.Katsura(P,3) # regenerate to prevent caching
sage: I.groebner_basis('singular:stdfglm')
[a - 60*c^3 + 158/7*c^2 + 8/7*c - 1, b + 30*c^3 - 79/7*c^2 + 3/7*c, c^4 - 10/21*c^3 + 1/84*c

sage: I = sage.rings.ideal.Katsura(P,3) # regenerate to prevent caching
sage: I.groebner_basis('singular:slimgb')
[a - 60*c^3 + 158/7*c^2 + 8/7*c - 1, b + 30*c^3 - 79/7*c^2 + 3/7*c, c^4 - 10/21*c^3 + 1/84*c
```

Note that `toy:buchberger` does not return the reduced Groebner basis,

```
sage: I = sage.rings.ideal.Katsura(P,3) # regenerate to prevent caching
sage: I.groebner_basis('toy:buchberger')
[a^2 - a + 2*b^2 + 2*c^2,
 a*b + b*c - 1/2*b, a + 2*b + 2*c - 1,
 b^2 + 4/3*b*c - 1/3*b + c^2 - 1/3*c,
 b*c - 1/10*b + 6/5*c^2 - 2/5*c,
 b + 30*c^3 - 79/7*c^2 + 3/7*c,
 c^4 - 10/21*c^3 + 1/84*c^2 + 1/84*c]
```

but that `toy:buchberger2` does.

```
sage: I = sage.rings.ideal.Katsura(P,3) # regenerate to prevent caching
sage: I.groebner_basis('toy:buchberger2')
[a - 60*c^3 + 158/7*c^2 + 8/7*c - 1, b + 30*c^3 - 79/7*c^2 + 3/7*c, c^4 - 10/21*c^3 + 1/84*c

sage: I = sage.rings.ideal.Katsura(P,3) # regenerate to prevent caching
sage: I.groebner_basis('macaulay2:gb') # optional - macaulay2
[a - 60*c^3 + 158/7*c^2 + 8/7*c - 1, b + 30*c^3 - 79/7*c^2 + 3/7*c, c^4 - 10/21*c^3 + 1/84*c

sage: I = sage.rings.ideal.Katsura(P,3) # regenerate to prevent caching
sage: I.groebner_basis('magma:GroebnerBasis') # optional - magma
[a - 60*c^3 + 158/7*c^2 + 8/7*c - 1, b + 30*c^3 - 79/7*c^2 + 3/7*c, c^4 - 10/21*c^3 + 1/84*c
```

Groebner bases over **Z** can be computed. However, the native implementation is very slow. If available Macaulay2 is used, which is an optional Sage package.

```
sage: P.<a,b,c> = PolynomialRing(ZZ,3)
sage: I = P * (a + 2*b + 2*c - 1, a^2 - a + 2*b^2 + 2*c^2, 2*a*b + 2*b*c - b)
sage: I.groebner_basis()                                  # optional - macaulay2
...
[b^3 - b*c^2 - 24*c^3 - b^2 - 6*b*c + 2*c^2 + 2*c,
 2*b*c^2 + 36*c^3 - 9*b*c - 24*c^2 + 2*b + 4*c,
 42*c^3 + b^2 + 2*b*c - 14*c^2 + b,
 2*b^2 - 4*b*c - 6*c^2 + 2*c,
 10*b*c + 12*c^2 - b - 4*c,
 a + 2*b + 2*c - 1]

sage: I.groebner_basis('macaulay2') # optional - macaulay2
[b^3 + b*c^2 + 12*c^3 + b^2 + b*c - 4*c^2,
 2*b*c^2 - 6*c^3 + b^2 + 5*b*c + 8*c^2 - b - 2*c,
 42*c^3 + b^2 + 2*b*c - 14*c^2 + b,
 2*b^2 - 4*b*c - 6*c^2 + 2*c, 10*b*c + 12*c^2 - b - 4*c,
 a + 2*b + 2*c - 1]
```

Sage also supports local orderings:

```
sage: P.<x,y,z> = PolynomialRing(QQ,3,order='negdegrevlex')
sage: I = P * (  x*y*z + z^5, 2*x^2 + y^3 + z^7, 3*z^5 +y ^5 )
sage: I.groebner_basis()
[x^2 + 1/2*y^3, x*y*z + z^5, y^5 + 3*z^5, y^4*z - 2*x*z^5, z^6]
```

We can represent every element in the ideal as a combination of the generators using the `lift()` method:

```
sage: P.<x,y,z> = PolynomialRing(QQ,3)
sage: I = P * ( x*y*z + z^5, 2*x^2 + y^3 + z^7, 3*z^5 +y ^5 )
sage: J = Ideal(I.groebner_basis())
sage: f = sum(P.random_element(terms=2)*f for f in I.gens())
sage: f
1/2*y^2*z^7 - 1/4*y*z^8 + 2*x*z^5 + 95*z^6 + 1/2*y^5 - 1/4*y^4*z + x^2*y^2 + 3/2*x^2*y*z + 9
sage: f.lift(I.gens())
[2*x + 95*z, 1/2*y^2 - 1/4*y*z, 0]
sage: l = f.lift(J.gens()); l
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, -1/2*y^2 + 1/4*y*z, 1/2*y^2*z^2 - 1/4*y*z^3 + 2*x +
sage: sum(map(mul, zip(l,J.gens()))) == f
True
```

ALGORITHM: Uses Singular, Magma (if available), Macaulay2 (if available), or a toy implementation.

groebner_fan(*is_groebner_basis=False, symmetry=None, verbose=False*)

Return the Groebner fan of this ideal.

The base ring must be $\mathbf{Q}$ or a finite field $\mathbf{F}_p$ of with $p <= 32749$.

EXAMPLES:

```
sage: P.<x,y> = PolynomialRing(QQ)
sage: i = ideal(x^2 - y^2 + 1)
sage: g = i.groebner_fan()
sage: g.reduced_groebner_bases()
[[x^2 - y^2 + 1], [-x^2 + y^2 - 1]]
```

INPUT:

- `is_groebner_basis` - bool (default False). if True, then I.gens() must be a Groebner basis with respect to the standard degree lexicographic term order.
- `symmetry` - default: None; if not None, describes symmetries of the ideal
- `verbose` - default: False; if True, printout useful info during computations

homogenize(*var='h'*)

Return homogeneous ideal spanned by the homogeneous polynomials generated by homogenizing the generators of this ideal.

INPUT:

•h - variable name or variable in cover ring (default: 'h')

EXAMPLE:

```
sage: P.<x,y,z> = PolynomialRing(GF(2))
sage: I = Ideal([x^2*y + z + 1, x + y^2 + 1]); I
Ideal (x^2*y + z + 1, y^2 + x + 1) of Multivariate
Polynomial Ring in x, y, z over Finite Field of size 2

sage: I.homogenize()
Ideal (x^2*y + z*h^2 + h^3, y^2 + x*h + h^2) of
Multivariate Polynomial Ring in x, y, z, h over Finite
Field of size 2

sage: I.homogenize(y)
Ideal (x^2*y + y^3 + y^2*z, x*y) of Multivariate
Polynomial Ring in x, y, z over Finite Field of size 2

       sage: I = Ideal([x^2*y + z^3 + y^2*x, x + y^2 + 1])
sage: I.homogenize()
Ideal (x^2*y + x*y^2 + z^3, y^2 + x*h + h^2) of
Multivariate Polynomial Ring in x, y, z, h over Finite
Field of size 2
```

is_homogeneous()

Return `True` if this ideal is spanned by homogeneous polynomials, i.e. if it is a homogeneous ideal.

EXAMPLE:

```
sage: P.<x,y,z> = PolynomialRing(QQ,3)
sage: I = sage.rings.ideal.Katsura(P)
sage: I
Ideal (x + 2*y + 2*z - 1, x^2 + 2*y^2 + 2*z^2 - x, 2*x*y +
2*y*z - y) of Multivariate Polynomial Ring in x, y, z over
Rational Field

sage: I.is_homogeneous()
False

sage: J = I.homogenize()
sage: J
Ideal (x + 2*y + 2*z - h, x^2 + 2*y^2 + 2*z^2 - x*h, 2*x*y
+ 2*y*z - y*h) of Multivariate Polynomial Ring in x, y, z,
h over Rational Field

sage: J.is_homogeneous()
True
```

normal_basis(*algorithm='libsingular', singular=Singular*)

Returns a vector space basis (consisting of monomials) of the quotient ring by the ideal, resp. of a free module by the module, in case it is finite dimensional and if the input is a standard basis with respect to the ring ordering.

INPUT: algorithm - defaults to use libsingular, if it is anything else we will use the kbase() command

EXAMPLES:

```
sage: R.<x,y,z> = PolynomialRing(QQ)
sage: I = R.ideal(x^2+y^2+z^2-4, x^2+2*y^2-5, x*z-1)
```

```
sage: I.normal_basis()
[y*z^2, z^2, y*z, z, x*y, y, x, 1]
sage: I.normal_basis(algorithm='singular')
[y*z^2, z^2, y*z, z, x*y, y, x, 1]
```

plot(**args, **kwds*)

Plot the real zero locus of this principal ideal.

INPUT:

- `self` - a principal ideal in 2 variables
- `algorithm` - set this to 'surf' if you want 'surf' to plot the ideal (default: None)
- `*args` - optional tuples `(variable, minimum, maximum)` for plotting dimensions
- `**kwds` - optional keyword arguments passed on to `implicit_plot`

EXAMPLES:

Implicit plotting in 2-d:

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: I = R.ideal([y^3 - x^2])
sage: I.plot()                              # cusp

sage: I = R.ideal([y^2 - x^2 - 1])
sage: I.plot((x,-3, 3), (y, -2, 2))  # hyperbola

sage: I = R.ideal([y^2 + x^2*(1/4) - 1])
sage: I.plot()                              # ellipse

sage: I = R.ideal([y^2-(x^2-1)*(x-2)])
sage: I.plot()                              # elliptic curve

sage: f = ((x+3)^3 + 2*(x+3)^2 - y^2)*(x^3 - y^2)*((x-3)^3-2*(x-3)^2-y^2)
sage: I = R.ideal(f)
sage: I.plot()                              # the Singular logo
```

This used to be trac #5267:

```
sage: I = R.ideal([-x^2*y+1])
sage: I.plot()
```

AUTHORS:

- Martin Albrecht (2008-09)

reduce(*f*)

Reduce an element modulo the reduced Groebner basis for this ideal. This returns 0 if and only if the element is in this ideal. In any case, this reduction is unique up to monomial orders.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ, 2)
sage: I = (x^3 + y, y)*R
sage: I.reduce(y)
0
sage: I.reduce(x^3)
0
sage: I.reduce(x - y)
x

sage: I = (y^2 - (x^3 + x))*R
sage: I.reduce(x^3)
y^2 - x
```

```
sage: I.reduce(x^6)
y^4 - 2*x*y^2 + x^2
sage: (y^2 - x)^2
y^4 - 2*x*y^2 + x^2
```

Note: Requires computation of a Groebner basis, which can be a very expensive operation.

weil_restriction()

Compute the Weil restriction of this ideal over some extension field.

A Weil restriction of scalars - denoted $Res_{L/k}$ - is a functor which, for any finite extension of fields L/k and any algebraic variety X over L, produces another corresponding variety $Res_{L/k}(X)$, defined over k. It is useful for reducing questions about varieties over large fields to questions about more complicated varieties over smaller fields.

This function does not compute this Weil restriction directly but computes on generating sets of polynomial ideals:

Let d be the degree of the field extension L/k, let a a generator of L/k and p the minimal polynomial of L/k. Denote this ideal by I.

Specifically, this function first maps each variable x to its representation over k: $\sum_{i=0}^{d-1} a^i x_i$. Then each generator of I is evaulated over these representations and reduced modulo the minimal polynomial p. The result is interpreted as a univariate polynomial in a and its coefficients are the new generators of the returned ideal.

If the input and the output ideals are radical, this is equivalent to the statement about algebraic varieties above.

EXAMPLE:

```
sage: k.<a> = GF(2^2)
sage: P.<x,y> = PolynomialRing(k,2)
sage: I = Ideal([x*y + 1, a*x + 1])
sage: I.variety()
[{y: a, x: a + 1}]
sage: J = I.weil_restriction()
sage: J
Ideal (x1*y0 + x0*y1 + x1*y1, x0*y0 + x1*y1 + 1, x0 + x1, x1 + 1) of
Multivariate Polynomial Ring in x0, x1, y0, y1 over Finite Field of size 2
sage: J += sage.rings.ideal.FieldIdeal(J.ring()) # ensure radical ideal
sage: J.variety()
[{y1: 1, x1: 1, x0: 1, y0: 0}]

sage: J.weil_restriction() # returns J
Ideal (x1*y0 + x0*y1 + x1*y1, x0*y0 + x1*y1 + 1, x0 + x1, x1 + 1, x0^2 + x0,
       x1^2 + x1, y0^2 + y0, y1^2 + y1)
       of Multivariate Polynomial Ring in x0, x1, y0, y1 over Finite Field of size 2

sage: k.<a> = GF(3^5)
sage: P.<x,y,z> = PolynomialRing(k)
sage: I = sage.rings.ideal.Katsura(P)
sage: I.dimension()
0
sage: I.variety()
[{y: 0, z: 0, x: 1}]

sage: J = I.weil_restriction(); J
Ideal (x4 - y4 - z4, x3 - y3 - z3, x2 - y2 - z2, x1 - y1 - z1, x0 - y0 - z0 - 1,
       x2^2 - x1*x3 - x0*x4 + x4^2 - y2^2 + y1*y3 + y0*y4 - y4^2 - z2^2 + z1*z3 + z0*z4 - z4
       -x1*x2 - x0*x3 - x3*x4 - x4^2 + y1*y2 + y0*y3 + y3*y4 + y4^2 + z1*z2 + z0*z3 + z3*z4
       x1^2 - x0*x2 + x3^2 - x2*x4 + x3*x4 - y1^2 + y0*y2 - y3^2 + y2*y4 - y3*y4 - z1^2 + z0
       -x0*x1 - x2*x3 - x3^2 - x1*x4 + x2*x4 + y0*y1 + y2*y3 + y3^2 + y1*y4 - y2*y4 + z0*z1
```

```
        x0^2 + x2*x3 + x1*x4 - y0^2 - y2*y3 - y1*y4 - z0^2 - z2*z3 - z1*z4 - x0,
        -x4*y0 - x3*y1 - x2*y2 - x1*y3 - x0*y4 - x4*y4 - y4*z0 - y3*z1 - y2*z2 - y1*z3 - y0*z
        -x3*y0 - x2*y1 - x1*y2 - x0*y3 - x4*y3 - x3*y4 + x4*y4 - y3*z0 - y2*z1 - y1*z2 - y0*z
        -x2*y0 - x1*y1 - x0*y2 - x4*y2 - x3*y3 + x4*y3 - x2*y4 + x3*y4 - y2*z0 - y1*z1 - y0*z
        -x1*y0 - x0*y1 - x4*y1 - x3*y2 + x4*y2 - x2*y3 + x3*y3 - x1*y4 + x2*y4 - y1*z0 - y0*z
        -x0*y0 + x4*y1 + x3*y2 + x2*y3 + x1*y4 - y0*z0 + y4*z1 + y3*z2 + y2*z3 + y1*z4 - y0)
        x0, x1, x2, x3, x4, y0, y1, y2, y3, y4, z0, z1, z2, z3, z4 over Finite Field of size
sage: J += sage.rings.ideal.FieldIdeal(J.ring()) # ensure radical ideal
sage: J.variety()
[{y1: 0, y4: 0, z2: 0, y2: 0, x0: 1, y0: 0, x2: 0, z4: 0, z3: 0, x4: 0, x1: 0, z1: 0, z0: 0,
```

Weil restrictions are often used to study elliptic curves over extension fields so we give a simple example involving those:

```
sage: K.<a> = QuadraticField(1/3)
sage: E = EllipticCurve(K,[1,2,3,4,5])
```

We pick a point on `E`:

```
sage: p = E.lift_x(1); p
(1 : 2 : 1)

sage: I = E.defining_ideal(); I
Ideal (-x^3 - 2*x^2*z + x*y*z + y^2*z - 4*x*z^2 + 3*y*z^2 - 5*z^3)
of Multivariate Polynomial Ring in x, y, z over Number Field in a with defining polynomial x
```

Of course, the point `p` is a root of all generators of `I`:

```
sage: [f.subs(x=1,y=2,z=1) for f in I.gens()]
[0]
```

`I` is also radical:

```
sage: I.radical() == I
True
```

So we compute its Weil restriction:

```
sage: J = I.weil_restriction()
sage: J
Ideal (-3*x0^2*x1 - 1/3*x1^3 - 4*x0*x1*z0 + x1*y0*z0 + x0*y1*z0 + 2*y0*y1*z0 - 4*x1*z0^2 + 3
        - 2/3*x1^2*z1 + x0*y0*z1 + y0^2*z1 + 1/3*x1*y1*z1 + 1/3*y1^2*z1 - 8*x0*z0*z1 + 6*y0*
       -x0^3 - x0*x1^2 - 2*x0^2*z0 - 2/3*x1^2*z0 + x0*y0*z0 + y0^2*z0 + 1/3*x1*y1*z0 + 1/3*y
        + 1/3*x1*y0*z1 + 1/3*x0*y1*z1 + 2/3*y0*y1*z1 - 8/3*x1*z0*z1 + 2*y1*z0*z1 - 4/3*x0*z1
of Multivariate Polynomial Ring in x0, x1, y0, y1, z0, z1 over Rational Field
```

We can check that the point `p` is still a root of all generators of `J`:

```
sage: [f.subs(x0=1,y0=2,z0=1,x1=0,y1=0,z1=0) for f in J.gens()]
[0, 0]
```

Note: Based on a Singular implementation by Michael Brickenstein

class MPolynomialIdeal_macaulay2_repr()

An ideal in a multivariate polynomial ring, which has an underlying Macaulay2 ring associated to it.

EXAMPLES:

```
sage: R.<x,y,z,w> = PolynomialRing(ZZ, 4)
sage: I = ideal(x*y-z^2, y^2-w^2)
sage: I
Ideal (x*y - z^2, y^2 - w^2) of Multivariate Polynomial Ring in x, y, z, w over Integer Ring
```

class MPolynomialIdeal_magma_repr()

class MPolynomialIdeal_singular_repr()

An ideal in a multivariate polynomial ring, which has an underlying Singular ring associated to it.

associated_primes(**args, **kwds*)

Return a list of primary ideals (and their associated primes) such that their intersection is I = `self`.

An ideal Q is called primary if it is a proper ideal of the ring R and if whenever $ab \in Q$ and $a \notin Q$ then $b^n \in Q$ for some $n \in \mathbf{Z}$.

If Q is a primary ideal of the ring R, then the radical ideal P of Q, i.e. $P = \{a \in R, a^n \in Q\}$ for some $n \in \mathbf{Z}$, is called the *associated prime* of Q.

If I is a proper ideal of the ring R then there exists a decomposition in primary ideals Q_i such that

- their intersection is I
- none of the Q_i contains the intersection of the rest, and
- the associated prime ideals of Q_i are pairwise different.

This method returns the associated primes of the Q_i.

INPUT:

- `algorithm` - string:
- `'sy'` - (default) use the shimoyama-yokoyama algorithm
- `'gtz'` - use the gianni-trager-zacharias algorithm

OUTPUT:

- `list` - a list of primary ideals and their associated primes [(primary ideal, associated prime), ...]

EXAMPLES:

```
sage: R.<x,y,z> = PolynomialRing(QQ, 3, order='lex')
sage: p = z^2 + 1; q = z^3 + 2
sage: I = (p*q^2, y-z^2)*R
sage: pd = I.associated_primes(); pd
[Ideal (z^3 + 2, y - z^2) of Multivariate Polynomial Ring in x, y, z over Rational Field,
 Ideal (z^2 + 1, y + 1) of Multivariate Polynomial Ring in x, y, z over Rational Field]
```

ALGORITHM: Uses Singular.

REFERENCES:

- Thomas Becker and Volker Weispfenning. Groebner Bases - A Computational Approach To Commutative Algebra. Springer, New York 1993.

basis_is_groebner(*singular=Singular*)

Returns `True` if the generators of `self` (`self.gens()`) form a Groebner basis.

Let I be the set of generators of this ideal. The check is performed by trying to lift $Syz(LM(I))$ to $Syz(I)$ as I forms a Groebner basis if and only if for every element S in $Syz(LM(I))$:

$$S \cdot G = \sum_{i=0}^{m} h_i g_i \rightarrow_G 0.$$

.

ALGORITHM: Uses Singular

EXAMPLE:

```
sage: R.<a,b,c,d,e,f,g,h,i,j> = PolynomialRing(GF(127),10)
sage: I = sage.rings.ideal.Cyclic(R,4)
sage: I.basis_is_groebner()
False
sage: I2 = Ideal(I.groebner_basis())
sage: I2.basis_is_groebner()
True
```

A more complicated example:

```
sage: R.<U6,U5,U4,U3,U2, u6,u5,u4,u3,u2, h> = PolynomialRing(GF(7583))
sage: l = [u6 + u5 + u4 + u3 + u2 - 3791*h, \
           U6 + U5 + U4 + U3 + U2 - 3791*h, \
           U2*u2 - h^2, U3*u3 - h^2, U4*u4 - h^2, \
           U5*u4 + U5*u3 + U4*u3 + U5*u2 + U4*u2 + U3*u2 - 3791*U5*h - 3791*U4*h - 3791*U3*h
           U4*u5 + U3*u5 + U2*u5 + U3*u4 + U2*u4 + U2*u3 - 3791*u5*h - 3791*u4*h - 3791*u3*h
           U5*u5 - h^2, U4*U2*u3 + U5*U3*u2 + U4*U3*u2 + U3^2*u2 - 3791*U5*U3*h - 3791*U4*U3
            - 3791*U4*U2*h + U3*U2*h - 3791*U2^2*h - 3791*U4*u3*h - 3791*U4*u2*h - 3791*U3*u
           U3*u5*u4 + U2*u5*u4 + U3*u4^2 + U2*u4^2 + U2*u4*u3 - 3791*u5*u4*h - 3791*u4^2*h -
           U2*u5*u4*u3 + U2*u4^2*u3 + U2*u4*u3^2 - 3791*u5*u4*u3*h - 3791*u4^2*u3*h - 3791*u
           U5^2*U4*u3 + U5*U4^2*u3 + U5^2*U4*u2 + U5*U4^2*u2 + U5^2*U3*u2 + 2*U5*U4*U3*u2 +
            + U5*U4*U3*h - 3791*U5*U3^2*h - 3791*U5^2*U2*h + U5*U4*U2*h + U5*U3*U2*h - 3791*
            - U4^2*h^2 - 947*U5*U3*h^2 - U4*U3*h^2 - 948*U5*U2*h^2 - U4*U2*h^2 - 1422*U5*h^3
           u5*u4*u3*u2*h + u4^2*u3*u2*h + u4*u3^2*u2*h + u4*u3*u2^2*h + 2*u5*u4*u3*h^2 + 2*u
            + 2*u5*u3*u2*h^2 + 1899*u4*u3*u2*h^2, \
           U5^2*U4*U3*u2 + U5*U4^2*U3*u2 + U5*U4*U3^2*u2 - 3791*U5^2*U4*U3*h - 3791*U5*U4^2*
            + 3791*U5*U4*U3*u2*h + U5^2*U4*h^2 + U5*U4^2*h^2 + U5^2*U3*h^2 - U4^2*U3*h^2 - U
            - U5*U3*U2*h^2 - U4*U3*U2*h^2 + 3791*U5*U4*h^3 + 3791*U5*U3*h^3 + 3791*U4*U3*h^3
           u4^2*u3*u2*h^2 + 1515*u5*u3^2*u2*h^2 + u4*u3^2*u2*h^2 + 1515*u5*u4*u2^2*h^2 + 151
            + 1521*u5*u4*u3*h^3 - 3028*u4^2*u3*h^3 - 3028*u4*u3^2*h^3 + 1521*u5*u4*u2*h^3 -
           U5^2*U4*U3*U2*h + U5*U4^2*U3*U2*h + U5*U4*U3^2*U2*h + U5*U4*U3*U2^2*h + 2*U5^2*U4
            + 2*U5^2*U4*U2*h^2 + 2*U5*U4^2*U2*h^2 + 2*U5^2*U3*U2*h^2 - 2*U4^2*U3*U2*h^2 - 2*
             - 2*U5*U4*U2^2*h^2 - 2*U5*U3*U2^2*h^2 - 2*U4*U3*U2^2*h^2 - U5*U4*U3*h^3 - U5*U4

sage: Ideal(l).basis_is_groebner()
False
sage: gb = Ideal(l).groebner_basis()
sage: Ideal(gb).basis_is_groebner()
True
```

Note: From the Singular Manual for the reduce function we use in this method: 'The result may have no meaning if the second argument (`self`) is not a standard basis'. I (malb) believe this refers to the mathematical fact that the results may have no meaning if self is no standard basis, i.e., Singular doesn't 'add' any additional 'nonsense' to the result. So we may actually use reduce to determine if self is a Groebner basis.

complete_primary_decomposition(**args, **kwds*)

Return a list of primary ideals and their associated primes such that the intersection of the primary ideal Q_i is I = `self`.

An ideal Q is called primary if it is a proper ideal of the ring R and if whenever $ab \in Q$ and $a \notin Q$ then $b^n \in Q$ for some $n \in \mathbf{Z}$.

If Q is a primary ideal of the ring R, then the radical ideal P of Q, i.e. $P = \{a \in R, a^n \in Q\}$ for some $n \in \mathbf{Z}$, is called the *associated prime* of Q.

If I is a proper ideal of the ring R then there exists a decomposition in primary ideals Q_i such that

- their intersection is I
- none of the Q_i contains the intersection of the rest, and
- the associated prime ideals of Q_i are pairwise different.

This method returns these Q_i and their associated primes.

INPUT:

- `algorithm` - string:
- `'sy'` - (default) use the shimoyama-yokoyama algorithm
- `'gtz'` - use the gianni-trager-zacharias algorithm

OUTPUT:

- `list` - a list of primary ideals and their associated primes [(primary ideal, associated prime), ...]

EXAMPLES:

```
sage: R.<x,y,z> = PolynomialRing(QQ, 3, order='lex')
sage: p = z^2 + 1; q = z^3 + 2
sage: I = (p*q^2, y-z^2)*R
sage: pd = I.complete_primary_decomposition(); pd
[(Ideal (z^6 + 4*z^3 + 4, y - z^2) of Multivariate Polynomial Ring in x, y, z over Rational
  Ideal (z^3 + 2, y - z^2) of Multivariate Polynomial Ring in x, y, z over Rational Field),
 (Ideal (z^2 + 1, y + 1) of Multivariate Polynomial Ring in x, y, z over Rational Field,
  Ideal (z^2 + 1, y + 1) of Multivariate Polynomial Ring in x, y, z over Rational Field)]

sage: I.complete_primary_decomposition(algorithm = 'gtz')
[(Ideal (z^6 + 4*z^3 + 4, y - z^2) of Multivariate Polynomial Ring in x, y, z over Rational
  Ideal (z^3 + 2, y - z^2) of Multivariate Polynomial Ring in x, y, z over Rational Field),
 (Ideal (z^2 + 1, y - z^2) of Multivariate Polynomial Ring in x, y, z over Rational Field,
  Ideal (z^2 + 1, y - z^2) of Multivariate Polynomial Ring in x, y, z over Rational Field)]

sage: reduce(lambda Qi,Qj: Qi.intersection(Qj), [Qi for (Qi,radQi) in pd]) == I
True

sage: [Qi.radical() == radQi for (Qi,radQi) in pd]
[True, True]
```

ALGORITHM: Uses Singular.

REFERENCES:

- Thomas Becker and Volker Weispfenning. Groebner Bases - A Computational Approach To Commutative Algebra. Springer, New York 1993.

dimension (*singular=Singular*)

The dimension of the ring modulo this ideal.

EXAMPLE:

```
sage: P.<x,y,z> = PolynomialRing(GF(32003),order='degrevlex')
sage: I = ideal(x^2-y,x^3)
sage: I.dimension()
1
```

For polynomials over a finite field of order too large for Singular, this falls back on a toy implementation of Buchberger to compute the Groebner basis, then uses the algorithm described in Chapter 9, Section 1 of Cox, Little, and O'Shea's "Ideals, Varieties, and Algorithms".

EXAMPLE:

```
sage: R.<x,y> = PolynomialRing(GF(2147483659),order='lex')
sage: I = R.ideal([x*y,x*y+1])
sage: I.dimension()
verbose 0 (...: multi_polynomial_ideal.py, dimension) Warning: falling back to very slow toy
0
sage: I=ideal([x*(x*y+1),y*(x*y+1)])
sage: I.dimension()
verbose 0 (...: multi_polynomial_ideal.py, dimension) Warning: falling back to very slow toy
1
sage: I = R.ideal([x^3*y,x*y^2])
sage: I.dimension()
verbose 0 (...: multi_polynomial_ideal.py, dimension) Warning: falling back to very slow toy
1
sage: R.<x,y> = PolynomialRing(GF(2147483659),order='lex')
sage: I = R.ideal(0)
sage: I.dimension()
verbose 0 (...: multi_polynomial_ideal.py, dimension) Warning: falling back to very slow toy
2
```

ALGORITHM: Uses Singular, unless the characteristic is too large.

Note: Requires computation of a Groebner basis, which can be a very expensive operation.

elimination_ideal(**args, **kwds*)

Returns the elimination ideal this ideal with respect to the variables given in `variables`.

INPUT:

- `variables` - a list or tuple of variables in `self.ring()`

EXAMPLE:

```
sage: R.<x,y,t,s,z> = PolynomialRing(QQ,5)
sage: I = R * [x-t,y-t^2,z-t^3,s-x+y^3]
sage: I.elimination_ideal([t,s])
Ideal (y^2 - x*z, x*y - z, x^2 - y) of Multivariate
Polynomial Ring in x, y, t, s, z over Rational Field
```

ALGORITHM: Uses SINGULAR

Note: Requires computation of a Groebner basis, which can be a very expensive operation.

genus()

Return the genus of the projective curve defined by this ideal, which must be 1 dimensional.

EXAMPLE: Consider the hyperelliptic curve $y^2 = 4x^5 - 30x^3 + 45x - 22$ over $\mathbf{Q}$, it has genus 2:

```
sage: P, x = PolynomialRing(QQ,"x").objgen()
sage: f = 4*x^5 - 30*x^3 + 45*x - 22
sage: C = HyperellipticCurve(f); C
Hyperelliptic Curve over Rational Field defined by y^2 = 4*x^5 - 30*x^3 + 45*x - 22
sage: C.genus()
2

sage: P.<x,y> = PolynomialRing(QQ)
sage: f = y^2 - 4*x^5 - 30*x^3 + 45*x - 22
sage: I = Ideal([f])
sage: I.genus()
2
```

hilbert_polynomial()

Return the Hilbert polynomial of this ideal.

Let I = `self` be a homogeneous ideal and R = `self.ring()` be a graded commutative algebra ($R = \oplus R_d$) over a field K. The Hilbert polynomial is the unique polynomial $HP(t)$ with rational coefficients such that $HP(d) = dim_K R_d$ for all but finitely many positive integers d.

EXAMPLE:

```
sage: P.<x,y,z> = PolynomialRing(QQ)
sage: I = Ideal([x^3*y^2 + 3*x^2*y^2*z + y^3*z^2 + z^5])
sage: I.hilbert_polynomial()
5*t - 5
```

hilbert_series(*singular=Singular*)

Return the Hilbert series of this ideal.

Let I = `self` be a homogeneous ideal and R = `self.ring()` be a graded commutative algebra ($R = \oplus R_d$) over a field K. Then the Hilbert function is defined as $H(d) = dim_K R_d$ and the Hilbert series of I is defined as the formal power series $HS(t) = \sum_0^\infty H(d)t^d$.

This power series can be expressed as $HS(t) = Q(t)/(1-t)^n$ where $Q(t)$ is a polynomial over Z and n the number of variables in R. This method returns $Q(t)/(1-t)^n$.

EXAMPLE:

```
sage: P.<x,y,z> = PolynomialRing(QQ)
sage: I = Ideal([x^3*y^2 + 3*x^2*y^2*z + y^3*z^2 + z^5])
```

```
sage: I.hilbert_series()
(-t^4 - t^3 - t^2 - t - 1)/(-t^2 + 2*t - 1)
```

integral_closure(**args, **kwds*)

Let I = `self`.

Returns the integral closure of $I, ..., I^p$, where sI is an ideal in the polynomial ring $R = k[x(1), ...x(n)]$. If p is not given, or $p = 0$, compute the closure of all powers up to the maximum degree in t occurring in the closure of $R[It]$ (so this is the last power whose closure is not just the sum/product of the smaller). If r is given and `r is True`, `I.integral_closure()` starts with a check whether I is already a radical ideal.

INPUT:

- `p` - powers of I (default: 0)
- `r` - check whether self is a radical ideal first (default: True)

EXAMPLE:

```
sage: R.<x,y> = QQ[]
sage: I = ideal([x^2,x*y^4,y^5])
sage: I.integral_closure()
[x^2, y^5, -x*y^3]
```

ALGORITHM: Use Singular

interreduced_basis(**args, **kwds*)

If this ideal is spanned by $(f_1, ..., f_n)$ this method returns $(g_1, ..., g_s)$ such that:

- $(f_1, ..., f_n) = (g_1, ..., g_s)$
- $LT(g_i)! = LT(g_j)$ for all $i! = j$
- $LT(g_i)$ does not divide m for all monomials m of $\{g_1, ..., g_{i-1}, g_{i+1}, ..., g_s\}$
- $LC(g_i) == 1$ for all i.

EXAMPLE:

```
sage: R.<x,y,z> = PolynomialRing(QQ)
sage: I = Ideal([z*x+y^3,z+y^3,z+x*y])
sage: I.interreduced_basis()
[x*z - z, x*y + z, y^3 + z]

sage: R.<x,y,z> = PolynomialRing(QQ,order='negdegrevlex')
sage: I = Ideal([z*x+y^3,z+y^3,z+x*y])
sage: I.interreduced_basis()
[x*z + y^3, x*y - y^3, z + y^3]
```

ALGORITHM: Uses Singular's interred command or `toy_buchberger.inter_reduction` if conversion to Singular fails.

intersection(**args, **kwds*)

Return the intersection of the two ideals.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ, 2, order='lex')
sage: I = x*R
sage: J = y*R
sage: I.intersection(J)
Ideal (x*y) of Multivariate Polynomial Ring in x, y over Rational Field
```

The following simple example illustrates that the product need not equal the intersection.

```
sage: I = (x^2, y)*R
sage: J = (y^2, x)*R
```

```
sage: K = I.intersection(J); K
Ideal (y^2, x*y, x^2) of Multivariate Polynomial Ring in x, y over Rational Field
sage: IJ = I*J; IJ
Ideal (x^2*y^2, x^3, y^3, x*y) of Multivariate Polynomial Ring in x, y over Rational Field
sage: IJ == K
False
```

minimal_associated_primes(**args, **kwds*)

OUTPUT:

- `list` - a list of prime ideals

EXAMPLES:

```
sage: R.<x,y,z> = PolynomialRing(QQ, 3, 'xyz')
sage: p = z^2 + 1; q = z^3 + 2
sage: I = (p*q^2, y-z^2)*R
sage: I.minimal_associated_primes ()
[Ideal (z^2 + 1, -z^2 + y) of Multivariate Polynomial Ring
in x, y, z over Rational Field, Ideal (z^3 + 2, -z^2 + y)
of Multivariate Polynomial Ring in x, y, z over Rational
Field]
```

ALGORITHM: Uses Singular.

plot(*singular=Singular*)

If you somehow manage to install surf, perhaps you can use this function to implicitly plot the real zero locus of this ideal (if principal).

INPUT:

- `self` - must be a principal ideal in 2 or 3 vars over QQ.

EXAMPLES:

Implicit plotting in 2-d:

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: I = R.ideal([y^3 - x^2])
sage: I.plot()        # cusp         optional - surf
sage: I = R.ideal([y^2 - x^2 - 1])
sage: I.plot()        # hyperbola    optional - surf
sage: I = R.ideal([y^2 + x^2*(1/4) - 1])
sage: I.plot()        # ellipse      optional - surf
sage: I = R.ideal([y^2-(x^2-1)*(x-2)])
sage: I.plot()        # elliptic curve  optional - surf
```

Implicit plotting in 3-d:

```
sage: R.<x,y,z> = PolynomialRing(QQ,3)
sage: I = R.ideal([y^2 + x^2*(1/4) - z])
sage: I.plot()          # a cone         optional - surf
sage: I = R.ideal([y^2 + z^2*(1/4) - x])
sage: I.plot()          # same code, from a different angle  optional - surf
sage: I = R.ideal([x^2*y^2+x^2*z^2+y^2*z^2-16*x*y*z])
sage: I.plot()          # Steiner surface   optional - surf
```

AUTHORS:

- David Joyner (2006-02-12)

primary_decomposition(*algorithm='sy'*)

Return a list of primary ideals such that their intersection is I = `self`.

An ideal Q is called primary if it is a proper ideal of the ring R and if whenever $ab \in Q$ and $a \notin Q$ then $b^n \in Q$ for some $n \in \mathbf{Z}$.

If I is a proper ideal of the ring R then there exists a decomposition in primary ideals Q_i such that

- their intersection is I
- none of the Q_i contains the intersection of the rest, and
- the associated prime ideals of Q_i are pairwise different.

This method returns these Q_i.

INPUT:

- `algorithm` - string:
- `'sy'` - (default) use the shimoyama-yokoyama algorithm
- `'gtz'` - use the gianni-trager-zacharias algorithm

EXAMPLES:

```
sage: R.<x,y,z> = PolynomialRing(QQ, 3, order='lex')
sage: p = z^2 + 1; q = z^3 + 2
sage: I = (p*q^2, y-z^2)*R
sage: pd = I.primary_decomposition(); pd
[Ideal (z^6 + 4*z^3 + 4, y - z^2) of Multivariate Polynomial Ring in x, y, z over Rational F
 Ideal (z^2 + 1, y + 1) of Multivariate Polynomial Ring in x, y, z over Rational Field]

sage: reduce(lambda Qi,Qj: Qi.intersection(Qj), pd) == I
True
```

ALGORITHM: Uses Singular.

REFERENCES:

- Thomas Becker and Volker Weispfenning. Groebner Bases - A Computational Approach To Commutative Algebra. Springer, New York 1993.

quotient (**args, **kwds*)

Given ideals I = `self` and J in the same polynomial ring P, return the ideal quotient of I by J consisting of the polynomials a of P such that $\{aJ \subset I\}$.

This is also referred to as the colon ideal $(I{:}J)$.

INPUT:

- `J` - multivariate polynomial ideal

EXAMPLE:

```
sage: R.<x,y,z> = PolynomialRing(GF(181),3)
sage: I = Ideal([x^2+x*y*z,y^2-z^3*y,z^3+y^5*x*z])
sage: J = Ideal([x])
sage: Q = I.quotient(J)
sage: y*z + x in I
False
sage: x in J
True
sage: x * (y*z + x) in I
True
```

radical (**args, **kwds*)

The radical of this ideal.

EXAMPLES:

This is an obviously not radical ideal:

```
sage: R.<x,y,z> = PolynomialRing(QQ, 3)
sage: I = (x^2, y^3, (x*z)^4 + y^3 + 10*x^2)*R
sage: I.radical()
Ideal (y, x) of Multivariate Polynomial Ring in x, y, z over Rational Field
```

That the radical is correct is clear from the Groebner basis.

```
sage: I.groebner_basis()
[y^3, x^2]
```

This is the example from the Singular manual:

```
sage: p = z^2 + 1; q = z^3 + 2
sage: I = (p*q^2, y-z^2)*R
sage: I.radical()
Ideal (z^2 - y, y^2*z + y*z + 2*y + 2) of Multivariate Polynomial Ring in x, y, z over Ratio
```

Note: From the Singular manual: A combination of the algorithms of Krick/Logar and Kemper is used. Works also in positive characteristic (Kempers algorithm).

```
sage: R.<x,y,z> = PolynomialRing(GF(37), 3)
sage: p = z^2 + 1; q = z^3 + 2
sage: I = (p*q^2, y - z^2)*R
sage: I.radical()
Ideal (z^2 - y, y^2*z + y*z + 2*y + 2) of Multivariate Polynomial Ring in x, y, z over Finit
```

reduced_basis(**args, **kwds*)

Warning: This function is deprecated. It will be removed in a future release of Sage. Please use the `interreduced_basis()` function instead.

If this ideal is spanned by $(f_1, ..., f_n)$ this method returns $(g_1, ..., g_s)$ such that:

- $(f_1, ..., f_n) = (g_1, ..., g_s)$
- $LT(g_i) != LT(g_j)$ for all $i != j$
- $LT(g_i)$ does not divide m for all monomials m of $\{g_1, ..., g_{i-1}, g_{i+1}, ..., g_s\}$
- $LC(g_i) == 1$ for all i.

EXAMPLES:

```
sage: R.<x,y,z> = PolynomialRing(QQ)
sage: I = Ideal([z*x+y^3,z+y^3,z+x*y])
sage: I.reduced_basis()
doctest:...: DeprecationWarning: This function is deprecated. It will be removed in a future
[x*z - z, x*y + z, y^3 + z]

sage: R.<x,y,z> = PolynomialRing(QQ,order='negdegrevlex')
sage: I = Ideal([z*x+y^3,z+y^3,z+x*y])
sage: I.reduced_basis()
[x*z + y^3, x*y - y^3, z + y^3]
```

ALGORITHM:

Uses Singular's interred command or `toy_buchberger.inter_reduction` if conversion to Singular fails.

syzygy_module()

Computes the first syzygy (i.e., the module of relations of the given generators) of the ideal.

EXAMPLE:

```
sage: R.<x,y> = PolynomialRing(QQ)
sage: f = 2*x^2 + y
sage: g = y
sage: h = 2*f + g
sage: I = Ideal([f,g,h])
sage: M = I.syzygy_module(); M
[       -2        -1         1]
[       -y 2*x^2 + y         0]
sage: G = vector(I.gens())
```

```
sage: M*G
(0, 0)
```

ALGORITHM: Uses Singular's syz command

transformed_basis(**args, **kwds*)

Returns a lex or other_ring Groebner Basis for this ideal.

INPUT:

- algorithm - see below for options.
- other_ring - only valid for algorithm 'fglm', if provided conversion will be performed to this ring. Otherwise a lex Groebner basis will be returned.

ALGORITHMS:

fglm FGLM algorithm. The input ideal must be given with a reduced Groebner Basis of a zero-dimensional ideal

gwalk Groebner Walk algorithm (*default*)

awalk1 'first alternative' algorithm

awalk2 'second alternative' algorithm

twalk Tran algorithm

fwalk Fractal Walk algorithm

EXAMPLES:

```
sage: R.<x,y,z> = PolynomialRing(QQ,3)
sage: I = Ideal([y^3+x^2,x^2*y+x^2, x^3-x^2, z^4-x^2-y])
sage: I = Ideal(I.groebner_basis())
sage: S.<z,x,y> = PolynomialRing(QQ,3,order='lex')
sage: J = Ideal(I.transformed_basis('fglm',S))
sage: J
Ideal (y^4 + y^3, x*y^3 - y^3, x^2 + y^3, z^4 + y^3 - y)
 of Multivariate Polynomial Ring in z, x, y over Rational Field

sage: R.<z,y,x>=PolynomialRing(GF(32003),3,order='lex')
sage: I=Ideal([y^3+x*y*z+y^2*z+x*z^3,3+x*y+x^2*y+y^2*z])
sage: I.transformed_basis('gwalk')
[y^9 - y^7*x^2 - y^7*x - y^6*x^3 - y^6*x^2 - 3*y^6 - 3*y^5*x - y^3*x^7
 - 3*y^3*x^6 - 3*y^3*x^5 - y^3*x^4 - 9*y^2*x^5 - 18*y^2*x^4 - 9*y^2*x^3
 - 27*y*x^3 - 27*y*x^2 - 27*x,
 z*x + 8297*y^8*x^2 + 8297*y^8*x + 3556*y^7 - 8297*y^6*x^4 + 15409*y^6*x^3 - 8297*y^6*x^2
 - 8297*y^5*x^5 + 15409*y^5*x^4 - 8297*y^5*x^3 + 3556*y^5*x^2 + 3556*y^5*x + 3556*y^4*x^3
 + 3556*y^4*x^2 - 10668*y^4 - 10668*y^3*x - 8297*y^2*x^9 - 1185*y^2*x^8 + 14224*y^2*x^7
 - 1185*y^2*x^6 - 8297*y^2*x^5 - 14223*y*x^7 - 10666*y*x^6 - 10666*y*x^5 - 14223*y*x^4
 + x^5 + 2*x^4 + x^3, z*y^2 + y*x^2 + y*x + 3]
```

ALGORITHM: Uses Singular

triangular_decomposition(*algorithm=None, singular=Singular*)

Decompose zero-dimensional ideal self into triangular sets.

This requires that the given basis is reduced w.r.t. to the lexicographical monomial ordering. If the basis of self does not have this property, the required Groebner basis is computed implicitly.

INPUT:

- algorithm - string or None (default: None)
  ALGORITHMS:
  - singular:triangL - decomposition of self into triangular systems (Lazard).
  - singular:triangLfak - decomp. of self into tri. systems plus factorization.
  - singular:triangM - decomposition of self into triangular systems (Moeller).

OUTPUT: a list T of lists t such that the variety of `self` is the union of the varieties of t in L and each t is in triangular form.

EXAMPLE:

```
sage: P.<e,d,c,b,a> = PolynomialRing(QQ,5,order='lex')
sage: I = sage.rings.ideal.Cyclic(P)
sage: GB = Ideal(I.groebner_basis('singular:stdfglm'))
sage: GB.triangular_decomposition('singular:triangLfak')
[Ideal (a - 1, b - 1, c - 1, d^2 + 3*d + 1, e + d + 3) of Multivariate Polynomial Ring in e,
Ideal (a - 1, b - 1, c^2 + 3*c + 1, d + c + 3, e - 1) of Multivariate Polynomial Ring in e,
Ideal (a - 1, b^2 + 3*b + 1, c + b + 3, d - 1, e - 1) of Multivariate Polynomial Ring in e,
Ideal (a - 1, b^4 + b^3 + b^2 + b + 1, c - b^2, d - b^3, e + b^3 + b^2 + b + 1) of Multivari
Ideal (a^2 + 3*a + 1, b - 1, c - 1, d - 1, e + a + 3) of Multivariate Polynomial Ring in e,
Ideal (a^2 + 3*a + 1, b + a + 3, c - 1, d - 1, e - 1) of Multivariate Polynomial Ring in e,
Ideal (a^4 - 4*a^3 + 6*a^2 + a + 1, 11*b^2 - 6*b*a^3 + 26*b*a^2 - 41*b*a + 4*b + 8*a^3 - 31*
Ideal (a^4 + a^3 + a^2 + a + 1, b - 1, c + a^3 + a^2 + a + 1, d - a^3, e - a^2) of Multivari
Ideal (a^4 + a^3 + a^2 + a + 1, b - a, c - a, d^2 + 3*d*a + a^2, e + d + 3*a) of Multivariat
Ideal (a^4 + a^3 + a^2 + a + 1, b - a, c^2 + 3*c*a + a^2, d + c + 3*a, e - a) of Multivariat
Ideal (a^4 + a^3 + a^2 + a + 1, b^2 + 3*b*a + a^2, c + b + 3*a, d - a, e - a) of Multivariat
Ideal (a^4 + a^3 + a^2 + a + 1, b^3 + b^2*a + b^2 + b*a^2 + b*a + b + a^3 + a^2 + a + 1, c +
Ideal (a^4 + a^3 + 6*a^2 - 4*a + 1, 11*b^2 - 6*b*a^3 - 10*b*a^2 - 39*b*a - 2*b - 16*a^3 - 23
```

variety(*ring=None, proof=True*)

Return the variety of `self`.

Given a zero-dimensional ideal I (== `self`) of a polynomial ring P whose order is lexicographic, return the variety of I as a list of dictionaries with (variable, value) pairs. By default, the variety of the ideal over its coefficient field K is returned; `ring` can be specified to find the variety over a different ring.

These dictionaries have cardinality equal to the number of variables in P and represent assignments of values to these variables such that all polynomials in I vanish.

If `ring` is specified, then a triangular decomposition of `self` is found over the original coefficient field K; then the triangular systems are solved using root-finding over `ring`. This is particularly useful when K is `QQ` (to allow fast symbolic computation of the triangular decomposition) and `ring` is `RR`, `AA`, `CC`, or `QQbar` (to compute the whole real or complex variety of the ideal).

Note that with `ring``=``RR` or `CC`, computation is done numerically and potentially inaccurately; in particular, the number of points in the real variety may be miscomputed. With `ring``=``AA` or `QQbar`, computation is done exactly (which may be much slower, of course).

INPUT:

- `ring` - return roots in the `ring` instead of the base ring of this ideal (default: `None`)
- `proof` - return a provably correct result (default: `True`)

EXAMPLE:

```
sage: K.<w> = GF(27) # this example is from the MAGMA handbook
sage: P.<x, y> = PolynomialRing(K, 2, order='lex')
sage: I = Ideal([ x^8 + y + 2, y^6 + x*y^5 + x^2 ])
sage: I = Ideal(I.groebner_basis()); I
Ideal (x - y^47 - y^45 + y^44 - y^43 + y^41 - y^39 - y^38
- y^37 - y^36 + y^35 - y^34 - y^33 + y^32 - y^31 + y^30 +
y^28 + y^27 + y^26 + y^25 - y^23 + y^22 + y^21 - y^19 -
y^18 - y^16 + y^15 + y^13 + y^12 - y^10 + y^9 + y^8 + y^7
- y^6 + y^4 + y^3 + y^2 + y - 1, y^48 + y^41 - y^40 + y^37
- y^36 - y^33 + y^32 - y^29 + y^28 - y^25 + y^24 + y^2 + y
+ 1) of Multivariate Polynomial Ring in x, y over Finite
Field in w of size 3^3

sage: V = I.variety(); V
[{y: w^2 + 2, x: 2*w}, {y: w^2 + w, x: 2*w + 1}, {y: w^2 + 2*w, x: 2*w + 2}]
```

```
sage: [f.subs(v) for f in I.gens() for v in V] # check that all polynomials vanish
[0, 0, 0, 0, 0, 0]
```

However, we only account for solutions in the ground field and not in the algebraic closure:

```
sage: I.vector_space_dimension()
48
```

Here we compute the points of intersection of a hyperbola and a circle, in several fields:

```
sage: K.<x, y> = PolynomialRing(QQ, 2, order='lex')
sage: I = Ideal([ x*y - 1, (x-2)^2 + (y-1)^2 - 1])
sage: I = Ideal(I.groebner_basis()); I
Ideal (x + y^3 - 2*y^2 + 4*y - 4, y^4 - 2*y^3 + 4*y^2 - 4*y + 1)
of Multivariate Polynomial Ring in x, y over Rational Field
```

These two curves have one rational intersection:

```
sage: I.variety()
[{y: 1, x: 1}]
```

There are two real intersections:

```
sage: I.variety(ring=RR)
[{y: 0.361103080528647, x: 2.76929235423863},
 {y: 1.00000000000000, x: 1.00000000000000}]
sage: I.variety(ring=AA)
[{x: 2.769292354238632?, y: 0.3611030805286474?},
 {x: 1, y: 1}]
```

and a total of four intersections:

```
sage: I.variety(ring=CC)
[{y: 0.31944845973567... - 1.6331702409152...*I,
  x: 0.11535382288068... + 0.58974280502220...*I},
 {y: 0.31944845973567... + 1.6331702409152...*I,
  x: 0.11535382288068... - 0.58974280502220...*I},
 {y: 0.36110308052864..., x: 2.7692923542386...},
 {y: 1.00000000000000, x: 1.00000000000000}]
sage: I.variety(ring=QQbar)
[{y: 0.3194484597356763? - 1.633170240915238?*I,
  x: 0.11535382288068429? + 0.5897428050222055?*I},
 {y: 0.3194484597356763? + 1.633170240915238?*I,
  x: 0.11535382288068429? - 0.5897428050222055?*I},
 {y: 0.3611030805286474?, x: 2.769292354238632?},
 {y: 1, x: 1}]
```

If the ground field's characteristic is too large for Singular, we resort to a toy implementation:

```
sage: R.<x,y> = PolynomialRing(GF(2147483659),order='lex')
sage: I=ideal([x^3-2*y^2,3*x+y^4])
sage: I.variety()
verbose 0 (...: multi_polynomial_ideal.py, variety) Warning: falling back to very slow toy i
verbose 0 (...: multi_polynomial_ideal.py, groebner_basis) Warning: falling back to very slo
[{y: 0, x: 0}]
```

TESTS:

```
sage: K.<w> = GF(27)
sage: P.<x, y> = PolynomialRing(K, 2, order='lex')
sage: I = Ideal([ x^8 + y + 2, y^6 + x*y^5 + x^2 ])
```

Testing the robustness of the Singular interface

```
sage: T = I.triangular_decomposition('singular:triangLfak')
sage: I.variety()
[{y: w^2 + 2, x: 2*w}, {y: w^2 + w, x: 2*w + 1}, {y: w^2 + 2*w, x: 2*w + 2}]
```

Testing that a bug is indeed fixed.

```
sage: R = PolynomialRing(GF(2), 30, ['x%d'%(i+1) for i in range(30)], order='lex')
sage: R.inject_variables()
Defining...
sage: I = Ideal([x1 + 1, x2, x3 + 1, x5*x10 + x10 + x18, x5*x11 + x11, \
                 x5*x18, x6, x7 + 1, x9, x10*x11 + x10 + x18, x10*x18 + x18, \
                 x11*x18, x12, x13, x14, x15, x16 + 1, x17 + x18 + 1, x19, x20, \
                 x21 + 1, x22, x23, x24, x25 + 1, x28 + 1, x29 + 1, x30, x8, \

{x14: 0, x24: 0, x16: 1, x1: 1, x3: 1, x2: 0, x5: 1, x4: 0, x19: 0, x18: 0, x7: 1, x6: 0, x1
{x14: 0, x24: 0, x16: 1, x1: 1, x3: 1, x2: 0, x5: 1, x4: 1, x19: 0, x18: 0, x7: 1, x6: 0, x1
{x14: 0, x24: 0, x16: 1, x1: 1, x3: 1, x2: 0, x5: 1, x4: 0, x19: 0, x18: 0, x7: 1, x6: 0, x1
{x14: 0, x24: 0, x16: 1, x1: 1, x3: 1, x2: 0, x5: 1, x4: 1, x19: 0, x18: 0, x7: 1, x6: 0, x1
{x14: 0, x24: 0, x16: 1, x1: 1, x3: 1, x2: 0, x5: 0, x4: 0, x19: 0, x18: 1, x7: 1, x6: 0, x1
{x14: 0, x24: 0, x16: 1, x1: 1, x3: 1, x2: 0, x5: 0, x4: 1, x19: 0, x18: 1, x7: 1, x6: 0, x1
{x14: 0, x24: 0, x16: 1, x1: 1, x3: 1, x2: 0, x5: 0, x4: 0, x19: 0, x18: 0, x7: 1, x6: 0, x1
{x14: 0, x24: 0, x16: 1, x1: 1, x3: 1, x2: 0, x5: 0, x4: 1, x19: 0, x18: 0, x7: 1, x6: 0, x1
{x14: 0, x24: 0, x16: 1, x1: 1, x3: 1, x2: 0, x5: 1, x4: 0, x19: 0, x18: 0, x7: 1, x6: 0, x1
{x14: 0, x24: 0, x16: 1, x1: 1, x3: 1, x2: 0, x5: 1, x4: 1, x19: 0, x18: 0, x7: 1, x6: 0, x1
{x14: 0, x24: 0, x16: 1, x1: 1, x3: 1, x2: 0, x5: 1, x4: 0, x19: 0, x18: 0, x7: 1, x6: 0, x1
{x14: 0, x24: 0, x16: 1, x1: 1, x3: 1, x2: 0, x5: 1, x4: 1, x19: 0, x18: 0, x7: 1, x6: 0, x1
{x14: 0, x24: 0, x16: 1, x1: 1, x3: 1, x2: 0, x5: 0, x4: 0, x19: 0, x18: 1, x7: 1, x6: 0, x1
{x14: 0, x24: 0, x16: 1, x1: 1, x3: 1, x2: 0, x5: 0, x4: 1, x19: 0, x18: 1, x7: 1, x6: 0, x1
```

ALGORITHM: Uses triangular decomposition.

vector_space_dimension()

Return the vector space dimension of the ring modulo this ideal. If the ideal is not zero-dimensional, a TypeError is raised.

ALGORITHM: Uses Singular.

EXAMPLE:

```
sage: R.<u,v> = PolynomialRing(QQ)
sage: g = u^4 + v^4 + u^3 + v^3
sage: I = ideal(g) + ideal(g.gradient())
sage: I.dimension()
0
sage: I.vector_space_dimension()
4
```

class RedSBContext (*singular=Singular*)
Within this context all Singular Groebner basis calculations are reduced automatically.

AUTHORS:

•Martin Albrecht

is_MPolynomialIdeal (*x*)
Return `True` if the provided argument `x` is an ideal in the multivariate polynomial ring.

INPUT:

•`x` - an arbitrary object

EXAMPLES:

```
sage: from sage.rings.polynomial.all import is_MPolynomialIdeal
sage: P.<x,y,z> = PolynomialRing(QQ)
sage: I = [x + 2*y + 2*z - 1, x^2 + 2*y^2 + 2*z^2 - x, 2*x*y + 2*y*z - y]
```

Sage distinguishes between a list of generators for an ideal and the ideal itself. This distinction is inconsistent with Singular but matches Magma's behavior.

```
sage: is_MPolynomialIdeal(I)
False

sage: I = Ideal(I)
sage: is_MPolynomialIdeal(I)
True
```

redSB (*func*)
Decorator to force a reduced Singular groebner basis.

TESTS:

```
sage: P.<a,b,c,d,e> = PolynomialRing(GF(127))
sage: J = sage.rings.ideal.Cyclic(P).homogenize()
sage: from sage.misc.sageinspect import sage_getsource
sage: "buchberger" in sage_getsource(J.interreduced_basis)
True
```

Note: This decorator is used automatically internally so the user does not need to use it manually.

28.11 Symmetric Ideals of Infinite Polynomial Rings

This module provides an implementation of ideals of polynomial rings in a countably infinite number of variables that are invariant under variable permuation. Such ideals are called 'Symmetric Ideals' in the rest of this document. Our implementation is based on the theory of M. Aschenbrenner and C. Hillar.

AUTHORS:

- Simon King <simon.king@uni-jena.de>

class SymmetricIdeal (*ring, gens, coerce=True*)
Ideal in an Infinite Polynomial Ring, invariant under permutation of variable indices

THEORY:

An Infinite Polynomial Ring with finitely many generators $x_*, y_*, ...$ over a field F is a free commutative F-algebra generated by infinitely many 'variables' $x_0, x_1, x_2, ..., y_0, y_1, y_2, ...$ We refer to the natural number n as the *index* of the variable x_n. See more detailed description at `infinite_polynomial_ring`

Infinite Polynomial Rings are equipped with a permutation action by permuting positive variable indices, i.e., $x_n^P = x_{P(n)}, y_n^P = y_{P(n)}, ...$ for any permutation P. Note that the variables $x_0, y_0, ...$ of index zero are invariant under that action.

A *Symmetric Ideal* is an ideal in an infinite polynomial ring X that is invariant under the permutation action. In other words, if $\mathfrak{S}_\infty$ denotes the symmetric group of $1, 2, ...$, then a Symmetric Ideal is a right $X[\mathfrak{S}_\infty]$-submodule of X.

It is known by work of Aschenbrenner and Hillar [AB2007] that an Infinite Polynomial Ring X with a single generator x_* is noetherian, in the sense that any Symmetric Ideal $I \subset X$ is finitely generated modulo addition, multiplication by elements of X, and permutation of variable indices (hence, it is a finitely generated right $X[\mathfrak{S}_\infty]$-module).

Moreover, if X is equipped with a lexicographic monomial ordering with $x_1 < x_2 < x_3...$ then there is an algorithm of Buchberger type that computes a Groebner basis G for I that allows for computation of a unique normal form, that is zero precisely for the elements of I – see [AB2008]. See `groebner_basis()` for more details.

Our implementation allows more than one generator and also provides degree lexicographic and degree reverse lexicographic monomial orderings – we do, however, not guarantee termination of the Buchberger algorithm in these cases.

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: I=X*(x[1]^2+y[2]^2,x[1]*x[2]*y[3]+x[1]*y[4])
sage: I == loads(dumps(I))
True
sage: latex(I)
\left(y_{2}^{2} + x_{1}^{2}, y_{4} x_{1} + y_{3} x_{2} x_{1}\right)\Bold{Q}[x_{\ast}, y_{\ast}][
```

The default ordering is lexicographic. We now compute a Groebner basis:

```
sage: J=I.groebner_basis()
sage: J
[x1^4 + x1^3, x2*x1^2 - x1^3, x2^2 - x1^2, y1*x1^3 + y1*x1^2, y1*x2 + y1*x1^2, y1^2 + x1^2, y2*x
```

Ideal membership in `I` can now be tested by commuting symmetric reduction modulo `J`:

```
sage: I.reduce(J)
Symmetric Ideal (0, 0) of Infinite polynomial ring in x, y over Rational Field
```

Note that the Groebner basis is not point-wise invariant under permutation. However, any element of `J` has symmetric reduction zero even after applying a permutation:

```
sage: P=Permutation([1, 4, 3, 2])
sage: J[2]
x2^2 - x1^2
sage: J[2]^P
x4^2 - x1^2
sage: J.__contains__(J[2]^P)
False
sage: [[(p^P).reduce(J) for p in J] for P in Permutations(4)]
[[0, 0, 0, 0, 0, 0, 0],
 [0, 0, 0, 0, 0, 0, 0],
 [0, 0, 0, 0, 0, 0, 0],
 [0, 0, 0, 0, 0, 0, 0],
```

```
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0]]
```

Since `I` is not a Groebner basis, it is no surprise that it can not detect ideal membership:

```
sage: [p.reduce(I) for p in J]
[x1^4 + x1^3, x2*x1^2 - x1^3, x2^2 - x1^2, y1*x1^3 + y1*x1^2, y1*x2 + y1*x1^2, y1^2 + x1^2, y2*x
```

Note we give no guarantee that the computation of a symmetric Groebner basis will terminate in an order different from lexicographic.

When multiplying Symmetric Ideals or raising them to some integer power, the permutation action is taken into account, so that the product is indeed the product of ideals in the mathematical sense.

```
sage: I=X*(x[1])
sage: I*I
Symmetric Ideal (x1^2, x2*x1) of Infinite polynomial ring in x, y over Rational Field
sage: I^3
Symmetric Ideal (x1^3, x2*x1^2, x2^2*x1, x3*x2*x1) of Infinite polynomial ring in x, y over Rati
sage: I*I == X*(x[1]^2)
False
```

groebner_basis()

Return a symmetric Groebner basis (type `Sequence`) of self.

INPUT:

- `tailreduce` (optional, default False) - if True, use tail reduction in intermediate computations
- `reduced` (optional, default True) - return the reduced normalised Groebner basis
- `algorithm` (optional) - determine the algorithm (see below for available algorithms)
- `report` (optional) - print information on the progress of computation.
- `use_full_group` (optional, default False) - if True then proceed as originally suggested by [AB2008]. Our default method should be faster, see `symmetrisation()` for more details.

The computation of symmetric Groebner bases also involves the computation of *classical* Groebner bases, i.e., of Groebner bases for ideals in polynomial rings with finitely many variables. For these computations, Sage provides the following ALGORITHMS:

'' autoselect (default)

'singular:groebner' Singular's `groebner` command

'singular:std' Singular's `std` command

'singular:stdhilb' Singular's `stdhib` command
'singular:stdfglm' Singular's `stdfglm` command
'singular:slimgb' Singular's `slimgb` command
'libsingular:std' libSingular's `std` command
'libsingular:slimgb' libSingular's `slimgb` command
'toy:buchberger' Sage's toy/educational buchberger without strategy
'toy:buchberger2' Sage's toy/educational buchberger with strategy
'toy:d_basis' Sage's toy/educational d_basis algorithm
'macaulay2:gb' Macaulay2's `gb` command (if available)
'magma:GroebnerBasis' Magma's `Groebnerbasis` command (if available)

If only a system is given - e.g. 'magma' - the default algorithm is chosen for that system.

Note: The Singular and libSingular versions of the respective algorithms are identical, but the former calls an external Singular process while the later calls a C function, i.e. the calling overhead is smaller.

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: I1 = X*(x[1]+x[2],x[1]*x[2])
sage: I1.groebner_basis()
[x1]
sage: I2 = X*(y[1]^2*y[3]+y[1]*x[3])
sage: I2.groebner_basis()
[y1*x2^2 - y1*x2*x1, y2*x2*x1 - y2*x1^2, y2*y1*x2 - y2*y1*x1, y2*y1^2 + y1*x2, y2^2*y1 + y2*
```

When using the algorithm originally suggested by Aschenbrenner and Hillar, the result is the same, but the computation takes much longer:

```
sage: I2.groebner_basis(use_full_group=True)
[y1*x2^2 - y1*x2*x1, y2*x2*x1 - y2*x1^2, y2*y1*x2 - y2*y1*x1, y2*y1^2 + y1*x2, y2^2*y1 + y2*
```

Last, we demonstrate how the report on the progress of computations looks like:

```
sage: I1.groebner_basis(report=True, reduced=True)
Symmetric interreduction
[1/2]  >

```

interreduced_basis()

A fully symmetrically reduced generating set (type Sequence) of self.

This does essentially the same as interreduction() with the option 'tailreduce', but it returns a Sequence rather than a SymmetricIdeal.

EXAMPLES:

```
sage: X.<x> = InfinitePolynomialRing(QQ)
sage: I=X*(x[1]+x[2],x[1]*x[2])
sage: I.interreduced_basis()
[-x1^2, x2 + x1]
```

interreduction(*tailreduce=True, sorted=False, report=None, RStrat=None*)

Return symmetrically interreduced form of self

INPUT:

- tailreduce (optional) - If True, the interreduction is also performed on the non-leading monomials.
- sorted (optional) - If True, it is assumed that the generators of self are already increasingly sorted.

- report (optional) - If not None, some information on the progress of computation is printed
- RStrat (optional) - A SymmetricReductionStrategy to which the polynomials resulting from the interreduction will be added. If RStrat already contains some polynomials, they will be used in the interreduction. The effect is to compute in a quotient ring.

RETURN: A Symmetric Ideal J (sorted list of generators) coinciding with self as an ideal, so that any generator is symmetrically reduced w.r.t. the other generators. Note that the leading coefficients of the result are not necessarily 1.

EXAMPLES:

```
sage: X.<x> = InfinitePolynomialRing(QQ)
sage: I=X*(x[1]+x[2],x[1]*x[2])
sage: I.interreduction()
Symmetric Ideal (-x1^2, x2 + x1) of Infinite polynomial ring in x over Rational Field
```

Here, we show the report option:

```
sage: I.interreduction(report=True)
Symmetric interreduction
[1/2]  >
[2/2] : >
[1/2]  >
[2/2] T[1] >
>
Symmetric Ideal (-x1^2, x2 + x1) of Infinite polynomial ring in x over Rational Field
```

[m/n] indicates that polynomial number m is considered and the total number of polynomials under consideration is n. '-> 0' is printed if a zero reduction occured. The rest of the report is as described in sage.rings.polynomial.symmetric_reduction.SymmetricReductionStrategy.reduce().

Last, we demonstrate the use of the optional parameter RStrat:

```
sage: from sage.rings.polynomial.symmetric_reduction import SymmetricReductionStrategy
sage: R = SymmetricReductionStrategy(X)
sage: R
Symmetric Reduction Strategy in Infinite polynomial ring in x over Rational Field
sage: I.interreduction(RStrat=R)
Symmetric Ideal (-x1^2, x2 + x1) of Infinite polynomial ring in x over Rational Field
sage: R
Symmetric Reduction Strategy in Infinite polynomial ring in x over Rational Field, modulo
    x1^2,
    x2 + x1
sage: R = SymmetricReductionStrategy(X,[x[1]^2])
sage: I.interreduction(RStrat=R)
Symmetric Ideal (x2 + x1) of Infinite polynomial ring in x over Rational Field
```

normalisation()

Return an ideal that coincides with self, so that all generators have leading coefficient 1.

Possibly occuring zeroes are removed from the generator list.

EXAMPLES:

```
sage: X.<x> = InfinitePolynomialRing(QQ)
sage: I = X*(1/2*x[1]+2/3*x[2], 0, 4/5*x[1]*x[2])
sage: I.normalisation()
Symmetric Ideal (x2 + 3/4*x1, x2*x1) of Infinite polynomial ring in x over Rational Field
```

reduce(*I, tailreduce=False*)

Symmetric reduction of self by another Symmetric Ideal or list of Infinite Polynomials.

INPUT:

- I – a Symmetric Ideal or a list of Infinite Polynomials

- `tailreduce` (optional) – if it is True, the non-leading terms will be reduced as well.

Reducing an element p of an Infinite Polynomial Ring X by some other element q means the following:

1. Let M and N be the leading terms of p and q.
2. Test whether there is a permutation P that does not does not diminish the variable indices occoring in N and preserves their order, so that there is some term $T \in X$ with $TN^P = M$. If there is no such permutation, return p
3. Replace p by $p - Tq^P$ and continue with step 1.

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: I = X*(y[1]^2*y[3]+y[1]*x[3])
sage: I.reduce([y[2]^2*y[1]])
Symmetric Ideal (y3*y1^2 + y1*x3) of Infinite polynomial ring in x, y over Rational Field
```

The preceding is correct, since any permutation that turns `y[2]^2*y[1]` into a factor of `y[1]^2*y[3]` interchanges the variable indices 1 and 2 – which is not allowed. However, reduction by `y[1]^2*y[2]` works, since one can change variable index 1 into 2 and 2 into 3:

```
sage: I.reduce([y[1]^2*y[2]])
Symmetric Ideal (y1*x3) of Infinite polynomial ring in x, y over Rational Field
```

The next example shows that tail reduction is not done, unless it is explicitly adviced. The input can also be a symmetric ideal:

```
sage: J = (x[2])*X
sage: I.reduce(J)
Symmetric Ideal (y3*y1^2 + y1*x3) of Infinite polynomial ring in x, y over Rational Field
sage: I.reduce(J, tailreduce=True)
Symmetric Ideal (y3*y1^2) of Infinite polynomial ring in x, y over Rational Field
```

squeezed()

Reduce the variable indices occuring in self

OUTPUT: A Symmetric Ideal whose generators are the result of applying `squeezed()` to the generators of self.

NOTE: The output describes the same Symmetric Ideal as self.

EXAMPLES:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ,implementation='sparse')
sage: I = X*(x[1000]*y[100],x[50]*y[1000])
sage: I.squeezed()
Symmetric Ideal (y1*x2, y2*x1) of Infinite polynomial ring in x, y over Rational Field
```

symmetric_basis()

A symmetrised generating set (type `Sequence`) of self.

This does essentially the same as `symmetrisation()` with the option 'tailreduce', and it returns a `Sequence` rather than a `SymmetricIdeal`.

EXAMPLES:

```
sage: X.<x> = InfinitePolynomialRing(QQ)
sage: I = X*(x[1]+x[2], x[1]*x[2])
sage: I.symmetric_basis()
[x1^2, x2 + x1]
```

symmetrisation(*N=None, tailreduce=False, report=None, use_full_group=False*)

Apply permutations to the generators of self and interreduce

INPUT:

- N (optional) – apply permutations in Sym(N). Default is the maximal variable index occuring in the generators of `self.interreduction().squeezed()`.
- tailreduce (optional) – If True, perform tail reductions
- report (optional) – If not None, report on the progress of computations
- use_full_group (optional) – If True, apply *all* elements of Sym(N) to the generators of self (this is what [AB2008] originally suggests). The default is to apply all elementary transpositions to the generators of `self.squeezed()`, interreduce, and repeat until the result stabilises, which is often much faster than applying all of Sym(N), and we are convinced that both methods yield the same result.

OUTPUT: A symetrically interreduced symmetric ideal with respect to which any Sym(N)-translate of a generator of self is symmetrically reducible, where by default N is the maximal variable index that occurs in the generators of `self.interreduction().squeezed()`.

NOTE: If `I` is a symmetric ideal whose generators are monomials, then `I.symmetrisation()` is its reduced Groebner basis. It should be noted that without symmetrisation, monomial generators, in general, do not form a Groebner basis.

EXAMPLES:

```
sage: X.<x> = InfinitePolynomialRing(QQ)
sage: I = X*(x[1]+x[2], x[1]*x[2])
sage: I.symmetrisation()
Symmetric Ideal (-x1^2, x2 + x1) of Infinite polynomial ring in x over Rational Field
sage: I.symmetrisation(N=3)
Symmetric Ideal (-2*x1) of Infinite polynomial ring in x over Rational Field
sage: I.symmetrisation(N=3, use_full_group=True)
Symmetric Ideal (-2*x1) of Infinite polynomial ring in x over Rational Field
```

28.12 Symmetric Reduction of Infinite Polynomials

`SymmetricReductionStrategy` provides a framework for efficient symmetric reduction of Infinite Polynomials, see `infinite_polynomial_element`.

AUTHORS:

- Simon King <simon.king@uni-jena.de>

THEORY: According to M. Aschenbrenner and C. Hillar [AB2007], Symmetric Reduction of an element p of an Infinite Polynomial Ring X by some other element q means the following:

1. Let M and N be the leading terms of p and q.
2. Test whether there is a permutation P that does not does not diminish the variable indices occuring in N and preserves their order, so that there is some term $T \in X$ with $TN^P = M$. If there is no such permutation, return p
3. Replace p by $p - Tq^P$ and continue with step 1.

When reducing one polynomial p with respect to a list L of other polynomials, there usually is a choice of order on which the efficiency crucially depends. Also it helps to modify the polynomials on the list in order to simplify the basic reduction steps.

The preparation of L may be expensive. Hence, if the same list is used many times then it is reasonable to perform the preparation only once. This is the background of `SymmetricReductionStrategy`.

Our current strategy is to keep the number of terms in the polynomials as small as possible. For this, we sort L by increasing number of terms. If several elements of L allow for a reduction of p, we chose the one with the smallest number of terms. Later on, it should be possible to implement further strategies for choice.

When adding a new polynomial q to L, we first reduce q with respect to L. Then, we test heuristically whether it is possible to reduce the number of terms of the elements of L by reduction modulo q. That way, we see best chances to keep the number of terms in intermediate reduction steps relatively small.

EXAMPLES:

First, we create an infinite polynomial ring and one of its elements:

```
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: p = y[1]^2*y[3]+y[1]*x[3]
```

We want to symmetrically reduce it by another polynomial. So, we put this other polynomial into a list and create a Symmetric Reduction Strategy object:

```
sage: from sage.rings.polynomial.symmetric_reduction import SymmetricReductionStrategy
sage: S = SymmetricReductionStrategy(X, [y[2]^2*y[1]])
sage: S
Symmetric Reduction Strategy in Infinite polynomial ring in x, y over Rational Field, modulo
    y2^2*y1
sage: S.reduce(p)
y3*y1^2 + y1*x3
```

The preceding is correct, since any permutation that turns `y[2]^2*y[1]` into a factor of `y[1]^2*y[3]` interchanges the variable indices 1 and 2 – which is not allowed in a symmetric reduction. However, reduction by `y[1]^2*y[2]` works, since one can change variable index 1 into 2 and 2 into 3. So, we add this to `S`:

```
sage: S.add_generator(y[1]^2*y[2])
sage: S
Symmetric Reduction Strategy in Infinite polynomial ring in x, y over Rational Field, modulo
    y2*y1^2,
    y2^2*y1
sage: S.reduce(p)
y1*x3
```

The next example shows that tail reduction is not done, unless it is explicitly adviced:

```
sage: S.reduce(y[3] + 2*y[2]*y[1]^2 + 3*y[2]^2*y[1])
y3 + 3*y2^2*y1 + 2*y2*y1^2
sage: S.tailreduce(y[3] + 2*y[2]*y[1]^2 + 3*y[2]^2*y[1])
y3
```

However, it is possible to ask for tailreduction already when the Symmetric Reduction Strategy is created:

```
sage: S2 = SymmetricReductionStrategy(X, [y[2]^2*y[1],y[1]^2*y[2]], tailreduce=True)
sage: S2
Symmetric Reduction Strategy in Infinite polynomial ring in x, y over Rational Field, modulo
    y2*y1^2,
    y2^2*y1
with tailreduction
sage: S2.reduce(y[3] + 2*y[2]*y[1]^2 + 3*y[2]^2*y[1])
y3
```

class SymmetricReductionStrategy()

A framework for efficient symmetric reduction of InfinitePolynomial, see `infinite_polynomial_element`.

INPUT:

- Parent, an Infinite Polynomial Ring, see infinite_polynomial_element.
- L, a list of elements of Parent (default: L=[]) with respect to which reduction will be done
- good_input: If this optional parameter is true, it is assumed that each element of L is symmetrically reduced with respect to the previous elements of L

EXAMPLES:

```
sage: X.<y> = InfinitePolynomialRing(QQ)
sage: from sage.rings.polynomial.symmetric_reduction import SymmetricReductionStrategy
sage: S = SymmetricReductionStrategy(X, [y[2]^2*y[1],y[1]^2*y[2]], good_input=True)
sage: S.reduce(y[3] + 2*y[2]*y[1]^2 + 3*y[2]^2*y[1])
y3 + 3*y2^2*y1 + 2*y2*y1^2
sage: S.tailreduce(y[3] + 2*y[2]*y[1]^2 + 3*y[2]^2*y[1])
y3
```

add_generator()

Add another polynomial to self

NOTE: Previously added polynomials may be modified. All input is prepared in view of an efficient symmetric reduction.

EXAMPLES:

```
sage: from sage.rings.polynomial.symmetric_reduction import SymmetricReductionStrategy
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: S = SymmetricReductionStrategy(X)
sage: S
Symmetric Reduction Strategy in Infinite polynomial ring in x, y over Rational Field
sage: S.add_generator(y[3] + y[1]*(x[3]+x[1]))
sage: S
Symmetric Reduction Strategy in Infinite polynomial ring in x, y over Rational Field, modulo
    y3 + y1*x3 + y1*x1
```

Note that the first added polynomial will be simplified when adding a suitable second polynomial:

```
sage: S.add_generator(x[2]+x[1])
sage: S
Symmetric Reduction Strategy in Infinite polynomial ring in x, y over Rational Field, modulo
    y3,
    x2 + x1
```

By default, reduction is applied to any newly added polynomial. This can be avoided by specifying the optional parameter 'good_input':

```
sage: S.add_generator(y[2]+y[1]*x[2])
sage: S
Symmetric Reduction Strategy in Infinite polynomial ring in x, y over Rational Field, modulo
    y3,
    y2 + y1*x2,
    x2 + x1
sage: S.reduce(x[3]+x[2])
-2*x1
sage: S.add_generator(x[3]+x[2], good_input=True)
sage: S
Symmetric Reduction Strategy in Infinite polynomial ring in x, y over Rational Field, modulo
    y3,
    x3 + x2,
    y2 + y1*x2,
    x2 + x1
```

In the previous example, x[3] + x[2] is added without being reduced to zero.

gens()

Return the list of Infinite Polynomials modulo which self reduces

EXAMPLES:

```
sage: X.<y> = InfinitePolynomialRing(QQ)
sage: from sage.rings.polynomial.symmetric_reduction import SymmetricReductionStrategy
sage: S = SymmetricReductionStrategy(X, [y[2]^2*y[1],y[1]^2*y[2]])
sage: S
Symmetric Reduction Strategy in Infinite polynomial ring in y over Rational Field, modulo
    y2*y1^2,
    y2^2*y1
sage: S.gens()
[y2*y1^2, y2^2*y1]
```

reduce()

Symmetric reduction of an infinite polynomial

By default, tail reduction is done if and only if it was specified when creating self. If the optional parameter 'notail' is True, tail reduction is avoided. However, we do *not* guarantee that there will be no tail reduction at all in that case.

If tail reduction shall be forced, use `tailreduce()`.

Information on the progress of computation can be obtained by specifying the optional parameter `report`.

EXAMPLES:

```
sage: from sage.rings.polynomial.symmetric_reduction import SymmetricReductionStrategy
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: S = SymmetricReductionStrategy(X, [x[3]], tailreduce=True)
sage: S.reduce(y[4]*x[1] + y[1]*x[4])
y4*x1
sage: S.reduce(y[4]*x[1] + y[1]*x[4], notail=True)
y4*x1 + y1*x4
```

Last, we demonstrate the 'report' option:

```
sage: S = SymmetricReductionStrategy(X, [y[2]+x[1],y[2]*y[3]+y[1]*x[2]+x[4],x[3]+x[2]])
sage: S
Symmetric Reduction Strategy in Infinite polynomial ring in x, y over Rational Field, modulo
    x3 + x2,
    y2 + x1,
    y1*x2 + x4 + x1^2
sage: S.reduce(y[3] + y[1]*x[3] + y[1]*x[1],report=True)
:::>
y1*x1 + x4 + x1^2 - x1
```

Each ':' indicates that one reduction of the leading monomial was performed. Eventually, the '>' indicates that the computation is finished.

reset()

Remove all polynomials from self

EXAMPLES:

```
sage: X.<y> = InfinitePolynomialRing(QQ)
sage: from sage.rings.polynomial.symmetric_reduction import SymmetricReductionStrategy
sage: S = SymmetricReductionStrategy(X, [y[2]^2*y[1],y[1]^2*y[2]])
sage: S
Symmetric Reduction Strategy in Infinite polynomial ring in y over Rational Field, modulo
    y2*y1^2,
    y2^2*y1
sage: S.reset()
sage: S
Symmetric Reduction Strategy in Infinite polynomial ring in y over Rational Field
```

setgens()

Define the list of Infinite Polynomials modulo which self reduces

INPUT:

L, a list

NOTE:

It is not tested if L is a good input. That method simply assigns a *copy* of L to the generators of self.

EXAMPLES:

```
sage: from sage.rings.polynomial.symmetric_reduction import SymmetricReductionStrategy
sage: X.<y> = InfinitePolynomialRing(QQ)
sage: S = SymmetricReductionStrategy(X, [y[2]^2*y[1],y[1]^2*y[2]])
sage: R = SymmetricReductionStrategy(X)
sage: R.setgens(S.gens())
sage: R
Symmetric Reduction Strategy in Infinite polynomial ring in y over Rational Field, modulo
    y2*y1^2,
    y2^2*y1
sage: R.gens() is S.gens()
False
sage: R.gens() == S.gens()
True
```

tailreduce()

Symmetric reduction of an infinite polynomial, with forced tail reduction

Information on the progress of computation can be obtained by specifying the optional parameter 'report'.

EXAMPLES:

```
sage: from sage.rings.polynomial.symmetric_reduction import SymmetricReductionStrategy
sage: X.<x,y> = InfinitePolynomialRing(QQ)
sage: S = SymmetricReductionStrategy(X, [x[3]])
sage: S.reduce(y[4]*x[1] + y[1]*x[4])
y4*x1 + y1*x4
sage: S.tailreduce(y[4]*x[1] + y[1]*x[4])
y4*x1
```

Last, we demonstrate the 'report' option:

```
sage: S = SymmetricReductionStrategy(X, [y[2]+x[1],y[2]*y[3]+y[1]*x[2]+x[4],x[3]+x[2]])
sage: S
Symmetric Reduction Strategy in Infinite polynomial ring in x, y over Rational Field, modulo
    x3 + x2,
    y2 + x1,
    y1*x2 + x4 + x1^2
sage: S.tailreduce(y[3] + y[1]*x[3] + y[1]*x[1],report=True)
T[3]:::>
T[3]:>
y1*x1 - x2 + x1^2 - x1
```

The protocol means the following.

- 'T[3]' means that we currently do tail reduction for a polynomial with three terms.
- ':::>' means that there were three reductions of leading terms.
- The tail of the result of the preceding reduction still has three terms. One reduction of leading terms was possible, and then the final result was obtained.

28.13 Educational Versions of Groebner Basis Algorithms: Triangular Factorization.

In this file is the implementation of two algorithms in [Laz92].

The main algorithm is `Triangular`; a secondary algorithm, necessary for the first, is `ElimPolMin`. As per Lazard's formulation, the implementation works with any term ordering, not only lexicographic.

Lazard does not specify a few of the subalgorithms implemented as the functions

- `is_triangular`,
- `is_linearly_dependent`, and
- `linear_representation`.

The implementations are not hard, and the choice of algorithm is described with the relevant function.

No attempt was made to optimize these algorithms as the emphasis of this implementation is a clean and easy presentation.

Examples appear with the appropriate function.

AUTHORS:

- John Perry (2009-02-24): initial version, but some words of documentation were stolen shamelessly from Martin Albrecht's `toy_buchberger.py`.

REFERENCES:

coefficient_matrix(*polys*)

Generates the matrix `M` whose entries are the coefficients of `polys`. The entries of row `i` of `M` consist of the coefficients of `polys[i]`.

INPUT:

•`polys` - a list/tuple of polynomials

OUTPUT:

A matrix `M` of the coefficients of `polys`.

EXAMPLE:

```
sage: from sage.rings.polynomial.toy_variety import coefficient_matrix
sage: R.<x,y> = PolynomialRing(QQ)
sage: coefficient_matrix([x^2 + 1, y^2 + 1, x*y + 1])
[1 0 0 1]
[0 0 1 1]
[0 1 0 1]
```

Note: This function may be merged with `sage.crypto.mq.MPolynomialSystem_generic.coefficient_matrix` in the future.

elim_pol(*B, n=-1*)

Finds the unique monic polynomial of lowest degree and lowest variable in the ideal described by `B`.

For the purposes of the triangularization algorithm, it is necessary to preserve the ring, so `n` specifies which variable to check. By default, we check the last one, which should also be the smallest.

The algorithm may not work if you are trying to cheat: `B` should describe the Groebner basis of a zero-dimensional ideal. However, it is not necessary for the Groebner basis to be lexicographic.

The algorithm is taken from a 1993 paper by Lazard [Laz92].

INPUT:

- `B` - a list/tuple of polynomials or a multivariate polynomial ideal
- `n` - the variable to check (see above) (default: `-1`)

EXAMPLE:

```
sage: set_verbose(0)
sage: from sage.rings.polynomial.toy_variety import elim_pol
sage: R.<x,y,z> = PolynomialRing(GF(32003))
sage: p1 = x^2*(x-1)^3*y^2*(z-3)^3
sage: p2 = z^2 - z
sage: p3 = (x-2)^2*(y-1)^3
sage: I = R.ideal(p1,p2,p3)
sage: elim_pol(I.groebner_basis())
z^2 - z
```

is_linearly_dependent(*polys*)

Decides whether the polynomials of `polys` are linearly dependent. Here `polys` is a collection of polynomials.

The algorithm creates a matrix of coefficients of the monomials of `polys`. It computes the echelon form of the matrix, then checks whether any of the rows is the zero vector.

Essentially this relies on the fact that the monomials are linearly independent, and therefore is building a linear map from the vector space of the monomials to the canonical basis of `R^n`, where `n` is the number of distinct monomials in `polys`. There is a zero vector iff there is a linear dependence among `polys`.

The case where `polys=[]` is considered to be not linearly dependent.

INPUT:

- `polys` - a list/tuple of polynomials

OUTPUT:

`True` if the elements of `polys` are linearly dependent; `False` otherwise.

EXAMPLE:

```
sage: from sage.rings.polynomial.toy_variety import is_linearly_dependent
sage: R.<x,y> = PolynomialRing(QQ)
sage: B = [x^2 + 1, y^2 + 1, x*y + 1]
sage: p = 3*B[0] - 2*B[1] + B[2]
sage: is_linearly_dependent(B + [p])
True
sage: p = x*B[0]
sage: is_linearly_dependent(B + [p])
False
sage: is_linearly_dependent([])
False
```

is_triangular(*B*)

Check whether the basis `B` of an ideal is triangular. That is: check whether the largest variable in `B[i]` with respect to the ordering of the base ring `R` is `R.gens()[i]`.

The algorithm is based on the definition of a triangular basis, given by Lazard in 1992 in [Laz92].

INPUT:

- `B` - a list/tuple of polynomials or a multivariate polynomial ideal

OUTPUT:

`True` if the basis is triangular; `False` otherwise.

EXAMPLE:

```
sage: from sage.rings.polynomial.toy_variety import is_triangular
sage: R.<x,y,z> = PolynomialRing(QQ)
sage: p1 = x^2*y + z^2
sage: p2 = y*z + z^3
sage: p3 = y+z
sage: is_triangular(R.ideal(p1,p2,p3))
False
sage: p3 = z^2 - 3
sage: is_triangular(R.ideal(p1,p2,p3))
True
```

linear_representation(*p, polys*)

Assuming that `p` is a linear combination of `polys`, determines coefficients that describe the linear combination. This probably doesn't work for any inputs except `p`, a polynomial, and `polys`, a sequence of polynomials. If `p` is not in fact a linear combination of `polys`, the function raises an exception.

The algorithm creates a matrix of coefficients of the monomials of `polys` and `p`, with the coefficients of `p` in the last row. It augments this matrix with the appropriate identity matrix, then computes the echelon form of the augmented matrix. The last row should contain zeroes in the first columns, and the last columns contain a linear dependence relation. Solving for the desired linear relation is straightforward.

INPUT:

- `p` - a polynomial
- `polys` - a list/tuple of polynomials

OUTPUT:

If `n == len(polys)`, returns `[a[0],a[1],...,a[n-1]]` such that `p == a[0]*poly[0] + ... + a[n-1]*poly[n-1]`.

EXAMPLE:

```
sage: from sage.rings.polynomial.toy_variety import linear_representation
sage: R.<x,y> = PolynomialRing(GF(32003))
sage: B = [x^2 + 1, y^2 + 1, x*y + 1]
sage: p = 3*B[0] - 2*B[1] + B[2]
sage: linear_representation(p, B)
[3, 32001, 1]
```

triangular_factorization(*B, n=-1, proof=True*)

Compute the triangular factorization of the Groebner basis `B` of an ideal.

This will not work properly if `B` is not a Groebner basis!

The algorithm used is that described in a 1992 paper by Daniel Lazard [Laz92]. It is not necessary for the term ordering to be lexicographic.

INPUT:

- `B` - a list/tuple of polynomials or a multivariate polynomial ideal
- `n` - the recursion parameter (default: `-1`)

OUTPUT:

A list `T` of triangular sets `T_0`, `T_1`, etc.

EXAMPLE:

```
sage: set_verbose(0)
sage: from sage.rings.polynomial.toy_variety import triangular_factorization
sage: R.<x,y,z> = PolynomialRing(GF(32003))
sage: p1 = x^2*(x-1)^3*y^2*(z-3)^3
sage: p2 = z^2 - z
sage: p3 = (x-2)^2*(y-1)^3
sage: I = R.ideal(p1,p2,p3)
sage: triangular_factorization(I.groebner_basis(), proof=True)
...
NotImplementedError: proof = True factorization not implemented.  Call factor with proof=False.

sage: triangular_factorization(I.groebner_basis(), proof=False)
[[x^2 - 4*x + 4, y, z],
 [x^5 - 3*x^4 + 3*x^3 - x^2, y - 1, z],
 [x^2 - 4*x + 4, y, z - 1],
 [x^5 - 3*x^4 + 3*x^3 - x^2, y - 1, z - 1]]
```

28.14 Boolean Polynomials.

Elements of the quotient ring

$$\mathbf{F}_2[x_1, ..., x_n]/ < x_1^2 + x_1, ..., x_n^2 + x_n > .$$

are called boolean polynomials. Boolean polynomials arise naturally in cryptography, coding theory, formal logic, chip design and other areas. This implementation is a thin wrapper around the PolyBoRi library by Michael Brickenstein and Alexander Dreyer.

"Boolean polynomials can be modelled in a rather simple way, with both coefficients and degree per variable lying in `{0, 1}`. The ring of Boolean polynomials is, however, not a polynomial ring, but rather the quotient ring of the polynomial ring over the field with two elements modulo the field equations $x^2 = x$ for each variable x. Therefore, the usual polynomial data structures seem not to be appropriate for fast Groebner basis computations. We introduce a specialised data structure for Boolean polynomials based on zero-suppressed binary decision diagrams (ZDDs), which is capable of handling these polynomials more efficiently with respect to memory consumption and also computational speed. Furthermore, we concentrate on high-level algorithmic aspects, taking into account the new data structures as well as structural properties of Boolean polynomials." - [BD07]

AUTHORS:

- Michael Brickenstein: PolyBoRi author
- Alexander Dreyer: PolyBoRi author
- Burcin Erocal <burcin@erocal.org>: main Sage wrapper author
- Martin Albrecht <malb@informatik.uni-bremen.de>: some contributions to the Sage wrapper

EXAMPLES:

Consider the ideal

$$< ab + cd + 1, ace + de, abe + ce, bc + cde + 1 > .$$

First, we compute the lexicographical Groebner basis in the polynomial ring

$$R = \mathbf{F}_2[a, b, c, d, e].$$

```
sage: P.<a,b,c,d,e> = PolynomialRing(GF(2), 5, order='lex')
sage: I1 = ideal([a*b + c*d + 1, a*c*e + d*e, a*b*e + c*e, b*c + c*d*e + 1])
sage: for f in I1.groebner_basis():
...       f
a + c^2*d + c + d^2*e
b*c + d^3*e^2 + d^3*e + d^2*e^2 + d*e + e + 1
b*e + d*e^2 + d*e + e
c*e + d^3*e^2 + d^3*e + d^2*e^2 + d*e
d^4*e^2 + d^4*e + d^3*e + d^2*e^2 + d^2*e + d*e + e
```

If one wants to solve this system over the algebraic closure of $\mathbf{F}_2$ then this Groebner basis was the one to consider. If one wants solutions over $\mathbf{F}_2$ only then one adds the field polynomials to the ideal to force the solutions in $\mathbf{F}_2$.

```
sage: J = I1 + sage.rings.ideal.FieldIdeal(P)
sage: for f in J.groebner_basis():
...       f
a + d + 1
b + 1
c + 1
d^2 + d
e
```

So the solutions over $\mathbf{F}_2$ are $\{e = 0, d = 1, c = 1, b = 1, a = 0\}$ and $\{e = 0, d = 0, c = 1, b = 1, a = 1\}$.

We can express the restriction to $\mathbf{F}_2$ by considering the quotient ring. If I is an ideal in $\mathbb{F}[x_1, ..., x_n]$ then the ideals in the quotient ring $\mathbb{F}[x_1, ..., x_n]/I$ are in one-to-one correspondence with the ideals of $\mathbb{F}[x_0, ..., x_n]$ containing I (that is, the ideals J satisfying $I \subset J \subset P$).

```
sage: Q = P.quotient( sage.rings.ideal.FieldIdeal(P) )
sage: I2 = ideal([Q(f) for f in I1.gens()])
sage: for f in I2.groebner_basis():
...       f
abar + dbar + 1
bbar + 1
cbar + 1
ebar
```

This quotient ring is exactly what PolyBoRi handles well:

```
sage: B.<a,b,c,d,e> = BooleanPolynomialRing(5, order='lex')
sage: I2 = ideal([B(f) for f in I1.gens()])
sage: for f in I2.groebner_basis():
...       f
a + d + 1
b + 1
c + 1
e
```

Note that $d^2 + d$ is not representable in $B == Q$. Also note, that PolyBoRi cannot play out its strength in such small examples, i.e. working in the polynomial ring might be faster for small examples like this.

28.14.1 Implementation specific notes

PolyBoRi comes with a Python wrapper. However this wrapper does not match Sage's style and is written using Boost. Thus Sage's wrapper is a reimplementation of Python bindings to PolyBoRi's C++ library. This interface is written in

Cython like all of Sage's C/C++ library interfaces. An interface in PolyBoRi style is also provided which is effectively a reimplementation of the official Boost wrapper in Cython. This means that some functionality of the official wrapper might be missing from this wrapper and this wrapper might have bugs not present in the official Python interface.

28.14.2 Access to the original PolyBoRi interface

The re-implementation PolyBoRi's native wrapper is available to the user too:

```
sage: from polybori import *
sage: declare_ring([Block('x',2),Block('y',3)],globals())
Boolean PolynomialRing in x(0), x(1), y(0), y(1), y(2)
sage: r
Boolean PolynomialRing in x(0), x(1), y(0), y(1), y(2)

sage: [Variable(i) for i in xrange(r.ngens())]
[x(0), x(1), y(0), y(1), y(2)]
```

For details on this interface see:

http://polybori.sourceforge.net/doc/tutorial/tutorial.html.

Note that due to this duality of this interface some functions do not obey Sage's naming convention. For instance, `f.zerosIn` should be called `f.zeros_in` by Sage's standards. However, PolyBoRi expects the function `f.zerosIn`.

Also, the interface provides functions for compatibility with Sage accepting convenient Sage data types which are slower than their native PolyBoRi counterparts. For instance, sets of points can be represented as tuples of tuples (Sage) or as `BooleSets` (PolyBoRi) and naturally the second option is faster.

REFERENCES:

class BooleSet()

Return a new set of boolean monomials. This data type is also implemented on the top of ZDDs and allows to see polynomials from a different angle. Also, it makes high-level set operations possible, which are in most cases faster than operations handling individual terms, because the complexity of the algorithms depends only on the structure of the diagrams.

`BooleanPolynomials` can easily be converted to `BooleSets` by using the member function `set()`.

INPUT:

- `param` - either a `CCuddNavigator`, a `BooleSet` or `None`.
- `ring` - a boolean polynomial ring.

EXAMPLE:

```
sage: from polybori import BooleSet
sage: B.<a,b,c,d> = BooleanPolynomialRing(4)
sage: BS = BooleSet(B)
sage: BS
{}
```

Note: `BooleSet` prints as '{}' but are not Python dictionaries.

cartesianProduct()

Return the cartesian product of this set and the set `rhs`.

The Cartesian product of two sets X and Y is the set of all possible ordered pairs whose first component is a member of X and whose second component is a member of Y.

$$X \times Y = \{(x, y)|x \in X \text{ and } y \in Y\}.$$

EXAMPLE:

```
sage: B = BooleanPolynomialRing(5,'x')
sage: x0,x1,x2,x3,x4 = B.gens()
sage: f = x1*x2+x2*x3
sage: s = f.set(); s
{{x1,x2}, {x2,x3}}
sage: g = x4 + 1
sage: t = g.set(); t
{{x4}, {}}
sage: s.cartesianProduct(t)
{{x1,x2,x4}, {x1,x2}, {x2,x3,x4}, {x2,x3}}
```

change()

diff()

Return the set theoretic difference of this set and the set `rhs`.

The difference of two sets X and Y is defined as:

$$X \ Y = \{x|x \in X \text{ and } x \notin Y\}.$$

EXAMPLE:

```
sage: B = BooleanPolynomialRing(5,'x')
sage: x0,x1,x2,x3,x4 = B.gens()
sage: f = x1*x2+x2*x3
sage: s = f.set(); s
{{x1,x2}, {x2,x3}}
sage: g = x2*x3 + 1
sage: t = g.set(); t
{{x2,x3}, {}}
sage: s.diff(t)
{{x1,x2}}
```

divide()

empty()

Return `True` if this set is empty.

EXAMPLE:

```
sage: B.<a,b,c,d> = BooleanPolynomialRing(4)
sage: BS = (a*b + c).set()
sage: BS.empty()
False

sage: BS = B(0).set()
sage: BS.empty()
True
```

includeDivisors()

minimalElements()

nNodes()

Return the number of nodes in the ZDD.

EXAMPLE:

```
sage: B = BooleanPolynomialRing(5,'x')
sage: x0,x1,x2,x3,x4 = B.gens()
sage: f = x1*x2+x2*x3
sage: s = f.set(); s
{{x1,x2}, {x2,x3}}
sage: s.nNodes()
4
```

nSupport()

navigation()

Navigators provide an interface to diagram nodes, accessing their index as well as the corresponding then- and else-branches.

You should be very careful and always keep a reference to the original object, when dealing with navigators, as navigators contain only a raw pointer as data. For the same reason, it is necessary to supply the ring as argument, when constructing a set out of a navigator.

EXAMPLE:

```
sage: from polybori import BooleSet
sage: B = BooleanPolynomialRing(5,'x')
sage: x0,x1,x2,x3,x4 = B.gens()
sage: f = x1*x2+x2*x3*x4+x2*x4+x3+x4+1
sage: s = f.set(); s
{{x1,x2}, {x2,x3,x4}, {x2,x4}, {x3}, {x4}, {}}

sage: nav = s.navigation()
sage: BooleSet(nav,s.ring())
{{x1,x2}, {x2,x3,x4}, {x2,x4}, {x3}, {x4}, {}}

sage: nav.value()
1

sage: nav_else = nav.elseBranch()

sage: BooleSet(nav_else,s.ring())
{{x2,x3,x4}, {x2,x4}, {x3}, {x4}, {}}

sage: nav_else.value()
2
```

ring()

Return the parent ring.

EXAMPLE:

```
sage: B = BooleanPolynomialRing(5,'x')
sage: x0,x1,x2,x3,x4 = B.gens()
sage: f = x1*x2+x2*x3*x4+x2*x4+x3+x4+1
sage: f.set().ring() is B
True
```

set()

Return `self`.

EXAMPLE:

```
sage: B.<a,b,c,d> = BooleanPolynomialRing(4)
sage: BS = (a*b + c).set()
sage: BS.set() is BS
True
```

stableHash()

subset0()

subset1()

union()

Return the set theoretic union of this set and the set `rhs`.

The union of two sets X and Y is defined as:

$$X \cup Y = \{x | x \in X \text{ or } x \in Y\}.$$

EXAMPLE:

```
sage: B = BooleanPolynomialRing(5,'x')
sage: x0,x1,x2,x3,x4 = B.gens()
sage: f = x1*x2+x2*x3
sage: s = f.set(); s
{{x1,x2}, {x2,x3}}
sage: g = x2*x3 + 1
sage: t = g.set(); t
{{x2,x3}, {}}
sage: s.diff(t)
{{x1,x2}}
```

vars()

class **BooleSetIterator**()

next()

x.next() -> the next value, or raise StopIteration

class **BooleVariable**()

class **BooleanMonomial**()

Construct a boolean monomial object.

INPUT:

- `parent` - parent monoid this element lies in

EXAMPLE:

```
sage: from polybori import BooleanMonomialMonoid, BooleanMonomial
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: M = BooleanMonomialMonoid(P)
sage: BooleanMonomial(M)
1
```

Note: Use the `__call__` method of `BooleanMonomialMonoid` and not this constructor to construct these objects.

deg()

Return degree of this monomial.

EXAMPLES:

```
sage: from polybori import BooleanMonomialMonoid
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: M = BooleanMonomialMonoid(P)
sage: M(x*y).deg()
2
```

```
sage: M(x*x*y*z).deg()
3
```

degree()

Return degree of this monomial.

EXAMPLES:

```
sage: from polybori import BooleanMonomialMonoid
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: M = BooleanMonomialMonoid(P)
sage: M(x*y).degree()
2
```

divisors()

Return a set of boolean monomials with all divisors of this monomial.

EXAMPLE:

```
sage: B.<x,y,z> = BooleanPolynomialRing(3)
sage: f = x*y
sage: m = f.lm()
sage: m.divisors()
{{x,y}, {x}, {y}, {}}
```

index()

Return the variable index of the first variable in this monomial.

EXAMPLE:

```
sage: B.<x,y,z> = BooleanPolynomialRing(3)
sage: f = x*y
sage: m = f.lm()
sage: m.index()
0
```

iterindex()

Return an iterator over the indicies of the variables in self.

EXAMPLES:

```
sage: from polybori import BooleanMonomialMonoid
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: M = BooleanMonomialMonoid(P)
sage: list(M(x*z).iterindex())
[0, 2]
```

multiples()

Return a set of boolean monomials with all multiples of this monomial up the bound `rhs`.

INPUT:

- `rhs` - a boolean monomial

EXAMPLE:

```
sage: B.<x,y,z> = BooleanPolynomialRing(3)
sage: f = x
sage: m = f.lm()
sage: g = x*y*z
sage: n = g.lm()
sage: m.multiples(n)
{{x,y,z}, {x,y}, {x,z}, {x}}
sage: n.multiples(m)
{{x,y,z}}
```

Note: The returned set always contains `self` even if the bound `rhs` is smaller than `self`.

reducibleBy()

Return `True` if `self` is reducible by `rhs`.

INPUT:

- `rhs` - a boolean monomial

EXAMPLE:

```
sage: B.<x,y,z> = BooleanPolynomialRing(3)
sage: f = x*y
sage: m = f.lm()
sage: m.reducibleBy((x*y).lm())
True
sage: m.reducibleBy((x*z).lm())
False
```

set()

Return a boolean set of variables in this monomials.

EXAMPLE:

```
sage: B.<x,y,z> = BooleanPolynomialRing(3)
sage: f = x*y
sage: m = f.lm()
sage: m.set()
{{x,y}}
```

stableHash()

variables()

Return a list of the variables in this monomial.

EXAMPLE:

```
sage: from polybori import BooleanMonomialMonoid
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: M = BooleanMonomialMonoid(P)
sage: M(x*z).variables() # indirect doctest
[x, z]
```

class **BooleanMonomialIterator**()

An iterator over the variable indices of a monomial.

next()

x.next() -> the next value, or raise StopIteration

class **BooleanMonomialMonoid**()

Construct a boolean monomial monoid given a boolean polynomial ring.

This object provides a parent for boolean monomials.

INPUT:

- `polring` - the polynomial ring our monomials lie in

EXAMPLES:

```
sage: from polybori import BooleanMonomialMonoid
sage: P.<x,y> = BooleanPolynomialRing(2)
sage: M = BooleanMonomialMonoid(P)
sage: M
MonomialMonoid of Boolean PolynomialRing in x, y
```

```
sage: M.gens()
(x, y)
sage: type(M.gen(0))
<type 'sage.rings.polynomial.pbori.BooleanMonomial'>
```

gen()
Return the i-th generator of self.
INPUT:
- i - an integer

EXAMPLES:

```
sage: from polybori import BooleanMonomialMonoid
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: M = BooleanMonomialMonoid(P)
sage: M.gen(0)
x
sage: M.gen(2)
z

sage: P = BooleanPolynomialRing(1000, 'x')
sage: M = BooleanMonomialMonoid(P)
sage: M.gen(50)
x50
```

gens()
Return the tuple of generators of this monoid.
EXAMPLES:

```
sage: from polybori import BooleanMonomialMonoid
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: M = BooleanMonomialMonoid(P)
sage: M.gens()
(x, y, z)
```

ngens()
Returns the number of variables in this monoid.
EXAMPLES:

```
sage: from polybori import BooleanMonomialMonoid
sage: P = BooleanPolynomialRing(100, 'x')
sage: M = BooleanMonomialMonoid(P)
sage: M.ngens()
100
```

class **BooleanMonomialVariableIterator**()

next()
x.next() -> the next value, or raise StopIteration

class **BooleanMulAction**()

class **BooleanPolynomial**()
Construct a boolean polynomial object in the given boolean polynomial ring.
INPUT:
- parent - a boolean polynomial ring

TEST:

```
sage: from polybori import BooleanPolynomial
sage: B.<a,b,z> = BooleanPolynomialRing(3)
sage: BooleanPolynomial(B)
0
```

Note: Do not use this method to construct boolean polynomials, but use the appropriate __call__ method in the parent.

constant()

Return True if this element is constant.

EXAMPLE:

```
sage: B.<x,y,z> = BooleanPolynomialRing(3)
sage: x.constant()
False

sage: B(1).constant()
True
```

constant_coefficient()

Returns the constant coefficient of this boolean polynomial.

EXAMPLE: sage: B.<a,b> = BooleanPolynomialRing() sage: a.constant_coefficient() 0 sage: (a+1).constant_coefficient() 1

deg()

Return the degree of self. This is usually equivalent to the total degree except for weighted term orderings which are not implemented yet.

EXAMPLES:

```
sage: P.<x,y> = BooleanPolynomialRing(2)
sage: (x+y).degree()
1

sage: P(1).degree()
0

sage: (x*y + x + y + 1).degree()
2
```

degree()

Return the total degree of self.

EXAMPLES:

```
sage: P.<x,y> = BooleanPolynomialRing(2)
sage: (x+y).degree()
1

sage: P(1).degree()
0

sage: (x*y + x + y + 1).degree()
2
```

elength()

Return elimination length as used in the SlimGB algorithm.

EXAMPLE:

```
sage: P.<x,y> = BooleanPolynomialRing(2)
sage: x.elength()
```

```
1
sage: f = x*y + 1
sage: f.elength()
2
```

REFERENCES:

- Michael Brickenstein; SlimGB: Groebner Bases with Slim Polynomials http://www.mathematik.uni-kl.de/~zca/Reports_on_ca/35/paper_35_full.ps.gz

firstTerm()

Return the first term with respect to the lexicographical term ordering.

EXAMPLE:

```
sage: B.<a,b,z> = BooleanPolynomialRing(3,order='lex')
sage: f = b*z + a + 1
sage: f.firstTerm()
a
```

gradedPart()

Return graded part of this boolean polynomial of degree `deg`.

INPUT:

- `deg` - a degree

EXAMPLE:

```
sage: B.<a,b,c,d> = BooleanPolynomialRing(4)
sage: f = a*b*c + c*d + a*b + 1
sage: f.gradedPart(2)
a*b + c*d

sage: f.gradedPart(0)
1
```

TESTS:

```
sage: f.gradedPart(-1)
0
```

hasConstantPart()

Return `True` if this boolean polynomial has a constant part, i.e. if 1 is a term.

EXAMPLE:

```
sage: B.<a,b,c,d> = BooleanPolynomialRing(4)
sage: f = a*b*c + c*d + a*b + 1
sage: f.hasConstantPart()
True

sage: f = a*b*c + c*d + a*b
sage: f.hasConstantPart()
False
```

isOne()

Return `True` if this element is one.

EXAMPLE:

```
sage: B.<x,y,z> = BooleanPolynomialRing(3)
sage: x.isOne()
False
sage: B(0).isOne()
False
```

```
sage: B(1).isOne()
True
```

isZero()

Return `True` if this element is zero.

EXAMPLE:

```
sage: B.<x,y,z> = BooleanPolynomialRing(3)
sage: x.isZero()
False
sage: B(0).isZero()
True
sage: B(1).isZero()
False
```

is_constant()

Check if `self` is constant.

EXAMPLES:

```
sage: P.<x,y> = BooleanPolynomialRing(2)
sage: P(1).is_constant()
True

sage: P(0).is_constant()
True

sage: x.is_constant()
False

sage: (x*y).is_constant()
False
```

is_equal()

EXAMPLE:

```
sage: B.<a,b,z> = BooleanPolynomialRing(3)
sage: f = a*z + b + 1
sage: g = b + z
sage: f.is_equal(g)
False

sage: f.is_equal( (f + 1) - 1 )
True
```

is_homogeneous()

Return `True` if this element is a homogeneous polynomial.

EXAMPLES:

```
sage: P.<x, y> = BooleanPolynomialRing()
sage: (x+y).is_homogeneous()
True
sage: P(0).is_homogeneous()
True
sage: (x+1).is_homogeneous()
False
```

is_one()

Check if self is 1.

EXAMPLES:

```
sage: P.<x,y> = BooleanPolynomialRing(2)
sage: P(1).is_one()
True

sage: P.one_element().is_one()
True

sage: x.is_one()
False

sage: P(0).is_one()
False
```

is_unit()

Check if `self` is invertible in the parent ring.

Note that this condition is equivalent to being 1 for boolean polynomials.

EXAMPLE:

```
sage: P.<x,y> = BooleanPolynomialRing(2)
sage: P.one_element().is_unit()
True

sage: x.is_unit()
False
```

is_zero()

Check if `self` is zero.

EXAMPLES:

```
sage: P.<x,y> = BooleanPolynomialRing(2)
sage: P(0).is_zero()
True

sage: x.is_zero()
False

sage: P(1).is_zero()
False
```

lead()

Return the leading monomial of boolean polynomial, with respect to to the order of parent ring.

EXAMPLES:

```
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: (x+y+y*z).lead()
x

sage: P.<x,y,z> = BooleanPolynomialRing(3, order='deglex')
sage: (x+y+y*z).lead()
y*z
```

lexLead()

Return the leading monomial of boolean polynomial, with respect to the lexicographical term ordering.

EXAMPLES:

```
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: (x+y+y*z).lexLead()
x
```

```
sage: P.<x,y,z> = BooleanPolynomialRing(3, order='deglex')
sage: (x+y+y*z).lexLead()
x
```

lexLmDeg()

Return degree of leading monomial with respect to the lexicographical ordering.

EXAMPLE:

```
sage: B.<x,y,z> = BooleanPolynomialRing(3,order='lex')
sage: f = x + y*z
sage: f
x + y*z
sage: f.lexLmDeg()
1

sage: B.<x,y,z> = BooleanPolynomialRing(3,order='deglex')
sage: f = x + y*z
sage: f
y*z + x
sage: f.lexLmDeg()
1
```

lm()

Return the leading monomial of this boolean polynomial, with respect to the order of parent ring.

EXAMPLES:

```
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: (x+y+y*z).lm()
x

sage: P.<x,y,z> = BooleanPolynomialRing(3, order='deglex')
sage: (x+y+y*z).lm()
y*z
```

lmDeg()

Return the degree of the leading monomial with respect to the lexicographical orderings.

EXAMPLE:

```
sage: B.<x,y,z> = BooleanPolynomialRing(3,order='lex')
sage: f = x + y*z
sage: f
x + y*z
sage: f.lmDeg()
1

sage: B.<x,y,z> = BooleanPolynomialRing(3,order='deglex')
sage: f = x + y*z
sage: f
y*z + x
sage: f.lmDeg()
2
```

lmDivisors()

Return a `BooleSet` of all divisors of the leading monomial.

EXAMPLE:

```
sage: B.<a,b,z> = BooleanPolynomialRing(3)
sage: f = a*b + z + 1
```

```
sage: f.lmDivisors()
{{a,b}, {a}, {b}, {}}
```

lm_degree()

Returns the total degree of the leading monomial of `self`.

EXAMPLES:

```
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: p = x + y*z
sage: p.lm_degree()
1

sage: P.<x,y,z> = BooleanPolynomialRing(3,order='deglex')
sage: p = x + y*z
sage: p.lm_degree()
2

sage: P(0).lm_degree()
0
```

lt()

Return the leading term of this boolean polynomial, with respect to the order of the parent ring.

Note that for boolean polynomials this is equivalent to returning leading monomials.

EXAMPLES:

```
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: (x+y+y*z).lt()
x

sage: P.<x,y,z> = BooleanPolynomialRing(3, order='deglex')
sage: (x+y+y*z).lt()
y*z
```

mapEveryXToXPlusOne()

Map every variable `x_i` in this polynomial to $x_i + 1$.

EXAMPLE:

```
sage: B.<a,b,z> = BooleanPolynomialRing(3)
sage: f = a*b + z + 1; f
a*b + z + 1
sage: f.mapEveryXToXPlusOne()
a*b + a + b + z + 1
sage: f(a+1,b+1,z+1)
a*b + a + b + z + 1
```

monomial_coefficient()

Return the coefficient of the monomial `mon` in `self`, where `mon` must have the same parent as `self`.

INPUT:

- `mon` - a monomial

EXAMPLE:

```
sage: P.<x,y> = BooleanPolynomialRing(2)
sage: x.monomial_coefficient(x)
1
sage: x.monomial_coefficient(y)
0
sage: R.<x,y,z,a,b,c>=BooleanPolynomialRing(6)
```

```
sage: f=(1-x)*(1+y); f
x*y + x + y + 1

sage: f.monomial_coefficient(1)
1

sage: f.monomial_coefficient(0)
0
```

monomials()

Return a list of monomials appearing in `self` ordered largest to smallest.

EXAMPLE:

```
sage: P.<a,b,c> = BooleanPolynomialRing(3,order='lex')
sage: f = a + c*b
sage: f.monomials()
[a, b*c]

sage: P.<a,b,c> = BooleanPolynomialRing(3,order='degrevlex')
sage: f = a + c*b
sage: f.monomials()
[c*b, a]
```

nNodes()

nVars()

Return the number of variables used to form this boolean polynomial.

EXAMPLE:

```
sage: B.<a,b,c,d> = BooleanPolynomialRing(4)
sage: f = a*b*c + 1
sage: f.nVars()
3
```

navigation()

nvariables()

Return the number of variables used to form this boolean polynomial.

EXAMPLE:

```
sage: B.<a,b,c,d> = BooleanPolynomialRing(4)
sage: f = a*b*c + 1
sage: f.nvariables()
3
```

reduce()

Return the normal form of `self` w.r.t. `I`, i.e. return the remainder of `self` with respect to the polynomials in `I`. If the polynomial set/list `I` is not a Groebner basis the result is not canonical.

INPUT:

- `I` - a list/set of polynomials in self.parent(). If I is an ideal, the generators are used.

EXAMPLE:

```
sage: B.<x0,x1,x2,x3> = BooleanPolynomialRing(4)
sage: I = B.ideal((x0 + x1 + x2 + x3, \
                   x0*x1 + x1*x2 + x0*x3 + x2*x3, \
                   x0*x1*x2 + x0*x1*x3 + x0*x2*x3 + x1*x2*x3, \
                   x0*x1*x2*x3 + 1))
sage: gb = I.groebner_basis()
sage: f,g,h,i = I.gens()
```

```
sage: f.reduce(gb)
0
sage: p = f*g + x0*h + x2*i
sage: p.reduce(gb)
0
sage: p.reduce(I)
x1*x2*x3 + x2
```

Note: If this function is called repeatedly with the same I then it is advised to use PolyBoRi's `GroebnerStrategy` object directly, since that will be faster. See the source code of this function for details.

reducibleBy()

Return `True` if this boolean polynomial is reducible by the polynomial `rhs`.

INPUT:

- `rhs` - a boolean polynomial

EXAMPLE:

```
sage: B.<a,b,c,d> = BooleanPolynomialRing(4,order='degrevlex')
sage: f = (a*b + 1)*(c + 1)
sage: f.reducibleBy(d)
False
sage: f.reducibleBy(c)
True
sage: f.reducibleBy(c + 1)
True
```

ring()

Return the parent of this boolean polynomial.

EXAMPLE:

```
sage: B.<a,b,c,d> = BooleanPolynomialRing(4)
sage: a.ring() is B
True
```

set()

Return a `BooleSet` with all monomials appearing in this polynomial.

EXAMPLE:

```
sage: B.<a,b,z> = BooleanPolynomialRing(3)
sage: (a*b+z+1).set()
{{a,b}, {z}, {}}
```

spoly()

Return the S-Polynomial of this boolean polynomial and the other boolean polynomial `rhs`.

EXAMPLE:

```
sage: B.<a,b,c,d> = BooleanPolynomialRing(4)
sage: f = a*b*c + c*d + a*b + 1
sage: g = c*d + b
sage: f.spoly(g)
a*b + a*c*d + c*d + 1
```

stableHash()

subs()

Fixes some given variables in a given boolean polynomial and returns the changed boolean polynomials. The polynomial itself is not affected. The variable,value pairs for fixing are to be provided as dictionary of the form {variable:value} or named parameters (see examples below).

INPUT:

- `in_dict` - (optional) dict with variable:value pairs
- `**kwds` - names parameters

EXAMPLE:

```
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: f = x*y + z + y*z + 1
sage: f.subs(x=1)
y*z + y + z + 1
sage: f.subs(x=0)
y*z + z + 1

sage: f.subs(x=y)
y*z + y + z + 1

sage: f.subs({x:1},y=1)
0
sage: f.subs(y=1)
x + 1
sage: f.subs(y=1,z=1)
x + 1
sage: f.subs(z=1)
x*y + y
sage: f.subs({'x':1},y=1)
0
```

This method can work fully symbolic:

```
sage: f.subs(x=var('a'),y=var('b'),z=var('c'))
a*b + b*c + c + 1
sage: f.subs({'x':var('a'),'y':var('b'),'z':var('c')})
a*b + b*c + c + 1
```

totalDegree()

Return total degree of this boolean polynomial.

EXAMPLE:

```
sage: B.<a,b,c,d> = BooleanPolynomialRing(4)
sage: f = a*b*c + 1
sage: f.totalDegree()
3
```

total_degree()

Return the total degree of `self`.

EXAMPLES:

```
sage: P.<x,y> = BooleanPolynomialRing(2)
sage: (x+y).total_degree()
1

sage: P(1).total_degree()
0

sage: (x*y + x + y + 1).total_degree()
2
```

variables()

Return a list of all variables appearing in `self`.

EXAMPLE:

```
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: (x + y).variables()
[x, y]

sage: (x*y + z).variables()
[x, y, z]

sage: P.zero_element().variables()
[]

sage: P.one_element().variables()
[1]
```

varsAsMonomial()

Return a boolean monomial with all the variables appearing in `self`.

EXAMPLES:

```
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: (x + y).varsAsMonomial()
x*y

sage: (x*y + z).varsAsMonomial()
x*y*z

sage: P.zero_element().varsAsMonomial()
1

sage: P.one_element().varsAsMonomial()
1
```

TESTS:

```
sage: R = BooleanPolynomialRing(1, 'y')
sage: y.varsAsMonomial()
y
sage: R
Boolean PolynomialRing in y
```

zerosIn()

Return a set containing all elements of `s` where this boolean polynomial evaluates to zero.

If `s` is given as a `BooleSet`, then the return type is also a `BooleSet`. If `s` is a set/list/tuple of tuple this function returns a tuple of tuples.

INPUT:

- `s` - candidate points for evaluation to zero

EXAMPLE:

```
sage: B.<a,b,c,d> = BooleanPolynomialRing(4)
sage: f = a*b + c + d + 1
```

Now we create a set of points:

```
sage: s = a*b + a*b*c + c*d + 1
sage: s = s.set(); s
{{a,b,c}, {a,b}, {c,d}, {}}
```

This encodes the points (1,1,1,0), (1,1,0,0), (0,0,1,1) and (0,0,0,0). But of these only (1,1,0,0) evaluates to zero.

```
sage: f.zerosIn(s)
{{a,b}}

sage: f.zerosIn([(1,1,1,0), (1,1,0,0), (0,0,1,1), (0,0,0,0)])
((1, 1, 0, 0),)
```

class BooleanPolynomialIdeal()

groebner_basis()

Return a Groebner basis of this ideal.

INPUT:

- **red_tail - tail reductions in intermediate polynomials,** this options affects mainly heuristics. The reducedness of the output polynomials can only be guaranteed by the option redsb (default: `True`)
- `minsb` - return a minimal Groebner basis (default: `True`)
- `redsb` - return a minimal Groebner basis and all tails are reduced (default: `True`)
- `deg_bound` - only compute Groebner basis up to a given degree bound (default: `False`)
- `faugere` - turn off or on the linear algebra (default: `False`)
- `linear_algebra_in_last_block` - this affects the last block of block orderings and degree orderings. If it is set to `True` linear algebra takes affect in this block. (default: `True`)
- `selection_size` - maximum number of polynomials for parallel reductions (default: `1000`)
- `heuristic` - Turn off heuristic by setting `heuristic=False` (default: `True`)
- `lazy` - (default: `True`)
- `invert` - setting `invert=True` input and output get a transformation `x+1` for each variable `x`, which shouldn't effect the calculated GB, but the algorithm.
- `other_ordering_first` - possible values are `False` or an ordering code. In practice, many Boolean examples have very few solutions and a very easy Groebner basis. So, a complex walk algorithm (which cannot be implemented using the data structures) seems unnecessary, as such Groebner bases can be converted quite fast by the normal Buchberger algorithm from one ordering into another ordering. (default: `False`)
- `prot` - show protocol (default: `False`)
- `full_prot` - show full protocol (default: `False`)

EXAMPLES:

```
sage: P.<x0, x1, x2, x3> = BooleanPolynomialRing(4)
sage: I = P.ideal(x0*x1*x2*x3 + x0*x1*x3 + x0*x1 + x0*x2 + x0)
sage: I.groebner_basis()
[x0*x1 + x0*x2 + x0, x0*x2*x3 + x0*x3]
```

interreduced_basis()

If this ideal is spanned by `(f_1, ..., f_n)` this method returns `(g_1, ..., g_s)` such that:

- `(f_1,...,f_n) = (g_1,...,g_s)`
- `LT(g_i) != LT(g_j)` for all `i != j`'
- `LT(g_i)` does not divide `m` for all monomials `m` of `{g_1,...,g_{i-1},g_{i+1},...,g_s}`

EXAMPLE:

```
sage: sr = mq.SR(1, 1, 1, 4, gf2=True, polybori=True)
sage: F,s = sr.polynomial_system()
sage: I = F.ideal()
sage: I.interreduced_basis()
[k000*s000 + k002*s000 + k002*s001 + k002*s003 + k003*s001 + k003*s002 + k003*s003 + s001 +
 k000*s001 + k001*s003 + k002*s000 + k002*s001 + k002*s003 + k003*s000 + s001,
```

```
k000*s002 + k001*s000 + k001*s001 + k001*s003 + k002*s001 + k003*s000 + k003*s002 + s001,
k000*s003 + k001*s001 + k001*s002 + k001*s003 + k002*s001 + k003*s000 + k003*s001 + s001 +
k001*s000 + k001*s003 + k002*s000 + k002*s001 + k003*s000 + k003*s002 + k003*s003 + s001 +
k001*s001 + k001*s003 + k002*s000 + k002*s001 + k002*s003 + k003*s002 + k003*s003 + k003,
k001*s002 + k002*s000 + k002*s003 + k003*s001 + k003*s002 + s003 + 1,
k001*s003 + k002*s000 + k002*s001 + k002*s002 + s001 + k001 + k003 + 1,
k001*k000 + k002*k000 + k003*s002 + k003,
k002*s000 + k002*s002 + k003*s001 + k003*s002 + s001 + k000 + k001 + k002,
k002*s001 + k002*s003 + k003*s000 + k003*s001 + s003 + k000 + k001 + k003,
k002*s002 + k003*s003 + s000 + s001 + k000 + k001 + 1,
k002*s003 + k003*s000 + k003*s001 + k003*s002 + k003*s003 + s002 + s003 + k001,
k002*k000 + k000 + k002 + 1,
k002*k001 + k003*s002 + k003*k002 + k002 + k003,
k003*s001 + k003*s002 + k003*s003 + k001,
k003*k000 + s001 + 1,
k003*k001 + s001 + k000 + k003,
k003*k002 + s001 + k002 + 1,
k100 + x103 + s001 + s002 + 1,
k101 + x102 + x103 + s002,
k102 + x100 + x103 + s001 + s002 + s003,
k103 + x101 + x102 + x103,
x100 + x103 + s001 + s003 + 1,
x101 + x102 + x103 + s001 + s002 + s003 + 1,
x102 + x103 + s002 + s003 + 1,
x103 + s003 + 1,
w100 + k000 + 1,
w101,
w102 + k002 + 1,
w103 + k003 + 1,
s000 + s001,
s001 + k002 + k003 + 1,
s002 + k002 + k003 + 1,
s003 + k002 + 1,
k001]
```

reduce()

Reduce an element modulo the reduced Groebner basis for this ideal. This returns 0 if and only if the element is in this ideal. In any case, this reduction is unique up to monomial orders.

EXAMPLE:

```
sage: P = PolynomialRing(GF(2),10, 'x')
sage: B = BooleanPolynomialRing(10,'x')
sage: I = sage.rings.ideal.Cyclic(P)
sage: I = B.ideal([B(f) for f in I.gens()])
sage: gb = I.groebner_basis()
sage: I.reduce(gb[0])
0
sage: I.reduce(gb[0] + 1)
1
sage: I.reduce(gb[0]*gb[1])
0
sage: I.reduce(gb[0]*B.gen(1))
0
```

class **BooleanPolynomialIterator**()

Iterator over the monomials of a boolean polynomial.

next()

x.next() -> the next value, or raise StopIteration

class BooleanPolynomialRing()

Construct a boolean polynomial ring with the following parameters:

INPUT:

- n - number of variables (an integer > 1)
- **names - names of ring variables, may be a string or** list/tuple
- order - term order (default: lex)

EXAMPLES:

```
sage: R.<x, y, z> = BooleanPolynomialRing()
sage: R
Boolean PolynomialRing in x, y, z

sage: p = x*y + x*z + y*z
sage: x*p
x*y*z + x*y + x*z

sage: R.term_order()
Lexicographic term order

sage: R = BooleanPolynomialRing(5,'x',order='deglex(3),deglex(2)')
sage: R.term_order()
deglex(3),deglex(2) term order

sage: R = BooleanPolynomialRing(3,'x',order='degrevlex')
sage: R.term_order()
Degree reverse lexicographic term order
```

TESTS:

```
sage: P.<x,y> = BooleanPolynomialRing(2,order='degrevlex')
sage: x > y
True

sage: P.<x0, x1, x2, x3> = BooleanPolynomialRing(4,order='degrevlex(2),degrevlex(2)')
sage: x0 > x1
True
sage: x2 > x3
True
```

cover_ring()

Return $R = \mathbf{F}_2[vars]$ if $vars$ is the ordered list of variable names of this ring. R also has the same term ordering as this ring.

EXAMPLE:

```
sage: B.<x,y> = BooleanPolynomialRing(2)
sage: R = B.cover_ring(); R
Multivariate Polynomial Ring in x, y over Finite Field of size 2

sage: B.term_order() == R.term_order()
True
```

The cover ring is cached:

```
sage: B.cover_ring() is B.cover_ring()
True
```

defining_ideal()

Return $I =< x_i^2 + x_i >\subset R$ where $R = \mathbf{F}_2[vars]$, $vars$ the ordered list of variables/variable names of this ring and x_i any element in $vars$.

EXAMPLE:

```
sage: B.<x,y> = BooleanPolynomialRing(2)
sage: I = B.defining_ideal(); I
Ideal (x^2 + x, y^2 + y) of Multivariate Polynomial Ring
in x, y over Finite Field of size 2
```

gen()

Returns the i-th generator of this boolean polynomial ring.

INPUT:

- `i` - an integer or a boolean monomial in one variable

EXAMPLES:

```
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: P.gen()
x
sage: P.gen(2)
z
sage: m = x.monomials()[0]
sage: P.gen(m)
x
```

TESTS:

```
sage: P.<x,y,z> = BooleanPolynomialRing(3, order='dp')
sage: P.gen(0)
x
```

gens()

Return the tuple of variables in this ring.

EXAMPLES:

```
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: P.gens()
(x, y, z)

sage: P = BooleanPolynomialRing(10,'x')
sage: P.gens()
(x0, x1, x2, x3, x4, x5, x6, x7, x8, x9)
```

TESTS:

```
sage: P.<x,y,z> = BooleanPolynomialRing(3,order='degrevlex')
sage: P.gens()
(x, y, z)
```

ideal()

Create an ideal in this ring.

INPUT:

- `gens` - list or tuple of generators
- `coerce` - bool (default: True) automatically coerce the given polynomials to this ring to form the ideal

EXAMPLES:

```
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: P.ideal(x+y)
Ideal (x + y) of Boolean PolynomialRing in x, y, z

sage: P.ideal(x*y, y*z)
Ideal (x*y, y*z) of Boolean PolynomialRing in x, y, z

sage: P.ideal([x+y, z])
Ideal (x + y, z) of Boolean PolynomialRing in x, y, z
```

interpolation_polynomial()

Return the lexicographically minimal boolean polynomial for the given sets of points.

Given two sets of points `zeros` - evaluating to zero - and `ones` - evaluating to one -, compute the lexicographically minimal boolean polynomial satisfying these points.

INPUT:

- `zeros` - the set of interpolation points mapped to zero
- `ones` - the set of interpolation points mapped to one

EXAMPLE:

First we create a random-ish boolean polynomial.

```
sage: B.<a,b,c,d,e,f> = BooleanPolynomialRing(6)
sage: f = a*b*c*e + a*d*e + a*f + b + c + e + f + 1
```

Now we find interpolation points mapping to zero and to one.

```
sage: zeros = set([(1, 0, 1, 0, 0, 0), (1, 0, 0, 0, 1, 0), \
                   (0, 0, 1, 1, 1, 1), (1, 0, 1, 1, 1, 1), \
                   (0, 0, 0, 0, 1, 0), (0, 1, 1, 1, 1, 0), \
                   (1, 1, 0, 0, 0, 1), (1, 1, 0, 1, 0, 1)])
sage: ones = set([(0, 0, 0, 0, 0, 0), (1, 0, 1, 0, 1, 0), \
                  (0, 0, 0, 1, 1, 1), (1, 0, 0, 1, 0, 1), \
                  (0, 0, 0, 0, 1, 1), (0, 1, 1, 0, 1, 1), \
                  (0, 1, 1, 1, 1, 1), (1, 1, 1, 0, 1, 0)])
sage: [f(*p) for p in zeros]
[0, 0, 0, 0, 0, 0, 0, 0]
sage: [f(*p) for p in ones]
[1, 1, 1, 1, 1, 1, 1, 1]
```

Finally, we find the lexicographically smallest interpolation polynomial using PolyBoRi .

```
sage: g = B.interpolation_polynomial(zeros, ones); g
b*f + c + d*f + d + e*f + e + 1

sage: [g(*p) for p in zeros]
[0, 0, 0, 0, 0, 0, 0, 0]
sage: [g(*p) for p in ones]
[1, 1, 1, 1, 1, 1, 1, 1]
```

Alternatively, we can work with PolyBoRi's native `BooleSet`'s. This example is from the PolyBoRi tutorial:

```
sage: B = BooleanPolynomialRing(4,"x0,x1,x2,x3")
sage: x = B.gen
sage: V=(x(0)+x(1)+x(2)+x(3)+1).set(); V
{{x0}, {x1}, {x2}, {x3}, {}}
sage: f=x(0)*x(1)+x(1)+x(2)+1
sage: z = f.zerosIn(V); z
```

```
{{x1}, {x2}}
sage: o = V.diff(z); o
{{x0}, {x3}, {}}
sage: B.interpolation_polynomial(z,o)
x1 + x2 + 1
```

ALGORITHM: Calls `interpolate_smallest_lex` as described in the PolyBoRi tutorial.

ngens()

Returns the number of variables in this boolean polynomial ring.

EXAMPLES:

```
sage: P.<x,y> = BooleanPolynomialRing(2)
sage: P.ngens()
2

sage: P = BooleanPolynomialRing(1000, 'x')
sage: P.ngens()
1000
```

random_element()

Return a random boolean polynomial. Generated polynomial has the given number of terms, and at most given degree.

INPUT:

- `degree` - maximum degree (default: 2)
- `terms` - number of terms (default: 5)
- `choose_degree` - choose degree of monomials randomly first, rather than monomials uniformly random
- `vars_set` - list of integer indicies of generators of self to use in the generated polynomial

EXAMPLES:

```
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: P.random_element(degree=3, terms=4)
x*y*z + x*z + y*z + z

sage: P.random_element(degree=1, terms=2)
z + 1
```

TESTS:

```
sage: P.random_element(degree=4)
...
ValueError: Given degree should be less than or equal to number of variables (3)

sage: t = P.random_element(degree=1, terms=5)
...
ValueError: Cannot generate random polynomial with 5 terms and maximum degree 1 using 3 vari

sage: t = P.random_element(degree=2,terms=5,vars_set=(0,1))
...
ValueError: Cannot generate random polynomial with 5 terms using 2 variables
```

class **BooleanPolynomialVector**()

append()

class **BooleanPolynomialVectorIterator**()

next()
x.next() -> the next value, or raise StopIteration

class **CCuddNavigator**()

constant()
elseBranch()
terminalOne()
thenBranch()
value()

class **DD**()

empty()

VariableBlock()

class VariableBlockFalse()

class VariableBlockTrue()

class VariableBlock_base()

add_up_polynomials()

append_ring_block()

change_ordering()

contained_vars()

free_m4ri()

get_cring()
Return the currently active global ring, this is only relevant for the native PolyBoRi interface.

```
sage: from polybori import declare_ring, get_cring, Block
sage: R = declare_ring([Block('x',2),Block('y',3)],globals())
sage: Q = get_cring(); Q
Boolean PolynomialRing in x(0), x(1), y(0), y(1), y(2)
sage: R is Q
True
```

get_order_code()

get_var_mapping()
Return a variable mapping between variables of `other` and `ring`. When other is a parent object, the mapping defines images for all variables of other. If it is an element, only variables occurring in other are mapped.

Raises `NameError` if no such mapping is possible.

EXAMPLES:

```
sage: P.<x,y,z> = BooleanPolynomialRing(3)
sage: R.<z,y> = QQ[]
sage: sage.rings.polynomial.pbori.get_var_mapping(P,R)
[z, y]
sage: sage.rings.polynomial.pbori.get_var_mapping(P, z^2)
[z, None]

sage: R.<z,x> = BooleanPolynomialRing(2)
sage: sage.rings.polynomial.pbori.get_var_mapping(P,R)
[z, x]
sage: sage.rings.polynomial.pbori.get_var_mapping(P, x^2)
[None, x]
```

have_degree_order()

if_then_else()
The opposite of navigating down a ZDD using navigators is to construct new ZDDs in the same way, namely giving their else- and then-branch as well as the index value of the new node.

INPUT:

- `root` - a variable
- `a` - the if branch, a `BooleSet` or a `BoolePolynomial`
- `b` - the else branch, a `BooleSet` or a `BoolePolynomial`

EXAMPLE:

```
sage: from polybori import if_then_else
sage: B = BooleanPolynomialRing(6,'x')
sage: x0,x1,x2,x3,x4,x5 = B.gens()
sage: f0 = x2*x3+x3
sage: f1 = x4
sage: if_then_else(x1, f0, f1)
{{x1,x2,x3}, {x1,x3}, {x4}}

sage: if_then_else(x1.lm().index(),f0,f1)
{{x1,x2,x3}, {x1,x3}, {x4}}

sage: if_then_else(x5, f0, f1)
...
IndexError: index of root must be less than the values of roots of the branches.
```

interpolate()

interpolate_smallest_lex()

ll_red_nf()

ll_red_nf_noredsb()

map_every_x_to_x_plus_one()

mod_mon_set()

mod_var_set()

mult_fact_sim_C()

nf3()

parallel_reduce()

recursively_insert()

red_tail()

set_cring()

Set the currently active global ring, this is only relevant for the native PolyBoRi interface.

```
sage: from polybori import *
sage: declare_ring([Block('x',2),Block('y',3)],globals())
Boolean PolynomialRing in x(0), x(1), y(0), y(1), y(2)
sage: R = get_cring(); R
Boolean PolynomialRing in x(0), x(1), y(0), y(1), y(2)

sage: declare_ring([Block('x',2),Block('y',2)],globals())
Boolean PolynomialRing in x(0), x(1), y(0), y(1)

sage: get_cring()
Boolean PolynomialRing in x(0), x(1), y(0), y(1)

sage: set_cring(R)
sage: get_cring()
Boolean PolynomialRing in x(0), x(1), y(0), y(1), y(2)
```

set_variable_name()

top_index()
Return the highest index in the parameter s.

INPUT:

- s - BooleSet, BooleMonomial, BoolePolynomial

EXAMPLE:

```
sage: B.<x,y,z> = BooleanPolynomialRing(3)
sage: from polybori import top_index
sage: top_index(x.lm())
0
sage: top_index(y*z)
1
sage: top_index(x + 1)
0
```

unpickle_BooleanPolynomial()
Unpickle boolean polynomials

EXAMPLE:

```
sage: T = TermOrder('deglex',2)+TermOrder('deglex',2)
sage: P.<a,b,c,d> = BooleanPolynomialRing(4,order=T)
sage: loads(dumps(a+b)) == a+b # indirect doctest
True
```

unpickle_BooleanPolynomialRing()
Unpickle boolean polynomial rings.

EXAMPLE:

```
sage: T = TermOrder('deglex',2)+TermOrder('deglex',2)
sage: P.<a,b,c,d> = BooleanPolynomialRing(4,order=T)
sage: loads(dumps(P)) == P  # indirect doctest
True
```

zeros()

28.15 Generic Convolution.

Asymptotically fast convolution of lists over any commutative ring in which the multiply-by-two map is injective. (More precisely, if $x \in R$, and $x = 2^k * y$ for some $k \geq 0$, we require that $R(x/2^k)$ returns y.)

The main function to be exported is convolution().

EXAMPLES:

```
sage: convolution([1, 2, 3, 4, 5], [6, 7])
[6, 19, 32, 45, 58, 35]
```

The convolution function is reasonably fast, even though it is written in pure Python. For example, the following takes less than a second:

```
sage: v=convolution(range(1000), range(1000))
```

ALGORITHM: Converts the problem to multiplication in the ring $S[x]/(x^M - 1)$, where $S = R[y]/(y^K + 1)$ (where R is the original base ring). Performs FFT with respect to the roots of unity $1, y, y^2, \ldots, y^{2K-1}$ in S. The FFT/IFFT are accomplished with just additions and subtractions and rotating python lists. (I think this algorithm is essentially due to Schonhage, not completely sure.) The pointwise multiplications are handled recursively, switching to a classical algorithm at some point.

Complexity is O(n log(n) log(log(n))) additions/subtractions in R and O(n log(n)) multiplications in R.

AUTHORS:

- David Harvey (2007-07): first implementation
- William Stein: editing the docstrings for inclusion in Sage.

convolution(*L1, L2*)

Returns convolution of non-empty lists L1 and L2. L1 and L2 may have arbitrary lengths.

EXAMPLES:

```
sage: convolution([1, 2, 3], [4, 5, 6, 7])
[4, 13, 28, 34, 32, 21]
```

```
sage: R = Integers(47)
sage: L1 = [R.random_element() for _ in range(1000)]
sage: L2 = [R.random_element() for _ in range(3756)]
sage: L3 = convolution(L1, L2)
sage: L3[2000] == sum([L1[i] * L2[2000-i] for i in range(1000)])
True
sage: len(L3) == 1000 + 3756 - 1
True
```

CHAPTER

TWENTYNINE

POWER SERIES RINGS

29.1 Univariate Power Series Rings

EXAMPLES: Power series rings are constructed in the standard Sage fashion.

```
sage: R.<t> = PowerSeriesRing(QQ)
sage: R.random_element(6)
-4 - 1/2*t^2 - 1/95*t^3 + 1/2*t^4 - 12*t^5 + O(t^6)
```

The default precision is specified at construction, but does not bound the precision of created elements.

```
sage: R.<t> = PowerSeriesRing(QQ, default_prec=5)
sage: R.random_element(6)
1/2 - 1/4*t + 2/3*t^2 - 5/2*t^3 + 2/3*t^5 + O(t^6)

sage: S = R([1, 3, 5, 7]); S  # XXX + O(t^5)
1 + 3*t + 5*t^2 + 7*t^3

sage: S.truncate(3)
5*t^2 + 3*t + 1

sage: S.<w> = PowerSeriesRing(QQ)
sage: S.base_ring()
Rational Field
```

An iterated example:

```
sage: R.<t> = PowerSeriesRing(ZZ)
sage: S.<t2> = PowerSeriesRing(R)
sage: S
Power Series Ring in t2 over Power Series Ring in t over Integer Ring
sage: S.base_ring()
Power Series Ring in t over Integer Ring
```

We compute with power series over the symbolic ring.

```
sage: K.<t> = PowerSeriesRing(SR, 5)
sage: a, b, c = var('a,b,c')
sage: f = a + b*t + c*t^2 + O(t^3)
sage: f*f
```

```
a^2 + 2*a*b*t + (2*a*c + b^2)*t^2 + O(t^3)
sage: f = sqrt(2) + sqrt(3)*t + O(t^3)
sage: f^2
2 + 2*sqrt(2)*sqrt(3)*t + 3*t^2 + O(t^3)
```

Elements are first coerced to constants in base_ring, then coerced into the PowerSeriesRing:

```
sage: R.<t> = PowerSeriesRing(ZZ)
sage: f = Mod(2, 3) * t; (f, f.parent())
(2*t, Power Series Ring in t over Ring of integers modulo 3)
```

We make a sparse power series.

```
sage: R.<x> = PowerSeriesRing(QQ, sparse=True); R
Sparse Power Series Ring in x over Rational Field
sage: f = 1 + x^1000000
sage: g = f*f
sage: g.degree()
2000000
```

We make a sparse Laurent series from a power series generator:

```
sage: R.<t> = PowerSeriesRing(QQ, sparse=True)
sage: latex(-2/3*(1/t^3) + 1/t + 3/5*t^2 + O(t^5))
\frac{-\frac{2}{3}}{t^{3}} + \frac{1}{t} + \frac{3}{5}t^{2} + O(t^{5})
sage: S = parent(1/t); S
Sparse Laurent Series Ring in t over Rational Field
```

AUTHORS:

- William Stein: the code
- Jeremy Cho (2006-05-17): some examples (above)

TESTS:

```
sage: R.<t> = PowerSeriesRing(QQ)
sage: R == loads(dumps(R))
True
```

```
sage: R.<x> = PowerSeriesRing(QQ, sparse=True)
sage: R == loads(dumps(R))
True
```

PowerSeriesRing(*base_ring, name=None, default_prec=20, names=None, sparse=False*)

Create a power series ring.

INPUT:

- `base_ring` - a commutative ring
- `name` - name of the indeterminate
- `default_prec` - (default: 20) the default precision used if an exact object must be changed to an approximate object in order to do an arithmetic operation.
- `sparse` - (default: False) whether power series are represented as sparse objects.

There is a unique power series ring over each base ring with given variable name. Two power series over the same base ring with different variable names are not equal or isomorphic.

EXAMPLES:

```
sage: R = PowerSeriesRing(QQ, 'x'); R
Power Series Ring in x over Rational Field

sage: S = PowerSeriesRing(QQ, 'y'); S
Power Series Ring in y over Rational Field

sage: R = PowerSeriesRing(QQ, 10)
...
ValueError: first letter of variable name must be a letter

sage: S = PowerSeriesRing(QQ, 'x', default_prec = 15); S
Power Series Ring in x over Rational Field
sage: S.default_prec()
15
```

class **PowerSeriesRing_domain**(*base_ring, name=None, default_prec=20, sparse=False, use_lazy_mpoly_ring=False*)

class **PowerSeriesRing_generic**(*base_ring, name=None, default_prec=20, sparse=False, use_lazy_mpoly_ring=False*)

A power series ring.

base_extend(*R*)

Returns the power series ring over R in the same variable as self, assuming there is a canonical coerce map from the base ring of self to R.

EXAMPLES:

```
sage: R.<T> = GF(7)[[]]; R
Power Series Ring in T over Finite Field of size 7
sage: R.change_ring(ZZ)
Power Series Ring in T over Integer Ring
sage: R.base_extend(ZZ)
...
TypeError: no base extension defined
```

change_ring(*R*)

Returns the power series ring over R in the same variable as self.

EXAMPLES:

```
sage: R.<T> = QQ[[]]; R
Power Series Ring in T over Rational Field
sage: R.change_ring(GF(7))
Power Series Ring in T over Finite Field of size 7
sage: R.base_extend(GF(7))
...
TypeError: no base extension defined
sage: R.base_extend(QuadraticField(3,'a'))
Power Series Ring in T over Number Field in a with defining polynomial x^2 - 3
```

characteristic()

Return the characteristic of this power series ring, which is the same as the characteristic of the base ring of the power series ring.

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(ZZ)
sage: R.characteristic()
0
sage: R.<w> = Integers(2^50)[[]]; R
Power Series Ring in w over Ring of integers modulo 1125899906842624
sage: R.characteristic()
1125899906842624
```

construction()

Returns the functorial construction of self, namely, completion of the univariate polynomial ring with respect to the indeterminate (to a given precision).

EXAMPLE:

```
sage: R = PowerSeriesRing(ZZ, 'x')
sage: c, S = R.construction(); S
Univariate Polynomial Ring in x over Integer Ring
sage: R == c(S)
True
```

gen(*n=0*)

Return the generator of this power series ring.

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(ZZ)
sage: R.gen()
t
sage: R.gen(3)
...
IndexError: generator n>0 not defined
```

is_atomic_repr()

Return False since power objects do not appear atomically, i.e., they have plus and spaces.

is_dense()

is_exact()

is_field()

Return False since the ring of power series over any ring is never a field.

is_finite()

Return False since the ring of power series over any ring is never finite.

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(ZZ)
sage: R.is_finite()
False
```

is_sparse()

laurent_series_ring()

If this is the power series ring $R[[t]]$, this function returns the Laurent series ring $R((t))$.

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(ZZ)
sage: R.laurent_series_ring()
Laurent Series Ring in t over Integer Ring
```

ngens()

Return the number of generators of this power series ring.

This is always 1.

EXAMPLES:

```
sage: R.<t> = ZZ[[]]
sage: R.ngens()
1
```

random_element(*prec, bound=None*)

Return a random power series.

INPUT:

- `prec` - an integer
- `bound` - an integer (default: None, which tries to spread choice across ring, if implemented)

OUTPUT:

- `power series` - a power series such that the coefficient of x^i, for i up to `degree`, are coercions to the base ring of random integers between -`bound` and `bound`.

IMPLEMENTATION: Call the random_element method on the underlying polynomial ring.

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(QQ)
sage: R.random_element(5)
-4 - 1/2*t^2 - 1/95*t^3 + 1/2*t^4 + O(t^5)
sage: R.random_element(5,20)
1/15 + 19/17*t + 10/3*t^2 + 5/2*t^3 + 1/2*t^4 + O(t^5)
```

class **PowerSeriesRing_over_field**(*base_ring, name=None, default_prec=20, sparse=False, use_lazy_mpoly_ring=False*)

fraction_field()

Return the fraction field of this power series ring, which is defined since this is over a field.

This fraction field is just the Laurent series ring over the base field.

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(GF(7))
sage: R.fraction_field()
Laurent Series Ring in t over Finite Field of size 7
sage: Frac(R)
Laurent Series Ring in t over Finite Field of size 7
```

is_PowerSeriesRing(*R*)

Return True if R is a power series ring.

EXAMPLES:

```
sage: from sage.rings.power_series_ring import is_PowerSeriesRing
sage: is_PowerSeriesRing(10)
False
sage: is_PowerSeriesRing(QQ[['x']])
True
```

unpickle_power_series_ring_v0(*base_ring, name, default_prec, sparse*)

29.2 Power Series

Sage provides an implementation of dense and sparse power series over any Sage base ring.

AUTHORS:

- William Stein

- David Harvey (2006-09-11): added solve_linear_de() method
- Robert Bradshaw (2007-04): sqrt, rmul, lmul, shifting
- Robert Bradshaw (2007-04): Cython version

EXAMPLE:

```
sage: R.<x> = PowerSeriesRing(ZZ)
sage: R([1,2,3])
1 + 2*x + 3*x^2
sage: R([1,2,3], 10)
1 + 2*x + 3*x^2 + O(x^10)
sage: f = 1 + 2*x - 3*x^3 + O(x^4); f
1 + 2*x - 3*x^3 + O(x^4)
sage: f^10
1 + 20*x + 180*x^2 + 930*x^3 + O(x^4)
sage: g = 1/f; g
1 - 2*x + 4*x^2 - 5*x^3 + O(x^4)
sage: g * f
1 + O(x^4)
```

In Python (as opposed to Sage) create the power series ring and its generator as follows:

```
sage: R, x = objgen(PowerSeriesRing(ZZ, 'x'))
sage: parent(x)
Power Series Ring in x over Integer Ring
```

EXAMPLE:

This example illustrates that coercion for power series rings is consistent with coercion for polynomial rings.

```
sage: poly_ring1.<gen1> = PolynomialRing(QQ)
sage: poly_ring2.<gen2> = PolynomialRing(QQ)
sage: huge_ring.<x> = PolynomialRing(poly_ring1)
```

The generator of the first ring gets coerced in as itself, since it is the base ring.

```
sage: huge_ring(gen1)
gen1
```

The generator of the second ring gets mapped via the natural map sending one generator to the other.

```
sage: huge_ring(gen2)
x
```

With power series the behavior is the same.

```
sage: power_ring1.<gen1> = PowerSeriesRing(QQ)
sage: power_ring2.<gen2> = PowerSeriesRing(QQ)
sage: huge_power_ring.<x> = PowerSeriesRing(power_ring1)
sage: huge_power_ring(gen1)
gen1
sage: huge_power_ring(gen2)
x
```

TODO: Rewrite valuation so it is *carried* along after any calculation, so in almost all cases f.valuation() is instant. Also, if you add f and g and their valuations are the same, note that we only have to look at terms at positions = f.valuation().

class PowerSeries()

A power series.

O()

Return this series plus $O(x^{\text{prec}})$. Does not change self.

V()

If $f = \sum a_m x^m$, then this function returns $\sum a_m x^{nm}$.

add_bigoh()

Returns the power series of precision at most prec got by adding $O(q^{\text{prec}})$ to f, where q is the variable.

EXAMPLES:

```
sage: R.<A> = RDF[[]]
sage: f = (1+A+O(A^5))^5; f
1.0 + 5.0*A + 10.0*A^2 + 10.0*A^3 + 5.0*A^4 + O(A^5)
sage: f.add_bigoh(3)
1.0 + 5.0*A + 10.0*A^2 + O(A^3)
sage: f.add_bigoh(5)
1.0 + 5.0*A + 10.0*A^2 + 10.0*A^3 + 5.0*A^4 + O(A^5)
```

base_extend()

Return a copy of this power series but with coefficients in R.

The following coercion uses base_extend implicitly:

```
sage: R.<t> = ZZ[['t']]
sage: (t - t^2) * Mod(1, 3)
t + 2*t^2
```

base_ring()

Return the base ring that this power series is defined over.

EXAMPLES:

```
sage: R.<t> = GF(49,'alpha')[[]]
sage: (t^2 + O(t^3)).base_ring()
Finite Field in alpha of size 7^2
```

change_ring()

Change if possible the coefficients of self to lie in R.

EXAMPLES:

```
sage: R.<T> = QQ[[]]; R
Power Series Ring in T over Rational Field
sage: f = 1 - 1/2*T + 1/3*T^2 + O(T^3)
sage: f.base_extend(GF(5))
...
TypeError: no base extension defined
sage: f.change_ring(GF(5))
1 + 2*T + 2*T^2 + O(T^3)
sage: f.change_ring(GF(3))
...
ZeroDivisionError: Inverse does not exist.
```

We can only change ring if there is a __call__ coercion defined. The following succeeds because ZZ(K(4)) is defined.

```
sage: K.<a> = NumberField(cyclotomic_polynomial(3), 'a')
sage: R.<t> = K[['t']]
sage: (4*t).change_ring(ZZ)
4*t
```

This does not succeed because ZZ(K(a+1)) is not defined.

```
sage: K.<a> = NumberField(cyclotomic_polynomial(3), 'a')
sage: R.<t> = K[['t']]
sage: ((a+1)*t).change_ring(ZZ)
...
TypeError: Unable to coerce a + 1 to an integer
```

coefficients()

Return the nonzero coefficients of self.

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(QQ)
sage: f = t + t^2 - 10/3*t^3
sage: f.coefficients()
[1, 1, -10/3]
```

common_prec()

Returns minimum precision of f and self.

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(QQ)

sage: f = t + t^2 + O(t^3)
sage: g = t + t^3 + t^4 + O(t^4)
sage: f.common_prec(g)
3
sage: g.common_prec(f)
3

sage: f = t + t^2 + O(t^3)
sage: g = t^2
sage: f.common_prec(g)
3
sage: g.common_prec(f)
3

sage: f = t + t^2
sage: f = t^2
sage: f.common_prec(g)
+Infinity
```

degree()

Return the degree of this power series, which is by definition the degree of the underlying polynomial.

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(QQ, sparse=True)
sage: f = t^100000 + O(t^10000000)
sage: f.degree()
100000
```

derivative()

The formal derivative of this power series, with respect to variables supplied in args.

Multiple variables and iteration counts may be supplied; see documentation for the global derivative() function for more details.

See Also:

`_derivative()`

EXAMPLES:

```
sage: R.<x> = PowerSeriesRing(QQ)
sage: g = -x + x^2/2 - x^4 + O(x^6)
sage: g.derivative()
-1 + x - 4*x^3 + O(x^5)
sage: g.derivative(x)
-1 + x - 4*x^3 + O(x^5)
sage: g.derivative(x, x)
1 - 12*x^2 + O(x^4)
sage: g.derivative(x, 2)
1 - 12*x^2 + O(x^4)
```

egf()

Returns the exponential generating function associated to self.

This function is known as serlaplace in GP/PARI.

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(QQ)
sage: f = t + t^2 + 2*t^3
sage: f.egf()
t + 1/2*t^2 + 1/3*t^3
```

exp()

Returns exp of this power series to the indicated precision.

INPUT:

- `prec` - integer; default is self.parent().default_prec

ALGORITHM: See PowerSeries.solve_linear_de().

Note:

- Screwy things can happen if the coefficient ring is not a field of characteristic zero. See PowerSeries.solve_linear_de().

AUTHORS:

- David Harvey (2006-09-08): rewrote to use simplest possible "lazy" algorithm.
- David Harvey (2006-09-10): rewrote to use divide-and-conquer strategy.
- David Harvey (2006-09-11): factored functionality out to solve_linear_de().
- Sourav Sen Gupta, David Harvey (2008-11): handle constant term

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(QQ, default_prec=10)
```

Check that $\exp(t)$ is, well, $\exp(t)$:

```
sage: (t + O(t^10)).exp()
1 + t + 1/2*t^2 + 1/6*t^3 + 1/24*t^4 + 1/120*t^5 + 1/720*t^6 + 1/5040*t^7 + 1/40320*t^8 + 1/
```

Check that $\exp(\log(1+t))$ is $1+t$:

```
sage: (sum([-(-t)^n/n for n in range(1, 10)]) + O(t^10)).exp()
1 + t + O(t^10)
```

Check that $\exp(2t + t^2 - t^5)$ is whatever it is:

```
sage: (2*t + t^2 - t^5 + O(t^10)).exp()
1 + 2*t + 3*t^2 + 10/3*t^3 + 19/6*t^4 + 8/5*t^5 - 7/90*t^6 - 538/315*t^7 - 425/168*t^8 - 306
```

Check requesting lower precision:

```
sage: (t + t^2 - t^5 + O(t^10)).exp(5)
1 + t + 3/2*t^2 + 7/6*t^3 + 25/24*t^4 + O(t^5)
```

Can't get more precision than the input:

```
sage: (t + t^2 + O(t^3)).exp(10)
1 + t + 3/2*t^2 + O(t^3)
```

Check some boundary cases:

```
sage: (t + O(t^2)).exp(1)
1 + O(t)
sage: (t + O(t^2)).exp(0)
O(t^0)
```

Handle nonzero constant term (fixes trac #4477):

```
sage: R.<x> = PowerSeriesRing(RR)
sage: (1 + x + x^2 + O(x^3)).exp()
2.71828182845905 + 2.71828182845905*x + 4.07742274268857*x^2 + O(x^3)

sage: R.<x> = PowerSeriesRing(ZZ)
sage: (1 + x + O(x^2)).exp()
...
ArithmeticError: exponential of constant term does not belong to coefficient ring (consider

sage: R.<x> = PowerSeriesRing(GF(5))
sage: (1 + x + O(x^2)).exp()
...
ArithmeticError: constant term of power series does not support exponentiation
```

exponents()

Return the exponents appearing in self with nonzero coefficients.

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(QQ)
sage: f = t + t^2 - 10/3*t^3
sage: f.exponents()
[1, 2, 3]
```

is_dense()

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(ZZ)
sage: t.is_dense()
True
sage: R.<t> = PowerSeriesRing(ZZ, sparse=True)
sage: t.is_dense()
False
```

is_gen()

Returns True if this the generator (the variable) of the power series ring.

EXAMPLES:

```
sage: R.<t> = QQ[[]]
sage: t.is_gen()
True
sage: (1 + 2*t).is_gen()
False
```

Note that this only returns true on the actual generator, not on something that happens to be equal to it.

```
sage: (1*t).is_gen()
False
sage: 1*t == t
True
```

is_sparse()

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(ZZ)
sage: t.is_sparse()
False
sage: R.<t> = PowerSeriesRing(ZZ, sparse=True)
sage: t.is_sparse()
True
```

is_square()

Returns True if this function has a square root in this ring, e.g. there is an element y in `self.parent()` such that $y^2 =$ "$self$".

ALGORITHM: If the base ring is a field, this is true whenever the power series has even valuation and the leading coefficient is a perfect square.

For an integral domain, it attempts the square root in the fraction field and tests whether or not the result lies in the original ring.

EXAMPLES:

```
sage: K.<t> = PowerSeriesRing(QQ, 't', 5)
sage: (1+t).is_square()
True
sage: (2+t).is_square()
False
sage: (2+t.change_ring(RR)).is_square()
True
sage: t.is_square()
False
sage: K.<t> = PowerSeriesRing(ZZ, 't', 5)
sage: (1+t).is_square()
False
sage: f = (1+t)^100
sage: f.is_square()
True
```

is_unit()

Returns whether this power series is invertible, which is the case precisely when the constant term is invertible.

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(ZZ)
sage: (-1 + t - t^5).is_unit()
True
sage: (3 + t - t^5).is_unit()
False
```

AUTHORS:

- David Harvey (2006-09-03)

laurent_series()

Return the Laurent series associated to this power series, i.e., this series considered as a Laurent series.

EXAMPLES:

```
sage: k.<w> = QQ[[]]
sage: f = 1+17*w+15*w^3+O(w^5)
sage: parent(f)
Power Series Ring in w over Rational Field
sage: g = f.laurent_series(); g
1 + 17*w + 15*w^3 + O(w^5)
```

list()

ogf()

Returns the ordinary generating function associated to self.

This function is known as serlaplace in GP/PARI.

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(QQ)
sage: f = t + t^2/factorial(2) + 2*t^3/factorial(3)
sage: f.ogf()
t + t^2 + 2*t^3
```

padded_list()

Return a list of coefficients of self up to (but not including) q^n.

Includes 0's in the list on the right so that the list has length n.

INPUT:

- n - an integer that is at least 0

EXAMPLES:

```
sage: R.<q> = PowerSeriesRing(QQ)
sage: f = 1 - 17*q + 13*q^2 + 10*q^4 + O(q^7)
sage: f.list()
[1, -17, 13, 0, 10]
sage: f.padded_list(7)
[1, -17, 13, 0, 10, 0, 0]
sage: f.padded_list(10)
[1, -17, 13, 0, 10, 0, 0, 0, 0, 0]
sage: f.padded_list(3)
[1, -17, 13]
```

polynomial()

prec()

The precision of $... + O(x^r)$ is by definition r.

EXAMPLES:

```
sage: R.<t> = ZZ[[]]
sage: (t^2 + O(t^3)).prec()
3
sage: (1 - t^2 + O(t^100)).prec()
100
```

shift()

Returns this power series multiplied by the power t^n. If n is negative, terms below t^n will be discarded. Does not change this power series.

Note: Despite the fact that higher order terms are printed to the right in a power series, right shifting decreases the powers of t, while left shifting increases them. This is to be consistent with polynomials, integers, etc.

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(QQ['y'], 't', 5)
sage: f = ~(1+t); f
1 - t + t^2 - t^3 + t^4 + O(t^5)
sage: f.shift(3)
t^3 - t^4 + t^5 - t^6 + t^7 + O(t^8)
sage: f >> 2
1 - t + t^2 + O(t^3)
sage: f << 10
t^10 - t^11 + t^12 - t^13 + t^14 + O(t^15)
sage: t << 29
t^30
```

AUTHORS:

- Robert Bradshaw (2007-04-18)

solve_linear_de()

Obtains a power series solution to an inhomogeneous linear differential equation of the form:

$$f'(t) = a(t)f(t) + b(t).$$

INPUT:

- `self` - the power series $a(t)$
- `b` - the power series $b(t)$ (default is zero)
- `f0` - the constant term of f ("initial condition") (default is 1)
- `prec` - desired precision of result (this will be reduced if either a or b have less precision available)

OUTPUT: the power series f, to indicated precision

ALGORITHM: A divide-and-conquer strategy; see the source code. Running time is approximately $M(n)\log n$, where $M(n)$ is the time required for a polynomial multiplication of length n over the coefficient ring. (If you're working over something like RationalField(), running time analysis can be a little complicated because the coefficients tend to explode.)

Note:

- If the coefficient ring is a field of characteristic zero, then the solution will exist and is unique.
- For other coefficient rings, things are more complicated. A solution may not exist, and if it does it may not be unique. Generally, by the time the nth term has been computed, the algorithm will have attempted divisions by $n!$ in the coefficient ring. So if your coefficient ring has enough 'precision', and if your coefficient ring can perform divisions even when the answer is not unique, and if you know in advance that a solution exists, then this function will find a solution (otherwise it will probably crash).

AUTHORS:

- David Harvey (2006-09-11): factored functionality out from exp() function, cleaned up precision tests a bit

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(QQ, default_prec=10)

sage: a = 2 - 3*t + 4*t^2 + O(t^10)
sage: b = 3 - 4*t^2 + O(t^7)
sage: f = a.solve_linear_de(prec=5, b=b, f0=3/5)
sage: f
 3/5 + 21/5*t + 33/10*t^2 - 38/15*t^3 + 11/24*t^4 + O(t^5)
sage: f.derivative() - a*f - b
 O(t^4)
```

```
sage: a = 2 - 3*t + 4*t^2
sage: b = b = 3 - 4*t^2
sage: f = a.solve_linear_de(b=b, f0=3/5)
...
ValueError: cannot solve differential equation to infinite precision

sage: a.solve_linear_de(prec=5, b=b, f0=3/5)
 3/5 + 21/5*t + 33/10*t^2 - 38/15*t^3 + 11/24*t^4 + O(t^5)
```

sqrt()

The square root function.

INPUT:

- prec - integer (default: None): if not None and the series has infinite precision, truncates series at precision prec.
- extend - bool (default: False); if True, return a square root in an extension ring, if necessary. Otherwise, raise a ValueError if the square is not in the base power series ring. For example, if extend is True the square root of a power series with odd degree leading coefficient is defined as an element of a formal extension ring.
- name - if extend is True, you must also specify the print name of the formal square root.
- all - bool (default: False); if True, return all square roots of self, instead of just one.

ALGORITHM: Newton's method

$$x_{i+1} = \frac{1}{2}(x_i + self/x_i)$$

EXAMPLES:

```
sage: K.<t> = PowerSeriesRing(QQ, 't', 5)
sage: sqrt(t^2)
t
sage: sqrt(1+t)
1 + 1/2*t - 1/8*t^2 + 1/16*t^3 - 5/128*t^4 + O(t^5)
sage: sqrt(4+t)
2 + 1/4*t - 1/64*t^2 + 1/512*t^3 - 5/16384*t^4 + O(t^5)
sage: u = sqrt(2+t, prec=2, extend=True, name = 'alpha'); u
alpha
sage: u^2
2 + t
sage: u.parent()
Univariate Quotient Polynomial Ring in alpha over Power Series Ring in t over Rational Field
sage: K.<t> = PowerSeriesRing(QQ, 't', 50)
sage: sqrt(1+2*t+t^2)
1 + t
sage: sqrt(t^2 +2*t^4 + t^6)
t + t^3
sage: sqrt(1 + t + t^2 + 7*t^3)^2
1 + t + t^2 + 7*t^3 + O(t^50)
sage: sqrt(K(0))
0
sage: sqrt(t^2)
t

sage: K.<t> = PowerSeriesRing(CDF, 5)
sage: v = sqrt(-1 + t + t^3, all=True); v
[1.0*I - 0.5*I*t - 0.125*I*t^2 - 0.5625*I*t^3 - 0.2890625*I*t^4 + O(t^5),
 -1.0*I + 0.5*I*t + 0.125*I*t^2 + 0.5625*I*t^3 + 0.2890625*I*t^4 + O(t^5)]
sage: [a^2 for a in v]
[-1.0 + 1.0*t + 1.0*t^3 + O(t^5), -1.0 + 1.0*t + 1.0*t^3 + O(t^5)]
```

A formal square root:

```
sage: K.<t> = PowerSeriesRing(QQ, 5)
sage: f = 2*t + t^3 + O(t^4)
sage: s = f.sqrt(extend=True, name='sqrtf'); s
sqrtf
sage: s^2
2*t + t^3 + O(t^4)
sage: parent(s)
Univariate Quotient Polynomial Ring in sqrtf over Power Series Ring in t over Rational Field
```

AUTHORS:

- Robert Bradshaw
- William Stein

square_root()

Return the square root of self in this ring. If this cannot be done then an error will be raised.

This function succeeds if and only if `self.is_square()`

EXAMPLES:

```
sage: K.<t> = PowerSeriesRing(QQ, 't', 5)
sage: (1+t).square_root()
1 + 1/2*t - 1/8*t^2 + 1/16*t^3 - 5/128*t^4 + O(t^5)
sage: (2+t).square_root()
...
ValueError: Square root does not live in this ring.
sage: (2+t.change_ring(RR)).square_root()
1.41421356237309 + 0.353553390593274*t - 0.0441941738241592*t^2 + 0.0110485434560398*t^3 - 0
sage: t.square_root()
...
ValueError: Square root not defined for power series of odd valuation.
sage: K.<t> = PowerSeriesRing(ZZ, 't', 5)
sage: f = (1+t)^20
sage: f.square_root()
1 + 10*t + 45*t^2 + 120*t^3 + 210*t^4 + O(t^5)
sage: f = 1+t
sage: f.square_root()
...
ValueError: Square root does not live in this ring.
```

AUTHORS:

- Robert Bradshaw

truncate()

The polynomial obtained from power series by truncation.

EXAMPLES:

```
sage: R.<I> = GF(2)[[]]
sage: f = 1/(1+I+O(I^8)); f
1 + I + I^2 + I^3 + I^4 + I^5 + I^6 + I^7 + O(I^8)
sage: f.truncate(5)
I^4 + I^3 + I^2 + I + 1
```

valuation()

Return the valuation of this power series.

This is equal to the valuation of the underlying polynomial.

EXAMPLES: Sparse examples:

```
sage: R.<t> = PowerSeriesRing(QQ, sparse=True)
sage: f = t^100000 + O(t^10000000)
sage: f.valuation()
100000
sage: R(0).valuation()
+Infinity
```

Dense examples:

```
sage: R.<t> = PowerSeriesRing(ZZ)
sage: f = 17*t^100 +O(t^110)
sage: f.valuation()
100
sage: t.valuation()
1
```

valuation_zero_part()

Factor self as as $q^n \cdot (a_0 + a_1 q + \cdots)$ with a_0 nonzero. Then this function returns $a_0 + a_1 q + \cdots$.

Note: This valuation zero part need not be a unit if, e.g., a_0 is not invertible in the base ring.

EXAMPLES:

```
sage: R.<t> = PowerSeriesRing(QQ)
sage: ((1/3)*t^5*(17-2/3*t^3)).valuation_zero_part()
17/3 - 2/9*t^3
```

In this example the valuation 0 part is not a unit:

```
sage: R.<t> = PowerSeriesRing(ZZ, sparse=True)
sage: u = (-2*t^5*(17-t^3)).valuation_zero_part(); u
-34 + 2*t^3
sage: u.is_unit()
False
sage: u.valuation()
0
```

variable()

EXAMPLES:

```
sage: R.<x> = PowerSeriesRing(Rationals())
sage: f = x^2 + 3*x^4 + O(x^7)
sage: f.variable()
'x'
```

AUTHORS:

- David Harvey (2006-08-08)

is_PowerSeries()

make_element_from_parent_v0()

make_powerseries_poly_v0()

29.3 Laurent Series Rings

EXAMPLES:

```
sage: R = LaurentSeriesRing(QQ, "x")
sage: R.base_ring()
Rational Field
```

```
sage: S = LaurentSeriesRing(GF(17)['x'], 'y')
sage: S
Laurent Series Ring in y over Univariate Polynomial Ring in x over
Finite Field of size 17
sage: S.base_ring()
Univariate Polynomial Ring in x over Finite Field of size 17
```

LaurentSeriesRing(*base_ring, name=None, names=None, sparse=False*)

EXAMPLES:

```
sage: R = LaurentSeriesRing(QQ, 'x'); R
Laurent Series Ring in x over Rational Field
sage: x = R.0
sage: g = 1 - x + x^2 - x^4 +O(x^8); g
1 - x + x^2 - x^4 + O(x^8)
sage: g = 10*x^(-3) + 2006 - 19*x + x^2 - x^4 +O(x^8); g
10*x^-3 + 2006 - 19*x + x^2 - x^4 + O(x^8)
```

You can also use more mathematical notation when the base is a field:

```
sage: Frac(QQ[['x']])
Laurent Series Ring in x over Rational Field
sage: Frac(GF(5)['y'])
Fraction Field of Univariate Polynomial Ring in y over Finite Field of size 5
```

Here the fraction field is not just the Laurent series ring, so you can't use the `Frac` notation to make the Laurent series ring.

```
sage: Frac(ZZ[['t']])
Fraction Field of Power Series Ring in t over Integer Ring
```

Laurent series rings are determined by their variable and the base ring, and are globally unique.

```
sage: K = Qp(5, prec = 5)
sage: L = Qp(5, prec = 200)
sage: R.<x> = LaurentSeriesRing(K)
sage: S.<y> = LaurentSeriesRing(L)
sage: R is S
False
sage: T.<y> = LaurentSeriesRing(Qp(5,prec=200))
sage: S is T
True
sage: W.<y> = LaurentSeriesRing(Qp(5,prec=199))
sage: W is T
False
```

class **LaurentSeriesRing_domain**(*base_ring, name=None, sparse=False*)

class **LaurentSeriesRing_field**(*base_ring, name=None, sparse=False*)

class **LaurentSeriesRing_generic**(*base_ring, name=None, sparse=False*)

Univariate Laurent Series Ring

EXAMPLES:

```
sage: K, q = LaurentSeriesRing(CC, 'q').objgen(); K
Laurent Series Ring in q over Complex Field with 53 bits of precision
sage: loads(K.dumps()) == K
True
```

base_extend(*R*)
Returns the laurent series ring over R in the same variable as self, assuming there is a canonical coerce map from the base ring of self to R.

change_ring(*R*)

characteristic()

default_prec()

gen(*n=0*)

is_dense()

is_exact()

is_field()

is_sparse()

ngens()

power_series_ring()
If this is the Laurent series ring $R((t))$, return the power series ring $R[[t]]$.
EXAMPLES:

```
sage: R = LaurentSeriesRing(QQ, "x")
sage: R.power_series_ring()
Power Series Ring in x over Rational Field
```

set_default_prec(*n*)

is_LaurentSeriesRing(*x*)

29.4 Laurent Series

EXAMPLES:

```
sage: R.<t> = LaurentSeriesRing(GF(7), 't'); R
Laurent Series Ring in t over Finite Field of size 7
sage: f = 1/(1-t+O(t^10)); f
1 + t + t^2 + t^3 + t^4 + t^5 + t^6 + t^7 + t^8 + t^9 + O(t^10)
```

Laurent series are immutable:

```
sage: f[2]
1
sage: f[2] = 5
...
IndexError: Laurent series are immutable
```

We compute with a Laurent series over the complex mpfr numbers.

```
sage: K.<q> = Frac(CC[['q']])
sage: K
Laurent Series Ring in q over Complex Field with 53 bits of precision
sage: q
1.00000000000000*q
```

Saving and loading.

```
sage: loads(q.dumps()) == q
True
sage: loads(K.dumps()) == K
True
```

IMPLEMENTATION: Laurent series in Sage are represented internally as a power of the variable times the unit part (which need not be a unit - it's a polynomial with nonzero constant term). The zero Laurent series has unit part 0.

AUTHORS:

- William Stein: original version
- David Joyner (2006-01-22): added examples
- Robert Bradshaw (2007-04): optimizations, shifting
- Robert Bradshaw: Cython version

class LaurentSeries()

A Laurent Series.

add_bigoh()

EXAMPLES:

```
sage: R.<t> = LaurentSeriesRing(QQ)
sage: f = t^2 + t^3 + O(t^10); f
t^2 + t^3 + O(t^10)
sage: f.add_bigoh(5)
t^2 + t^3 + O(t^5)
```

change_ring()

coefficients()

Return the nonzero coefficients of self.

EXAMPLES:

```
sage: R.<t> = LaurentSeriesRing(QQ)
sage: f = -5/t^(2) + t + t^2 - 10/3*t^3
sage: f.coefficients()
[-5, 1, 1, -10/3]
```

common_prec()

Returns minimum precision of f and self.

EXAMPLES:

```
sage: R.<t> = LaurentSeriesRing(QQ)

sage: f = t^(-1) + t + t^2 + O(t^3)
sage: g = t + t^3 + t^4 + O(t^4)
sage: f.common_prec(g)
3
sage: g.common_prec(f)
3

sage: f = t + t^2 + O(t^3)
sage: g = t^(-3) + t^2
sage: f.common_prec(g)
3
sage: g.common_prec(f)
3
```

```
sage: f = t + t^2
sage: f = t^2
sage: f.common_prec(g)
+Infinity

sage: f = t^(-3) + O(t^(-2))
sage: g = t^(-5) + O(t^(-1))
sage: f.common_prec(g)
-2
```

copy()

degree()

Return the degree of a polynomial equivalent to this power series modulo big oh of the precision.

EXAMPLES:

```
sage: x = Frac(QQ[['x']]).0
sage: g = x^2 - x^4 + O(x^8)
sage: g.degree()
4
sage: g = -10/x^5 + x^2 - x^4 + O(x^8)
sage: g.degree()
4
```

derivative()

The formal derivative of this Laurent series, with respect to variables supplied in args.

Multiple variables and iteration counts may be supplied; see documentation for the global derivative() function for more details.

See Also:

_derivative()

EXAMPLES:

```
sage: R.<x> = LaurentSeriesRing(QQ)
sage: g = 1/x^10 - x + x^2 - x^4 + O(x^8)
sage: g.derivative()
-10*x^-11 - 1 + 2*x - 4*x^3 + O(x^7)
sage: g.derivative(x)
-10*x^-11 - 1 + 2*x - 4*x^3 + O(x^7)

sage: R.<t> = PolynomialRing(ZZ)
sage: S.<x> = LaurentSeriesRing(R)
sage: f = 2*t/x + (3*t^2 + 6*t)*x + O(x^2)
sage: f.derivative()
-2*t*x^-2 + (3*t^2 + 6*t) + O(x)
sage: f.derivative(x)
-2*t*x^-2 + (3*t^2 + 6*t) + O(x)
sage: f.derivative(t)
2*x^-1 + (6*t + 6)*x + O(x^2)
```

exponents()

Return the exponents appearing in self with nonzero coefficients.

EXAMPLES:

```
sage: R.<t> = LaurentSeriesRing(QQ)
sage: f = -5/t^(2) + t + t^2 - 10/3*t^3
sage: f.exponents()
[-2, 1, 2, 3]
```

integral()

The formal integral of this Laurent series with 0 constant term.

EXAMPLES: The integral may or may not be defined if the base ring is not a field.

```
sage: t = LaurentSeriesRing(ZZ, 't').0
sage: f = 2*t^-3 + 3*t^2 + O(t^4)
sage: f.integral()
-t^-2 + t^3 + O(t^5)

sage: f = t^3
sage: f.integral()
...
ArithmeticError: Coefficients of integral cannot be coerced into the base ring
```

The integral of 1/t is $\log(t)$, which is not given by a Laurent series:

```
sage: t = Frac(QQ['t']).0
sage: f = -1/t^3 - 31/t + O(t^3)
sage: f.integral()
...
ArithmeticError: The integral of is not a Laurent series, since t^-1 has nonzero coefficient
```

Another example with just one negative coefficient:

```
sage: A.<t> = QQ[[]]
sage: f = -2*t^(-4) + O(t^8)
sage: f.integral()
2/3*t^-3 + O(t^9)
sage: f.integral().derivative() == f
True
```

is_unit()

Returns True if this is Laurent series is a unit in this ring.

EXAMPLES:

```
sage: R.<t> = LaurentSeriesRing(QQ)
sage: (2+t).is_unit()
True
sage: f = 2+t^2+O(t^10); f.is_unit()
True
sage: 1/f
1/2 - 1/4*t^2 + 1/8*t^4 - 1/16*t^6 + 1/32*t^8 + O(t^10)
sage: R(0).is_unit()
False
sage: R.<s> = LaurentSeriesRing(ZZ)
sage: f = 2 + s^2 + O(s^10)
sage: f.is_unit()
False
sage: 1/f
...
ArithmeticError: division not defined
```

ALGORITHM: A Laurent series is a unit if and only if its "unit part" is a unit.

is_zero()

EXAMPLES:

```
sage: x = Frac(QQ['x']).0
sage: f = 1/x + x + x^2 + 3*x^4 + O(x^7)
sage: f.is_zero()
0
```

```
sage: z = 0*f
sage: z.is_zero()
1
```

list()

EXAMPLES:

```
sage: R.<t> = LaurentSeriesRing(QQ)
sage: f = -5/t^(2) + t + t^2 - 10/3*t^3
sage: f.list()
[-5, 0, 0, 1, 1, -10/3]
```

power_series()

EXAMPLES:

```
sage: R.<t> = LaurentSeriesRing(ZZ)
sage: f = 1/(1-t+O(t^10)); f.parent()
Laurent Series Ring in t over Integer Ring
sage: g = f.power_series(); g
1 + t + t^2 + t^3 + t^4 + t^5 + t^6 + t^7 + t^8 + t^9 + O(t^10)
sage: parent(g)
Power Series Ring in t over Integer Ring
sage: f = 3/t^2 +  t^2 + t^3 + O(t^10)
sage: f.power_series()
...
ArithmeticError: self is a not a power series
```

prec()

This function returns the n so that the Laurent series is of the form (stuff) + $O(t^n)$. It doesn't matter how many negative powers appear in the expansion. In particular, prec could be negative.

EXAMPLES:

```
sage: x = Frac(QQ[['x']]).0
sage: f = x^2 + 3*x^4 + O(x^7)
sage: f.prec()
7
sage: g = 1/x^10 - x + x^2 - x^4 + O(x^8)
sage: g.prec()
8
```

shift()

Returns this laurent series multiplied by the power t^n. Does not change this series.

Note: Despite the fact that higher order terms are printed to the right in a power series, right shifting decreases the powers of t, while left shifting increases them. This is to be consistant with polynomials, integers, etc.

EXAMPLES:

```
sage: R.<t> = LaurentSeriesRing(QQ['y'])
sage: f = (t+t^-1)^4; f
t^-4 + 4*t^-2 + 6 + 4*t^2 + t^4
sage: f.shift(10)
t^6 + 4*t^8 + 6*t^10 + 4*t^12 + t^14
sage: f >> 10
t^-14 + 4*t^-12 + 6*t^-10 + 4*t^-8 + t^-6
sage: t << 4
t^5
sage: t + O(t^3) >> 4
t^-3 + O(t^-1)
```

AUTHORS:

•Robert Bradshaw (2007-04-18)

truncate()
Returns the laurent series of degree ‘ < n‘ which is equivalent to self modulo x^n.

truncate_neg()
Returns the laurent series equivalent to self except without any degree n terms.

This is equivalent to ‘`self - self.truncate(n)`‘.

valuation()
EXAMPLES:

```
sage: x = Frac(QQ[['x']]).0
sage: f = 1/x + x^2 + 3*x^4 + O(x^7)
sage: g = 1 - x + x^2 - x^4 + O(x^8)
sage: f.valuation()
-1
sage: g.valuation()
0
```

valuation_zero_part()
EXAMPLES:

```
sage: x = Frac(QQ[['x']]).0
sage: f = x + x^2 + 3*x^4 + O(x^7)
sage: f/x
1 + x + 3*x^3 + O(x^6)
sage: f.valuation_zero_part()
1 + x + 3*x^3 + O(x^6)
sage: g = 1/x^7 - x + x^2 - x^4 + O(x^8)
sage: g.valuation_zero_part()
1 - x^8 + x^9 - x^11 + O(x^15)
```

variable()
EXAMPLES:

```
sage: x = Frac(QQ[['x']]).0
sage: f = 1/x + x^2 + 3*x^4 + O(x^7)
sage: f.variable()
'x'
```

is_LaurentSeries()

make_element_from_parent()

CHAPTER

THIRTY

ALGEBRAS

30.1 Free algebras

AUTHORS:

- David Kohel (2005-09)
- William Stein (2006-11-01): add all doctests; implemented many things.

EXAMPLES:

```
sage: F = FreeAlgebra(ZZ,3,'x,y,z')
sage: F.base_ring()
Integer Ring
sage: G = FreeAlgebra(F, 2, 'm,n'); G
Free Algebra on 2 generators (m, n) over Free Algebra on 3 generators (x, y, z) over Integer Ring
sage: G.base_ring()
Free Algebra on 3 generators (x, y, z) over Integer Ring
```

TESTS:

```
sage: F = FreeAlgebra(GF(5),3,'x')
sage: F == loads(dumps(F))
True

sage: F.<x,y,z> = FreeAlgebra(GF(5),3)
sage: F == loads(dumps(F))
True

sage: F = FreeAlgebra(GF(5),3, ['xx', 'zba', 'Y'])
sage: F == loads(dumps(F))
True

sage: F = FreeAlgebra(GF(5),3, 'abc')
sage: F == loads(dumps(F))
True

sage: F = FreeAlgebra(FreeAlgebra(ZZ,1,'a'), 2, 'x')
sage: F == loads(dumps(F))
True
```

FreeAlgebra(*R, n, names*)

Return the free algebra over the ring R on n generators with given names.

INPUT:

- R - ring
- n - integer
- names - string or list/tuple of n strings

OUTPUT: a free algebra

EXAMPLES:

```
sage: FreeAlgebra(GF(5),3,'x')
Free Algebra on 3 generators (x0, x1, x2) over Finite Field of size 5
sage: F.<x,y,z> = FreeAlgebra(GF(5),3)
sage: (x+y+z)^2
x^2 + x*y + x*z + y*x + y^2 + y*z + z*x + z*y + z^2
sage: FreeAlgebra(GF(5),3, 'xx, zba, Y')
Free Algebra on 3 generators (xx, zba, Y) over Finite Field of size 5
sage: FreeAlgebra(GF(5),3, 'abc')
Free Algebra on 3 generators (a, b, c) over Finite Field of size 5
sage: FreeAlgebra(GF(5),1, 'z')
Free Algebra on 1 generators (z,) over Finite Field of size 5
sage: FreeAlgebra(GF(5),1, ['alpha'])
Free Algebra on 1 generators (alpha,) over Finite Field of size 5
sage: FreeAlgebra(FreeAlgebra(ZZ,1,'a'), 2, 'x')
Free Algebra on 2 generators (x0, x1) over Free Algebra on 1 generators (a,) over Integer Ring
```

Free algebras are globally unique:

```
sage: F = FreeAlgebra(ZZ,3,'x,y,z')
sage: G = FreeAlgebra(ZZ,3,'x,y,z')
sage: F is G
True
```

Free algebras commute with their base ring.

```
sage: K.<a,b> = FreeAlgebra(QQ,2)
sage: K.is_commutative()
False
sage: L.<c> = FreeAlgebra(K,1)
sage: L.is_commutative()
False
sage: s = a*b^2 * c^3; s
a*b^2*c^3
sage: parent(s)
Free Algebra on 1 generators (c,) over Free Algebra on 2 generators (a, b) over Rational Field
sage: c^3 * a * b^2
a*b^2*c^3
```

class **FreeAlgebra_generic**(*R, n, names*)

The free algebra on n generators over a base ring.

EXAMPLES:

```
sage: F.<x,y,z> = FreeAlgebra(QQ, 3); F
Free Algebra on 3 generators (x, y, z) over Rational Field
sage: mul(F.gens())
x*y*z
```

```
sage: mul([ F.gen(i%3) for i in range(12) ])
x*y*z*x*y*z*x*y*z*x*y*z
sage: mul([ F.gen(i%3) for i in range(12) ]) + mul([ F.gen(i%2) for i in range(12) ])
x*y*x*y*x*y*x*y*x*y*x*y + x*y*z*x*y*z*x*y*z*x*y*z
sage: (2 + x*z + x^2)^2 + (x - y)^2
4 + 5*x^2 - x*y + 4*x*z - y*x + y^2 + x^4 + x^3*z + x*z*x^2 + x*z*x*z
```

coerce_map_from_impl(*R*)

gen(*i*)

The i-th generator of the algebra.

EXAMPLES:

```
sage: F = FreeAlgebra(ZZ,3,'x,y,z')
sage: F.gen(0)
x
```

is_commutative()

Return True if this free algebra is commutative.

EXAMPLES:

```
sage: R.<x> = FreeAlgebra(QQ,1)
sage: R.is_commutative()
True
sage: R.<x,y> = FreeAlgebra(QQ,2)
sage: R.is_commutative()
False
```

is_field()

Return True if this Free Algebra is a field, which is only if the base ring is a field and there are no generators

EXAMPLES:

```
sage: A=FreeAlgebra(QQ,0,'')
sage: A.is_field()
True
sage: A=FreeAlgebra(QQ,1,'x')
sage: A.is_field()
False
```

monoid()

The free monoid of generators of the algebra.

EXAMPLES:

```
sage: F = FreeAlgebra(ZZ,3,'x,y,z')
sage: F.monoid()
Free monoid on 3 generators (x, y, z)
```

ngens()

The number of generators of the algebra.

EXAMPLES:

```
sage: F = FreeAlgebra(ZZ,3,'x,y,z')
sage: F.ngens()
3
```

quo(*mons, mats, names*)

Returns a quotient algebra defined via the action of a free algebra A on a (finitely generated) free module. The input for the quotient algebra is a list of monomials (in the underlying monoid for A) which form a free basis for the module of A, and a list of matrices, which give the action of the free generators of A on this monomial basis.

quotient (*mons, mats, names*)
Returns a quotient algebra defined via the action of a free algebra A on a (finitely generated) free module. The input for the quotient algebra is a list of monomials (in the underlying monoid for A) which form a free basis for the module of A, and a list of matrices, which give the action of the free generators of A on this monomial basis.

is_FreeAlgebra (*x*)
Return True if x is a free algebra; otherwise, return False.

EXAMPLES:

```
sage: from sage.algebras.free_algebra import is_FreeAlgebra
sage: is_FreeAlgebra(5)
False
sage: is_FreeAlgebra(ZZ)
False
sage: is_FreeAlgebra(FreeAlgebra(ZZ,100,'x'))
True
```

30.2 Free algebra elements

AUTHORS:

- David Kohel (2005-09)

TESTS:

```
sage: R.<x,y> = FreeAlgebra(QQ,2)
sage: x == loads(dumps(x))
True
sage: x*y
x*y
sage: (x*y)^0
1
sage: (x*y)^3
x*y*x*y*x*y
```

class FreeAlgebraElement (*A, x*)
A free algebra element.

30.3 Free algebra quotients

TESTS:

```
sage: n = 2
sage: A = FreeAlgebra(QQ,n,'x')
sage: F = A.monoid()
sage: i, j = F.gens()
sage: mons = [ F(1), i, j, i*j ]
sage: r = len(mons)
sage: M = MatrixSpace(QQ,r)
sage: mats = [M([0,1,0,0, -1,0,0,0, 0,0,0,-1, 0,0,1,0]), M([0,0,1,0, 0,0,0,1, -1,0,0,0, 0,-1,0,0]) ]
sage: H2.<i,j> = A.quotient(mons,mats)
```

```
sage: H2 == loads(dumps(H2))
True
sage: i == loads(dumps(i))
True
```

class **FreeAlgebraQuotient**(*A, mons, mats, names*)

dimension()
The rank of the algebra (as a free module).

free_algebra()
The free algebra generating the algebra.

gen(*i*)
The i-th generator of the algebra.

matrix_action()

module()
The free module of the algebra.

monoid()
The free monoid of generators of the algebra.

monomial_basis()
The free monoid of generators of the algebra as elements of a free monoid.

ngens()
The number of generators of the algebra.

rank()
The rank of the algebra (as a free module).

30.4 Free algebra quotient elements

AUTHORS:

- David Kohel (2005-09)

class **FreeAlgebraQuotientElement**(*A, x*)

vector()

is_FreeAlgebraQuotientElement(*x*)

30.5 The Steenrod algebra

AUTHORS:

- John H. Palmieri (2008-07-30): version 0.9

This module defines the mod p Steenrod algebra $\mathcal{A}_p$, some of its properties, and ways to define elements of it.

From a topological point of view, $\mathcal{A}_p$ is the algebra of stable cohomology operations on mod p cohomology; thus for any topological space X, its mod p cohomology algebra $H^*(X, \mathbf{F}_p)$ is a module over $\mathcal{A}_p$.

From an algebraic point of view, $\mathcal{A}_p$ is an $\mathbf{F}_p$-algebra; when $p = 2$, it is generated by elements Sq^i for $i \geq 0$ (the *Steenrod squares*), and when p is odd, it is generated by elements $\mathcal{P}^i$ for $i \geq 0$ (the *Steenrod reduced 'p'th powers*) along with an element β (the *mod 'p' Bockstein*). The Steenrod algebra is graded: Sq^i is in degree i for each i, β is in degree 1, and $\mathcal{P}^i$ is in degree $2(p-1)i$.

The unit element is Sq^0 when $p = 2$ and $\mathcal{P}^0$ when p is odd. The generating elements also satisfy the *Adem relations*. At the prime 2, these have the form

$$\mathrm{Sq}^a \mathrm{Sq}^b = \sum_{c=0}^{[a/2]} \binom{b-c-1}{a-2c} \mathrm{Sq}^{a+b-c} \mathrm{Sq}^c.$$

At odd primes, they are a bit more complicated. See Steenrod and Epstein [SE] for full details. These relations lead to the existence of the *Serre-Cartan* basis for $\mathcal{A}_p$.

The mod p Steenrod algebra has the structure of a Hopf algebra, and Milnor [Mil] has a beautiful description of the dual, leading to a construction of the *Milnor basis* for $\mathcal{A}_p$. In this module, elements in the Steenrod algebra are represented, by default, using the Milnor basis.

See the documentation for `SteenrodAlgebra` for many more details and examples.

class SteenrodAlgebraFactory()

The mod p Steenrod algebra

INPUT:

- `p` - positive prime integer (optional, default = 2)
- `basis` - string (optional, default = 'milnor')

OUTPUT:

- mod p Steenrod algebra with given basis

This returns the mod p Steenrod algebra, elements of which are printed using basis.

EXAMPLES:

Some properties of the Steenrod algebra are available:

```
sage: A = SteenrodAlgebra(2)
sage: A.ngens()  # number of generators
+Infinity
sage: A.gen(5)   # 5th generator
Sq(32)
sage: A.order()
+Infinity
sage: A.is_finite()
False
sage: A.is_commutative()
False
sage: A.is_noetherian()
False
sage: A.is_integral_domain()
False
```

```
sage: A.is_field()
False
sage: A.is_division_algebra()
False
sage: A.category()
Category of algebras over Finite Field of size 2
```

There are methods for constructing elements of the Steenrod algebra:

```
sage: A2 = SteenrodAlgebra(2); A2
mod 2 Steenrod algebra
sage: A2.Sq(1,2,6)
Sq(1,2,6)
sage: A2.Q(3,4)  # product of Milnor primitives Q_3 and Q_4
Sq(0,0,0,1,1)
sage: A2.pst(2,3)  # Margolis pst element
Sq(0,0,4)
sage: A5 = SteenrodAlgebra(5); A5
mod 5 Steenrod algebra
sage: A5.P(1,2,6)
P(1,2,6)
sage: A5.Q(3,4)
Q_3 Q_4
sage: A5.Q(3,4) * A5.P(1,2,6)
Q_3 Q_4 P(1,2,6)
sage: A5.pst(2,3)
P(0,0,25)
```

You can test whether elements are contained in the Steenrod algebra:

```
sage: w = Sq(2) * Sq(4)
sage: w in SteenrodAlgebra(2)
True
sage: w in SteenrodAlgebra(17)
False
```

Different bases for the Steenrod algebra:

There are two standard vector space bases for the mod p Steenrod algebra: the Milnor basis and the Serre-Cartan basis. When $p = 2$, there are also several other, less well-known, bases. See the documentation for the function 'steenrod_algebra_basis' for full descriptions of each of the implemented bases.

This module implements the following bases at all primes:

- 'milnor': Milnor basis.
- 'serre-cartan' or 'adem' or 'admissible': Serre-Cartan basis.

It implements the following bases when $p = 2$:

- 'wood_y': Wood's Y basis.
- 'wood_z': Wood's Z basis.
- 'wall', 'wall_long': Wall's basis.
- 'arnon_a', 'arnon_a_long': Arnon's A basis.
- 'arnon_c': Arnon's C basis.
- 'pst', 'pst_rlex', 'pst_llex', 'pst_deg', 'pst_revz': various P_t^s-bases.
- 'comm', 'comm_rlex', 'comm_llex', 'comm_deg', 'comm_revz', or these with '_long' appended: various commutator bases.

When defining a Steenrod algebra, you can specify a basis. Then elements of that Steenrod algebra are printed in that basis

```
sage: adem = SteenrodAlgebra(2, 'adem')
sage: x = adem.Sq(2,1)  # Sq(-) always means a Milnor basis element
sage: x
Sq^{4} Sq^{1} + Sq^{5}
sage: y = Sq(0,1)     # unadorned Sq defines elements w.r.t. Milnor basis
sage: y
Sq(0,1)
sage: adem(y)
Sq^{2} Sq^{1} + Sq^{3}
sage: adem5 = SteenrodAlgebra(5, 'serre-cartan')
sage: adem5.P(0,2)
P^{10} P^{2} + 4 P^{11} P^{1} + P^{12}
```

You can get a list of basis elements in a given dimension:

```
sage: A3 = SteenrodAlgebra(3, 'milnor')
sage: A3.basis(13)
(Q_1 P(2), Q_0 P(3))
```

As noted above, several of the bases ('arnon_a', 'wall', 'comm') have alternate, longer, representations. These provide ways of expressing elements of the Steenrod algebra in terms of the Sq^{2^n}.

```
sage: A_long = SteenrodAlgebra(2, 'arnon_a_long')
sage: A_long(Sq(6))
Sq^{1} Sq^{2} Sq^{1} Sq^{2} + Sq^{2} Sq^{4}
sage: SteenrodAlgebra(2, 'wall_long')(Sq(6))
Sq^{2} Sq^{1} Sq^{2} Sq^{1} + Sq^{2} Sq^{4}
sage: SteenrodAlgebra(2, 'comm_deg_long')(Sq(6))
s_{1} s_{2} s_{12} + s_{2} s_{4}
```

Testing unique parents:

```
sage: S0 = SteenrodAlgebra(2)
sage: S1 = SteenrodAlgebra(2)
sage: S0 is S1
True
```

create_key (*p=2, basis='milnor'*)

This is an internal function that is used to ensure unique parents. Not for public consumption.

EXAMPLES:

```
sage: SteenrodAlgebra.create_key()
(2, 'milnor')
```

create_object (*version, key, **extra_args*)

This is an internal function that is used to ensure unique parents. Not for public consumption.

EXAMPLES:

```
sage: SteenrodAlgebra.create_object(1,(11,'milnor'))
mod 11 Steenrod algebra
```

class **SteenrodAlgebra_generic** (*p=2, basis='milnor'*)

The mod p Steenrod algebra.

Users should not call this, but use the function 'SteenrodAlgebra' instead. See that function for extensive documentation.

EXAMPLES:

```
sage: sage.algebras.steenrod_algebra.SteenrodAlgebra_generic()
mod 2 Steenrod algebra
sage: sage.algebras.steenrod_algebra.SteenrodAlgebra_generic(5)
mod 5 Steenrod algebra
sage: sage.algebras.steenrod_algebra.SteenrodAlgebra_generic(5, 'adem')
mod 5 Steenrod algebra
```

P (**nums*)

The element $P(a, b, c, ...)$

INPUT:

- `a, b, c, ...` - non-negative integers

OUTPUT: element of the Steenrod algebra given by the single basis element P(a, b, c, ...)

Note that at the prime 2, this is the same element as Sq$(a, b, c, ...)$.

EXAMPLES:

```
sage: A = SteenrodAlgebra(2)
sage: A.P(5)
Sq(5)
sage: B = SteenrodAlgebra(3)
sage: B.P(5,1,1)
P(5,1,1)
```

Q (**nums*)

The element $Q_{n0}Q_{n1}...$, given by specifying the subscripts.

INPUT:

- `n0, n1, ...` - non-negative integers

OUTPUT: The element $Q_{n0}Q_{n1}...$

Note that at the prime 2, Q_n is the element Sq$(0, 0, ..., 1)$, where the 1 is in the $(n + 1)^{st}$ position.

Compare this to the method 'Q_exp', which defines a similar element, but by specifying the tuple of exponents.

EXAMPLES:

```
sage: A2 = SteenrodAlgebra(2)
sage: A5 = SteenrodAlgebra(5)
sage: A2.Q(2,3)
Sq(0,0,1,1)
sage: A5.Q(1,4)
Q_1 Q_4
sage: A5.Q(1,4) == A5.Q_exp(0,1,0,0,1)
True
```

Q_exp (**nums*)

The element $Q_0^{e_0}Q_1^{e_1}...$, given by specifying the exponents.

INPUT:

- `e0, e1, ...` - 0s and 1s

OUTPUT: The element $Q_0^{e_0}Q_1^{e_1}...$

Note that at the prime 2, Q_n is the element Sq$(0, 0, ..., 1)$, where the 1 is in the $(n + 1)^{st}$ position.

Compare this to the method 'Q', which defines a similar element, but by specifying the tuple of subscripts of terms with exponent 1.

EXAMPLES:

```
sage: A2 = SteenrodAlgebra(2)
sage: A5 = SteenrodAlgebra(5)
sage: A2.Q_exp(0,0,1,1,0)
Sq(0,0,1,1)
sage: A5.Q_exp(0,0,1,1,0)
Q_2 Q_3
sage: A5.Q(2,3)
Q_2 Q_3
sage: A5.Q_exp(0,0,1,1,0) == A5.Q(2,3)
True
```

basis(*n*)

Basis for self in dimension n

INPUT:

- n - non-negative integer

OUTPUT:

- basis - tuple of Steenrod algebra elements

EXAMPLES:

```
sage: A3 = SteenrodAlgebra(3)
sage: A3.basis(13)
(Q_1 P(2), Q_0 P(3))
sage: SteenrodAlgebra(2, 'adem').basis(12)
(Sq^{12},
Sq^{11} Sq^{1},
Sq^{9} Sq^{2} Sq^{1},
Sq^{8} Sq^{3} Sq^{1},
Sq^{10} Sq^{2},
Sq^{9} Sq^{3},
Sq^{8} Sq^{4})
```

category()

The Steenrod algebra is an algebra over F_p.

EXAMPLES:

```
sage: A = SteenrodAlgebra(3)
sage: A.category()
Category of algebras over Finite Field of size 3
```

gen(*i=0*)

The ith generator of the Steenrod algebra.

INPUT:

- i - non-negative integer

OUTPUT: the ith generator of the Steenrod algebra

The i^{th} generator is $Sq(2^i)$ at the prime 2; when p is odd, the 0th generator is $\beta = Q(0)$, and for $i > 0$, the i^{th} generator is $P(p^{i-1})$.

EXAMPLES:

```
sage: A = SteenrodAlgebra(2)
sage: A.gen(4)
Sq(16)
sage: A.gen(200)
Sq(1606938044258990275541962092341162602522202993782792835301376)
sage: B = SteenrodAlgebra(5)
sage: B.gen(0)
```

```
Q_0
sage: B.gen(2)
P(5)
```

gens()
List of generators for the Steenrod algebra. Not implemented (mainly because the list of generators is infinite).
EXAMPLES:

```
sage: A3 = SteenrodAlgebra(3, 'adem')
sage: A3.gens()
...
NotImplementedError: 'gens' is not implemented for the Steenrod algebra.
```

is_commutative()
The Steenrod algebra is not commutative.
EXAMPLES:

```
sage: A = SteenrodAlgebra(3)
sage: A.is_commutative()
False
```

is_division_algebra()
The Steenrod algebra is not a division algebra.
EXAMPLES:

```
sage: A = SteenrodAlgebra(3)
sage: A.is_division_algebra()
False
```

is_field()
The Steenrod algebra is not a field.
EXAMPLES:

```
sage: A = SteenrodAlgebra(3)
sage: A.is_field()
False
```

is_finite()
The Steenrod algebra is not finite.
EXAMPLES:

```
sage: A = SteenrodAlgebra(3)
sage: A.is_finite()
False
```

is_integral_domain()
The Steenrod algebra is not an integral domain.
EXAMPLES:

```
sage: A = SteenrodAlgebra(3)
sage: A.is_integral_domain()
False
```

is_noetherian()
The Steenrod algebra is not noetherian.
EXAMPLES:

```
sage: A = SteenrodAlgebra(3)
sage: A.is_noetherian()
False
```

ngens()

Number of generators of the Steenrod algebra.

This returns infinity, since the Steenrod algebra is infinitely generated.

EXAMPLES:

```
sage: A = SteenrodAlgebra(3)
sage: A.ngens()
+Infinity
```

order()

The Steenrod algebra has infinite order.

EXAMPLES:

```
sage: A = SteenrodAlgebra(3)
sage: A.order()
+Infinity
```

pst(*s, t*)

The Margolis element P_t^s.

INPUT:

- s - non-negative integer
- t - positive integer
- p - positive prime number

OUTPUT: element of the Steenrod algebra

This returns the Margolis element P_t^s of the mod p Steenrod algebra: the element equal to $P(0, 0, ..., 0, p^s)$, where the p^s is in position t.

EXAMPLES:

```
sage: A2 = SteenrodAlgebra(2)
sage: A2.pst(3,5)
Sq(0,0,0,0,8)
sage: A2.pst(1,2) == Sq(4)*Sq(2) + Sq(2)*Sq(4)
True
sage: SteenrodAlgebra(5).pst(3,5)
P(0,0,0,0,125)
```

class SteenrodAlgebra_mod_two(*p=2, basis='milnor'*)

The mod 2 Steenrod algebra.

Users should not call this, but use the function 'SteenrodAlgebra' instead. See that function for extensive documentation. (This differs from SteenrodAlgebra_generic only in that it has a method 'Sq' for defining elements.)

Sq(**nums*)

Milnor element $\mathrm{Sq}(a, b, c, ...)$.

INPUT:

- a, b, c, ... - non-negative integers

OUTPUT: element of the Steenrod algebra

This returns the Milnor basis element $\mathrm{Sq}(a, b, c, ...)$.

EXAMPLES:

```
sage: A = SteenrodAlgebra(2)
sage: A.Sq(5)
Sq(5)
sage: A.Sq(5,0,2)
Sq(5,0,2)
```

Entries must be non-negative integers; otherwise, an error results.

get_basis_name(*basis, p*)

Return canonical basis named by string basis at the prime p.

INPUT:

- basis - string
- p - positive prime number

OUTPUT:

- basis_name - string

EXAMPLES:

```
sage: sage.algebras.steenrod_algebra.get_basis_name('adem', 2)
'serre-cartan'
sage: sage.algebras.steenrod_algebra.get_basis_name('milnor', 2)
'milnor'
sage: sage.algebras.steenrod_algebra.get_basis_name('MiLNoR', 5)
'milnor'
sage: sage.algebras.steenrod_algebra.get_basis_name('pst-llex', 2)
'pst_llex'
```

30.6 Steenrod algebra elements

AUTHORS: - John H. Palmieri (2008-07-30: version 0.9)

This package provides for basic algebra with elements in the mod p Steenrod algebra. In this package, elements in the Steenrod algebra are represented, by default, using the Milnor basis.

EXAMPLES:

Basic arithmetic, $p = 2$. To construct an element of the mod 2 Steenrod algebra, use the function Sq:

```
sage: a = Sq(1,2)
sage: b = Sq(4,1)
sage: z = a + b
sage: z
Sq(1,2) + Sq(4,1)
sage: Sq(4) * Sq(1,2)
Sq(1,1,1) + Sq(2,3) + Sq(5,2)
sage: z**2          # non-negative exponents work as they should
Sq(1,2,1) + Sq(4,1,1)
sage: z**0
Sq(0)
```

Basic arithmetic, $p > 2$. To construct an element of the mod p Steenrod algebra when p is odd, you should first define a Steenrod algebra, using the SteenrodAlgebra command:

```
sage: SteenrodAlgebra()    # 2 is the default prime
mod 2 Steenrod algebra
sage: A3 = SteenrodAlgebra(3)
sage: A3
mod 3 Steenrod algebra
```

Having done this, the newly created algebra `A3` has methods `Q` and `P` which construct elements of `A3`:

```
sage: c = A3.Q(1,3,6); c
Q_1 Q_3 Q_6
sage: d = A3.P(2,0,1); d
P(2,0,1)
sage: c * d
Q_1 Q_3 Q_6 P(2,0,1)
sage: e = A3.P(3)
sage: d * e
P(5,0,1)
sage: e * d
P(1,1,1) + P(5,0,1)
sage: c * c
0
sage: e ** 3
2 P(1,2)
```

Note that one can construct an element like `c` above in one step, without first constructing the algebra:

```
sage: c = SteenrodAlgebra(3).Q(1,3,6)
sage: c
Q_1 Q_3 Q_6
```

And of course, you can do similar constructions with the mod 2 Steenrod algebra:

```
sage: A = SteenrodAlgebra(2); A
mod 2 Steenrod algebra
sage: A.Sq(2,3,5)
Sq(2,3,5)
sage: A.P(2,3,5)    # when p=2, P = Sq
Sq(2,3,5)
sage: A.Q(1,4)      # when p=2, this gives a product of Milnor primitives
Sq(0,1,0,0,1)
```

Regardless of the prime, each element has an `excess`, and if the element is homogeneous, a `degree`. The excess of $\mathrm{Sq}(i_1, i_2, i_3, ...)$ is $i_1 + i_2 + i_3 + ...$; when p is odd, the excess of $Q_0^{e_0} Q_1^{e_1} ... \mathcal{P}(r_1, r_2, ...)$ is $\sum e_i + 2 \sum r_i$. The excess of a linear combination of Milnor basis elements is the minimum of the excesses of those basis elements.

The degree of $\mathrm{Sq}(i_1, i_2, i_3, ...)$ is $sum(2^n - 1) i_n$, and when p is odd, the degree of $Q_0^{\epsilon_0} Q_1^{\epsilon_1} ... \mathcal{P}(r_1, r_2, ...)$ is $\sum \epsilon_i (2p^i - 1) + \sum r_j (2p^j - 2)$. The degree of a linear combination of such terms is only defined if the terms all have the same degree.

Here are some simple examples:

```
sage: z = Sq(1,2) + Sq(4,1)
sage: z.degree()
7
sage: (Sq(0,0,1) + Sq(5,3)).degree()
Element is not homogeneous.
```

```
sage: Sq(7,2,1).excess()
10
sage: z.excess()
3
sage: B = SteenrodAlgebra(3)
sage: x = B.Q(1,4)
sage: y = B.P(1,2,3)
sage: x.degree()
166
sage: x.excess()
2
sage: y.excess()
12
```

Elements have a `weight` in the May filtration, which (when $p = 2$) is related to the `height` function defined by Wall:

```
sage: Sq(2,1,5).may_weight()
9
sage: Sq(2,1,5).wall_height()
[2, 3, 2, 1, 1]
sage: b = Sq(4)*Sq(8) + Sq(8)*Sq(4)
sage: b.may_weight()
2
sage: b.wall_height()
[0, 0, 1, 1]
```

Odd primary May weights:

```
sage: A5 = SteenrodAlgebra(5)
sage: a = A5.Q(1,2,4)
sage: b = A5.P(1,2,1)
sage: a.may_weight()
10
sage: b.may_weight()
8
sage: (a * b).may_weight()
18
sage: A5.P(0,0,1).may_weight()
3
```

Since the Steenrod algebra is a Hopf algebra, every element has an antipode.

```
sage: d = Sq(0,0,1); d
Sq(0,0,1)
sage: d.antipode()
Sq(0,0,1)
sage: Sq(4).antipode()
Sq(1,1) + Sq(4)
sage: (Sq(4) * Sq(2)).antipode()
Sq(6)
sage: SteenrodAlgebra(7).P(3,1).antipode()
P(3,1)
```

Applying the antipode twice returns the original element:

```
sage: y = Sq(8)*Sq(4)
sage: y == (y.antipode()).antipode()
True
```

You can treat elements of the Steenrod algebra like lists of Milnor basis elements:

```
sage: y = Sq(4) * Sq(1,2); y
Sq(1,1,1) + Sq(2,3) + Sq(5,2)
sage: for m in y: m
Sq(1,1,1)
Sq(2,3)
Sq(5,2)
sage: [(m.degree(),m.excess()) for m in y]
[(11, 3), (11, 5), (11, 7)]
```

Once you've define a Steenrod algebra, the method `pst` is another way to define elements of it: `pst(s,t)` defines the Margolis element $P(s,t)$, the basis element $\mathcal{P}(0,...,0,p^s)$ with p^s in position t:

```
sage: A2 = SteenrodAlgebra(2)
sage: Q2 = A2.pst(0,3)
sage: Q2
Sq(0,0,1)
sage: Q2*Q2
0
sage: A2.pst(1,2) == Sq(2)*Sq(4) + Sq(4)*Sq(2)
True
sage: A5 = SteenrodAlgebra(5)
sage: A5.pst(2,2)
P(0,25)
```

There are a number of different bases available in which to represent elements of the Steenrod algebra. When $p > 2$, the choices are the Milnor basis ('milnor') or the Serre-Cartan basis ('serre-cartan' or 'adem' or 'admissible'). When $p = 2$, the choices are those, along with Wood's Y basis ('wood_y'), Wood's Z basis ('wood_z'), Wall's basis ('wall' or 'wall_long'), Arnon's A basis ('arnon_a' or 'arnon_a_long'), Arnon's C basis ('arnon_c'), various $P(s,t)$ bases ('pst_ORDER' for various values of ORDER), and various commutator bases ('comm_ORDER' or 'comm_ORDER_long' for various values of ORDER).

See documentation for the function `steenrod_algebra_basis` for full descriptions of these bases.

To access representations of elements with respect to these different bases, you can either use the `basis` method for an element, or define a Steenrod algebra with respect to a particular basis and then use that:

```
sage: c = Sq(2) * Sq(1); c
Sq(0,1) + Sq(3)
sage: c.basis('serre-cartan')
Sq^{2} Sq^{1}
sage: c.basis('milnor')
Sq(0,1) + Sq(3)
sage: adem = SteenrodAlgebra(2, 'serre-cartan')
sage: x = Sq(7,3,1)    # top class in the subalagebra A(2)
sage: adem(x)
Sq^{17} Sq^{5} Sq^{1}
sage: SteenrodAlgebra(2, 'pst')(x)
P^{0}_{1} P^{0}_{2} P^{1}_{1} P^{0}_{3} P^{1}_{2} P^{2}_{1}
```

Multiplication works within bases:

```
sage: adem = SteenrodAlgebra(2, 'adem')
sage: x = adem.Sq(5)
sage: y = adem.Sq(1)
sage: x * y
Sq^{5} Sq^{1}
```

When multiplying elements defined with respect to different bases, the result is printed in the basis of the left-hand factor:

```
sage: milnor = SteenrodAlgebra(2, 'milnor')
sage: xm = milnor.Sq(5)
sage: ym = milnor.Sq(1)
sage: xm * ym
Sq(3,1)
sage: xm * y
Sq(3,1)
sage: x * ym
Sq^{5} Sq^{1}
```

Several of these bases ('arnon_a', 'wall', 'comm') have alternate, longer, representations. These provide ways of expressing elements of the Steenrod algebra in terms of the Sq^{2^n}.

```
sage: Sq(6).basis('arnon_a_long')
Sq^{1} Sq^{2} Sq^{1} Sq^{2} + Sq^{2} Sq^{4}
sage: Sq(6).basis('wall_long')
Sq^{2} Sq^{1} Sq^{2} Sq^{1} + Sq^{2} Sq^{4}
sage: SteenrodAlgebra(2,'comm_deg_long')(Sq(6))
s_{1} s_{2} s_{12} + s_{2} s_{4}
```

INTERNAL DOCUMENTATION:

Here are details on the class `SteenrodAlgebraElement` (for people who want to delve into or extend the code):

Attributes for a `SteenrodAlgebraElement` self:

- `self._base_field`: $GF(p)$, where p is the associated prime
- `self._prime`: p
- `self._basis`: basis in which to print this element
- `self._raw`: dictionary. keys are basis names, taken from `_steenrod_basis_unique_names`, and the associated values are dictionaries themselves; if the dictionary is nonempty, it gives the representation for that element in the given basis. If it is empty, that means that the representation in that basis hasn't been computed yet. The representation of an element with respect to a basis (other than the Milnor basis, which is how elements are stored internally) isn't computed until requested, either by calling the method `_basis_dictionary('basis_name')`, or more typically, by calling the method `basis('basis_name')` or by defining a Steenrod algebra at that basis and applying its call method to the element.

The dictionaries are defined as follows. In the Milnor basis at the prime 2, for example, since monomials are of the form $\mathrm{Sq}(a, b, c, ...)$, then monomials are stored as tuples of integers `(a,b,c,...)`. Thus if

$$y = \mathrm{Sq}(5, 3) + \mathrm{Sq}(0, 0, 2),$$

then `y._raw['milnor']` is `{(0, 0, 2): 1, (5, 3): 1}`. (The 1's following the colons are the coefficients of the monomials associated to the tuples.) Each basis has its own representation as a dictionary; Arnon's C

basis represents basis elements as tuples of integers, just like the Milnor basis and the Serre-Cartan basis, while the other bases represent basis elements as tuples of pairs of integers. From the descriptions of the bases given in the file 'steenrod_algebra_bases.py', it should be clear how to associate a tuple of pairs of integers to a basis element. See also the function `string_rep`.

When the element is initially defined by calling `Sq` or `SteenrodAlgebraElement`, typically only the 'milnor' dictionary is non-empty, while if the element is defined by the function `steenrod_algebra_basis`, its dictionary for the given basis is also initialized correctly. For example:

```
sage: B = steenrod_algebra_basis(6,'adem'); B
(Sq^{6}, Sq^{5} Sq^{1}, Sq^{4} Sq^{2})
sage: x = B[1]; x
Sq^{5} Sq^{1}
sage: x._raw
{'milnor': {(3, 1): 1}, 'serre-cartan': {(5, 1): 1}}
```

Note that the keys 'milnor' and 'serre-cartan' (a synonym for 'adem') have nonempty associated values.

When any element is converted to another basis (by changing the basis and then printing the element), its dictionary for that basis gets stored, as well:

```
sage: x.basis('arnona')
X^{0}_{0} X^{1}_{0} X^{1}_{1}
sage: x._raw
{'arnona': {((0, 0), (1, 0), (1, 1)): 1},
'milnor': {(3, 1): 1},
'serre-cartan': {(5, 1): 1}}
```

Methods for a `SteenrodAlgebraElement` self:

Most of these are self-explanatory.

- `_mul_`: multiply two elements. This is done using Milnor multiplication, the code for which is in a separate file, 'steenrod_milnor_multiplication'. In a long computation, it seems that a lot of time is spent here, so one way to speed things up would be to optimize the Milnor multiplication routine.
- `_basis_dictionary`: compute the dictionary of the element with respect to the given basis. This is basically done by doing a basis conversion from the Milnor basis to the given basis. There are two parts to this function; first, some elements (e.g., $\mathrm{Sq}(2^n)$) may be easy to convert directly. This is done one basis at a time, and so takes up most of the lines of code. If the element is not recognizable as being easy to convert, then the function `milnor_convert` from the file 'steenrod_algebra_bases.py' is called. This does linear algebra: it computes the Milnor basis and the new basis in the appropriate dimension, computes the change-of-basis matrix, etc.
- `basis`: display the element in the given basis.
- `milnor`: display the element in the Milnor basis.
- `serre_cartan`: display the element in the Serre-Cartan basis.
- `adem`: display the element in the Serre-Cartan basis.
- `_repr_` and `_latex_` call the function `string_rep`, which has cases depending on the basis.

Sq(**nums*)

Milnor element Sq(a,b,c,...).

INPUT:

- `a, b, c, ...` - non-negative integers

OUTPUT: element of the Steenrod algebra

This returns the Milnor basis element ' ext{Sq}(a, b, c, ...)'.

EXAMPLES:

```
sage: Sq(5)
Sq(5)
sage: Sq(5) + Sq(2,1) + Sq(5)  # addition is mod 2:
Sq(2,1)
sage: (Sq(4,3) + Sq(7,2)).degree()
13
```

Entries must be non-negative integers; otherwise, an error results.

This function is a good way to define elements of the Steenrod algebra.

class SteenrodAlgebraElement(*poly, p=2, basis='milnor'*)

Element of the mod p Steenrod algebra.

At the prime 2, use the function 'Sq' to define these, as in 'w=Sq(4,3,3)' or 'z=Sq(1,2)+Sq(4,1)' or 'q=Sq(8)*Sq(4) + Sq(12)'.

At odd primes, use the methods 'P' and 'Q' to define these, as in 'w=SteenrodAlgebra(3).Q(1,5) * SteenrodAlgebra(3).P(4,3)'.

EXAMPLES:

```
sage: w = Sq(4,3,3)
sage: w
Sq(4,3,3)
```

The function 'Sq', together with addition, provides an easy way to define elements when $p = 2$:

```
sage: b = Sq(3) + Sq(0,1)
sage: b
Sq(0,1) + Sq(3)
```

When p is odd, first define a Steenrod algebra to specify the prime, and then use the methods 'P' and 'Q', together with multiplication and addition:

```
sage: A7 = SteenrodAlgebra(7)
sage: u = A7.Q(0,4); u
Q_0 Q_4
sage: v = A7.P(1,2,3); v
P(1,2,3)
sage: u * v
Q_0 Q_4 P(1,2,3)
sage: 10 * u * v
3 Q_0 Q_4 P(1,2,3)
sage: u + v
P(1,2,3) + Q_0 Q_4
```

additive_order()

The additive order of any nonzero element of the mod p Steenrod algebra is p.

OUTPUT:

- `order` - positive prime number

EXAMPLES:

```
sage: z = Sq(4) + Sq(6) + Sq(0)
sage: z.additive_order()
2
sage: (Sq(3) + Sq(3)).additive_order()
1
```

adem()

Serre-Cartan representation of self.

OUTPUT: Serre-Cartan representation of self.

EXAMPLES:

```
sage: x = Sq(0,1); x
Sq(0,1)
sage: x.serre_cartan()
Sq^{2} Sq^{1} + Sq^{3}
sage: x.adem()  # 'adem' is a synonym for 'serre_cartan'
Sq^{2} Sq^{1} + Sq^{3}
```

antipode()

Antipode of element.

OUTPUT:

- `antipode` - element of the Steenrod algebra

Algorithm: according to a result of Milnor's, the antipode of $\mathrm{Sq}(n)$ is the sum of all of the Milnor basis elements in dimension n. So: convert the element to the Serre-Cartan basis and use this formula for the antipode of $\mathrm{Sq}(n)$, together with the fact that the antipode is an antihomomorphism: if we call the antipode c, then $c(ab) = c(b)c(a)$.

At odd primes, a similar method is used: the antipode of $P(n)$ is the sum of the Milnor P basis elements in dimension $n * 2(p-1)$, and the antipode of $\beta = Q_0$ is $-Q_0$. So convert to the Serre-Cartan basis, as in the $p = 2$ case.

EXAMPLES:

```
sage: d = Sq(0,0,1); d
Sq(0,0,1)
sage: d.antipode()
Sq(0,0,1)
sage: Sq(4).antipode()
Sq(1,1) + Sq(4)
sage: (Sq(4) * Sq(2)).antipode()
Sq(6)
sage: A3 = SteenrodAlgebra(3)
sage: A3.P(2).antipode()
P(2)
sage: A3.P(2,1).antipode()
2 P(2,1)
```

Applying the antipode twice returns the original element:

```
sage: y = Sq(8)*Sq(4)
sage: y == (y.antipode()).antipode()
True
sage: z = A3.P(1,1)
```

```
sage: z == (z.antipode()).antipode()
True
sage: w = A3.Q(5)
sage: w == (w.antipode()).antipode()
True
sage: a = SteenrodAlgebra(7).P(55)
sage: a == a.antipode().antipode()
True
```

TESTS:

```
sage: all(a.antipode().antipode() == a for a in steenrod_algebra_basis(201, basis='adem', p=
True
sage: all(a.antipode().antipode() == a for a in steenrod_algebra_basis(100, basis='milnor',
True
sage: all(a.antipode().antipode() == a for a in steenrod_algebra_basis(30, basis='milnor', p
True
sage: all(a.antipode().antipode() == a for a in steenrod_algebra_basis(33, basis='adem', p=2
True
```

basis (*basis*)

Representation of element with respect to basis.

INPUT:

- `basis` - string, basis in which to work.

OUTPUT: Representation of self in given basis

The choices for basis are:

- 'milnor' for the Milnor basis.
- 'serre-cartan', 'serre_cartan', 'sc', 'adem', 'admissible' for the Serre-Cartan basis.
- 'wood_y' for Wood's Y basis.
- 'wood_z' for Wood's Z basis.
- 'wall' for Wall's basis.
- 'wall_long' for Wall's basis, alternate representation
- 'arnon_a' for Arnon's A basis.
- 'arnon_a_long' for Arnon's A basis, alternate representation.
- 'arnon_c' for Arnon's C basis.
- 'pst', 'pst_rlex', 'pst_llex', 'pst_deg', 'pst_revz' for various P_t^s-bases.
- 'comm', 'comm_rlex', 'comm_llex', 'comm_deg', 'comm_revz' for various commutator bases.
- 'comm_long', 'comm_rlex_long', etc., for commutator bases, alternate representations.

See documentation for the function 'steenrod_algebra_basis' for descriptions of the different bases.

EXAMPLES:

```
sage: c = Sq(2) * Sq(1)
sage: c.basis('milnor')
Sq(0,1) + Sq(3)
sage: c.basis('serre-cartan')
Sq^{2} Sq^{1}
sage: d = Sq(0,0,1)
sage: d.basis('arnonc')
Sq^{2} Sq^{5} + Sq^{4} Sq^{2} Sq^{1} + Sq^{4} Sq^{3} + Sq^{7}
```

degree ()

Degree of element.

OUTPUT:

- `degree` - None, or non-negative integer

The degree of $\mathrm{Sq}(i_1, i_2, i_3, ...)$ is $i_1 + 3i_2 + 7i_3 + ... + (2^n - 1)i_n + ...$ When p is odd, the degree of $Q_0^{e_0} Q_1^{e_1} ... P(r_1, r_2, ...)$ is $\sum e_i(2p^i - 1) + \sum r_j(2p^j - 2)$.

The degree of a sum is undefined (and this returns 'None'), unless each summand has the same degree: that is, unless the element is homogeneous.

EXAMPLES:

```
sage: a = Sq(1,2,1)
sage: a.degree()
14
sage: for a in Sq(3) + Sq(5,1): a.degree()
3
8
sage: (Sq(3) + Sq(5,1)).degree()
Element is not homogeneous.
sage: B = SteenrodAlgebra(3)
sage: x = B.Q(1,4)
sage: y = B.P(1,2,3)
sage: x.degree()
166
sage: y.degree()
192
```

excess()

Excess of element.

OUTPUT:

- `excess` - non-negative integer

The excess of $\mathrm{Sq}(a, b, c, ...)$ is $a + b + c + ...$ When p is odd, the excess of $Q_0^{e_0} Q_1^{e_1} ... P(r_1, r_2, ...)$ is $\sum e_i + 2\sum r_i$.

The excess of a linear combination of Milnor basis elements is the minimum of the excesses of those basis elements.

See [Kra] for the proofs of these assertions.

EXAMPLES:

```
sage: a = Sq(1,2,3)
sage: a.excess()
6
sage: (Sq(0,0,1) + Sq(4,1) + Sq(7)).excess()
1
sage: [m.excess() for m in (Sq(0,0,1) + Sq(4,1) + Sq(7))]
[1, 5, 7]
sage: [m for m in (Sq(0,0,1) + Sq(4,1) + Sq(7))]
[Sq(0,0,1), Sq(4,1), Sq(7)]
sage: B = SteenrodAlgebra(7)
sage: a = B.Q(1,2,5)
sage: b = B.P(2,2,3)
sage: a.excess()
3
sage: b.excess()
14
sage: (a + b).excess()
3
sage: (a * b).excess()
17
```

REFERENCES:

- [Kra] D. Kraines, "On excess in the Milnor basis," Bull. London Math. Soc. 3 (1971), 363-365.

is_decomposable()

return True if element is decomposable, False otherwise.

OUTPUT:

- `decomposable` - boolean

That is, if element is in the square of the augmentation ideal, return True; otherwise, return False.

EXAMPLES:

```
sage: a = Sq(6)
sage: a.is_decomposable()
True
sage: for i in range(9):
...       if not Sq(i).is_decomposable():
...           print Sq(i)
Sq(0)
Sq(1)
Sq(2)
Sq(4)
Sq(8)
```

is_nilpotent()

True if element is not a unit, False otherwise.

EXAMPLES:

```
sage: z = Sq(4,2) + Sq(7,1) + Sq(3,0,1)
sage: z.is_nilpotent()
True
sage: u = 1 + Sq(3,1)
sage: u == Sq(0) + Sq(3,1)
True
sage: u.is_nilpotent()
False
```

is_unit()

True if element has a nonzero scalar multiple of P(0) as a summand, False otherwise.

EXAMPLES:

```
sage: z = Sq(4,2) + Sq(7,1) + Sq(3,0,1)
sage: z.is_unit()
False
sage: u = 1 + Sq(3,1)
sage: u == Sq(0) + Sq(3,1)
True
sage: u.is_unit()
True
sage: A5 = SteenrodAlgebra(5)
sage: v = A5.P(0)
sage: (v + v + v).is_unit()
True
```

may_weight()

May's 'weight' of element.

OUTPUT:

- `weight` - non-negative integer

If we let $F_*(A)$ be the May filtration of the Steenrod algebra, the weight of an element x is the integer k so that x is in $F_k(A)$ and not in $F_{k+1}(A)$. According to Theorem 2.6 in May's thesis [May], the weight of a Milnor basis element is computed as follows: first, to compute the weight of $P(r_1, r_2, ...)$, write each r_i in base p as $r_i = \sum_j p^j r_{ij}$. Then each nonzero binary digit r_{ij} contributes i to the weight: the weight

is $\sum_{i,j} ir_{ij}$. When p is odd, the weight of Q_i is $i+1$, so the weight of a product $Q_{i_1}Q_{i_2}...$ is equal $(i_1+1)+(i_2+1)+....$ Then the weight of $Q_{i_1}Q_{i_2}...P(r_1,r_2,...)$ is the sum of $(i_1+1)+(i_2+1)+...$ and $\sum_{i,j} ir_{ij}$.

The weight of a sum of basis elements is the minimum of the weights of the summands.

When $p=2$, we compute the weight on Milnor basis elements by adding up the terms in their 'height' - see the method 'wall_height' for documentation. (When p is odd, the height of an element is not defined.)

EXAMPLES:

```
sage: Sq(0).may_weight()
0
sage: a = Sq(4)
sage: a.may_weight()
1
sage: b = Sq(4)*Sq(8) + Sq(8)*Sq(4)
sage: b.may_weight()
2
sage: Sq(2,1,5).wall_height()
[2, 3, 2, 1, 1]
sage: Sq(2,1,5).may_weight()
9
sage: A5 = SteenrodAlgebra(5)
sage: a = A5.Q(1,2,4)
sage: b = A5.P(1,2,1)
sage: a.may_weight()
10
sage: b.may_weight()
8
sage: (a * b).may_weight()
18
sage: A5.P(0,0,1).may_weight()
3
```

REFERENCES:

- [May]: J. P. May, "The cohomology of restricted Lie algebras and of Hopf algebras; application to the Steenrod algebra." Thesis, Princeton Univ., 1964.

milnor()

Milnor representation of self.

OUTPUT: Milnor representation of self.

EXAMPLES:

```
sage: A = SteenrodAlgebra(2, 'adem')
sage: x = A (Sq(5) * Sq(2) * Sq(1)); x
Sq^{5} Sq^{2} Sq^{1}
sage: x.milnor()
Sq(1,0,1) + Sq(5,1)
```

serre_cartan()

Serre-Cartan representation of self.

OUTPUT: Serre-Cartan representation of self.

EXAMPLES:

```
sage: x = Sq(0,1); x
Sq(0,1)
sage: x.serre_cartan()
Sq^{2} Sq^{1} + Sq^{3}
sage: x.adem()  # 'adem' is a synonym for 'serre_cartan'
Sq^{2} Sq^{1} + Sq^{3}
```

wall_height()

Wall's 'height' of element.

OUTPUT:

- height - list of non-negative integers

The height of an element of the mod 2 Steenrod algebra is a list of non-negative integers, defined as follows: if the element is a monomial in the generators $\mathrm{Sq}(2^i)$, then the i^{th} entry in the list is the number of times $\mathrm{Sq}(2^i)$ appears. For an arbitrary element, write it as a sum of such monomials; then its height is the maximum, ordered right-lexicographically, of the heights of those monomials.

When p is odd, the height of an element is not defined.

According to Theorem 3 in [Wall], the height of the Milnor basis element $\mathrm{Sq}(r_1, r_2, ...)$ is obtained as follows: write each r_i in binary as $r_i = \sum_j 2^j r_{ij}$. Then each nonzero binary digit r_{ij} contributes 1 to the k^{th} entry in the height, for $j \leq k \leq i + j - 1$.

EXAMPLES:

```
sage: Sq(0).wall_height()
[]
sage: a = Sq(4)
sage: a.wall_height()
[0, 0, 1]
sage: b = Sq(4)*Sq(8) + Sq(8)*Sq(4)
sage: b.wall_height()
[0, 0, 1, 1]
sage: Sq(0,0,3).wall_height()
[1, 2, 2, 1]
```

REFERENCES:

- [Wall]: C. T. C. Wall, "Generators and relations for the Steenrod algebra," Ann. of Math. (2) **72** (1960), 429-444.

adem(*x*)

Serre-Cartan representation of x.

INPUT:

- x - element of the Steenrod algebra

OUTPUT: Serre-Cartan representation of x

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import serre_cartan
sage: x = Sq(3,2); x
Sq(3,2)
sage: serre_cartan(x)
Sq^{7} Sq^{2}
```

admissible(*x*)

Serre-Cartan representation of x.

INPUT:

- x - element of the Steenrod algebra

OUTPUT: Serre-Cartan representation of x

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import serre_cartan
sage: x = Sq(3,2); x
Sq(3,2)
sage: serre_cartan(x)
Sq^{7} Sq^{2}
```

arnonA_long_mono_to_string(*mono, latex=False, p=2*)

Alternate string representation of element of Arnon's A basis.

This is used by the _repr_ and _latex_ methods.

INPUT:

- `mono` - tuple of pairs of non-negative integers (m,k) with $m >= k$

OUTPUT:

- `string` - concatenation of strings of the form '$Sq(2^m)$'

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import arnonA_long_mono_to_string
sage: arnonA_long_mono_to_string(((1,2),(3,0)))
'Sq^{8} Sq^{4} Sq^{2} Sq^{1}'
sage: arnonA_long_mono_to_string(((1,2),(3,0)),latex=True)
'\text{Sq}^{8} \text{Sq}^{4} \text{Sq}^{2} \text{Sq}^{1}'
```

The empty tuple represents the unit element Sq(0):

```
sage: arnonA_long_mono_to_string(())
'Sq(0)'
```

arnonA_mono_to_string(*mono, latex=False, p=2*)

String representation of element of Arnon's A basis.

This is used by the _repr_ and _latex_ methods.

INPUT:

- `mono` - tuple of pairs of non-negative integers (m,k) with $m >= k$

OUTPUT:

- `string` - concatenation of 'X_k^m' for each pair (m,k)

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import arnonA_mono_to_string
sage: arnonA_mono_to_string(((1,2),(3,0)))
'X^{1}_{2} X^{3}_{0}'
sage: arnonA_mono_to_string(((1,2),(3,0)),latex=True)
'X^{1}_{2} X^{3}_{0}'
```

The empty tuple represents the unit element Sq(0):

```
sage: arnonA_mono_to_string(())
'Sq(0)'
```

base_p_expansion(*n, p*)

Return list of digits in the base p expansion of n.

INPUT:

- n - non-negative integer
- p - positive prime number

OUTPUT: list of digits in the base p expansion of n

EXAMPLES:

```
sage: sage.algebras.steenrod_algebra_element.base_p_expansion(10,2)
[0, 1, 0, 1]
sage: sage.algebras.steenrod_algebra_element.base_p_expansion(10,3)
[1, 0, 1]
sage: sage.algebras.steenrod_algebra_element.base_p_expansion(10,5)
[0, 2]
sage: sage.algebras.steenrod_algebra_element.base_p_expansion(10,7)
[3, 1]
sage: sage.algebras.steenrod_algebra_element.base_p_expansion(0,7)
[]
sage: sage.algebras.steenrod_algebra_element.base_p_expansion(100000,13)
[4, 9, 6, 6, 3]
```

check_and_trim(*nums*)

Check that list or tuple consists of non-negative integers, and strip trailing zeroes.

INPUT:

- nums - a list or tuple

OUTPUT:

- new - a list or tuple

If nums contains anything other than a non-negative integer, raise an exception, identifying the right-most problematic entry. Otherwise, return a new list or tuple, obtained from nums by omitting any zeroes from the end.

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import check_and_trim
sage: check_and_trim([3,4,1])
[3, 4, 1]
sage: a=[3,2,1,0,0]
sage: check_and_trim(a)
[3, 2, 1]
sage: a    # check_and_trim doesn't affect its input
[3, 2, 1, 0, 0]
sage: check_and_trim([0]*127)
[]
sage: check_and_trim((1,2,3,4,0,0,0))  # works on tuples, too
(1, 2, 3, 4)
```

comm_long_mono_to_string(*mono, latex=False, p=2*)

Alternate string representation of element of a commutator basis.

Okay in low dimensions, but gets unwieldy as the dimension increases.

INPUT:

- mono - tuple of pairs of integers (s,t) with $s >= 0$, $t > 0$

OUTPUT:

- string - concatenation of $s_{2^s \ldots 2^{(s+t-1)}}$ for each pair (s,t)

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import comm_long_mono_to_string
sage: comm_long_mono_to_string(((1,2),(0,3)))
's_{24} s_{124}'
sage: comm_long_mono_to_string(((1,2),(0,3)),latex=True)
's_{24} s_{124}'
```

The empty tuple represents the unit element Sq(0):

```
sage: comm_long_mono_to_string(())
'Sq(0)'
```

comm_mono_to_string(*mono, latex=False, p=2*)

String representation of element of a commutator basis.

This is used by the _repr_ and _latex_ methods.

INPUT:

- mono - tuple of pairs of integers (s,t) with $s >= 0$, $t > 0$

OUTPUT:

- string - concatenation of '$c_{s,t}$' for each pair (s,t)

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import comm_mono_to_string
sage: comm_mono_to_string(((1,2),(0,3)))
'c_{1,2} c_{0,3}'
sage: comm_mono_to_string(((1,2),(0,3)),latex=True)
'c_{1,2} c_{0,3}'
```

The empty tuple represents the unit element Sq(0):

```
sage: comm_mono_to_string(())
'Sq(0)'
```

convert_perm(*m*)

Convert tuple m of non-negative integers to a permutation in one-line form.

INPUT:

- m - tuple of non-negative integers with no repetitions

OUTPUT:

- list - conversion of m to a permutation of the set 1,2,...,len(m)

If m=(3,7,4), then one can view m as representing the permutation of the set 3,4,7 sending 3 to 3, 4 to 7, and 7 to 4. This function converts m to the list [1,3,2], which represents essentially the same permutation, but of the set 1,2,3. This list can then be passed to Permutation, and its signature can be computed.

EXAMPLES:

```
sage: sage.algebras.steenrod_algebra_element.convert_perm((3,7,4))
[1, 3, 2]
sage: sage.algebras.steenrod_algebra_element.convert_perm((5,0,6,3))
[2, 4, 1, 3]
```

degree(x)

Degree of x.

INPUT:

- x - element of the Steenrod algebra

OUTPUT:

- degree - non-negative integer or None

The degree of $\mathrm{Sq}(i_1, i_2, i_3, ...)$ is $i_1 + 3i_2 + 7i_3 + ... + (2^n - 1)i_n + ...$ When p is odd, the degree of $Q_0^{e_0} Q_1^{e_1} ... P(r_1, r_2, ...)$ is $\sum e_i(2p^i - 1) + \sum r_j(2p^j - 2)$.

The degree of a sum is undefined (and this function returns None), unless each summand has the same degree: that is, unless the element is homogeneous.

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import degree
sage: a = Sq(1,2,1)
sage: degree(a)
14
sage: degree(Sq(3) + Sq(5,1))
Element is not homogeneous.
sage: B = SteenrodAlgebra(3)
sage: x = B.Q(1,4)
sage: y = B.P(1,2,3)
sage: degree(x)
166
sage: degree(y)
192
```

excess(x)

Excess of x.

INPUT:

- x - element of the Steenrod algebra

OUTPUT:

- excess - non-negative integer

The excess of $\mathrm{Sq}(a, b, c, ...)$ is $a + b + c + ...$. When p is odd, the excess of $Q_0^{e_0} Q_1^{e_1} \dots P(r_1, r_2, \dots)$ is $\sum e_i + 2\sum r_i$.

The excess of a linear combination of Milnor basis elements is the minimum of the excesses of those basis elements.

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import excess
sage: a = Sq(1,2,3)
sage: excess(a)
6
sage: excess(Sq(0,0,1) + Sq(4,1) + Sq(7))
1
sage: [excess(m) for m in (Sq(0,0,1) + Sq(4,1) + Sq(7))]
[1, 5, 7]
sage: B = SteenrodAlgebra(7)
sage: a = B.Q(1,2,5)
sage: b = B.P(2,2,3)
```

```
sage: excess(a)
3
sage: excess(b)
14
sage: excess(a + b)
3
sage: excess(a * b)
17
```

integer_base_2_log(*n*)

Largest integer k so that $2^k <= n$

INPUT:

- n - positive integer

OUTPUT:

- k - integer

This returns the integer k so that $2^k <= n$ and $2^{k+1} > n$.

EXAMPLES:

```
sage: sage.algebras.steenrod_algebra_element.integer_base_2_log(7)
2
sage: sage.algebras.steenrod_algebra_element.integer_base_2_log(8)
3
sage: sage.algebras.steenrod_algebra_element.integer_base_2_log(9)
3
```

milnor(*x*)

Milnor representation of x.

INPUT:

- x - element of the Steenrod algebra

OUTPUT: Milnor representation of x

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import milnor
sage: x = Sq(5) * Sq(2) * Sq(1); x.adem()
Sq^{5} Sq^{2} Sq^{1}
sage: milnor(x)
Sq(1,0,1) + Sq(5,1)
```

milnor_mono_to_string(*mono, latex=False, p=2*)

String representation of element of the Milnor basis.

This is used by the _repr_ and _latex_ methods.

INPUT:

- mono - if $p = 2$, tuple of non-negative integers (a,b,c,...); if $p > 2$, pair of tuples of non-negative integers ((e0, e1, e2, ...), (r1, r2, ...))
- latex - boolean (optional, default False), if true, output LaTeX string
- p - positive prime number (optional, default 2)

OUTPUT:

- rep - string

This returns a string like 'Sq(a,b,c,...)' when p=2, or a string like 'Q_e0 Q_e1 Q_e2 ... P(r1, r2, ...)' when p is odd.

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import milnor_mono_to_string
sage: milnor_mono_to_string((1,2,3,4))
'Sq(1,2,3,4)'
sage: milnor_mono_to_string((1,2,3,4),latex=True)
'\text{Sq}(1,2,3,4)'
sage: milnor_mono_to_string(((1,0), (2,3,1)), p=3)
'Q_1 Q_0 P(2,3,1)'
sage: milnor_mono_to_string(((1,0), (2,3,1)), latex=True, p=3)
'Q_{1} Q_{0} \mathcal{P}(2,3,1)'
```

The empty tuple represents the unit element Sq(0) (or P(0) at an odd prime):

```
sage: milnor_mono_to_string(())
'Sq(0)'
sage: milnor_mono_to_string((), p=5)
'P(0)'
```

pst (*s, t, p=2*)

The Margolis element P_t^s.

INPUT:

- s - non-negative integer
- t - positive integer
- p - positive prime number (optional, default 2)

OUTPUT: element of the Steenrod algebra

This returns the Margolis element P_t^s of the mod p Steenrod algebra: the element equal to $P(0, 0, ..., 0, p^s)$, where the p^s is in position t.

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import pst
sage: pst(3,5)
Sq(0,0,0,0,8)
sage: pst(1,2) + Sq(4)*Sq(2) + Sq(2)*Sq(4)
0
sage: pst(3,5,5)
P(0,0,0,0,125)
sage: pst(3,5,p=5)
P(0,0,0,0,125)
```

pst_mono_to_string (*mono, latex=False, p=2*)

String representation of element of a P_t^s-basis.

This is used by the _repr_ and _latex_ methods.

INPUT:

- mono - tuple of pairs of integers (s,t) with $s >= 0$, $t > 0$

OUTPUT:

- string - concatenation of 'P_t^s' for each pair (s,t)

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import pst_mono_to_string
sage: pst_mono_to_string(((1,2),(0,3)))
'P^{1}_{2} P^{0}_{3}'
sage: pst_mono_to_string(((1,2),(0,3)),latex=True)
'P^{1}_{2} P^{0}_{3}'
```

The empty tuple represents the unit element Sq(0):

```
sage: pst_mono_to_string(())
'Sq(0)'
```

serre_cartan(*x*)

Serre-Cartan representation of x.

INPUT:

- x - element of the Steenrod algebra

OUTPUT: Serre-Cartan representation of x

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import serre_cartan
sage: x = Sq(3,2); x
Sq(3,2)
sage: serre_cartan(x)
Sq^{7} Sq^{2}
```

serre_cartan_mono_to_string(*mono, latex=False, p=2*)

String representation of element of the Serre-Cartan basis.

This is used by the _repr_ and _latex_ methods.

INPUT:

- mono - tuple of positive integers (a,b,c,...) when $p = 2$, or tuple (e0, n1, e1, n2, ...) when $p > 2$, where each ei is 0 or 1, and each ni is positive
- latex - boolean (optional, default False), if true, output LaTeX string
- p - positive prime number (optional, default 2)

OUTPUT:

- rep - string

This returns a string like '$Sq^a Sq^b Sq^c$... when $p = 2$, or a string like $\beta^{e0} P^{n1} \beta^{e1} P^{n2}$... when p is odd.

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import serre_cartan_mono_to_string
sage: serre_cartan_mono_to_string((1,2,3,4))
'Sq^{1} Sq^{2} Sq^{3} Sq^{4}'
sage: serre_cartan_mono_to_string((1,2,3,4),latex=True)
'\\text{Sq}^{1} \\text{Sq}^{2} \\text{Sq}^{3} \\text{Sq}^{4}'
sage: serre_cartan_mono_to_string((0,5,1,1,0), p=3)
'P^{5} beta P^{1}'
sage: serre_cartan_mono_to_string((0,5,1,1,0), p=3, latex=True)
'\\mathcal{P}^{5} \\beta \\mathcal{P}^{1}'
```

The empty tuple represents the unit element Sq^0 (or P^0 at an odd prime):

```
sage: serre_cartan_mono_to_string(())
'Sq^{0}'
sage: serre_cartan_mono_to_string((), p=7)
'P^{0}'
```

string_rep(*element, latex=False, sort=True*)

String representation of element.

INPUT:

- `element` - element of the Steenrod algebra
- `latex` - boolean (optional, default False), if True, output LaTeX string
- `sort` - boolean (optional, default True), if True, sort output

OUTPUT:

- `string` - string representation of element in current basis

If latex is True, output a string suitable for LaTeX; otherwise, output a plain string. If sort is True, sort element left lexicographically; otherwise, no sorting is done, and so the order in which the summands are printed may be unpredictable.

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import string_rep
sage: a = Sq(0,0,2)
sage: A = SteenrodAlgebra(2, 'admissible')
sage: string_rep(A(a))
'Sq^{8} Sq^{4} Sq^{2} + Sq^{9} Sq^{4} Sq^{1} + Sq^{10} Sq^{3} Sq^{1} +
Sq^{10} Sq^{4} + Sq^{11} Sq^{2} Sq^{1} + Sq^{12} Sq^{2} + Sq^{13} Sq^{1}
+ Sq^{14}'
sage: b = Sq(0,2)
sage: string_rep(A(b),latex=True)
'\text{Sq}^{4} \text{Sq}^{2} + \text{Sq}^{5} \text{Sq}^{1} +
\text{Sq}^{6}'
sage: A_wood_z = SteenrodAlgebra(2, 'woodz')
sage: string_rep(A_wood_z(a))
'Sq^{6} Sq^{7} Sq^{1} + Sq^{14} + Sq^{4} Sq^{7} Sq^{3} + Sq^{4} Sq^{7}
Sq^{2} Sq^{1} + Sq^{12} Sq^{2} + Sq^{8} Sq^{6} + Sq^{8} Sq^{4} Sq^{2}'
sage: string_rep(SteenrodAlgebra(2, 'arnonc')(a), sort=False)
'Sq^{4} Sq^{4} Sq^{6} + Sq^{6} Sq^{8} + Sq^{4} Sq^{2} Sq^{8} + Sq^{4}
Sq^{6} Sq^{4} + Sq^{8} Sq^{4} Sq^{2} + Sq^{8} Sq^{6}'
sage: string_rep(SteenrodAlgebra(2, 'arnonc')(a))
'Sq^{4} Sq^{2} Sq^{8} + Sq^{4} Sq^{4} Sq^{6} + Sq^{4} Sq^{6} Sq^{4} +
Sq^{6} Sq^{8} + Sq^{8} Sq^{4} Sq^{2} + Sq^{8} Sq^{6}'
sage: string_rep(SteenrodAlgebra(2, 'pst_llex')(a))
'P^{1}_{3}'
sage: Ac = SteenrodAlgebra(2, 'comm_revz')
sage: string_rep(Ac(a),latex=True,sort=False)
'c_{0,2} c_{0,3} c_{2,1} + c_{1,3} + c_{0,1} c_{1,1} c_{0,3} c_{2,1}'
sage: string_rep(Ac(a),latex=True)
'c_{0,1} c_{1,1} c_{0,3} c_{2,1} + c_{0,2} c_{0,3} c_{2,1} + c_{1,3}'
sage: string_rep(a)
'Sq(0,0,2)'
sage: string_rep(a,latex=True)
'\text{Sq}(0,0,2)'
```

Some odd primary examples:

```
sage: A5 = SteenrodAlgebra(5)
sage: a = A5.P(5,1); b = A5.Q(0,1,3)
sage: string_rep(b)
'Q_0 Q_1 Q_3'
sage: string_rep(a, latex=True)
'\mathcal{P}(5,1)'
sage: A5sc = SteenrodAlgebra(5, 'serre-cartan')
sage: string_rep(A5sc(a))
'P^{10} P^{1} + 4 P^{11}'
```

wall_long_mono_to_string(*mono, latex=False, p=2*)

Alternate string representation of element of Wall's basis.

This is used by the _repr_ and _latex_ methods.

INPUT:

- mono - tuple of pairs of non-negative integers (m,k) with $m >= k$

OUTPUT:

- string - concatenation of terms of the form '$Sq(2^m)$'

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import wall_long_mono_to_string
sage: wall_long_mono_to_string(((1,2),(3,0)))
'Sq^{1} Sq^{2} Sq^{4} Sq^{8}'
sage: wall_long_mono_to_string(((1,2),(3,0)),latex=True)
'\text{Sq}^{1} \text{Sq}^{2} \text{Sq}^{4} \text{Sq}^{8}'
```

The empty tuple represents the unit element Sq(0):

```
sage: wall_long_mono_to_string(())
'Sq(0)'
```

wall_mono_to_string(*mono, latex=False, p=2*)

String representation of element of Wall's basis.

This is used by the _repr_ and _latex_ methods.

INPUT:

- mono - tuple of pairs of non-negative integers (m,k) with $m >= k$

OUTPUT:

- string - concatenation of 'Q^m_k' for each pair (m,k)

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import wall_mono_to_string
sage: wall_mono_to_string(((1,2),(3,0)))
'Q^{1}_{2} Q^{3}_{0}'
sage: wall_mono_to_string(((1,2),(3,0)),latex=True)
'Q^{1}_{2} Q^{3}_{0}'
```

The empty tuple represents the unit element Sq(0):

```
sage: wall_mono_to_string(())
'Sq(0)'
```

wood_mono_to_string(*mono, latex=False, p=2*)

String representation of element of Wood's Y and Z bases.

This is used by the _repr_ and _latex_ methods.

INPUT:

- `mono` - tuple of pairs of non-negative integers (s,t)

OUTPUT:

- `string` - concatenation of '$Sq^{2^s(2^{t+1}-1)}$' for each pair (s,t)

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_element import wood_mono_to_string
sage: wood_mono_to_string(((1,2),(3,0)))
'Sq^{14} Sq^{8}'
sage: wood_mono_to_string(((1,2),(3,0)),latex=True)
'\text{Sq}^{14} \text{Sq}^{8}'
```

The empty tuple represents the unit element Sq(0):

```
sage: wood_mono_to_string(())
'Sq(0)'
```

30.7 Steenrod algebra bases

AUTHORS:

- John H. Palmieri (2008-07-30): version 0.9

This package defines functions for computing various bases of the Steenrod algebra, and for converting between the Milnor basis and any other basis.

This packages implements a number of different bases, at least at the prime 2. The Milnor and Serre-Cartan bases are the most familiar and most standard ones, and all of the others are defined in terms of one of these. The bases are described in the documentation for the function `steenrod_algebra_basis`; also see the papers by Monks [M] and Wood [W] for more information about them. For commutator bases, see the preprint by Palmieri and Zhang [PZ].

- 'milnor': Milnor basis.
- 'serre-cartan' or 'adem' or 'admissible': Serre-Cartan basis.

The other bases are as follows; these are only defined when $p = 2$:

- 'wood_y': Wood's Y basis.
- 'wood_z': Wood's Z basis.
- 'wall', 'wall_long': Wall's basis.
- 'arnon_a', 'arnon_a_long': Arnon's A basis.
- 'arnon_c': Arnon's C basis.
- 'pst', 'pst_rlex', 'pst_llex', 'pst_deg', 'pst_revz': various P_t^s-bases.

- 'comm', 'comm_rlex', 'comm_llex', 'comm_deg', 'comm_revz', or these with '_long' appended: various commutator bases.

EXAMPLES:

```
sage: steenrod_algebra_basis(7,'milnor')
(Sq(0,0,1), Sq(1,2), Sq(4,1), Sq(7))
sage: steenrod_algebra_basis(5)   # milnor basis is the default
(Sq(2,1), Sq(5))
```

The third (optional) argument to `steenrod_algebra_basis` is the prime p:

```
sage: steenrod_algebra_basis(9, 'milnor', p=3)
(Q_1 P(1), Q_0 P(2))
sage: steenrod_algebra_basis(9, 'milnor', 3)
(Q_1 P(1), Q_0 P(2))
sage: steenrod_algebra_basis(17, 'milnor', 3)
(Q_2, Q_1 P(3), Q_0 P(0,1), Q_0 P(4))
```

Other bases:

```
sage: steenrod_algebra_basis(7,'admissible')
(Sq^{7}, Sq^{6} Sq^{1}, Sq^{4} Sq^{2} Sq^{1}, Sq^{5} Sq^{2})
sage: [x.basis('milnor') for x in steenrod_algebra_basis(7,'admissible')]
[Sq(7),
Sq(4,1) + Sq(7),
Sq(0,0,1) + Sq(1,2) + Sq(4,1) + Sq(7),
Sq(1,2) + Sq(7)]
sage: Aw = SteenrodAlgebra(2, basis = 'wall_long')
sage: [Aw(x) for x in steenrod_algebra_basis(7,'admissible')]
[Sq^{1} Sq^{2} Sq^{4},
Sq^{2} Sq^{4} Sq^{1},
Sq^{4} Sq^{2} Sq^{1},
Sq^{4} Sq^{1} Sq^{2}]
sage: steenrod_algebra_basis(13,'admissible',p=3)
(beta P^{3}, P^{3} beta)
sage: steenrod_algebra_basis(5,'wall')
(Q^{2}_{2} Q^{0}_{0}, Q^{1}_{1} Q^{1}_{0})
sage: steenrod_algebra_basis(5,'wall_long')
(Sq^{4} Sq^{1}, Sq^{2} Sq^{1} Sq^{2})
sage: steenrod_algebra_basis(5,'pst-rlex')
(P^{0}_{1} P^{2}_{1}, P^{1}_{1} P^{0}_{2})
```

This file also contains a function `milnor_convert` which converts elements from the (default) Milnor basis representation to a representation in another basis. The output is a dictionary which gives the new representation; its form depends on the chosen basis. For example, in the basis of admissible sequences (a.k.a. the Serre-Cartan basis), each basis element is of the form $\mathrm{Sq}^a\mathrm{Sq}^b...$, and so is represented by a tuple $(a, b, ...)$ of integers. Thus the dictionary has such tuples as keys, with the coefficient of the basis element as the associated value:

```
sage: from sage.algebras.steenrod_algebra_bases import milnor_convert
sage: milnor_convert(Sq(2)*Sq(4) + Sq(2)*Sq(5), 'admissible')
{(5, 1): 1, (6, 1): 1, (6,): 1}
sage: milnor_convert(Sq(2)*Sq(4) + Sq(2)*Sq(5), 'pst')
{((1, 1), (2, 1)): 1, ((0, 1), (1, 1), (2, 1)): 1, ((0, 2), (2, 1)): 1}
```

Users shouldn't need to call `milnor_convert`; they should use the `basis` method to view a single element in another basis, or define a Steenrod algebra with a different default basis and work in that algebra:

```
sage: x = Sq(2)*Sq(4) + Sq(2)*Sq(5)
sage: x
Sq(3,1) + Sq(4,1) + Sq(6) + Sq(7)
sage: x.basis('milnor')  # 'milnor' is the default basis
Sq(3,1) + Sq(4,1) + Sq(6) + Sq(7)
sage: x.basis('adem')
Sq^{5} Sq^{1} + Sq^{6} + Sq^{6} Sq^{1}
sage: x.basis('pst')
P^{0}_{1} P^{1}_{1} P^{2}_{1} + P^{0}_{2} P^{2}_{1} + P^{1}_{1} P^{2}_{1}
sage: A = SteenrodAlgebra(2, basis='pst')
sage: A(Sq(2) * Sq(4) + Sq(2) * Sq(5))
P^{0}_{1} P^{1}_{1} P^{2}_{1} + P^{0}_{2} P^{2}_{1} + P^{1}_{1} P^{2}_{1}
```

INTERNAL DOCUMENTATION:

If you want to implement a new basis for the Steenrod algebra:

In the file 'steenrod_algebra.py':

- add functionality to `get_basis_name`: this should accept as input various synonyms for the basis, and its output should be an element of `_steenrod_basis_unique_names` (see the next file).

In the file 'steenrod_algebra_element.py':

- add name of basis to `_steenrod_basis_unique_names`
- add functionality to `string_rep`, which probably involves adding a `BASIS_mono_to_string` function
- add functionality to the `_basis_dictionary` method

In this file 'steenrod_algebra_bases.py':

- add appropriate lines to `steenrod_algebra_basis`
- add a function to compute the basis in a given dimension (to be called by `steenrod_algebra_basis`)

REFERENCES:

- [M] K. G. Monks, "Change of basis, monomial relations, and P_t^s bases for the Steenrod algebra," J. Pure Appl. Algebra 125 (1998), no. 1-3, 235-260.
- [PZ] J. H. Palmieri and J. J. Zhang, "Commutators in the Steenrod algebra," preprint (2008)
- [W] R. M. W. Wood, "Problems in the Steenrod algebra," Bull. London Math. Soc. 30 (1998), no. 5, 449-517.

Q(*m, k, basis*)

Compute Q_k^m (Wall basis) and X_k^m (Arnon's A basis).

INPUT:

- `m, k` - non-negative integers with $m >= k$
- `basis` - 'wall' or 'arnona'

OUTPUT: element of Steenrod algebra

If basis is 'wall', this returns $Q_k^m = Sq(2^k)Sq(2^{k+1})...Sq(2^m)$. If basis is 'arnona', it returns the reverse of this: $X_k^m = Sq(2^m)...Sq(2^{k+1})Sq(2^k)$

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_bases import Q
sage: Q(2,2,'wall')
Sq(4)
sage: Q(2,2,'arnona')
Sq(4)
sage: Q(3,2,'wall')
Sq(6,2) + Sq(12)
sage: Q(3,2,'arnona')
Sq(0,4) + Sq(3,3) + Sq(6,2) + Sq(12)
```

arnonC_basis(*n, bound=1*)

Arnon's C basis in dimension n.

INPUT:

- n - non-negative integer
- bound - positive integer (optional)

OUTPUT: tuple of basis elements in dimension n

The elements of Arnon's C basis are monomials of the form $\mathrm{Sq}^{t_1}...\mathrm{Sq}^{t_m}$ where for each i, we have $t_i \leq 2t_{i+1}$ and $2^i | t_{m-i}$.

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_bases import arnonC_basis
sage: arnonC_basis(7)
(Sq^{7}, Sq^{2} Sq^{5}, Sq^{4} Sq^{3}, Sq^{4} Sq^{2} Sq^{1})
```

If optional argument bound is present, include only those monomials whose first term is at least as large as bound:

```
sage: arnonC_basis(7,3)
(Sq^{7}, Sq^{4} Sq^{3}, Sq^{4} Sq^{2} Sq^{1})
```

atomic_basis(*n, basis, long=False*)

Basis for dimension n made of elements in 'atomic' degrees: degrees of the form $2^i(2^j - 1)$.

INPUT:

- n - non-negative integer
- basis - string, the name of the basis

OUTPUT: tuple of basis elements in dimension n

The atomic bases include Wood's Y and Z bases, Wall's basis, Arnon's A basis, the P_t^s-bases, and the commutator bases. (All of these bases are constructed similarly, hence their constructions have been consolidated into a single function. Also, see the documentation for 'steenrod_algebra_basis' for descriptions of them.)

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_bases import atomic_basis
sage: atomic_basis(6,'woody')
(Sq^{2} Sq^{3} Sq^{1}, Sq^{4} Sq^{2}, Sq^{6})
sage: atomic_basis(8,'woodz')
(Sq^{4} Sq^{3} Sq^{1}, Sq^{7} Sq^{1}, Sq^{6} Sq^{2}, Sq^{8})
sage: atomic_basis(6,'woodz') == atomic_basis(6, 'woody')
True
sage: atomic_basis(9,'woodz') == atomic_basis(9, 'woody')
False
```

Wall's basis:

```
sage: atomic_basis(6,'wall')
(Q^{1}_{1} Q^{1}_{0} Q^{0}_{0}, Q^{2}_{2} Q^{1}_{1}, Q^{2}_{1})
```

Elements of the Wall basis have an alternate, 'long' representation as monomials in the Sq^{2^n} s:

```
sage: atomic_basis(6, 'wall', long=True)
(Sq^{2} Sq^{1} Sq^{2} Sq^{1}, Sq^{4} Sq^{2}, Sq^{2} Sq^{4})
```

Arnon's A basis:

```
sage: atomic_basis(7,'arnona')
(X^{0}_{0} X^{1}_{1} X^{2}_{2},
X^{0}_{0} X^{2}_{1},
X^{1}_{0} X^{2}_{2},
X^{2}_{0})
```

These also have a 'long' representation:

```
sage: atomic_basis(7,'arnona',long=True)
(Sq^{1} Sq^{2} Sq^{4},
Sq^{1} Sq^{4} Sq^{2},
Sq^{2} Sq^{1} Sq^{4},
Sq^{4} Sq^{2} Sq^{1})
```

P_t^s-bases:

```
sage: atomic_basis(7,'pst_rlex')
(P^{0}_{1} P^{1}_{1} P^{2}_{1},
P^{0}_{1} P^{1}_{2},
P^{2}_{1} P^{0}_{2},
P^{0}_{3})
sage: atomic_basis(7,'pst_llex')
(P^{0}_{1} P^{1}_{1} P^{2}_{1},
P^{0}_{1} P^{1}_{2},
P^{0}_{2} P^{2}_{1},
P^{0}_{3})
sage: atomic_basis(7,'pst_deg')
(P^{0}_{1} P^{1}_{1} P^{2}_{1},
P^{0}_{1} P^{1}_{2},
P^{0}_{2} P^{2}_{1},
P^{0}_{3})
sage: atomic_basis(7,'pst_revz')
(P^{0}_{1} P^{1}_{1} P^{2}_{1},
P^{0}_{1} P^{1}_{2},
P^{0}_{2} P^{2}_{1},
P^{0}_{3})
```

Commutator bases:

```
sage: atomic_basis(7,'comm_rlex')
(c_{0,1} c_{1,1} c_{2,1}, c_{0,1} c_{1,2}, c_{2,1} c_{0,2}, c_{0,3})
sage: atomic_basis(7,'comm_llex')
(c_{0,1} c_{1,1} c_{2,1}, c_{0,1} c_{1,2}, c_{0,2} c_{2,1}, c_{0,3})
sage: atomic_basis(7,'comm_deg')
(c_{0,1} c_{1,1} c_{2,1}, c_{0,1} c_{1,2}, c_{0,2} c_{2,1}, c_{0,3})
sage: atomic_basis(7,'comm_revz')
(c_{0,1} c_{1,1} c_{2,1}, c_{0,1} c_{1,2}, c_{0,2} c_{2,1}, c_{0,3})
```

Long representations of commutator bases:

```
sage: atomic_basis(7,'comm_revz', long=True)
(s_{1} s_{2} s_{4}, s_{1} s_{24}, s_{12} s_{4}, s_{124})
```

commutator(*s, t*)

Returns the t^{th} iterated commutator of consecutive Sq^{2^i} 's.

INPUT: s, t: integers

OUTPUT: element of the Steenrod algebra

If t=1, return $Sq(2^s)$. Otherwise, return the commutator $[commutator(s, t-1), \mathrm{Sq}(2^{s+t-1})]$.

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_bases import commutator
sage: commutator(1,2)
Sq(0,2)
sage: commutator(0,4)
Sq(0,0,0,1)
sage: commutator(2,2)
Sq(0,4) + Sq(3,3)
```

Note: `commutator(0,n)` is equal to $\mathrm{Sq}(0, ..., 0, 1)$, with the 1 in the n^{th} spot. commutator(i,n) always has $\mathrm{Sq}(0, ..., 0, 2^i)$, with 2^i in the n^{th} spot, as a summand, but there may be other terms, as the example of commutator(2,2) illustrates.

That is, commutator(s,t) is equal to P^s_t, possibly plus other Milnor basis elements.

convert_from_milnor_matrix(*n, basis, p=2*)

Change-of-basis matrix, Milnor to 'basis', in dimension n.

INPUT:

- `n` - non-negative integer, the dimension
- `basis` - string, the basis to which to convert
- `p` - positive prime number (optional, default 2)

OUTPUT:

- `matrix` - change-of-basis matrix, a square matrix over GF(p)

(This is not really intended for casual users, so no error checking is made on the integer n, the basis name, or the prime.)

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_bases import convert_from_milnor_matrix, convert_to_mi
sage: convert_from_milnor_matrix(12,'wall')
[1 0 0 1 0 0 0]
[0 0 1 1 0 0 0]
[0 0 0 1 0 1 1]
[0 0 0 1 0 0 0]
[1 0 1 0 1 0 0]
[1 1 1 0 0 0 0]
[1 0 1 0 1 0 1]
sage: convert_from_milnor_matrix(38,'serre_cartan')
72 x 72 dense matrix over Finite Field of size 2
sage: x = convert_to_milnor_matrix(20,'wood_y')
sage: y = convert_from_milnor_matrix(20,'wood_y')
sage: x*y
```

```
[1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
[0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
[0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0]
[0 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 1 0 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 1 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 1 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 1 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 1 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 1 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 1 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 1 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0 1 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0 0 1 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 0]
[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1]
```

The function takes an optional argument, the prime p over which to work:

```
sage: convert_from_milnor_matrix(17,'adem',3)
[2 1 1 2]
[0 2 0 1]
[1 2 0 0]
[0 1 0 0]
```

convert_to_milnor_matrix(*n, basis, p=2*)

Change-of-basis matrix, 'basis' to Milnor, in dimension n, at the prime p.

INPUT:

- `n` - non-negative integer, the dimension
- `basis` - string, the basis from which to convert
- `p` - positive prime number (optional, default 2)

OUTPUT:

- `matrix` - change-of-basis matrix, a square matrix over GF(p)

(This is not really intended for casual users, so no error checking is made on the integer n, the basis name, or the prime.)

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_bases import convert_to_milnor_matrix
sage: convert_to_milnor_matrix(5, 'adem')
[0 1]
[1 1]
sage: convert_to_milnor_matrix(45, 'milnor')
111 x 111 dense matrix over Finite Field of size 2
sage: convert_to_milnor_matrix(12,'wall')
[1 0 0 1 0 0 0]
[1 1 0 0 0 1 0]
[0 1 0 1 0 0 0]
[0 0 0 1 0 0 0]
[1 1 0 0 1 0 0]
[0 0 1 1 1 0 1]
[0 0 0 0 1 0 1]
```

The function takes an optional argument, the prime p over which to work:

```
sage: convert_to_milnor_matrix(17,'adem',3)
[0 0 1 1]
[0 0 0 1]
[1 1 1 1]
[0 1 0 1]
sage: convert_to_milnor_matrix(48,'adem',5)
[0 1]
[1 1]
sage: convert_to_milnor_matrix(36,'adem',3)
[0 0 1]
[0 1 0]
[1 2 0]
```

list_to_hist (*list*)

Given list of positive integers [a,b,c,...], return corresponding 'histogram'.

That is, in the output [n1, n2, ...], n1 is the number of 1's in the original list, n2 is the number of 2's, etc.

INPUT:

- `list` - list of positive integers

OUTPUT:

- `answer` - list of non-negative integers

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_bases import list_to_hist
sage: list_to_hist([1,2,3,4,2,1,2])
[2, 3, 1, 1]
sage: list_to_hist([2,2,2,2])
[0, 4]
```

make_elt_homogeneous (*poly*)

Break element of the Steenrod algebra into a list of homogeneous pieces.

INPUT:

- `poly` - an element of the Steenrod algebra

OUTPUT: list of homogeneous elements of the Steenrod algebra whose sum is poly

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_bases import make_elt_homogeneous
sage: make_elt_homogeneous(Sq(2)*Sq(4) + Sq(2)*Sq(5))
[Sq(3,1) + Sq(6), Sq(4,1) + Sq(7)]
```

milnor_P_basis (*n, p=2*)

Milnor P basis in dimension n.

INPUT:

- `n` - non-negative integer
- `p` - positive prime number (optional, default 2)

OUTPUT:

- tuple of mod p Milnor P basis elements in dimension n

At the prime 2, the Milnor P basis consists of symbols of the form $\mathrm{Sq}(m_1, m_2, ..., m_t)$, where each m_i is a non-negative integer and if $t > 1$, then $m_t \neq 0$. At odd primes, it consists of symbols of the form $P(m_1, m_2, ..., m_t)$, where each m_i is a non-negative integer, and if $t > 1$, then $m_t \neq 0$.

Thus at the prime 2, this is just the Milnor basis. At odd primes, it is a subset of the Milnor basis of those terms with no Q factors.

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_bases import milnor_P_basis
sage: milnor_P_basis(7)
(Sq(0,0,1), Sq(1,2), Sq(4,1), Sq(7))
sage: milnor_P_basis(7, 2)
(Sq(0,0,1), Sq(1,2), Sq(4,1), Sq(7))
sage: milnor_P_basis(9, 3)
()
sage: milnor_P_basis(17, 3)
()
sage: milnor_P_basis(48, p=5)
(P(0,1), P(6))
sage: len(milnor_P_basis(100,3))
11
sage: len(milnor_P_basis(200,7))
0
sage: len(milnor_P_basis(240,7))
3
```

milnor_basis(*n, p=2*)

Milnor basis in dimension n.

INPUT:

- n - non-negative integer
- p - positive prime number (optional, default 2)

OUTPUT: tuple of mod p Milnor basis elements in dimension n

At the prime 2, the Milnor basis consists of symbols of the form $\mathrm{Sq}(m_1, m_2, ..., m_t)$, where each m_i is a non-negative integer and if $t > 1$, then $m_t \neq 0$. At odd primes, it consists of symbols of the form $Q_{e_1}Q_{e_2}...P(m_1, m_2, ..., m_t)$, where $0 \leq e_1 < e_2 < ...$, each m_i is a non-negative integer, and if $t > 1$, then $m_t \neq 0$.

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_bases import milnor_basis
sage: milnor_basis(7)
(Sq(0,0,1), Sq(1,2), Sq(4,1), Sq(7))
sage: milnor_basis(7, 2)
(Sq(0,0,1), Sq(1,2), Sq(4,1), Sq(7))
sage: milnor_basis(9, 3)
(Q_1 P(1), Q_0 P(2))
sage: milnor_basis(17, 3)
(Q_2, Q_1 P(3), Q_0 P(0,1), Q_0 P(4))
sage: milnor_basis(48, p=5)
(P(0,1), P(6))
sage: len(milnor_basis(100,3))
13
sage: len(milnor_basis(200,7))
0
sage: len(milnor_basis(240,7))
3
```

milnor_convert (*poly, basis*)

Convert an element of the Steenrod algebra in the Milnor basis to its representation in the chosen basis.

INPUT:

- `poly` - element of the Steenrod algebra
- `basis` - basis to which to convert

OUTPUT:

- `dict` - dictionary

This returns a dictionary of terms of the form (mono: coeff), where mono is a monomial in 'basis'. The form of mono depends on the chosen basis.

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_bases import milnor_convert
sage: milnor_convert(Sq(2)*Sq(4) + Sq(2)*Sq(5), 'adem')
{(5, 1): 1, (6, 1): 1, (6,): 1}
sage: A3 = SteenrodAlgebra(3)
sage: a = A3.Q(1) * A3.P(2,2); a
Q_1 P(2,2)
sage: milnor_convert(a, 'adem')
{(0, 9, 1, 2, 0): 1, (1, 9, 0, 2, 0): 2}
sage: milnor_convert(2 * a, 'adem')
{(0, 9, 1, 2, 0): 2, (1, 9, 0, 2, 0): 1}
sage: (Sq(2)*Sq(4) + Sq(2)*Sq(5)).basis('adem')
Sq^{5} Sq^{1} + Sq^{6} + Sq^{6} Sq^{1}
sage: a.basis('adem')
P^{9} beta P^{2} + 2 beta P^{9} P^{2}
sage: milnor_convert(Sq(2)*Sq(4) + Sq(2)*Sq(5), 'pst')
{((1, 1), (2, 1)): 1, ((0, 1), (1, 1), (2, 1)): 1, ((0, 2), (2, 1)): 1}
sage: (Sq(2)*Sq(4) + Sq(2)*Sq(5)).basis('pst')
P^{0}_{1} P^{1}_{1} P^{2}_{1} + P^{0}_{2} P^{2}_{1} + P^{1}_{1}
P^{2}_{1}
```

restricted_partitions (*n, list, no_repeats=False*)

List of 'restricted' partitions of n: partitions with parts taken from list.

INPUT:

- `n` - non-negative integer
- `list` - list of positive integers
- `no_repeats` - boolean (optional, default = False), if True, only return partitions with no repeated parts

This seems to be faster than RestrictedPartitions, although I don't know why. Maybe because all I want is the list of partitions (with each partition represented as a list), not the extra stuff provided by RestrictedPartitions.

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_bases import restricted_partitions
sage: restricted_partitions(10, [7,5,1])
[[7, 1, 1, 1], [5, 5], [5, 1, 1, 1, 1, 1], [1, 1, 1, 1, 1, 1, 1, 1, 1, 1]]
sage: restricted_partitions(10, [6,5,4,3,2,1], no_repeats=True)
[[6, 4], [6, 3, 1], [5, 4, 1], [5, 3, 2], [4, 3, 2, 1]]
sage: restricted_partitions(10, [6,4,2])
[[6, 4], [6, 2, 2], [4, 4, 2], [4, 2, 2, 2], [2, 2, 2, 2, 2]]
sage: restricted_partitions(10, [6,4,2], no_repeats=True)
[[6, 4]]
```

'list' may have repeated elements. If 'no_repeats' is False, this has no effect. If 'no_repeats' is True, and if the repeated elements appear consecutively in 'list', then each element may be used only as many times as it appears in 'list':

```
sage: restricted_partitions(10, [6,4,2,2], no_repeats=True)
[[6, 4], [6, 2, 2]]
sage: restricted_partitions(10, [6,4,2,2,2], no_repeats=True)
[[6, 4], [6, 2, 2], [4, 2, 2, 2]]
```

(If the repeated elements don't appear consecutively, the results are likely meaningless, containing several partitions more than once, for example.)

In the following examples, 'no_repeats' is False:

```
sage: restricted_partitions(10, [6,4,2])
[[6, 4], [6, 2, 2], [4, 4, 2], [4, 2, 2, 2], [2, 2, 2, 2, 2]]
sage: restricted_partitions(10, [6,4,2,2,2])
[[6, 4], [6, 2, 2], [4, 4, 2], [4, 2, 2, 2], [2, 2, 2, 2, 2]]
sage: restricted_partitions(10, [6,4,4,4,2,2,2,2,2,2])
[[6, 4], [6, 2, 2], [4, 4, 2], [4, 2, 2, 2], [2, 2, 2, 2, 2]]
```

serre_cartan_basis (*n, p=2, bound=1*)

Serre-Cartan basis in dimension n.

INPUT:

- `n` - non-negative integer
- `bound` - positive integer (optional)
- `prime` - positive prime number (optional, default 2)

OUTPUT: tuple of mod p Serre-Cartan basis elements in dimension n

The Serre-Cartan basis consists of 'admissible monomials in the Steenrod squares'. Thus at the prime 2, it consists of monomials $\mathrm{Sq}^{m_1}\mathrm{Sq}^{m_2}...\mathrm{Sq}^{m_t}$ with $m_i \geq 2m_{i+1}$ for each i. At odd primes, it consists of monomials $\beta^{e_0}P^{s_1}\beta^{e_1}P^{s_2}...P^{s_k}\beta^{e_k}$ with each e_i either 0 or 1, $s_i \geq ps_{i+1} + e_i$, and $s_k \geq 1$.

EXAMPLES:

```
sage: from sage.algebras.steenrod_algebra_bases import serre_cartan_basis
sage: serre_cartan_basis(7)
(Sq^{7}, Sq^{6} Sq^{1}, Sq^{4} Sq^{2} Sq^{1}, Sq^{5} Sq^{2})
sage: serre_cartan_basis(13,3)
(beta P^{3}, P^{3} beta)
sage: serre_cartan_basis(50,5)
(beta P^{5} P^{1} beta, beta P^{6} beta)
```

If optional argument bound is present, include only those monomials whose last term is at least bound (when p=2), or those for which $s_k - epsilon_k >= bound$ (when p is odd).

```
sage: serre_cartan_basis(7, bound=2)
(Sq^{7}, Sq^{5} Sq^{2})
sage: serre_cartan_basis(13, 3, bound=3)
(beta P^{3},)
```

steenrod_algebra_basis (*n, basis='milnor', p=2*)

Basis for the Steenrod algebra in degree n.

INPUT:

- `n` - non-negative integer

- `basis` - string, which basis to use (optional, default = 'milnor')
- `p` - positive prime number (optional, default = 2)

OUTPUT: tuple of basis elements for the Steenrod algebra in dimension n

The choices for the string basis are as follows:

- 'milnor': Milnor basis. When $p = 2$, the Milnor basis consists of symbols of the form $\mathrm{Sq}(m_1, m_2, ..., m_t)$, where each m_i is a non-negative integer and if $t > 1$, then the last entry $m_t > 0$. When p is odd, the Milnor basis consists of symbols of the form $Q_{e_1}Q_{e_2}...\mathcal{P}(m_1, m_2, ..., m_t)$, where $0 \leq e_1 < e_2 < ...$, each m_i is a non-negative integer, and if $t > 1$, then the last entry $m_t > 0$.
- 'serre-cartan' or 'adem' or 'admissible': Serre-Cartan basis. The Serre-Cartan basis consists of 'admissible monomials' in the Steenrod operations. Thus at the prime 2, it consists of monomials $\mathrm{Sq}^{m_1}\mathrm{Sq}^{m_2}...\mathrm{Sq}^{m_t}$ with $m_i \geq 2m_{i+1}$ for each i. At odd primes, it consists of monomials $\beta^{\epsilon_0}\mathcal{P}^{s_1}\beta^{\epsilon_1}\mathcal{P}^{s_2}...\mathcal{P}^{s_k}\beta^{\epsilon_k}$ with each ϵ_i either 0 or 1, $s_i \geq ps_{i+1} + \epsilon_i$, and $s_k \geq 1$.

  When $p = 2$, the element Sq^a equals the Milnor element $\mathrm{Sq}(a)$; when p is odd, $\mathcal{P}^a = \mathcal{P}(a)$ and $\beta = Q_0$. Hence for any Serre-Cartan basis element, one can represent it in the Milnor basis by computing an appropriate product using Milnor multiplication.

The rest of these bases are only defined when $p = 2$.

- 'wood_y': Wood's Y basis. For pairs of non-negative integers (m, k), let $w(m, k) = \mathrm{Sq}^{2^m(2^{k+1}-1)}$. Wood's Y basis consists of monomials $w(m_0, k_0)...w(m_t, k_t)$ with $(m_i, k_i) > (m_{i+1}, k_{i+1})$, in left lex order.
- 'wood_z': Wood's Z basis. For pairs of non-negative integers (m, k), let $w(m, k) = \mathrm{Sq}^{2^m(2^{k+1}-1)}$. Wood's Z basis consists of monomials $w(m_0, k_0)...w(m_t, k_t)$ with $(m_i+k_i, m_i) > (m_{i+1}+k_{i+1}, m_{i+1})$, in left lex order.
- 'wall' or 'wall_long': Wall's basis. For any pair of integers (m, k) with $m \geq k \geq 0$, let $Q_k^m = \mathrm{Sq}^{2^k}\mathrm{Sq}^{2^{k+1}}...\mathrm{Sq}^{2^m}$. The elements of Wall's basis are monomials $Q_{k_0}^{m_0}...Q_{k_t}^{m_t}$ with $(m_i, k_i) > (m_{i+1}, k_{i+1})$, ordered left lexicographically.

  (Note that Q_k^m is the reverse of the element X_k^m used in defining Arnon's A basis.)

  The standard way of printing elements of the Wall basis is to write elements in terms of the Q_k^m. If one sets the basis to 'wall_long' instead of 'wall', then each Q_k^m is expanded as a product of factors of the form Sq^{2^i}.
- 'arnon_a' or 'arnon_a_long': Arnon's A basis. For any pair of integers (m, k) with $m \geq k \geq 0$, let $X_k^m = \mathrm{Sq}^{2^m}\mathrm{Sq}^{2^{m-1}}...\mathrm{Sq}^{2^k}$. The elements of Arnon's A basis are monomials $X_{k_0}^{m_0}...X_{k_t}^{m_t}$ with $(m_i, k_i) < (m_{i+1}, k_{i+1})$, ordered left lexicographically.

  (Note that X_k^m is the reverse of the element Q_k^m used in defining Wall's basis.)

  The standard way of printing elements of Arnon's A basis is to write elements in terms of the X_k^m. If one sets the basis to 'arnon_a_long' instead of 'arnon_a', then each X_k^m is expanded as a product of factors of the form Sq^{2^i}.
- 'arnon_c': Arnon's C basis. The elements of Arnon's C basis are monomials of the form $\mathrm{Sq}^{t_1}...\mathrm{Sq}^{t_m}$ where for each i, we have $t_i \leq 2t_{i+1}$ and $2^i | t_{m-i}$.
- 'pst', 'pst_rlex', 'pst_llex', 'pst_deg', 'pst_revz': various P_t^s-bases. For integers $s \geq 0$ and $t > 0$, the element P_t^s is the Milnor basis element $\mathrm{Sq}(0, ..., 0, 2^s, 0, ...)$, with the nonzero entry in position t. To obtain a P_t^s-basis, for each set $\{P_{t_1}^{s_1}, ..., P_{t_k}^{s_k}\}$ of (distinct) P_t^s's, one chooses an ordering and forms the resulting monomial. The set of all such monomials then forms a basis, and so one gets a basis by choosing an ordering on each monomial.

The strings 'rlex', 'llex', etc., correspond to the following orderings. These are all 'global' - they give a global ordering on the P_t^s's, not different orderings depending on the monomial. They order the P_t^s's using the pair of integers (s, t) as follows:

- 'rlex': right lexicographic ordering
- 'llex': left lexicographic ordering
- 'deg': ordered by degree, which is the same as left lexicographic ordering on the pair $(s+t, t)$
- 'revz': left lexicographic ordering on the pair $(s+t, s)$, which is the reverse of the ordering used (on elements in the same degrees as the P_t^s's) in Wood's Z basis: 'revz' stands for 'reversed Z'. This is the default: 'pst' is the same as 'pst_revz'.
- 'comm', 'comm_rlex', 'comm_llex', 'comm_deg', 'comm_revz', or any of these with '_long' appended: various commutator bases. Let $c_{i,1} = \mathrm{Sq}^{2^i}$, let $c_{i,2} = [c_{i,1}, c_{i+1,1}]$, and inductively define $c_{i,k} = [c_{i,k-1}, c_{i+k-1,1}]$. Thus $c_{i,k}$ is a k-fold iterated commutator of the elements Sq^{2^i}, ..., $\mathrm{Sq}^{2^{i+k-1}}$. Note that $\dim c_{i,k} = \dim P_k^i$.

  To obtain a commutator basis, for each set $\{c_{s_1,t_1}, ..., c_{s_k,t_k}\}$ of (distinct) $c_{s,t}$'s, one chooses an ordering and forms the resulting monomial. The set of all such monomials then forms a basis, and so one gets a basis by choosing an ordering on each monomial. The strings 'rlex', etc., have the same meaning as for the orderings on P_t^s-bases. As with the P_t^s-bases, 'comm_revz' is the default: 'comm' means 'comm_revz'.

  The commutator bases have alternative representations, obtained by appending 'long' to their names: instead of, say, $c_{2,2}$, the representation is s_{48}, indicating the commutator of Sq^4 and Sq^8, and $c_{0,3}$, which is equal to $[[\mathrm{Sq}^1, \mathrm{Sq}^2], \mathrm{Sq}^4]$, is written as s_{124}.

EXAMPLES:

```
sage: steenrod_algebra_basis(7,'milnor')
(Sq(0,0,1), Sq(1,2), Sq(4,1), Sq(7))
sage: steenrod_algebra_basis(5)   # milnor basis is the default
(Sq(2,1), Sq(5))
```

The third (optional) argument to 'steenrod_algebra_basis' is the prime p:

```
sage: steenrod_algebra_basis(9, 'milnor', p=3)
(Q_1 P(1), Q_0 P(2))
sage: steenrod_algebra_basis(9, 'milnor', 3)
(Q_1 P(1), Q_0 P(2))
sage: steenrod_algebra_basis(17, 'milnor', 3)
(Q_2, Q_1 P(3), Q_0 P(0,1), Q_0 P(4))
```

Other bases:

```
sage: steenrod_algebra_basis(7,'admissible')
(Sq^{7}, Sq^{6} Sq^{1}, Sq^{4} Sq^{2} Sq^{1}, Sq^{5} Sq^{2})
sage: [x.basis('milnor') for x in steenrod_algebra_basis(7,'admissible')]
[Sq(7),
Sq(4,1) + Sq(7),
Sq(0,0,1) + Sq(1,2) + Sq(4,1) + Sq(7),
Sq(1,2) + Sq(7)]
sage: steenrod_algebra_basis(13,'admissible',p=3)
(beta P^{3}, P^{3} beta)
sage: steenrod_algebra_basis(5,'wall')
(Q^{2}_{2} Q^{0}_{0}, Q^{1}_{1} Q^{1}_{0})
sage: steenrod_algebra_basis(5,'wall_long')
(Sq^{4} Sq^{1}, Sq^{2} Sq^{1} Sq^{2})
sage: steenrod_algebra_basis(5,'pst-rlex')
(P^{0}_{1} P^{2}_{1}, P^{1}_{1} P^{0}_{2})
```

steenrod_basis_error_check(*dim, p*)

This performs crude error checking.

INPUT:

- dim - non-negative integer
- p - positive prime number

OUTPUT: None

This checks to see if the different bases have the same length, and if the change-of-basis matrices are invertible. If something goes wrong, an error message is printed.

This function checks at the prime p as the dimension goes up from 0, in which case the basis functions use the saved basis computations in lower dimensions in the computations. It also checks as the dimension goes down from the top, in which case it doesn't have access to the saved computations. (The saved computations are deleted first: the cache _steenrod_bases is set to {} before doing the computations.)

EXAMPLES:

```
sage: sage.algebras.steenrod_algebra_bases.steenrod_basis_error_check(12,2)
p=2, in decreasing order of dimension, starting in dimension 12.
down to dimension  10
down to dimension  5
p=2, now in increasing order of dimension, up to dimension 12
up to dimension  0
up to dimension  5
up to dimension  10
done checking
sage: sage.algebras.steenrod_algebra_bases.steenrod_basis_error_check(30,3)
p=3, in decreasing order of dimension, starting in dimension 30.
down to dimension  30
down to dimension  25
down to dimension  20
down to dimension  15
down to dimension  10
down to dimension  5
p=3, now in increasing order of dimension, up to dimension 30
up to dimension  0
up to dimension  5
up to dimension  10
up to dimension  15
up to dimension  20
up to dimension  25
done checking
```

xi_degrees(*n, p=2*)

Decreasing list of degrees of the xi_i's, starting in degree n.

INPUT:

- n - integer

OUTPUT:

- list - list of integers

When $p = 2$: decreasing list of the degrees of the ξ_i's with degree at most n.

At odd primes: decreasing list of these degrees, each divided by $2(p-1)$.

EXAMPLES:

```
sage: sage.algebras.steenrod_algebra_bases.xi_degrees(17)
[15, 7, 3, 1]
sage: sage.algebras.steenrod_algebra_bases.xi_degrees(17,p=3)
[13, 4, 1]
```

```
sage: sage.algebras.steenrod_algebra_bases.xi_degrees(400,p=17)
[307, 18, 1]
```

CHAPTER

THIRTYONE

QUATERNION ALGEBRAS

31.1 Quaternion Algebras

AUTHORS:

- Jon Bobber – 2009 rewrite
- William Stein – 2009 rewrite

This code is partly based on Sage code by David Kohel from 2005.

TESTS:

We test pickles:

```
sage: Q.<i,j,k> = QuaternionAlgebra(QQ,-5,-2)
sage: Q == loads(dumps(Q))
True
```

QuaternionAlgebra(*arg0, arg1=None, arg2=None, names='i, j, k'*)

There are three input formats:

- `QuaternionAlgebra(a, b)`: quaternion algebra generated by `i`, `j` subject to $i^2 = a$, $j^2 = b$, $j * i = -i * j$.
- `QuaternionAlgebra(K, a, b)`: same as above but over a field `K`. Here, `a` and `b` are nonzero elements of a field (`K`) of characteristic not 2, and we set $k = i * j$.
- `QuaternionAlgebra(D)`: a rational quaternion algebra with discriminant `D`, where $D > 1$ is a square-free integer.

EXAMPLES:

`QuaternionAlgebra(a, b)` - return quaternion algebra over the *smallest* field containing the nonzero elements `a` and `b` with generators `i`, `j`, `k` with $i^2 = a$, $j^2 = b$ and $j * i = -i * j$:

```
sage: QuaternionAlgebra(-2,-3)
Quaternion Algebra (-2, -3) with base ring Rational Field
sage: QuaternionAlgebra(GF(5)(2), GF(5)(3))
Quaternion Algebra (2, 3) with base ring Finite Field of size 5
sage: QuaternionAlgebra(2, GF(5)(3))
Quaternion Algebra (2, 3) with base ring Finite Field of size 5
sage: QuaternionAlgebra(QQ[sqrt(2)](-1), -5)
Quaternion Algebra (-1, -5) with base ring Number Field in sqrt2 with defining polynomial x^2 -
sage: QuaternionAlgebra(sqrt(-1), sqrt(-3))
```

```
Quaternion Algebra (I, sqrt(-3)) with base ring Symbolic Ring
sage: QuaternionAlgebra(0,0)
...
ValueError: a and b must be nonzero
sage: QuaternionAlgebra(GF(2)(1),1)
...
ValueError: a and b must be elements of a field with characteristic not 2
```

`QuaternionAlgebra(K, a, b)` - return quaternion algebra over the field `K` with generators `i`, `j`, `k` with $i^2 = a$, $j^2 = b$ and $i * j = -j * i$:

```
sage: QuaternionAlgebra(QQ, -7, -21)
Quaternion Algebra (-7, -21) with base ring Rational Field
sage: QuaternionAlgebra(QQ[sqrt(2)], -2,-3)
Quaternion Algebra (-2, -3) with base ring Number Field in sqrt2 with defining polynomial x^2 -
```

`QuaternionAlgebra(D)` - `D` is a squarefree integer; returns a rational quaternion algebra of discriminant `D`:

```
sage: QuaternionAlgebra(1)
Quaternion Algebra (-1, 1) with base ring Rational Field
sage: QuaternionAlgebra(2)
Quaternion Algebra (-1, -1) with base ring Rational Field
sage: QuaternionAlgebra(7)
Quaternion Algebra (-1, -7) with base ring Rational Field
sage: QuaternionAlgebra(2*3*5*7)
Quaternion Algebra (-22, 210) with base ring Rational Field
```

If the coefficients a and b in the definition of the quaternion algebra are not integral, then a slower generic type is used for arithmetic:

```
sage: type(QuaternionAlgebra(-1,-3).0)
<type 'sage.algebras.quatalg.quaternion_algebra_element.QuaternionAlgebraElement_rational_field'
sage: type(QuaternionAlgebra(-1,-3/2).0)
<type 'sage.algebras.quatalg.quaternion_algebra_element.QuaternionAlgebraElement_generic'>
```

Make sure caching is sane:

```
sage: A = QuaternionAlgebra(2,3); A
Quaternion Algebra (2, 3) with base ring Rational Field
sage: B = QuaternionAlgebra(GF(5)(2),GF(5)(3)); B
Quaternion Algebra (2, 3) with base ring Finite Field of size 5
sage: A is QuaternionAlgebra(2,3)
True
sage: B is QuaternionAlgebra(GF(5)(2),GF(5)(3))
True
sage: Q = QuaternionAlgebra(2); Q
Quaternion Algebra (-1, -1) with base ring Rational Field
sage: Q is QuaternionAlgebra(QQ,-1,-1)
True
sage: Q is QuaternionAlgebra(-1,-1)
True
sage: Q.<ii,jj,kk> = QuaternionAlgebra(15); Q.variable_names()
('ii', 'jj', 'kk')
sage: QuaternionAlgebra(15).variable_names()
('i', 'j', 'k')
```

class **QuaternionAlgebra_ab**(*base_ring, a, b, names='i, j, k'*)

The quaternion algebra of the form $(a, b/K)$, where $i^2 = a$, $j^2 = b$, and $j * i = -i * j$. K is a field not of characteristic 2 and a, b are nonzero elements of K.

See QuaternionAlgebra for many more examples.

EXAMPLES:

```
sage: QuaternionAlgebra(QQ, -7, -21)  # indirect doctest
Quaternion Algebra (-7, -21) with base ring Rational Field
```

discriminant()

Given a quaternion algebra A defined over the field of rational numbers, return the discriminant of A, i.e. the product of the ramified primes of A.

EXAMPLES:

```
sage: QuaternionAlgebra(210,-22).discriminant()
210
sage: QuaternionAlgebra(19).discriminant()
19
```

This raises a NotImplementedError if the base field is not the rational numbers:

```
sage: QuaternionAlgebra(QQ[sqrt(2)],3,19).discriminant()
...
NotImplementedError: base field must be rational numbers
```

gen(*i=0*)

Return the i^{th} generator of self.

INPUT:

- i - integer (optional, default 0)

EXAMPLES:

```
sage: Q.<ii,jj,kk> = QuaternionAlgebra(QQ,-1,-2); Q
Quaternion Algebra (-1, -2) with base ring Rational Field
sage: Q.gen(0)
ii
sage: Q.gen(1)
jj
sage: Q.gen(2)
kk
sage: Q.gens()
[ii, jj, kk]
```

ideal(*gens, left_order=None, right_order=None, check=True*)

Return the quaternion ideal with given gens over $\mathbf{Z}$. Neither a left or right order structure need be specified.

INPUT:

- gens – a list of elements of this quaternion order
- check – bool (default: True); if False, then gens must 4-tuple that forms a Hermite basis for an ideal
- left_order – a quaternion order or None
- right_order – a quaternion order or None

EXAMPLES:

```
sage: R = QuaternionAlgebra(-11,-1)
sage: R.ideal([2*a for a in R.basis()])
Fractional ideal (2, 2*i, 2*j, 2*k)
```

inner_product_matrix()

Return the inner product matrix associated to `self`, i.e. the Gram matrix of the reduced norm as a quadratic form on `self`. The standard basis 1, i, j, k is orthogonal, so this matrix is just the diagonal matrix with diagonal entries 1, a, b, ab.

EXAMPLES:

```
sage: Q.<i,j,k> = QuaternionAlgebra(-5,-19)
sage: Q.inner_product_matrix()
[  2   0   0   0]
[  0  10   0   0]
[  0   0  38   0]
[  0   0   0 190]

sage: R.<a,b> = QQ[]; Q.<i,j,k> = QuaternionAlgebra(Frac(R),a,b)
sage: Q.inner_product_matrix()
[    2     0     0     0]
[    0  -2*a     0     0]
[    0     0  -2*b     0]
[    0     0     0 2*a*b]
```

invariants()

Return the structural invariants a, b of this quaternion algebra: `self` is generated by i, j subject to $i^2 = a$, $j^2 = b$ and $j * i = -i * j$.

EXAMPLES:

```
sage: Q.<i,j,k> = QuaternionAlgebra(15)
sage: Q.invariants()
(-3, 5)
sage: i^2
-3
sage: j^2
5
```

maximal_order()

Return a maximal order in this quaternion algebra.

OUTPUT: an order in this quaternion algebra

EXAMPLES:

```
sage: QuaternionAlgebra(-1,-7).maximal_order()
Order of Quaternion Algebra (-1, -7) with base ring Rational Field with basis (1/2 + 1/2*j,
```

quaternion_order(*basis, check=True*)

Return the order of this quaternion order with given basis.

INPUT:

- `basis` - list of 4 elements of `self`
- `check` - bool (default: `True`)

EXAMPLES:

```
sage: Q.<i,j,k> = QuaternionAlgebra(-11,-1)
sage: Q.quaternion_order([1,i,j,k])
Order of Quaternion Algebra (-11, -1) with base ring Rational Field with basis (1, i, j, k)
```

We test out `check=False`:

```
sage: Q.quaternion_order([1,i,j,k], check=False)
Order of Quaternion Algebra (-11, -1) with base ring Rational Field with basis [1, i, j, k]
sage: Q.quaternion_order([i,j,k], check=False)
Order of Quaternion Algebra (-11, -1) with base ring Rational Field with basis [i, j, k]
```

ramified_primes()

Return the primes that ramify in this quaternion algebra. Currently only implemented over the rational numbers.

EXAMPLES:

```
sage: QuaternionAlgebra(QQ, -1, -1).ramified_primes()
[2]
```

class **QuaternionAlgebra_abstract**()

basis()

Return the fixed basis of `self`, which is 1, i, j, k, where i, j, k are the generators of `self`.

EXAMPLES:

```
sage: Q.<i,j,k> = QuaternionAlgebra(QQ,-5,-2)
sage: Q.basis()
(1, i, j, k)

sage: Q.<xyz,abc,theta> = QuaternionAlgebra(GF(9,'a'),-5,-2)
sage: Q.basis()
(1, xyz, abc, theta)
```

The basis is cached:

```
sage: Q.basis() is Q.basis()
True
```

inner_product_matrix()

Return the inner product matrix associated to `self`, i.e. the Gram matrix of the reduced norm as a quadratic form on `self`. The standard basis 1, i, j, k is orthogonal, so this matrix is just the diagonal matrix with diagonal entries 2, $2a$, $2b$, $2ab$.

EXAMPLES:

```
sage: Q.<i,j,k> = QuaternionAlgebra(-5,-19)
sage: Q.inner_product_matrix()
[  2   0   0   0]
[  0  10   0   0]
[  0   0  38   0]
[  0   0   0 190]
```

is_commutative()

Return `False` always, since all quaternion algebras are noncommutative.

EXAMPLES:

```
sage: Q.<i,j,k> = QuaternionAlgebra(QQ, -3,-7)
sage: Q.is_commutative()
False
```

is_division_algebra()

Return `True` if the quaternion algebra is a division algebra (i.e. every nonzero element in `self` is invertible), and `False` if the quaternion algebra is isomorphic to the 2x2 matrix algebra.

EXAMPLES:

```
sage: QuaternionAlgebra(QQ,-5,-2).is_division_algebra()
True
sage: QuaternionAlgebra(1).is_division_algebra()
False
sage: QuaternionAlgebra(2,9).is_division_algebra()
False
```

```
sage: QuaternionAlgebra(RR(2.),1).is_division_algebra()
...
NotImplementedError: base field must be rational numbers
```

is_exact()

Return `True` if elements of this quaternion algebra are represented exactly, i.e. there is no precision loss when doing arithmetic. A quaternion algebra is exact if and only if its base field is exact.

EXAMPLES:

```
sage: Q.<i,j,k> = QuaternionAlgebra(QQ, -3, -7)
sage: Q.is_exact()
True
sage: Q.<i,j,k> = QuaternionAlgebra(Qp(7), -3, -7)
sage: Q.is_exact()
False
```

is_field()

Return `False` always, since all quaternion algebras are noncommutative and all fields are commutative.

EXAMPLES:

```
sage: Q.<i,j,k> = QuaternionAlgebra(QQ, -3, -7)
sage: Q.is_field()
False
```

is_finite()

Return `True` if the quaternion algebra is finite as a set.

Algorithm: A quaternion algebra is finite if and only if the base field is finite.

EXAMPLES:

```
sage: Q.<i,j,k> = QuaternionAlgebra(QQ, -3, -7)
sage: Q.is_finite()
False
sage: Q.<i,j,k> = QuaternionAlgebra(GF(5), -3, -7)
sage: Q.is_finite()
True
```

is_integral_domain()

Return `False` always, since all quaternion algebras are noncommutative and integral domains are commutative (in Sage).

EXAMPLES:

```
sage: Q.<i,j,k> = QuaternionAlgebra(QQ, -3, -7)
sage: Q.is_integral_domain()
False
```

is_matrix_ring()

Return `True` if the quaternion algebra is isomorphic to the 2x2 matrix ring, and `False` if `self` is a division algebra (i.e. every nonzero element in `self` is invertible).

EXAMPLES:

```
sage: QuaternionAlgebra(QQ,-5,-2).is_matrix_ring()
False
sage: QuaternionAlgebra(1).is_matrix_ring()
True
sage: QuaternionAlgebra(2,9).is_matrix_ring()
True
sage: QuaternionAlgebra(RR(2.),1).is_matrix_ring()
...
NotImplementedError: base field must be rational numbers
```

is_noetherian()

Return `True` always, since any quaternion algebra is a noetherian ring (because it is a finitely generated module over a field).

EXAMPLES:

```
sage: Q.<i,j,k> = QuaternionAlgebra(QQ, -3, -7)
sage: Q.is_noetherian()
True
```

ngens()

Return the number of generators of the quaternion algebra as a K-vector space, not including 1. This value is always 3: the algebra is spanned by the standard basis 1, i, j, k.

EXAMPLES:

```
sage: Q.<i,j,k> = QuaternionAlgebra(QQ,-5,-2)
sage: Q.ngens()
3
sage: Q.gens()
[i, j, k]
```

order()

Return the number of elements of the quaternion algebra, or `+Infinity` if the algebra is not finite.

EXAMPLES:

```
sage: Q.<i,j,k> = QuaternionAlgebra(QQ, -3, -7)
sage: Q.order()
+Infinity
sage: Q.<i,j,k> = QuaternionAlgebra(GF(5), -3, -7)
sage: Q.order()
625
```

random_element(**args, **kwds*)

Return a random element of this quaternion algebra.

The `args` and `kwds` are passed to the `random_element` method of the base ring.

EXAMPLES:

```
sage: QuaternionAlgebra(QQ[sqrt(2)],-3,7).random_element()
-4 + (-1/95*sqrt2 - 1/2)*i + (-12*sqrt2 + 1/2)*j + (1/2*sqrt2 - 1)*k
sage: QuaternionAlgebra(-3,19).random_element()
-1/4 + 2/3*i - 5/2*j
sage: QuaternionAlgebra(GF(17)(2),3).random_element()
11 - i + 4*j + 13*k
```

Specify the numerator and denominator bounds:

```
sage: QuaternionAlgebra(-3,19).random_element(10^6,10^6)
-61003/263835 + 222181/103881*i - 7314/2707*j + 458453/129132*k
```

vector_space()

Return the vector space associated to `self` with inner product given by the reduced norm.

EXAMPLES:

```
sage: QuaternionAlgebra(-3,19).vector_space()
Ambient quadratic space of dimension 4 over Rational Field
Inner product matrix:
[   2    0    0    0]
[   0    6    0    0]
[   0    0  -38    0]
[   0    0    0 -114]
```

class **QuaternionFractionalIdeal**(*ring, gens, coerce=True*)

class **QuaternionFractionalIdeal_rational**(*basis, left_order=None, right_order=None, check=True*)

A fractional ideal in a rational quaternion algebra.

basis()

Return basis for this fractional ideal. The basis is in Hermite form.

OUTPUT: tuple

EXAMPLES:

```
sage: QuaternionAlgebra(-11,-1).maximal_order().unit_ideal().basis()
(1/2 + 1/2*j, 1/2*i + 1/2*k, j, k)
```

basis_matrix()

Return basis matrix M in Hermite normal form for self as a matrix with rational entries.

If Q is the ambient quaternion algebra, then the $\mathbf{Z}$-span of the rows of M viewed as linear combinations of Q.basis() = $[1, i, j, k]$ is the fractional ideal self. Also, M * M.denominator() is an integer matrix in Hermite normal form.

OUTPUT: matrix over $\mathbf{Q}$

EXAMPLES:

```
sage: QuaternionAlgebra(-11,-1).maximal_order().unit_ideal().basis_matrix()
[1/2   0 1/2   0]
[  0 1/2   0 1/2]
[  0   0   1   0]
[  0   0   0   1]
```

conjugate()

Return the ideal with generators the conjugates of the generators for self.

OUTPUT: a quaternionic fractional ideal

EXAMPLES:

```
sage: I = BrandtModule(3,5).right_ideals()[1]; I
Fractional ideal (2 + 6*j + 4*k, 2*i + 4*j + 34*k, 8*j + 32*k, 40*k)
sage: I.conjugate()
Fractional ideal (2 + 2*j + 28*k, 2*i + 4*j + 34*k, 8*j + 32*k, 40*k)
```

free_module()

Return the free module associated to this quaternionic fractional ideal, viewed as a submodule of `Q.free_module()`, where `Q` is the ambient quaternion algebra.

OUTPUT: free $\mathbf{Z}$-module of rank 4 embeded in an ambient $\mathbf{Q}^4$.

EXAMPLES:

```
sage: QuaternionAlgebra(-11,-1).maximal_order().unit_ideal().basis_matrix()
[1/2   0 1/2   0]
[  0 1/2   0 1/2]
[  0   0   1   0]
[  0   0   0   1]
```

gens()

Return the generators for this ideal, which are the same as the $\mathbf{Z}$-basis for this ideal.

EXAMPLES:

```
sage: QuaternionAlgebra(-11,-1).maximal_order().unit_ideal().gens()
(1/2 + 1/2*j, 1/2*i + 1/2*k, j, k)
```

gram_matrix()

Return the Gram matrix of this fractional ideal.

OUTPUT: 4x4 matrix over $\mathbf{Q}$.

EXAMPLES:

```
sage: I = BrandtModule(3,5).right_ideals()[1]; I
Fractional ideal (2 + 6*j + 4*k, 2*i + 4*j + 34*k, 8*j + 32*k, 40*k)
sage: I.gram_matrix()
[  640  1920  2112  1920]
[ 1920 14080 13440 16320]
[ 2112 13440 13056 15360]
[ 1920 16320 15360 19200]
```

is_equivalent(*I, J, B=10*)

Return `True` if `I` and `J` are equivalent as right ideals.

INPUT:

- `I` – a fractional quaternion ideal (self)
- `J` – a fractional quaternion ideal with same order as `I`
- `B` – a bound to compute and compare theta series before doing the full equivalence test

OUTPUT: bool

EXAMPLES:

```
sage: R = BrandtModule(3,5).right_ideals(); len(R)
2
sage: R[0].is_equivalent(R[1])
False
sage: R[0].is_equivalent(R[0])
True
sage: OO = R[0].quaternion_order()
sage: S = OO.right_ideal([3*a for a in R[0].basis()])
sage: R[0].is_equivalent(S)
True
```

left_order()

Return the left order associated to this fractional ideal.

OUTPUT: an order in a quaternion algebra

EXAMPLES:

```
sage: B = BrandtModule(11)
sage: R = B.maximal_order()
sage: I = R.unit_ideal()
sage: I.left_order()
Order of Quaternion Algebra (-1, -11) with base ring Rational Field with basis (1/2 + 1/2*j,
```

multiply_by_conjugate(*J*)

Return product of self and the conjugate Jbar of J.

INPUT:

- `J` – a quaternion ideal.

OUTPUT: a quaternionic fractional ideal.

EXAMPLES:

```
sage: R = BrandtModule(3,5).right_ideals()
sage: R[0].multiply_by_conjugate(R[1])
Fractional ideal (8 + 8*j + 112*k, 8*i + 16*j + 136*k, 32*j + 128*k, 160*k)
sage: R[0]*R[1].conjugate()
Fractional ideal (8 + 8*j + 112*k, 8*i + 16*j + 136*k, 32*j + 128*k, 160*k)
```

norm()

Return the norm of this fractional ideal.

OUTPUT: rational number

EXAMPLES:

```
sage: C = BrandtModule(37).right_ideals()
sage: [I.norm() for I in C]
[32, 64, 64]
```

quadratic_form()

Return the normalized quadratic form associated to this quaternion ideal.

OUTPUT: quadratic form

EXAMPLES:

```
sage: I = BrandtModule(11).right_ideals()[1]
sage: Q = I.quadratic_form(); Q
Quadratic form in 4 variables over Rational Field with coefficients:
[ 18 22 33 22 ]
[ * 7 22 11 ]
[ * * 22 0 ]
[ * * * 22 ]
sage: Q.theta_series(10)
1 + 12*q^2 + 12*q^3 + 12*q^4 + 12*q^5 + 24*q^6 + 24*q^7 + 36*q^8 + 36*q^9 + O(q^10)
sage: I.theta_series(10)
1 + 12*q^2 + 12*q^3 + 12*q^4 + 12*q^5 + 24*q^6 + 24*q^7 + 36*q^8 + 36*q^9 + O(q^10)
```

quaternion_algebra()

Return the ambient quaternion algebra that contains this fractional ideal.

OUTPUT: a quaternion algebra

EXAMPLES:

```
sage: I = BrandtModule(3,5).right_ideals()[1]; I
Fractional ideal (2 + 6*j + 4*k, 2*i + 4*j + 34*k, 8*j + 32*k, 40*k)
sage: I.quaternion_algebra()
Quaternion Algebra (-1, -3) with base ring Rational Field
```

quaternion_order()

Return the order for which this ideal is a left or right fractional ideal. If this ideal has both a left and right ideal structure, then the left order is returned. If it has neither structure, then an error is raised.

OUTPUT: QuaternionOrder

EXAMPLES:

```
sage: R = QuaternionAlgebra(-11,-1).maximal_order()
sage: R.unit_ideal().quaternion_order() is R
True
```

right_order()

Return the right order associated to this fractional ideal.

OUTPUT: an order in a quaternion algebra

EXAMPLES:

```
sage: I = BrandtModule(389).right_ideals()[1]; I
Fractional ideal (2 + 6*j + 2*k, i + 2*j + k, 8*j, 8*k)
sage: I.right_order()
Order of Quaternion Algebra (-2, -389) with base ring Rational Field with basis (1/2 + 1/2*j
sage: I.left_order()
...
ValueError: ideal not equipped with left order structure
```

ring()

Return ring that this is a fractional ideal for.

EXAMPLES:

```
sage: R = QuaternionAlgebra(-11,-1).maximal_order()
sage: R.unit_ideal().ring() is R
True
```

theta_series(*B*, *var='q'*)

Return normalized theta series of self, as a power series over **Z** in the variable `var`, which is 'q' by default.

The normalized theta series is by definition

$$\theta_I(q) = \sum_{x \in I} q^{\frac{N(x)}{N(I)}}$$

INPUT:

- `B` – positive integer
- `var` – string (default: 'q')

OUTPUT: power series

EXAMPLES:

```
sage: I = BrandtModule(11).right_ideals()[1]; I
Fractional ideal (2 + 6*j + 4*k, 2*i + 4*j + 2*k, 8*j, 8*k)
sage: I.norm()
64
sage: I.theta_series(5)
1 + 12*q^2 + 12*q^3 + 12*q^4 + O(q^5)
sage: I.theta_series(5,'T')
1 + 12*T^2 + 12*T^3 + 12*T^4 + O(T^5)
sage: I.theta_series(3)
1 + 12*q^2 + O(q^3)
```

theta_series_vector(*B*)

Return theta series coefficients of self, as a vector of B integers.

INPUT:

- `B` – positive integer

OUTPUT: vector over **Z** with `B` entries

EXAMPLES:

```
sage: I = BrandtModule(37).right_ideals()[1]; I
Fractional ideal (2 + 6*j + 2*k, i + 2*j + k, 8*j, 8*k)
sage: I.theta_series_vector(5)
(1, 0, 2, 2, 6)
sage: I.theta_series_vector(10)
(1, 0, 2, 2, 6, 4, 8, 6, 10, 10)
sage: I.theta_series_vector(5)
(1, 0, 2, 2, 6)
```

class QuaternionOrder(*A*, *basis*, *check=True*)

An order in a quaternion algebra.

EXAMPLES:

```
sage: QuaternionAlgebra(-1,-7).maximal_order()
Order of Quaternion Algebra (-1, -7) with base ring Rational Field with basis (1/2 + 1/2*j, 1/2*
sage: type(QuaternionAlgebra(-1,-7).maximal_order())
<class 'sage.algebras.quatalg.quaternion_algebra.QuaternionOrder'>
```

basis()

Return fix choice of basis for this quaternion order.

EXAMPLES:

```
sage: QuaternionAlgebra(-11,-1).maximal_order().basis()
(1/2 + 1/2*j, 1/2*i + 1/2*k, j, k)
```

discriminant()

Return the discriminant of this order, which we define as $\sqrt{det(Tr(e_i\bar{e_j}))}$, where $\{e_i\}$ is the basis of the order.

OUTPUT: rational number

EXAMPLES:

```
sage: QuaternionAlgebra(-11,-1).maximal_order().discriminant()
11
sage: S = BrandtModule(11,5).order_of_level_N()
sage: S.discriminant()
55
sage: type(S.discriminant())
<type 'sage.rings.rational.Rational'>
```

free_module()

Return the free $\mathbf{Z}$-module that corresponds to this order inside the vector space corresponding to the ambient quaternion algebra.

OUTPUT: a free $\mathbf{Z}$-module of rank 4

EXAMPLES:

```
sage: R = QuaternionAlgebra(-11,-1).maximal_order()
sage: R.basis()
(1/2 + 1/2*j, 1/2*i + 1/2*k, j, k)
sage: R.free_module()
Free module of degree 4 and rank 4 over Integer Ring
Echelon basis matrix:
[1/2   0 1/2   0]
[  0 1/2   0 1/2]
[  0   0   1   0]
[  0   0   0   1]
```

gen(n)

Return the n-th generator.

INPUT:

- n - an integer between 0 and 3, inclusive.

EXAMPLES:

```
sage: R = QuaternionAlgebra(-11,-1).maximal_order(); R
Order of Quaternion Algebra (-11, -1) with base ring Rational Field with basis (1/2 + 1/2*j,
sage: R.gen(0)
1/2 + 1/2*j
sage: R.gen(1)
1/2*i + 1/2*k
sage: R.gen(2)
j
sage: R.gen(3)
k
```

gens()

Return generators for self.

EXAMPLES:

```
sage: QuaternionAlgebra(-1,-7).maximal_order().gens()
(1/2 + 1/2*j, 1/2*i + 1/2*k, j, k)
```

intersection(*other*)

Return the intersection of this order with other.

INPUT:

- `other` - a quaternion order in the same ambient quaternion algebra

OUTPUT: a quaternion order

EXAMPLES:

```
sage: R = QuaternionAlgebra(-11,-1).maximal_order()
sage: R.intersection(R)
Order of Quaternion Algebra (-11, -1) with base ring Rational Field with basis (1/2 + 1/2*j,
```

We intersect various orders in the quaternion algebra ramified at 11:

```
sage: B = BrandtModule(11,3)
sage: R = B.maximal_order(); S = B.order_of_level_N()
sage: R.intersection(S)
Order of Quaternion Algebra (-1, -11) with base ring Rational Field with basis (1/2 + 1/2*j,
sage: R.intersection(S) == S
True
sage: B = BrandtModule(11,5)
sage: T = B.order_of_level_N()
sage: S.intersection(T)
Order of Quaternion Algebra (-1, -11) with base ring Rational Field with basis (1/2 + 1/2*j,
```

left_ideal(*gens, check=True*)

Return the ideal with given gens over $\mathbf{Z}$.

INPUT:

- `gens` – a list of elements of this quaternion order
- `check` – bool (default: `True`); if `False`, then `gens` must 4-tuple that forms a Hermite basis for an ideal

EXAMPLES:

```
sage: R = QuaternionAlgebra(-11,-1).maximal_order()
sage: R.left_ideal([2*a for a in R.basis()])
Fractional ideal (1 + j, i + k, 2*j, 2*k)
```

ngens()

Return the number of generators (which is 4).

EXAMPLES:

```
sage: QuaternionAlgebra(-1,-7).maximal_order().ngens()
4
```

quaternion_algebra()

Return ambient quaternion algebra that contains this quaternion order.

EXAMPLES:

```
sage: QuaternionAlgebra(-11,-1).maximal_order().quaternion_algebra()
Quaternion Algebra (-11, -1) with base ring Rational Field
```

random_element(**args, **kwds*)

Return a random element of this order.

The args and kwds are passed to the random_element method of the integer ring, and we return an element of the form

$$ae_1 + be_2 + ce_3 + de_4$$

where e_1, ..., e_4 are the basis of this order and a, b, c, d are random integers.

EXAMPLES:

```
sage: QuaternionAlgebra(-11,-1).maximal_order().random_element()
-4 + i - 4*j + k
sage: QuaternionAlgebra(-11,-1).maximal_order().random_element(-10,10)
-9/2 - 7/2*i - 7/2*j + 3/2*k
```

right_ideal(*gens, check=True*)

Return the ideal with given gens over **Z**.

INPUT:

- gens – a list of elements of this quaternion order
- check – bool (default: True); if False, then gens must 4-tuple that forms a Hermite basis for an ideal

EXAMPLES:

```
sage: R = QuaternionAlgebra(-11,-1).maximal_order()
sage: R.right_ideal([2*a for a in R.basis()])
Fractional ideal (1 + j, i + k, 2*j, 2*k)
```

unit_ideal()

Return the unit ideal in this quaternion order.

EXAMPLES:

```
sage: R = QuaternionAlgebra(-11,-1).maximal_order()
sage: I = R.unit_ideal(); I
Fractional ideal (1/2 + 1/2*j, 1/2*i + 1/2*k, j, k)
```

basis_for_quaternion_lattice(*gens*)

Return a basis for the **Z**-lattice in a quaternion algebra spanned by the given gens.

INPUT:

- gens – list of elements of a single quaternion algebra

EXAMPLES:

```
sage: A.<i,j,k> = QuaternionAlgebra(-1,-7)
sage: sage.algebras.quatalg.quaternion_algebra.basis_for_quaternion_lattice([i+j, i-j, 2*k, A(1/
[1/3, i + j, 2*j, 2*k]
```

is_QuaternionAlgebra(*A*)

Return True if A is of the QuaternionAlgebra data type.

EXAMPLES:

```
sage: sage.algebras.quatalg.quaternion_algebra.is_QuaternionAlgebra(QuaternionAlgebra(QQ,-1,-1))
True
sage: sage.algebras.quatalg.quaternion_algebra.is_QuaternionAlgebra(ZZ)
False
```

unpickle_QuaternionAlgebra_v0(**key*)

The 0th version of pickling for quaternion algebras.

EXAMPLES:

```
sage: Q = QuaternionAlgebra(-5,-19)
sage: f, t = Q.__reduce__()
sage: sage.algebras.quatalg.quaternion_algebra.unpickle_QuaternionAlgebra_v0(*t)
Quaternion Algebra (-5, -19) with base ring Rational Field
sage: loads(dumps(Q)) == Q
True
```

```
sage: loads(dumps(Q)) is Q
True
```

31.2 Elements of Quaternion Algebras

Sage allows for computation with elements of quaternion algebras over a nearly arbitrary base field of characteristic not 2. Sage also has very highly optimized implementation of arithmetic in rational quaternion algebras and quaternion algebras over number fields.

class QuaternionAlgebraElement_abstract()

conjugate()

Return the conjugate of the quaternion: if $\theta = x + yi + zj + wk$, return $x - yi - zj - wk$; that is, return theta.reduced_trace() - theta.

EXAMPLES:

```
sage: A.<i,j,k> = QuaternionAlgebra(QQ,-5,-2)
sage: a = 3*i - j + 2
sage: type(a)
<type 'sage.algebras.quatalg.quaternion_algebra_element.QuaternionAlgebraElement_rational_fi
sage: a.conjugate()
2 - 3*i + j
```

The "universal" test:

```
sage: K.<x,y,z,w,a,b> = QQ[]
sage: Q.<i,j,k> = QuaternionAlgebra(a,b)
sage: theta = x+y*i+z*j+w*k
sage: theta.conjugate()
x + (-y)*i + (-z)*j + (-w)*k
```

is_constant()

Return True if this quaternion is constant, i.e., has no i, j, or k term.

OUTPUT: bool

EXAMPLES:

```
sage: A.<i,j,k>=QuaternionAlgebra(-1,-2)
sage: A(1).is_constant()
True
sage: A(1+i).is_constant()
False
sage: A(i).is_constant()
False
```

reduced_characteristic_polynomial()

Return the reduced characteristic polynomial of this quaternion algebra element, which is $X^2 - tX + n$, where t is the reduced trace and n is the reduced norm.

INPUT: • var – string (default: 'x'); indeterminate of characteristic polynomial

EXAMPLES:

```
sage: A.<i,j,k>=QuaternionAlgebra(-1,-2)
sage: i.reduced_characteristic_polynomial()
x^2 + 1
sage: j.reduced_characteristic_polynomial()
x^2 + 2
```

```
sage: (i+j).reduced_characteristic_polynomial()
x^2 + 3
sage: (2+j+k).reduced_trace()
4
sage: (2+j+k).reduced_characteristic_polynomial('T')
T^2 - 4*T + 8
```

reduced_norm()

Return the reduced norm of self: if $\theta = x+yi+zj+wk$, then θ has reduced norm $x^2 - ay^2 - bz^2 + abw^2$.

EXAMPLES:

```
sage: K.<x,y,z,w,a,b> = QQ[]
sage: Q.<i,j,k> = QuaternionAlgebra(a,b)
sage: theta = x+y*i+z*j+w*k
sage: theta.reduced_norm()
w^2*a*b - y^2*a - z^2*b + x^2
```

reduced_trace()

Return the reduced trace of self: if $\theta = x + yi + zj + wk$, then θ has reduced trace $2x$.

EXAMPLES:

```
sage: K.<x,y,z,w,a,b> = QQ[]
sage: Q.<i,j,k> = QuaternionAlgebra(a,b)
sage: theta = x+y*i+z*j+w*k
sage: theta.reduced_trace()
2*x
```

class **QuaternionAlgebraElement_generic**()

TESTS:

We test pickling:

```
sage: R.<x> = Frac(QQ['x']); Q.<i,j,k> = QuaternionAlgebra(R,-5*x,-2)
sage: theta = x + i*x^3 + j*x^2 + k*x
sage: theta == loads(dumps(theta))
True
```

class **QuaternionAlgebraElement_number_field**()

class **QuaternionAlgebraElement_rational_field**()

TESTS:

We test pickling:

```
sage: Q.<i,j,k> = QuaternionAlgebra(QQ,-5,-2)
sage: i + j + k == loads(dumps(i+j+k))
True
```

coefficient_tuple()

Return 4-tuple of rational numbers which are the coefficients of this quaternion.

EXAMPLES:

```
sage: A.<i,j,k>=QuaternionAlgebra(-1,-2)
sage: (2/3 + 3/5*i + 4/3*j - 5/7*k).coefficient_tuple()
(2/3, 3/5, 4/3, -5/7)
```

conjugate()

Return the conjugate of this quaternion.

EXAMPLES:

```
sage: A.<i,j,k> = QuaternionAlgebra(QQ,-5,-2)
sage: a = 3*i - j + 2
sage: type(a)
<type 'sage.algebras.quatalg.quaternion_algebra_element.QuaternionAlgebraElement_rational_fi
sage: a.conjugate()
2 - 3*i + j
sage: b = 1 + 1/3*i + 1/5*j - 1/7*k
sage: b.conjugate()
1 - 1/3*i - 1/5*j + 1/7*k
```

denominator()

Return the lowest common multiple of the denominators of the coefficients of i, j and k for this quaternion.

EXAMPLES:

```
sage: A = QuaternionAlgebra(QQ, -1, -1)
sage: A.<i,j,k> = QuaternionAlgebra(QQ, -1, -1)
sage: a = (1/2) + (1/5)*i + (5/12)*j + (1/13)*k
sage: a
1/2 + 1/5*i + 5/12*j + 1/13*k
sage: a.denominator()
780
sage: lcm([2, 5, 12, 13])
780
sage: (a * a).denominator()
608400
sage: (a + a).denominator()
390
```

denominator_and_integer_coefficient_tuple()

Return 5-tuple d, x, y, z, w, where this rational quaternion is equal to $(x + yi + zj + wk)/d$ and x, y, z, w do not share a common factor with d.

OUTPUT: 5-tuple of Integers

EXAMPLES:

```
sage: A.<i,j,k>=QuaternionAlgebra(-1,-2)
sage: (2 + 3*i + 4/3*j - 5*k).denominator_and_integer_coefficient_tuple()
(3, 6, 9, 4, -15)
```

integer_coefficient_tuple()

Returns integer part of this quaternion, ignoring the common denominator.

OUTPUT: 4-tuple of Integers

EXAMPLES:

```
sage: A.<i,j,k>=QuaternionAlgebra(-1,-2)
sage: (2 + 3*i + 4/3*j - 5*k).integer_coefficient_tuple()
(6, 9, 4, -15)
```

is_constant()

Return True if this quaternion is constant, i.e., has no i, j, or k term.

OUTPUT: bool

EXAMPLES:

```
sage: A.<i,j,k>=QuaternionAlgebra(-1,-2)
sage: A(1/3).is_constant()
True
sage: A(-1).is_constant()
True
```

```
sage: (1+i).is_constant()
False
sage: j.is_constant()
False
```

reduced_norm()
Return the reduced norm of self. Given a quaternion $x + yi + zj + wk$, this is $x^2 - ay^2 - bz^2 + abw^2$.
EXAMPLES:

```
sage: K.<i,j,k> = QuaternionAlgebra(QQ, -5, -2)
sage: i.reduced_norm()
5
sage: j.reduced_norm()
2
sage: a = 1/3 + 1/5*i + 1/7*j + k
sage: a.reduced_norm()
22826/2205
```

reduced_trace()
Return the reduced trace of self, which is $2x$ if self is $x + iy + zj + wk$.
EXAMPLES:

```
sage: K.<i,j,k> = QuaternionAlgebra(QQ, -5, -2)
sage: i.reduced_trace()
0
sage: j.reduced_trace()
0
sage: a = 1/3 + 1/5*i + 1/7*j + k
sage: a.reduced_trace()
2/3
```

clear_mpz_globals()

gmp_randrange()

init_mpz_globals()

unpickle_QuaternionAlgebraElement_generic_v0()
EXAMPLES:

```
sage: K.<X> = QQ[]
sage: Q.<i,j,k> = QuaternionAlgebra(Frac(K), -5,-19); z = 2/3 + i*X - X^2*j + X^3*k
sage: f, t = z.__reduce__()
sage: sage.algebras.quatalg.quaternion_algebra_element.unpickle_QuaternionAlgebraElement_generic
2/3 + X*i + (-X^2)*j + X^3*k
sage: sage.algebras.quatalg.quaternion_algebra_element.unpickle_QuaternionAlgebraElement_generic
True
```

unpickle_QuaternionAlgebraElement_number_field_v0()
EXAMPLES:

```
sage: K.<a> = QQ[2^(1/3)]; Q.<i,j,k> = QuaternionAlgebra(K, -3, a); z = i + j
sage: f, t = z.__reduce__()
sage: sage.algebras.quatalg.quaternion_algebra_element.unpickle_QuaternionAlgebraElement_number_
i + j
sage: sage.algebras.quatalg.quaternion_algebra_element.unpickle_QuaternionAlgebraElement_number_
True
```

unpickle_QuaternionAlgebraElement_rational_field_v0()
EXAMPLES:

```
sage: Q.<i,j,k> = QuaternionAlgebra(-5,-19); a = 2/3 + i*5/7 - j*2/5 +19/2
sage: f, t = a.__reduce__()
sage: sage.algebras.quatalg.quaternion_algebra_element.unpickle_QuaternionAlgebraElement_rationa
61/6 + 5/7*i - 2/5*j
```

CHAPTER

THIRTYTWO

MATRICES AND SPACES OF MATRICES

Sage provides native support for working with matrices over any commutative or noncommutative ring. The parent object for a matrix is a matrix space `MatrixSpace(R, n, m)` of all $n \times m$ matrices over a ring R.

To create a matrix, either use the `matrix(...)` function or create a matrix space using the `MatrixSpace` command and coerce an object into it.

Matrices also act on row vectors, which you create using the `vector(...)` command or by making a `VectorSpace` and coercing lists into it. The natural action of matrices on row vectors is from the right. Sage currently does not have a column vector class (on which matrices would act from the left), but this is planned.

In addition to native Sage matrices, Sage also includes the following additional ways to compute with matrices:

- Several math software systems included with Sage have their own native matrix support, which can be used from Sage. E.g., PARI, GAP, Maxima, and Singular all have a notion of matrices.
- The GSL C-library is included with Sage, and can be used via Cython.
- The `scipy` module provides support for *sparse* numerical linear algebra, among many other things.
- The `numpy` module, which you load by typing `import numpy` is included standard with Sage. It contains a very sophisticated and well developed array class, plus optimized support for *numerical linear algebra*. Sage's matrices over RDF and CDF (native floating-point real and complex numbers) use numpy.

32.1 Matrix Spaces.

You can create any space $\mathrm{Mat}_{n\times m}(R)$ of either dense or sparse matrices with given number of rows and columns over any commutative or noncommutative ring.

EXAMPLES:

```
sage: MS = MatrixSpace(QQ,6,6,sparse=True); MS
Full MatrixSpace of 6 by 6 sparse matrices over Rational Field
sage: MS.base_ring()
Rational Field
sage: MS = MatrixSpace(ZZ,3,5,sparse=False); MS
Full MatrixSpace of 3 by 5 dense matrices over Integer Ring
```

TESTS:

```
sage: matrix(RR,2,2,sparse=True)
[0.000000000000000 0.000000000000000]
[0.000000000000000 0.000000000000000]
```

```
sage: matrix(GF(11),2,2,sparse=True)
[0 0]
[0 0]
```

MatrixSpace(*base_ring, nrows, ncols=None, sparse=False*)

Create with the command

MatrixSpace(base_ring , nrows [, ncols] [, sparse])

The default value of the optional argument sparse is False. The default value of the optional argument ncols is nrows.

INPUT:

- `base_ring` - a ring
- `nrows` - int, the number of rows
- `ncols` - (default nrows) int, the number of columns
- `sparse` - (default false) whether or not matrices are given a sparse representation

OUTPUT: The unique space of all nrows x ncols matrices over base_ring.

EXAMPLES:

```
sage: MS = MatrixSpace(RationalField(),2)
sage: MS.base_ring()
Rational Field
sage: MS.dimension()
4
sage: MS.dims()
(2, 2)
sage: B = MS.basis()
sage: B
[
[1 0]
[0 0],
[0 1]
[0 0],
[0 0]
[1 0],
[0 0]
[0 1]
]
sage: B[0]
[1 0]
[0 0]
sage: B[1]
[0 1]
[0 0]
sage: B[2]
[0 0]
[1 0]
sage: B[3]
[0 0]
[0 1]
sage: A = MS.matrix([1,2,3,4])
sage: A
[1 2]
[3 4]
sage: MS2 = MatrixSpace(RationalField(),2,3)
```

```
sage: B = MS2.matrix([1,2,3,4,5,6])
sage: A*B
[ 9 12 15]
[19 26 33]

sage: M = MatrixSpace(ZZ, 10)
sage: M
Full MatrixSpace of 10 by 10 dense matrices over Integer Ring
sage: loads(M.dumps()) == M
True
```

class **MatrixSpace_generic**(*base_ring, nrows, ncols=None, sparse=False*)

The space of all nrows x ncols matrices over base_ring.

EXAMPLES:

```
sage: MatrixSpace(ZZ,10,5)
Full MatrixSpace of 10 by 5 dense matrices over Integer Ring
sage: MatrixSpace(ZZ,10,2^31)
...                                                                    # 32-bit
ValueError: number of rows and columns must be less than 2^31 (on a 32-bit computer -- use a 64-
Full MatrixSpace of 10 by 2147483648 dense matrices over Integer Ring   # 64-bit
```

base_extend(*R*)

Return base extension of this matrix space to R.

INPUT:

- R - ring

OUTPUT: a matrix space

EXAMPLES:

```
sage: Mat(ZZ,3,5).base_extend(QQ)
Full MatrixSpace of 3 by 5 dense matrices over Rational Field
sage: Mat(QQ,3,5).base_extend(GF(7))
...
TypeError: no base extension defined
```

basis()

Returns a basis for this matrix space.

> **Warning:** This will of course compute every generator of this matrix space. So for large matrices, this could take a long time, waste a massive amount of memory (for dense matrices), and is likely not very useful. Don't use this on large matrix spaces.

EXAMPLES:

```
sage: Mat(ZZ,2,2).basis()
[
[1 0]
[0 0],
[0 1]
[0 0],
[0 0]
[1 0],
[0 0]
[0 1]
]
```

change_ring(*R*)

Return matrix space over R with otherwise same parameters as self.

INPUT:

- R - ring

OUTPUT: a matrix space

EXAMPLES:

```
sage: Mat(QQ,3,5).change_ring(GF(7))
Full MatrixSpace of 3 by 5 dense matrices over Finite Field of size 7
```

column_space()

Return the module spanned by all columns of matrices in this matrix space. This is a free module of rank the number of columns. It will be sparse or dense as this matrix space is sparse or dense.

EXAMPLES:

```
sage: M = Mat(GF(9,'a'),20,5,sparse=True); M.column_space()
Sparse vector space of dimension 20 over Finite Field in a of size 3^2
```

construction()

EXAMPLES:

```
sage: A = matrix(ZZ, 2, [1..4], sparse=True)
sage: A.parent().construction()
(MatrixFunctor, Integer Ring)
sage: A.parent().construction()[0](QQ['x'])
Full MatrixSpace of 2 by 2 sparse matrices over Univariate Polynomial Ring in x over Rationa
sage: parent(A/2)
Full MatrixSpace of 2 by 2 sparse matrices over Rational Field
```

dimension()

Returns (m rows) * (n cols) of self as Integer

EXAMPLES:

```
sage: MS = MatrixSpace(ZZ,4,6)
sage: u = MS.dimension()
sage: u - 24 == 0
True
```

dims()

Returns (m row, n col) representation of self dimension

EXAMPLES:

```
sage: MS = MatrixSpace(ZZ,4,6)
sage: MS.dims()
(4, 6)
```

gen(*n*)

Return the n-th generator of this matrix space.

This doesn't compute all basis matrices, so it is reasonably intelligent.

EXAMPLES:

```
sage: M = Mat(GF(7),10000,5); M.ngens()
50000
sage: a = M.10
sage: a[:4]
[0 0 0 0 0]
[0 0 0 0 0]
[1 0 0 0 0]
[0 0 0 0 0]
```

get_action_impl(*S, op, self_on_left*)

identity_matrix()

Create an identity matrix in self. (Must be a space of square matrices).

EXAMPLES:

```
sage: MS1 = MatrixSpace(ZZ,4)
sage: MS2 = MatrixSpace(QQ,3,4)
sage: I = MS1.identity_matrix()
sage: I
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: Er = MS2.identity_matrix()
...
TypeError: self must be a space of square matrices
```

is_dense()

Returns True if matrices in self are dense and False otherwise.

EXAMPLES:

```
sage: Mat(RDF,2,3).is_sparse()
False
sage: Mat(RR,123456,22,sparse=True).is_sparse()
True
```

is_finite()

EXAMPLES:

```
sage: MatrixSpace(GF(101), 10000).is_finite()
True
sage: MatrixSpace(QQ, 2).is_finite()
False
```

is_sparse()

Returns True if matrices in self are sparse and False otherwise.

EXAMPLES:

```
sage: Mat(GF(2011),10000).is_sparse()
False
sage: Mat(GF(2011),10000,sparse=True).is_sparse()
True
```

matrix(*x=0, coerce=True, copy=True, rows=True*)

Create a matrix in self. The entries can be specified either as a single list of length nrows*ncols, or as a list of lists.

EXAMPLES:

```
sage: M = MatrixSpace(ZZ, 2)
sage: M.matrix([[1,0],[0,-1]])
[ 1  0]
[ 0 -1]
sage: M.matrix([1,0,0,-1])
[ 1  0]
[ 0 -1]
sage: M.matrix([1,2,3,4])
[1 2]
[3 4]
sage: M.matrix([1,2,3,4],rows=False)
```

```
[1 3]
[2 4]
```

matrix_space(*nrows=None, ncols=None, sparse=False*)

Return the matrix space with given number of rows, columns and sparcity over the same base ring as self, and defaults the same as self.

EXAMPLES:

```
sage: M = Mat(GF(7),100,200)
sage: M.matrix_space(5000)
Full MatrixSpace of 5000 by 200 dense matrices over Finite Field of size 7
sage: M.matrix_space(ncols=5000)
Full MatrixSpace of 100 by 5000 dense matrices over Finite Field of size 7
sage: M.matrix_space(sparse=True)
Full MatrixSpace of 100 by 200 sparse matrices over Finite Field of size 7
```

ncols()

Return the number of columns of matrices in this space.

EXAMPLES:

```
sage: M = Mat(ZZ['x'],200000,500000,sparse=True)
sage: M.ncols()
500000
```

ngens()

Return the number of generators of this matrix space, which is the number of entries in the matrices in this space.

EXAMPLES:

```
sage: M = Mat(GF(7),100,200); M.ngens()
20000
```

nrows()

Return the number of rows of matrices in this space.

EXAMPLES:

```
sage: M = Mat(ZZ,200000,500000)
sage: M.nrows()
200000
```

random_element(*density=1, *args, **kwds*)

INPUT:

- `density` - integer (default: 1) rough measure of the proportion of nonzero entries in the random matrix
- `*args, **kwds` - rest of parameters may be passed to the random_element function of the base ring. ("may be", since this function calls the randomize function on the zero matrix, which need not call the random_element function of the base ring at all in general.)

EXAMPLES:

```
sage: Mat(ZZ,2,5).random_element()
[ -8   2   0   0   1]
[ -1   2   1 -95  -1]
sage: Mat(QQ,2,5).random_element(density=0.5)
[  2   0   0   0   1]
[  0   0   0 1/2   0]
sage: Mat(QQ,3,sparse=True).random_element()
[  -1  1/3    1]
[   0   -1    0]
```

```
[  -1    1 -1/4]
sage: Mat(GF(9,'a'),3,sparse=True).random_element()
[      1       2       1]
[2*a + 1       a       2]
[      2 2*a + 2       1]
```

row_space()

Return the module spanned by all rows of matrices in this matrix space. This is a free module of rank the number of rows. It will be sparse or dense as this matrix space is sparse or dense.

EXAMPLES:

```
sage: M = Mat(ZZ,20,5,sparse=False); M.row_space()
Ambient free module of rank 5 over the principal ideal domain Integer Ring
```

zero_matrix()

Return the zero matrix.

dict_to_list(*entries, nrows, ncols*)

Given a dictionary of coordinate tuples, return the list given by reading off the nrows*ncols matrix in row order.

EXAMLES:

```
sage: from sage.matrix.matrix_space import dict_to_list
sage: d = {}
sage: d[(0,0)] = 1
sage: d[(1,1)] = 2
sage: dict_to_list(d, 2, 2)
[1, 0, 0, 2]
sage: dict_to_list(d, 2, 3)
[1, 0, 0, 0, 2, 0]
```

is_MatrixSpace(*x*)

Returns True if self is an instance of MatrixSpace returns false if self is not an instance of MatrixSpace

EXAMPLES:

```
sage: from sage.matrix.matrix_space import is_MatrixSpace
sage: MS = MatrixSpace(QQ,2)
sage: A = MS.random_element()
sage: is_MatrixSpace(MS)
True
sage: is_MatrixSpace(A)
False
sage: is_MatrixSpace(5)
False
```

list_to_dict(*entries, nrows, ncols, rows=True*)

Given a list of entries, create a dictionary whose keys are coordinate tuples and values are the entries.

EXAMPLES:

```
sage: from sage.matrix.matrix_space import list_to_dict
sage: d = list_to_dict([1,2,3,4],2,2)
sage: d[(0,1)]
2
sage: d = list_to_dict([1,2,3,4],2,2,rows=False)
sage: d[(0,1)]
3
```

test_trivial_matrices_inverse(*ring, sparse=True, checkrank=True*)

Tests inversion, determinant and is_inverstible for trivial matrices.

This function is a helper to check that the inversion of trivial matrices (of size 0x0, nx0, 0xn or 1x1) is handled consistently by the various implementation of matrices. The coherency is checked through a bunch of assertions. If an inconsistency is found, an AssertionError is raised which should make clear what is the problem.

INPUT:

- `ring` - a ring
- `sparse` - a boolean
- `checkrank` - a boolean

OUTPUT:

- nothing if everything is correct otherwise raise an AssertionError

The methods determinant, is_invertible, rank and inverse are checked for

- the 0x0 empty identity matrix
- the 0x3 and 3x0 matrices
- the 1x1 null matrix [0]
- the 1x1 identity matrix [1]

If `checkrank` is `False` then the rank is not checked. This is used the check matrix over ring where echelon form is not implemented.

TODO: must be adapted to category check framework when ready (see trac #5274).

TESTS:

```
sage: from sage.matrix.matrix_space import test_trivial_matrices_inverse as tinv
sage: tinv(ZZ, sparse=True)
sage: tinv(ZZ, sparse=False)
sage: tinv(QQ, sparse=True)
sage: tinv(QQ, sparse=False)
sage: tinv(GF(11), sparse=True)
sage: tinv(GF(11), sparse=False)
sage: tinv(GF(2), sparse=True)
sage: tinv(GF(2), sparse=False)
sage: tinv(SR, sparse=True)
sage: tinv(SR, sparse=False)
sage: tinv(RDF, sparse=True)
sage: tinv(RDF, sparse=False)
sage: tinv(CDF, sparse=True)
sage: tinv(CDF, sparse=False)
sage: tinv(CyclotomicField(7), sparse=True)
sage: tinv(CyclotomicField(7), sparse=False)
```

TODO: As soon as rank of sparse matrix over QQ['x,y'] is implemented, please remove the following test and the `checkrank=False` in the next one:

sage: MatrixSpace(QQ['x,y'], 3, 3, sparse=True)(1).rank() Traceback (most recent call last): ... NotImplementedError: echelon form over Multivariate Polynomial Ring in x, y over Rational Field not yet implemented sage: tinv(QQ['x,y'], sparse=True, checkrank=False)

TODO: As soon as rank of dense matrix over QQ['x,y'] is implemented, please remove the following test and the `checkrank=False` in the next one:

sage: MatrixSpace(QQ['x,y'], 3, 3, sparse=False)(1).rank() Traceback (most recent call last): ... RuntimeError: BUG: matrix pivots should have been set but weren't, matrix parent = 'Full MatrixSpace of 3 by 3 dense matrices over Multivariate Polynomial Ring in x, y over Rational Field'

sage: tinv(QQ['x,y'], sparse=False, checkrank=False)

32.2 Matrix Constructor.

Matrix(**args, **kwds*)

Create a matrix.

INPUT: The matrix command takes the entries of a matrix, optionally preceded by a ring and the dimensions of the matrix, and returns a matrix.

The entries of a matrix can be specified as a flat list of elements, a list of lists (i.e., a list of rows), a list of Sage vectors, or a dictionary having positions as keys and matrix entries as values (see the examples). You can create a matrix of zeros by passing an empty list or the integer zero for the entries. To construct a multiple of the identity (cI), you can specify square dimensions and pass in c. Calling matrix() with a Sage object may return something that makes sense. Calling matrix() with a numpy array will convert the array to a matrix.

The ring, number of rows, and number of columns of the matrix can be specified by setting the ring, nrows, or ncols parameters or by passing them as the first arguments to the function in the order ring, nrows, ncols. The ring defaults to ZZ if it is not specified or cannot be determined from the entries. If the numbers of rows and columns are not specified and cannot be determined, then an empty 0x0 matrix is returned.

- `ring` - the base ring for the entries of the matrix.
- `nrows` - the number of rows in the matrix.
- `ncols` - the number of columns in the matrix.
- `sparse` - create a sparse matrix. This defaults to True when the entries are given as a dictionary, otherwise defaults to False.

OUTPUT:

a matrix

EXAMPLES:

```
sage: m=matrix(2); m; m.parent()
[0 0]
[0 0]
Full MatrixSpace of 2 by 2 dense matrices over Integer Ring

sage: m=matrix(2,3); m; m.parent()
[0 0 0]
[0 0 0]
Full MatrixSpace of 2 by 3 dense matrices over Integer Ring

sage: m=matrix(QQ,[[1,2,3],[4,5,6]]); m; m.parent()
[1 2 3]
[4 5 6]
Full MatrixSpace of 2 by 3 dense matrices over Rational Field

sage: v1=vector((1,2,3))
sage: v2=vector((4,5,6))
sage: m=matrix([v1,v2]); m; m.parent()
[1 2 3]

AUTHORS:

- ??: Initial implementation
- Jason Grout (2008-03): almost a complete rewrite, with bits and pieces from the original implementation

block_diagonal_matrix(*sub_matrices, **kwds)

Create a block matrix whose diagonal block entries are given by sub_matrices, with zero elsewhere.

See also `block_matrix`.

EXAMPLES:

```
sage: A = matrix(ZZ, 2, [1,2,3,4])
sage: block_diagonal_matrix(A, A)
[1 2|0 0]
[3 4|0 0]
[---+---]
[0 0|1 2]
[0 0|3 4]
```

The sub-matrices need not be square:

```
sage: B = matrix(QQ, 2, 3, range(6))
sage: block_diagonal_matrix(~A, B)
[  -2    1|   0    0    0]
[ 3/2 -1/2|   0    0    0]
[---------+--------------]
[   0    0|   0    1    2]
[   0    0|   3    4    5]
```

block_matrix(*sub_matrices, nrows=None, ncols=None, subdivide=True*)

Returns a larger matrix made by concatinating the sub_matrices (rows first, then columns). For example, the matrix

```
[ A B ]
[ C D ]
```

is made up of submatrices A, B, C, and D.

INPUT:

- `sub_matrices` - matrices (must be of the correct size, or constants)
- `nrows` - (optional) the number of block rows
- `ncols` - (optional) the number of block cols
- `subdivide` - boolean, whether or not to add subdivision information to the matrix

EXAMPLES:

```
sage: A = matrix(QQ, 2, 2, [3,9,6,10])
sage: block_matrix([A, -A, ~A, 100*A])
[    3     9|   -3    -9]
[    6    10|   -6   -10]
[-----------+-----------]
[-5/12   3/8|  300   900]
[  1/4  -1/8|  600  1000]
```

One can use constant entries:

```
sage: block_matrix([1, A, 0, 1])
[ 1  0| 3  9]
[ 0  1| 6 10]
[-----+-----]
[ 0  0| 1  0]
[ 0  0| 0  1]
```

One can specify the number of rows or columns (optional for square number of matrices):

```
sage: block_matrix([A, -A, ~A, 100*A], ncols=4)
[    3     9|   -3    -9|-5/12   3/8|  300   900]
[    6    10|   -6   -10|  1/4  -1/8|  600  1000]

sage: block_matrix([A, -A, ~A, 100*A], nrows=1)
[    3     9|   -3    -9|-5/12   3/8|  300   900]
[    6    10|   -6   -10|  1/4  -1/8|  600  1000]
```

It handle baserings nicely too:

```
sage: R.<x> = ZZ['x']
sage: block_matrix([1/2, A, 0, x-1])
[  1/2     0|    3     9]
[    0   1/2|    6    10]
[-----------+-----------]
[    0     0|x - 1     0]
[    0     0|    0 x - 1]
sage: block_matrix([1/2, A, 0, x-1]).parent()
Full MatrixSpace of 4 by 4 dense matrices over Univariate Polynomial Ring in x over Rational Fie
```

Subdivisions are optional:

```
sage: B = matrix(QQ, 2, 3, range(6))
sage: block_matrix([~A, B, B, ~A], subdivide=False)
[-5/12   3/8     0     1     2]
[  1/4  -1/8     3     4     5]
[    0     1     2 -5/12   3/8]
[    3     4     5   1/4  -1/8]
```

diagonal_matrix(*arg0=None, arg1=None, arg2=None, sparse=None*)

INPUT:

Supported formats

1. diagonal_matrix(diagonal_entries, [sparse=True]): diagonal matrix with flat list of entries
2. diagonal_matrix(nrows, diagonal_entries, [sparse=True]): diagonal matrix with flat list of entries and the rest zeros
3. diagonal_matrix(ring, diagonal_entries, [sparse=True]): diagonal matrix over specified ring with flat list of entries
4. diagonal_matrix(ring, nrows, diagonal_entries, [sparse=True]): diagonal matrix over specified ring with flat list of entries and the rest zeros
5. diagonal_matrix(vect, [sparse=True]): diagonal matrix with entries taken from a vector

The sparse option is optional, must be explicitly named (i.e., sparse=True), and may be either True or False.

EXAMPLES:

Input format 1:

```
sage: diagonal_matrix([1,2,3])
[1 0 0]
[0 2 0]
[0 0 3]
```

Input format 2:

```
sage: diagonal_matrix(3, [1,2])
[1 0 0]
[0 2 0]
[0 0 0]
```

Input format 3:

```
sage: diagonal_matrix(GF(3), [1,2,3])
[1 0 0]
[0 2 0]
[0 0 0]
```

Input format 4:

```
sage: diagonal_matrix(GF(3), 3, [8,2])
[2 0 0]
[0 2 0]
[0 0 0]
```

Input format 5:

```
sage: diagonal_matrix(vector(GF(3),[1,2,3]))
[1 0 0]
[0 2 0]
[0 0 0]
```

identity_matrix(*ring, n=0, sparse=False*)

Return the $n \times n$ identity matrix over the given ring.

The default ring is the integers.

EXAMPLES:

```
sage: M = identity_matrix(QQ, 2); M
[1 0]
[0 1]
sage: M.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
sage: M = identity_matrix(2); M
[1 0]
[0 1]
sage: M.parent()
Full MatrixSpace of 2 by 2 dense matrices over Integer Ring
sage: M = identity_matrix(3, sparse=True); M
[1 0 0]
[0 1 0]
[0 0 1]
sage: M.parent()
Full MatrixSpace of 3 by 3 sparse matrices over Integer Ring
```

jordan_block(*eigenvalue, size, sparse=False*)

Form the Jordan block with the specified size associated with the eigenvalue.

INPUT:

- `eigenvalue` - eigenvalue for the diagonal entries of the block
- `size` - size of the Jordan block
- `sparse` - (default False) if True, return a sparse matrix

EXAMPLE:

```
sage: jordan_block(5, 3)
[5 1 0]
[0 5 1]
[0 0 5]
```

matrix(**args, **kwds*)

Create a matrix.

INPUT: The matrix command takes the entries of a matrix, optionally preceded by a ring and the dimensions of the matrix, and returns a matrix.

The entries of a matrix can be specified as a flat list of elements, a list of lists (i.e., a list of rows), a list of Sage vectors, or a dictionary having positions as keys and matrix entries as values (see the examples). You can create a matrix of zeros by passing an empty list or the integer zero for the entries. To construct a multiple of the identity (cI), you can specify square dimensions and pass in c. Calling matrix() with a Sage object may return something that makes sense. Calling matrix() with a numpy array will convert the array to a matrix.

The ring, number of rows, and number of columns of the matrix can be specified by setting the ring, nrows, or ncols parameters or by passing them as the first arguments to the function in the order ring, nrows, ncols. The ring defaults to ZZ if it is not specified or cannot be determined from the entries. If the numbers of rows and columns are not specified and cannot be determined, then an empty 0x0 matrix is returned.

- `ring` - the base ring for the entries of the matrix.
- `nrows` - the number of rows in the matrix.
- `ncols` - the number of columns in the matrix.
- `sparse` - create a sparse matrix. This defaults to True when the entries are given as a dictionary, otherwise defaults to False.

OUTPUT:

a matrix

EXAMPLES:

```
sage: m=matrix(2); m; m.parent()
[0 0]
[0 0]
Full MatrixSpace of 2 by 2 dense matrices over Integer Ring

sage: m=matrix(2,3); m; m.parent()
[0 0 0]
[0 0 0]
Full MatrixSpace of 2 by 3 dense matrices over Integer Ring

sage: m=matrix(QQ,[[1,2,3],[4,5,6]]); m; m.parent()
[1 2 3]
[4 5 6]
Full MatrixSpace of 2 by 3 dense matrices over Rational Field

sage: v1=vector((1,2,3))
sage: v2=vector((4,5,6))
sage: m=matrix([v1,v2]); m; m.parent()
[1 2 3]
[4 5 6]
Full MatrixSpace of 2 by 3 dense matrices over Integer Ring
```

```
sage: m=matrix(QQ,2,[1,2,3,4,5,6]); m; m.parent()
[1 2 3]
[4 5 6]
Full MatrixSpace of 2 by 3 dense matrices over Rational Field

sage: m=matrix(QQ,2,3,[1,2,3,4,5,6]); m; m.parent()
[1 2 3]
[4 5 6]
Full MatrixSpace of 2 by 3 dense matrices over Rational Field

sage: m=matrix({(0,1): 2, (1,1):2/5}); m; m.parent()
[  0   2]
[  0 2/5]
Full MatrixSpace of 2 by 2 sparse matrices over Rational Field

sage: m=matrix(QQ,2,3,{(1,1): 2}); m; m.parent()
[0 0 0]
[0 2 0]
Full MatrixSpace of 2 by 3 sparse matrices over Rational Field

sage: import numpy
sage: n=numpy.array([[1,2],[3,4]],float)
sage: m=matrix(n); m; m.parent()
[1.0 2.0]
[3.0 4.0]
Full MatrixSpace of 2 by 2 dense matrices over Real Double Field

sage: v = vector(ZZ, [1, 10, 100])
sage: m=matrix(v); m; m.parent()
[  1  10 100]
Full MatrixSpace of 1 by 3 dense matrices over Integer Ring
sage: m=matrix(GF(7), v); m; m.parent()
[1 3 2]
Full MatrixSpace of 1 by 3 dense matrices over Finite Field of size 7

sage: g = graphs.PetersenGraph()
sage: m = matrix(g); m; m.parent()

AUTHORS:

- ??: Initial implementation
- Jason Grout (2008-03): almost a complete rewrite, with bits and pieces from the original implementation

ncols_from_dict(*d*)

Given a dictionary that defines a sparse matrix, return the number of columns that matrix should have.

This is for internal use by the matrix function.

INPUT:

- d - dict

OUTPUT:

integer

EXAMPLES:

```
sage: sage.matrix.constructor.ncols_from_dict({})
0
```

Here the answer is 301 not 300, since there is a 0-th row.

```
sage: sage.matrix.constructor.ncols_from_dict({(4,300):10})
301
```

nrows_from_dict(*d*)

Given a dictionary that defines a sparse matrix, return the number of rows that matrix should have.

This is for internal use by the matrix function.

INPUT:

- d - dict

OUTPUT:

integer

EXAMPLES:

```
sage: sage.matrix.constructor.nrows_from_dict({})
0
```

Here the answer is 301 not 300, since there is a 0-th row.

:: sage: sage.matrix.constructor.nrows_from_dict({(300,4):10}) 301

prepare(*w*)

Given a list w of numbers, find a common ring that they all canonically map to, and return the list of images of the elements of w in that ring along with the ring.

This is for internal use by the matrix function.

INPUT:

- w - list

OUTPUT:

list, ring

EXAMPLES:

```
sage: sage.matrix.constructor.prepare([-2, Mod(1,7)])
([5, 1], Ring of integers modulo 7)
```

Notice that the elements must all canonically coerce to a common ring (since Sequence is called):

```
sage: sage.matrix.constructor.prepare([2/1, Mod(1,7)])
...
TypeError: unable to find a common ring for all elements
```

prepare_dict(*w*)

Given a dictionary w of numbers, find a common ring that they all canonically map to, and return the dictionary of images of the elements of w in that ring along with the ring.

This is for internal use by the matrix function.

INPUT:

- `w` - dict

OUTPUT:

dict, ring

EXAMPLES:

```
sage: sage.matrix.constructor.prepare_dict({(0,1):2, (4,10):Mod(1,7)})
({(0, 1): 2, (4, 10): 1}, Ring of integers modulo 7)
```

random_matrix(*R, nrows, ncols=None, sparse=False, density=1, *args, **kwds*)

Return a random matrix with entries in the ring R.

INPUT:

- `R` - a ring
- `nrows` - integer; number of rows
- `ncols` - (default: None); number of columns; if None defaults to nrows
- `sparse` - (default; False); whether or not matrix is sparse.
- `density` - integer (default: 1)
- `*args, **kwds` - passed on to randomize function

EXAMPLES:

```
sage: A = random_matrix(ZZ,50,x=2^16)     # entries are up to 2^16 i size
sage: A
50 x 50 dense matrix over Integer Ring
```

zero_matrix(*ring, nrows, ncols=None, sparse=False*)

Return the $nrows \times ncols$ zero matrix over the given ring.

The default ring is the integers.

EXAMPLES:

```
sage: M = zero_matrix(QQ, 2); M
[0 0]
[0 0]
sage: M.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
sage: M = zero_matrix(2, 3); M
[0 0 0]
[0 0 0]
sage: M.parent()
Full MatrixSpace of 2 by 3 dense matrices over Integer Ring
sage: M = zero_matrix(3, 1, sparse=True); M
[0]
[0]
[0]
sage: M.parent()
Full MatrixSpace of 3 by 1 sparse matrices over Integer Ring
```

32.3 Matrices over an arbitrary ring

AUTHORS:

- William Stein
- Martin Albrecht: conversion to Pyrex
- Jaap Spies: various functions
- Gary Zablackis: fixed a sign bug in generic determinant.
- William Stein and Robert Bradshaw - complete restructuring.
- Rob Beezer - refactor kernel functions.

Elements of matrix spaces are of class `Matrix` (or a class derived from Matrix). They can be either sparse or dense, and can be defined over any base ring.

EXAMPLES:

We create the 2×3 matrix

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{pmatrix}$$

as an element of a matrix space over $\mathbf{Q}$:

```
sage: M = MatrixSpace(QQ,2,3)
sage: A = M([1,2,3, 4,5,6]); A
[1 2 3]
[4 5 6]
sage: A.parent()
Full MatrixSpace of 2 by 3 dense matrices over Rational Field
```

Alternatively, we could create A more directly as follows (which would completely avoid having to create the matrix space):

```
sage: A = matrix(QQ, 2, [1,2,3, 4,5,6]); A
[1 2 3]
[4 5 6]
```

We next change the top-right entry of A. Note that matrix indexing is 0-based in Sage, so the top right entry is $(0, 2)$, which should be thought of as "row number 0, column number 2".

```
sage: A[0,2] = 389
sage: A
[  1   2 389]
[  4   5   6]
```

Also notice how matrices print. All columns have the same width and entries in a given column are right justified. Next we compute the reduced row echelon form of A.

```
sage: A.echelon_form()
[      1       0 -1933/3]
[      0       1  1550/3]
```

We save and load a matrix:

```
sage: A = matrix(Integers(8),3,range(9))
sage: loads(dumps(A)) == A
True
```

MUTABILITY: Matrices are either immutable or not. When initially created, matrices are typically mutable, so one can change their entries. Once a matrix A is made immutable using `A.set_immutable()` the entries of A cannot be changed, and A can never be made mutable again. However, properies of A such as its rank, characteristic polynomial, etc., are all cached so computations involving A may be more efficient. Once A is made immutable it cannot be changed back. However, one can obtain a mutable copy of A using `A.copy()`.

EXAMPLES:

```
sage: A = matrix(RR,2,[1,10,3.5,2])
sage: A.set_immutable()
sage: A.copy() is A
False
```

The echelon form method always returns immutable matrices with known rank.

EXAMPLES:

```
sage: A = matrix(Integers(8),3,range(9))
sage: A.determinant()
0
sage: A[0,0] = 5
sage: A.determinant()
1
sage: A.set_immutable()
sage: A[0,0] = 5
...
ValueError: matrix is immutable; please change a copy instead (use self.copy()).
```

32.3.1 Implementation and Design

Class Diagram (an x means that class is currently supported):

```
x Matrix
x   Matrix_sparse
x     Matrix_generic_sparse
x     Matrix_integer_sparse
x     Matrix_rational_sparse
      Matrix_cyclo_sparse
x     Matrix_modn_sparse
      Matrix_RR_sparse
      Matrix_CC_sparse
      Matrix_RDF_sparse
      Matrix_CDF_sparse

x  Matrix_dense
x     Matrix_generic_dense
x     Matrix_integer_dense
      Matrix_integer_2x2_dense
x     Matrix_rational_dense
      Matrix_cyclo_dense    -- idea: restrict scalars to QQ, compute charpoly there, then factor
x     Matrix_modn_dense
      Matrix_RR_dense
      Matrix_CC_dense
x     Matrix_real_double_dense
x     Matrix_complex_double_dense
```

The corresponding files in the sage/matrix library code directory are named

```
[matrix] [base ring] [dense or sparse].
```

See the files `matrix_template.pxd` and `matrix_template.pyx`.

```
New matrices types can only be implemented in Cython.

********** LEVEL 1  **********
NON-OPTIONAL
For each base field it is *absolutely* essential to completely
implement the following functionality for that base ring:

   * __new__       -- should use sage_malloc from ext/stdsage.pxi (only
                      needed if allocate memory)
   * __init__      -- this signature: 'def __init__(self, parent, entries, copy, coerce)'
   * __dealloc__   -- use sage_free (only needed if allocate memory)
   * set_unsafe(self, size_t i, size_t j, x) -- doesn't do bounds or any other checks; assumes x is
   * get_unsafe(self, size_t i, size_t j) -- doesn't do checks
   * __richcmp__    -- always the same (I don't know why its needed -- bug in PYREX).
********** LEVEL 2  **********

IMPORTANT (and *highly* recommended):

After getting the special class with all level 1 functionality to
work, implement all of the following (they should not change
functionality, except speed (always faster!) in any way):

   * def _pickle(self):
```

```
        return data, version
   * def _unpickle(self, data, int version)
        reconstruct matrix from given data and version; may assume _parent, _nrows, and _ncols are
        Use version numbers >= 0 so if you change the pickle strategy then
        old objects still unpickle.
   * cdef _list -- list of underlying elements (need not be a copy)
   * cdef _dict -- sparse dictionary of underlying elements
   * cdef _add_ -- add two matrices with identical parents
   * _matrix_times_matrix_c_impl -- multiply two matrices with compatible dimensions and
                                    identical base rings (both sparse or both dense)
   * cdef _cmp_c_impl -- compare two matrices with identical parents
   * cdef _lmul_c_impl -- multiply this matrix on the right by a scalar, i.e., self * scalar
   * cdef _rmul_c_impl -- multiply this matrix on the left by a scalar, i.e., scalar * self
   * __copy__
   * __neg__

The list and dict returned by _list and _dict will *not* be changed
by any internal algorithms and are not accessible to the user.

********** LEVEL 3  **********
OPTIONAL:

   * cdef _sub_
   * __invert__
   * _multiply_classical
   * __deepcopy__

Further special support:
   * Matrix windows -- to support Strassen multiplication for a given base ring.
   * Other functions, e.g., transpose, for which knowing the
     specific representation can be helpful.

.. note::

   - For caching, use self.fetch and self.cache.

   - Any method that can change the matrix should call
     ``check_mutability()`` first.  There are also many fast cdef'd bounds checking methods.

   - Kernels of matrices
     Implement only a left_kernel() or right_kernel() method, whichever requires
     the least overhead (usually meaning little or no transpose'ing).  Let the
     methods in the matrix2 class handle left, right, generic kernel distinctions.
```

32.4 Abstract base class for matrices.

For design documentation see matrix/docs.py.

class Matrix()

is_Matrix()

EXAMPLES:

```
sage: from sage.matrix.matrix import is_Matrix
sage: is_Matrix(0)
False
```

```
sage: is_Matrix(matrix([[1,2],[3,4]]))
True
```

32.5 Base class for matrices, part 0

Note: For design documentation see matrix/docs.py.

EXAMPLES:

```
sage: matrix(2,[1,2,3,4])
[1 2]
[3 4]
```

class Matrix()

A generic matrix.

The `Matrix` class is the base class for all matrix classes. To create a `Matrix`, first create a `MatrixSpace`, then coerce a list of elements into the `MatrixSpace`. See the documentation of `MatrixSpace` for more details.

EXAMPLES:

We illustrate matrices and matrix spaces. Note that no actual matrix that you make should have class Matrix; the class should always be derived from Matrix.

```
sage: M = MatrixSpace(CDF,2,3); M
Full MatrixSpace of 2 by 3 dense matrices over Complex Double Field
sage: a = M([1,2,3,  4,5,6]); a
[1.0 2.0 3.0]
[4.0 5.0 6.0]
sage: type(a)
<type 'sage.matrix.matrix_complex_double_dense.Matrix_complex_double_dense'>
sage: parent(a)
Full MatrixSpace of 2 by 3 dense matrices over Complex Double Field
```

```
sage: matrix(CDF, 2,3, [1,2,3, 4,5,6])
[1.0 2.0 3.0]
[4.0 5.0 6.0]
sage: Mat(CDF,2,3)(range(1,7))
[1.0 2.0 3.0]
[4.0 5.0 6.0]
```

```
sage: Q.<i,j,k> = QuaternionAlgebra(QQ, -1,-1)
sage: matrix(Q,2,1,[1,2])
[1]
[2]
```

act_on_polynomial()

Returns the polynomial f(self*x).

INPUT:

- `self` - an nxn matrix
- `f` - a polynomial in n variables x=(x1,...,xn)

OUTPUT: The polynomial f(self*x).

EXAMPLES:

```
sage: R.<x,y> = QQ[]
sage: x, y = R.gens()
sage: f = x**2 - y**2
sage: M = MatrixSpace(QQ, 2)
sage: A = M([1,2,3,4])
sage: A.act_on_polynomial(f)
-8*x^2 - 20*x*y - 12*y^2
```

add_multiple_of_column()

Add s times column j to column i.

EXAMPLES: We add -1 times the third column to the second column of an integer matrix, remembering to start numbering cols at zero:

```
sage: a = matrix(ZZ,2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: a.add_multiple_of_column(1,2,-1)
sage: a
[ 0 -1  2]
[ 3 -1  5]
```

To add a rational multiple, we first need to change the base ring:

```
sage: a = a.change_ring(QQ)
sage: a.add_multiple_of_column(1,0,1/3)
sage: a
[ 0 -1  2]
[ 3  0  5]
```

If not, we get an error message:

```
sage: a.add_multiple_of_column(1,0,i)
...
TypeError: Multiplying column by Symbolic Ring element cannot be done over Rational Field, u
```

add_multiple_of_row()

Add s times row j to row i.

EXAMPLES: We add -3 times the first row to the second row of an integer matrix, remembering to start numbering rows at zero:

```
sage: a = matrix(ZZ,2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: a.add_multiple_of_row(1,0,-3)
sage: a
[ 0  1  2]
[ 3  1 -1]
```

To add a rational multiple, we first need to change the base ring:

```
sage: a = a.change_ring(QQ)
sage: a.add_multiple_of_row(1,0,1/3)
sage: a
[   0    1    2]
[   3  4/3 -1/3]
```

If not, we get an error message:

```
sage: a.add_multiple_of_row(1,0,i)
...
TypeError: Multiplying row by Symbolic Ring element cannot be done over Rational Field, use
```

base_ring()

change_ring()

Return the matrix obtained by coercing the entries of this matrix into the given ring.

Always returns a copy (unless self is immutable, in which case returns self).

EXAMPLES:

```
sage: A = Matrix(QQ, 2, 2, [1/2, 1/3, 1/3, 1/4])
sage: A.parent()
 Full MatrixSpace of 2 by 2 dense matrices over Rational Field
sage: A.change_ring(GF(25,'a'))
[3 2]
[2 4]
sage: A.change_ring(GF(25,'a')).parent()
 Full MatrixSpace of 2 by 2 dense matrices over Finite Field in a of size 5^2
sage: A.change_ring(ZZ)
...
TypeError: matrix has denominators so can't change to ZZ.
```

Changing rings preserves subdivisions:

```
sage: A.subdivide([1], []); A
[1/2 1/3]
[-------]
[1/3 1/4]
sage: A.change_ring(GF(25,'a'))
[3 2]
[---]
[2 4]
```

commutator()

Return the commutator self*other - other*self.

EXAMPLES:

```
sage: A = Matrix(ZZ, 2, 2, range(4))
sage: B = Matrix(ZZ, 2, 2, [0, 1, 0, 0])
sage: A.commutator(B)
[-2 -3]
[ 0  2]
sage: A.commutator(B) == -B.commutator(A)
True
```

copy()

Make a copy of self. If self is immutable, the copy will be mutable.

> **Warning:** The individual elements aren't themselves copied (though the list is copied). This shouldn't matter, since ring elements are (almost!) always immutable in Sage.

EXAMPLES:

```
sage: R.<x> = QQ['x']
sage: a = matrix(R,2,[x+1,2/3,  x^2/2, 1+x^3]); a
[  x + 1     2/3]
[1/2*x^2 x^3 + 1]
sage: b = a.copy()
sage: b[0,0] = 5
sage: b
[      5     2/3]
[1/2*x^2 x^3 + 1]
sage: a
```

```
[  x + 1     2/3]
[1/2*x^2 x^3 + 1]

sage: b = copy(a)
sage: f = b[0,0]; f[0] = 10
...
IndexError: polynomials are immutable
```

dict()

Dictionary of the elements of self with keys pairs (i,j) and values the nonzero entries of self.

It is safe to change the returned dictionary.

EXAMPLES:

```
sage: R.<x,y> = QQ[]
sage: a = matrix(R,2,[x,y,0, 0,0,2*x+y]); a
[      x       y       0]
[      0       0 2*x + y]
sage: d = a.dict(); d
{(0, 1): y, (1, 2): 2*x + y, (0, 0): x}
```

Notice that changing the returned list does not change a (the list is a copy):

```
sage: d[0,0] = 25
sage: a
[      x       y       0]
[      0       0 2*x + y]
```

is_dense()

Returns True if this is a dense matrix.

In Sage, being dense is a property of the underlying representation, not the number of nonzero entries.

EXAMPLES:

```
sage: matrix(QQ,2,2,range(4)).is_dense()
True
sage: matrix(QQ,2,2,range(4),sparse=True).is_dense()
False
```

is_immutable()

Return True if this matrix is immutable.

See the documentation for self.set_immutable for more details about mutability.

EXAMPLES:

```
sage: A = Matrix(QQ['t','s'], 2, 2, range(4))
sage: A.is_immutable()
False
sage: A.set_immutable()
sage: A.is_immutable()
True
```

is_invertible()

Return True if this matrix is invertible.

EXAMPLES: The following matrix is invertible over $\mathbf{Q}$ but not over $\mathbf{Z}$.

```
sage: A = MatrixSpace(ZZ, 2)(range(4))
sage: A.is_invertible()
False
sage: A.matrix_over_field().is_invertible()
True
```

The inverse function is a constructor for matrices over the fraction field, so it can work even if A is not invertible.

```
sage: ~A   # inverse of A
[-3/2  1/2]
[   1    0]
```

The next matrix is invertible over $\mathbf{Z}$.

```
sage: A = MatrixSpace(IntegerRing(),2)([1,10,0,-1])
sage: A.is_invertible()
True
sage: ~A                # compute the inverse
[ 1 10]
[ 0 -1]
```

The following nontrivial matrix is invertible over $\mathbf{Z}[x]$.

```
sage: R.<x> = PolynomialRing(IntegerRing())
sage: A = MatrixSpace(R,2)([1,x,0,-1])
sage: A.is_invertible()
True
sage: ~A
[ 1  x]
[ 0 -1]
```

is_mutable()

Return True if this matrix is mutable.

See the documentation for self.set_immutable for more details about mutability.

EXAMPLES:

```
sage: A = Matrix(QQ['t','s'], 2, 2, range(4))
sage: A.is_mutable()
True
sage: A.set_immutable()
sage: A.is_mutable()
False
```

is_sparse()

Return True if this is a sparse matrix.

In Sage, being sparse is a property of the underlying representation, not the number of nonzero entries.

EXAMPLES:

```
sage: matrix(QQ,2,2,range(4)).is_sparse()
False
sage: matrix(QQ,2,2,range(4),sparse=True).is_sparse()
True
```

is_square()

Return True precisely if this matrix is square, i.e., has the same number of rows and columns.

EXAMPLES:

```
sage: matrix(QQ,2,2,range(4)).is_square()
True
sage: matrix(QQ,2,3,range(6)).is_square()
False
```

is_symmetric()

Returns True if this is a symmetric matrix.

iterates()

Let A be this matrix and v be a free module element. If rows is True, return a matrix whose rows are the

entries of the following vectors:

$$v, vA, vA^2, \ldots, vA^{n-1}.$$

If rows is False, return a matrix whose columns are the entries of the following vectors:

$$v, Av, A^2v, \ldots, A^{n-1}v.$$

INPUT:

- v - free module element
- n - nonnegative integer

EXAMPLES:

```
sage: A = matrix(ZZ,2, [1,1,3,5]); A
[1 1]
[3 5]
sage: v = vector([1,0])
sage: A.iterates(v,0)
[]
sage: A.iterates(v,5)
[  1   0]
[  1   1]
[  4   6]
[ 22  34]
[124 192]
```

Another example:

```
sage: a = matrix(ZZ,3,range(9)); a
[0 1 2]
[3 4 5]
[6 7 8]
sage: v = vector([1,0,0])
sage: a.iterates(v,4)
[  1   0   0]
[  0   1   2]
[ 15  18  21]
[180 234 288]
sage: a.iterates(v,4,rows=False)
[  1   0  15 180]
[  0   3  42 558]
[  0   6  69 936]
```

linear_combination_of_columns()

Return the linear combination of the columns of self given by the coefficients in the list v. Raise a ValueError if the length of v is longer than the number of columns of the matrix.

INPUT:

- v - list of length at most the number of columns of self (less is fine)

EXAMPLES:

```
sage: a = matrix(ZZ,2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: a.linear_combination_of_columns([1,1,1])
(3, 12)
sage: a.linear_combination_of_columns([0,0,0])
(0, 0)
sage: a.linear_combination_of_columns([1/2,2/3,3/4])
```

```
 (13/6, 95/12)
sage: matrix(QQ,2,0).linear_combination_of_columns([])
(0, 0)
```

The length of v can be less than the number of columns, but not more than the number of columns:

```
sage: A = matrix(QQ,2,3)
sage: A.linear_combination_of_columns([0])
(0, 0)
sage: A.linear_combination_of_columns([1,2,3,4])
...
ValueError: length of v must be at most the number of columns of self
```

linear_combination_of_rows()

Return the linear combination of the rows of self given by the coefficients in the list v. Raise a ValueError if the length of v is longer than the number of rows of the matrix.

INPUT:

- **v - list of length at most the number of rows of** self (less is fine)

EXAMPLES:

```
sage: a = matrix(ZZ,2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: a.linear_combination_of_rows([1,2])
(6, 9, 12)
sage: a.linear_combination_of_rows([0,0])
(0, 0, 0)
sage: a.linear_combination_of_rows([1/2,2/3])
(2, 19/6, 13/3)
sage: matrix(QQ,0,2).linear_combination_of_rows([])
(0, 0)
```

The length of v can be less than the number of rows, but not more than the number of rows:

```
sage: A = matrix(QQ,2,3)
sage: A.linear_combination_of_rows([0])
(0, 0, 0)
sage: A.linear_combination_of_rows([1,2,3])
...
ValueError: length of v must be at most the number of rows of self
```

list()

List of elements of self. It is safe to change the returned list.

EXAMPLES:

```
sage: R.<x,y> = QQ[]
sage: a = matrix(R,2,[x,y,x*y, y,x,2*x+y]); a
[      x       y     x*y]
[      y       x 2*x + y]
sage: v = a.list(); v
[x, y, x*y, y, x, 2*x + y]
```

Notice that changing the returned list does not change a (the list is a copy):

```
sage: v[0] = 25
sage: a
[      x       y     x*y]
[      y       x 2*x + y]
```

mod()

Return matrix mod p, over the reduced ring.

EXAMPLES:

```
sage: M = matrix(ZZ, 2, 2, [5, 9, 13, 15])
sage: M.mod(7)
[5 2]
[6 1]
sage: parent(M.mod(7))
Full MatrixSpace of 2 by 2 dense matrices over Ring of integers modulo 7
```

ncols()

Return the number of columns of this matrix.

EXAMPLES:

```
sage: M = MatrixSpace(QQ, 2, 3)
sage: A = M([1,2,3, 4,5,6])
sage: A
[1 2 3]
[4 5 6]
sage: A.ncols()
3
sage: A.nrows()
2
```

AUTHORS:

- Naqi Jaffery (2006-01-24): examples

nonpivots()

Return the list of i such that the i-th column of self is NOT a pivot column of the reduced row echelon form of self.

OUTPUT:

- `list` - sorted list of (Python) integers

EXAMPLES:

```
sage: a = matrix(QQ,3,3,range(9)); a
[0 1 2]
[3 4 5]
[6 7 8]
sage: a.echelon_form()
[ 1  0 -1]
[ 0  1  2]
[ 0  0  0]
sage: a.nonpivots()
[2]
```

nonzero_positions()

Returns the sorted list of pairs (i,j) such that self[i,j] != 0.

INPUT:

- `copy` - (default: True) It is safe to change the resulting list (unless you give the option copy=False).
- `column_order` - (default: False) If true, returns the list of pairs (i,j) such that self[i,j] != 0, but sorted by columns, i.e., column j=0 entries occur first, then column j=1 entries, etc.

EXAMPLES:

```
sage: a = matrix(QQ, 2,3, [1,2,0,2,0,0]); a
[1 2 0]
[2 0 0]
```

```
sage: a.nonzero_positions()
[(0, 0), (0, 1), (1, 0)]
sage: a.nonzero_positions(copy=False)
[(0, 0), (0, 1), (1, 0)]
sage: a.nonzero_positions(column_order=True)
[(0, 0), (1, 0), (0, 1)]
sage: a = matrix(QQ, 2,3, [1,2,0,2,0,0], sparse=True); a
[1 2 0]
[2 0 0]
sage: a.nonzero_positions()
[(0, 0), (0, 1), (1, 0)]
sage: a.nonzero_positions(copy=False)
[(0, 0), (0, 1), (1, 0)]
sage: a.nonzero_positions(column_order=True)
[(0, 0), (1, 0), (0, 1)]
```

nonzero_positions_in_column()

Return a sorted list of the integers j such that self[j,i] is nonzero, i.e., such that the j-th position of the i-th column is nonzero.

INPUT:

- i - an integer

OUTPUT: list

EXAMPLES:

```
sage: a = matrix(QQ, 3,2, [1,2,0,2,0,0]); a
[1 2]
[0 2]
[0 0]
sage: a.nonzero_positions_in_column(0)
[0]
sage: a.nonzero_positions_in_column(1)
[0, 1]
```

You'll get an IndexError, if you select an invalid column:

```
sage: a.nonzero_positions_in_column(2)
...
IndexError: matrix column index out of range
```

nonzero_positions_in_row()

Return the integers j such that self[i,j] is nonzero, i.e., such that the j-th position of the i-th row is nonzero.

INPUT:

- i - an integer

OUTPUT: list

EXAMPLES:

```
sage: a = matrix(QQ, 3,2, [1,2,0,2,0,0]); a
[1 2]
[0 2]
[0 0]
sage: a.nonzero_positions_in_row(0)
[0, 1]
sage: a.nonzero_positions_in_row(1)
[1]
sage: a.nonzero_positions_in_row(2)
[]
```

nrows()

Return the number of rows of this matrix.

EXAMPLES:

```
sage: M = MatrixSpace(QQ,6,7)
sage: A = M([1,2,3,4,5,6,7, 22,3/4,34,11,7,5,3, 99,65,1/2,2/3,3/5,4/5,5/6, 9,8/9, 9/8,7/6,6/
sage: A
[   1    2    3    4    5    6    7]
[  22  3/4   34   11    7    5    3]
[  99   65  1/2  2/3  3/5  4/5  5/6]
[   9  8/9  9/8  7/6  6/7   76    4]
[   0    9    8    7    6    5    4]
[ 123   99   91   28    6 1024    1]
sage: A.ncols()
7
sage: A.nrows()
6
```

AUTHORS:

- Naqi Jaffery (2006-01-24): examples

pivots()

Return the pivot column positions of this matrix as a list of Python integers.

This returns a list, of the position of the first nonzero entry in each row of the echelon form.

OUTPUT:

- `list` - a list of Python ints

EXAMPLES:

rank()

rescale_col()

Replace i-th col of self by s times i-th col of self.

INPUT:

- `i` - ith column
- `s` - scalar
- `start_row` - only rescale entries at this row and lower

EXAMPLES: We rescale the last column of a matrix over the rational numbers:

```
sage: a = matrix(QQ,2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: a.rescale_col(2,1/2); a
[  0   1   1]
[  3   4 5/2]
sage: R.<x> = QQ[]
```

We rescale the last column of a matrix over a polynomial ring:

```
sage: a = matrix(R,2,3,[1,x,x^2,x^3,x^4,x^5]); a
[  1   x x^2]
[x^3 x^4 x^5]
sage: a.rescale_col(2,1/2); a
[      1       x 1/2*x^2]
[    x^3     x^4 1/2*x^5]
```

We try and fail to rescale a matrix over the integers by a non-integer:

```
sage: a = matrix(ZZ,2,3,[0,1,2, 3,4,4]); a
[0 1 2]
[3 4 4]
sage: a.rescale_col(2,1/2)
...
TypeError: Rescaling column by Rational Field element cannot be done over Integer Ring, use
```

To rescale the matrix by 1/2, you must change the base ring to the rationals:

```
sage: a = a.change_ring(QQ); a
[0 1 2]
[3 4 4]
sage: a.rescale_col(2,1/2); a
[0 1 1]
[3 4 2]
```

rescale_row()

Replace i-th row of self by s times i-th row of self.

INPUT:

- `i` - ith row
- `s` - scalar
- `start_col` - only rescale entries at this column and to the right

EXAMPLES: We rescale the second row of a matrix over the rational numbers:

```
sage: a = matrix(QQ,3,range(6)); a
[0 1]
[2 3]
[4 5]
sage: a.rescale_row(1,1/2); a
[ 0   1]
[ 1 3/2]
[ 4   5]
```

We rescale the second row of a matrix over a polynomial ring:

```
sage: R.<x> = QQ[]
sage: a = matrix(R,3,[1,x,x^2,x^3,x^4,x^5]);a
[  1   x]
[x^2 x^3]
[x^4 x^5]
sage: a.rescale_row(1,1/2); a
[      1       x]
[1/2*x^2 1/2*x^3]
[    x^4     x^5]
```

We try and fail to rescale a matrix over the integers by a non-integer:

```
sage: a = matrix(ZZ,2,3,[0,1,2, 3,4,4]); a
[0 1 2]
[3 4 4]
sage: a.rescale_row(1,1/2)
...
TypeError: Rescaling row by Rational Field element cannot be done over Integer Ring, use cha
```

To rescale the matrix by 1/2, you must change the base ring to the rationals:

```
sage: a = a.change_ring(QQ); a
[0 1 2]
[3 4 4]
sage: a.rescale_col(1,1/2); a
```

```
[  0 1/2   2]
[  3   2   4]
```

set_col_to_multiple_of_col()

Set column i equal to s times column j.

EXAMPLES: We change the second column to -3 times the first column.

```
sage: a = matrix(ZZ,2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: a.set_col_to_multiple_of_col(1,0,-3)
sage: a
[ 0  0  2]
[ 3 -9  5]
```

If we try to multiply a column by a rational number, we get an error message:

```
sage: a.set_col_to_multiple_of_col(1,0,1/2)
...
TypeError: Multiplying column by Rational Field element cannot be done over Integer Ring, us
```

set_immutable()

Call this function to matrix a matrix immutable.

Matrices are always mutable by default, i.e., you can change their entries using `A[i,j] = x`. However, mutable matrices aren't hasheable, so can't be used as keys in dictionaries, etc. Also, often when implementing a class, you might compute a matrix associated to it, e.g., the matrix of a Hecke operator. If you return this matrix to the user you're really returning a reference and the user could then change an entry; this could be confusing. Thus you shoulds set such a matrix immutable.

EXAMPLES:

```
sage: A = Matrix(QQ, 2, 2, range(4))
sage: A.is_mutable()
True
sage: A[0,0] = 10
sage: A
[10   1]
[ 2   3]
```

Mutable matrices are not hasheable, so can't be used as keys for dictionaries:

```
sage: hash(A)
...
TypeError: mutable matrices are unhashable
sage: v = {A:1}
...
TypeError: mutable matrices are unhashable
```

If we make A immutable it suddenly is hasheable.

```
sage: A.set_immutable()
sage: A.is_mutable()
False
sage: A[0,0] = 10
...
ValueError: matrix is immutable; please change a copy instead (use self.copy()).
sage: hash(A)
12
sage: v = {A:1}; v
{[10  1]
 [ 2  3]: 1}
```

set_row_to_multiple_of_row()
Set row i equal to s times row j.

EXAMPLES: We change the second row to -3 times the first row:

```
sage: a = matrix(ZZ,2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: a.set_row_to_multiple_of_row(1,0,-3)
sage: a
[ 0  1  2]
[ 0 -3 -6]
```

If we try to multiply a row by a rational number, we get an error message:

```
sage: a.set_row_to_multiple_of_row(1,0,1/2)
...
TypeError: Multiplying row by Rational Field element cannot be done over Integer Ring, use c
```

str()
EXAMPLES:

```
sage: R = PolynomialRing(QQ,6,'z')
sage: a = matrix(2,3, R.gens())
sage: a.__repr__()
'[z0 z1 z2]\n[z3 z4 z5]'
```

subdivisions

swap_columns()
Swap columns c1 and c2 of self.

EXAMPLES: We create a rational matrix:

```
sage: M = MatrixSpace(QQ,3,3)
sage: A = M([1,9,-7,4/5,4,3,6,4,3])
sage: A
[  1   9  -7]
[4/5   4   3]
[  6   4   3]
```

Since the first column is numbered zero, this swaps the second and third columns:

```
sage: A.swap_columns(1,2); A
[  1  -7   9]
[4/5   3   4]
[  6   3   4]
```

swap_rows()
Swap rows r1 and r2 of self.

EXAMPLES: We create a rational matrix:

```
sage: M = MatrixSpace(QQ,3,3)
sage: A = M([1,9,-7,4/5,4,3,6,4,3])
sage: A
[  1   9  -7]
[4/5   4   3]
[  6   4   3]
```

Since the first row is numbered zero, this swaps the first and third rows:

```
sage: A.swap_rows(0,2); A
[  6   4   3]
```

```
[4/5   4   3]
[  1   9  -7]
```

with_added_multiple_of_column()

Add s times column j to column i, returning new matrix.

EXAMPLES: We add -1 times the third column to the second column of an integer matrix, remembering to start numbering cols at zero:

```
sage: a = matrix(ZZ,2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: b = a.with_added_multiple_of_column(1,2,-1); b
[ 0 -1  2]
[ 3 -1  5]
```

The original matrix is unchanged:

```
sage: a
[0 1 2]
[3 4 5]
```

Adding a rational multiple is okay, and reassigning a variable is okay:

```
sage: a = a.with_added_multiple_of_column(0,1,1/3); a
[ 1/3    1    2]
[13/3    4    5]
```

with_added_multiple_of_row()

Add s times row j to row i, returning new matrix.

EXAMPLES: We add -3 times the first row to the second row of an integer matrix, remembering to start numbering rows at zero:

```
sage: a = matrix(ZZ,2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: b = a.with_added_multiple_of_row(1,0,-3); b
[ 0  1  2]
[ 3  1 -1]
```

The original matrix is unchanged:

```
sage: a
[0 1 2]
[3 4 5]
```

Adding a rational multiple is okay, and reassigning a variable is okay:

```
sage: a = a.with_added_multiple_of_row(0,1,1/3); a
[   1  7/3 11/3]
[   3    4    5]
```

with_col_set_to_multiple_of_col()

Set column i equal to s times column j, returning a new matrix.

EXAMPLES: We change the second column to -3 times the first column.

```
sage: a = matrix(ZZ,2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: b = a.with_col_set_to_multiple_of_col(1,0,-3); b
[ 0  0  2]
[ 3 -9  5]
```

Note that the original matrix is unchanged:

```
sage: a
[0 1 2]
[3 4 5]
```

Adding a rational multiple is okay, and reassigning a variable is okay:

```
sage: a = a.with_col_set_to_multiple_of_col(1,0,1/2); a
[  0   0   2]
[  3 3/2   5]
```

with_rescaled_col()

Replaces i-th col of self by s times i-th col of self, returning new matrix.

EXAMPLES: We rescale the last column of a matrix over the integers:

```
sage: a = matrix(ZZ,2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: b = a.with_rescaled_col(2,-2); b
[  0   1  -4]
[  3   4 -10]
```

The original matrix is unchanged:

```
sage: a
[0 1 2]
[3 4 5]
```

Adding a rational multiple is okay, and reassigning a variable is okay:

```
sage: a = a.with_rescaled_col(1,1/3); a
[  0 1/3   2]
[  3 4/3   5]
```

with_rescaled_row()

Replaces i-th row of self by s times i-th row of self, returning new matrix.

EXAMPLES: We rescale the second row of a matrix over the integers:

```
sage: a = matrix(ZZ,3,2,range(6)); a
[0 1]
[2 3]
[4 5]
sage: b = a.with_rescaled_row(1,-2); b
[ 0  1]
[-4 -6]
[ 4  5]
```

The original matrix is unchanged:

```
sage: a
[0 1]
[2 3]
[4 5]
```

Adding a rational multiple is okay, and reassigning a variable is okay:

```
sage: a = a.with_rescaled_row(2,1/3); a
[  0   1]
[  2   3]
[4/3 5/3]
```

with_row_set_to_multiple_of_row()

Set row i equal to s times row j, returning a new matrix.

EXAMPLES: We change the second row to -3 times the first row:

```
sage: a = matrix(ZZ,2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: b = a.with_row_set_to_multiple_of_row(1,0,-3); b
[ 0  1  2]
[ 0 -3 -6]
```

Note that the original matrix is unchanged:

```
sage: a
[0 1 2]
[3 4 5]
```

Adding a rational multiple is okay, and reassigning a variable is okay:

```
sage: a = a.with_row_set_to_multiple_of_row(1,0,1/2); a
[  0   1   2]
[  0 1/2   1]
```

set_max_cols()

set_max_rows()

unpickle()

Unpickle a matrix. This is only used internally by Sage. Users should never call this function directly.

EXAMPLES: We illustrating saving and loading several different types of matrices.

OVER $\mathbf{Z}$:

```
sage: A = matrix(ZZ,2,range(4))
sage: loads(dumps(A))
[0 1]
[2 3]
```

Sparse OVER $\mathbf{Q}$:

Dense over $\mathbf{Q}[x, y]$:

Dense over finite field.

32.6 Base class for matrices, part 1

For design documentation see sage.matrix.docs.

TESTS:

```
sage: A = Matrix(GF(5),3,3,srange(9))
sage: A == loads(dumps(A))
True
```

class **Matrix**()

adjoint()

Returns the adjoint matrix of self (matrix of cofactors).

INPUT:

- M - a square matrix

OUTPUT:

- N - the adjoint matrix, such that N * M = M * N = M.parent(M.det())

ALGORITHM: Use PARI

EXAMPLES:

```
sage: M = Matrix(ZZ,2,2,[5,2,3,4]) ; M
[5 2]
[3 4]
sage: N = M.adjoint() ; N
[ 4 -2]
[-3  5]
sage: M * N
[14  0]
[ 0 14]
sage: N * M
[14  0]
[ 0 14]
sage: M = Matrix(QQ,2,2,[5/3,2/56,33/13,41/10]) ; M
[  5/3  1/28]
[33/13 41/10]
sage: N = M.adjoint() ; N
[ 41/10  -1/28]
[-33/13    5/3]
sage: M * N
[7363/1092          0]
[         0 7363/1092]
```

TODO: Only implemented for matrices over ZZ or QQ PARI can deal with more general base rings

augment()

Return the augmented matrix of the form:

```
[self | other].
```

EXAMPLES:

```
sage: M = MatrixSpace(QQ,2,2)
sage: A = M([1,2, 3,4])
sage: A
[1 2]
[3 4]
sage: N = MatrixSpace(QQ,2,1)
sage: B = N([9,8])
sage: B
[9]
[8]
sage: A.augment(B)
[1 2 9]
[3 4 8]
sage: B.augment(A)
[9 1 2]
[8 3 4]
sage: M = MatrixSpace(QQ,3,4)
sage: A = M([1,2,3,4, 0,9,8,7, 2/3,3/4,4/5,9/8])
sage: A
[  1   2   3   4]
[  0   9   8   7]
[2/3 3/4 4/5 9/8]
sage: N = MatrixSpace(QQ,3,2)
sage: B = N([1,2, 3,4, 4,5])
sage: B
```

```
[1 2]
[3 4]
[4 5]
sage: A.augment(B)
[  1   2   3   4   1   2]
[  0   9   8   7   3   4]
[2/3 3/4 4/5 9/8   4   5]
sage: B.augment(A)
[  1   2   1   2   3   4]
[  3   4   0   9   8   7]
[  4   5 2/3 3/4 4/5 9/8]
```

AUTHORS:

- Naqi Jaffery (2006-01-24): examples

block_sum()

Return the block matrix that has self and other on the diagonal:

```
[ self     0 ]
[    0 other ]
```

EXAMPLES:

```
sage: A = matrix(QQ[['t']], 2, range(1, 5))
sage: A.block_sum(100*A)
[  1   2   0   0]
[  3   4   0   0]
[  0   0 100 200]
[  0   0 300 400]
```

column()

Return the `i`'th column of this matrix as a vector.

This column is a dense vector if and only if the matrix is a dense matrix.

INPUT:

- `i` - integer
- `from_list` - bool (default: False); if true, returns the `i`'th element of `self.columns()` (see `columns()`), which may be faster, but requires building a list of all columns the first time it is called after an entry of the matrix is changed.

EXAMPLES:

```
sage: a = matrix(2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: a.column(1)
(1, 4)
```

If the column is negative, it wraps around, just like with list indexing, e.g., -1 gives the right-most column:

```
sage: a.column(-1)
(2, 5)
```

TESTS:

```
sage: a = matrix(2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: a.column(3)
...
IndexError: column index out of range
sage: a.column(-4)
```

```
...
IndexError: column index out of range
```

columns()

Return a list of the columns of self.

INPUT:

- **copy - (default: True) if True, return a copy of the list** of columns which is safe to change.

If self is sparse, returns columns as sparse vectors, and if self is dense returns them as dense vectors.

EXAMPLES:

```
sage: matrix(3, [1..9]).columns()
[(1, 4, 7), (2, 5, 8), (3, 6, 9)]
sage: matrix(RR, 2, [sqrt(2), pi, exp(1), 0]).columns()
[(1.41421356237310, 2.71828182845905), (3.14159265358979, 0.000000000000000)]
sage: matrix(RR, 0, 2, []).columns()
[(), ()]
sage: matrix(RR, 2, 0, []).columns()
[]
sage: m = matrix(RR, 3, 3, {(1,2): pi, (2, 2): -1, (0,1): sqrt(2)})
sage: parent(m.columns()[0])
Sparse vector space of dimension 3 over Real Field with 53 bits of precision
```

dense_columns()

Return list of the dense columns of self.

INPUT:

- copy - (default: True) if True, return a copy so you can modify it safely

EXAMPLES:

An example over the integers:

```
sage: a = matrix(3,3,range(9)); a
[0 1 2]
[3 4 5]
[6 7 8]
sage: a.dense_columns()
[(0, 3, 6), (1, 4, 7), (2, 5, 8)]
```

We do an example over a polynomial ring:

```
sage: R.<x> = QQ[ ]
sage: a = matrix(R, 2, [x,x^2, 2/3*x,1+x^5]); a
[      x     x^2]
[  2/3*x x^5 + 1]
sage: a.dense_columns()
[(x, 2/3*x), (x^2, x^5 + 1)]
sage: a = matrix(R, 2, [x,x^2, 2/3*x,1+x^5], sparse=True)
sage: c = a.dense_columns(); c
[(x, 2/3*x), (x^2, x^5 + 1)]
sage: parent(c[1])
Ambient free module of rank 2 over the principal ideal domain Univariate Polynomial Ring in
```

dense_matrix()

If this matrix is sparse, return a dense matrix with the same entries. If this matrix is dense, return this matrix (not a copy).

Note: The definition of "dense" and "sparse" in Sage have nothing to do with the number of nonzero entries. Sparse and dense are properties of the underlying representation of the matrix.

EXAMPLES:

```
sage: A = MatrixSpace(QQ,2, sparse=True)([1,2,0,1])
sage: A.is_sparse()
True
sage: B = A.dense_matrix()
sage: B.is_sparse()
False
sage: A*B
[1 4]
[0 1]
sage: A.parent()
Full MatrixSpace of 2 by 2 sparse matrices over Rational Field
sage: B.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
```

In Sage, the product of a sparse and a dense matrix is always dense:

```
sage: (A*B).parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
sage: (B*A).parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
```

TESTS:

Make sure that subdivisions are preserved when switching between dense and sparse matrices:

```
sage: a = matrix(ZZ, 3, range(9))
sage: a.subdivide([1,2],2)
sage: a.get_subdivisions()
([1, 2], [2])
sage: b = a.sparse_matrix().dense_matrix()
sage: b.get_subdivisions()
([1, 2], [2])
```

dense_rows()

Return list of the dense rows of self.

INPUT:

- copy - (default: True) if True, return a copy so you can modify it safely (note that the individual vectors in the copy should not be modified since they are mutable!)

EXAMPLES:

```
sage: m = matrix(3, range(9)); m
[0 1 2]
[3 4 5]
[6 7 8]
sage: v = m.dense_rows(); v
[(0, 1, 2), (3, 4, 5), (6, 7, 8)]
sage: v is m.dense_rows()
False
sage: m.dense_rows(copy=False) is m.dense_rows(copy=False)
True
sage: m[0,0] = 10
sage: m.dense_rows()
[(10, 1, 2), (3, 4, 5), (6, 7, 8)]
```

lift()

Return lift of self to the covering ring of the base ring R, which is by definition the ring returned by calling cover_ring() on R, or just R itself if the cover_ring method is not defined.

EXAMPLES:

```
sage: M = Matrix(Integers(7), 2, 2, [5, 9, 13, 15]) ; M
[5 2]
[6 1]
sage: M.lift()
[5 2]
[6 1]
sage: parent(M.lift())
Full MatrixSpace of 2 by 2 dense matrices over Integer Ring
```

The field QQ doesn't have a cover_ring method:

```
sage: hasattr(QQ, 'cover_ring')
False
```

So lifting a matrix over QQ gives back the same exact matrix.

```
sage: B = matrix(QQ, 2, [1..4])
sage: B.lift()
[1 2]
[3 4]
sage: B.lift() is B
True
```

matrix_from_columns()

Return the matrix constructed from self using columns with indices in the columns list.

EXAMPLES:

```
sage: M = MatrixSpace(Integers(8),3,3)
sage: A = M(range(9)); A
[0 1 2]
[3 4 5]
[6 7 0]
sage: A.matrix_from_columns([2,1])
[2 1]
[5 4]
[0 7]
```

matrix_from_rows()

Return the matrix constructed from self using rows with indices in the rows list.

EXAMPLES:

```
sage: M = MatrixSpace(Integers(8),3,3)
sage: A = M(range(9)); A
[0 1 2]
[3 4 5]
[6 7 0]
sage: A.matrix_from_rows([2,1])
[6 7 0]
[3 4 5]
```

matrix_from_rows_and_columns()

Return the matrix constructed from self from the given rows and columns.

EXAMPLES:

```
sage: M = MatrixSpace(Integers(8),3,3)
sage: A = M(range(9)); A
[0 1 2]
[3 4 5]
[6 7 0]
sage: A.matrix_from_rows_and_columns([1], [0,2])
```

```
[3 5]
sage: A.matrix_from_rows_and_columns([1,2], [1,2])
[4 5]
[7 0]
```

Note that row and column indices can be reordered or repeated:

```
sage: A.matrix_from_rows_and_columns([2,1], [2,1])
[0 7]
[5 4]
```

For example here we take from row 1 columns 2 then 0 twice, and do this 3 times.

```
sage: A.matrix_from_rows_and_columns([1,1,1],[2,0,0])
[5 3 3]
[5 3 3]
[5 3 3]
```

AUTHORS:

- Jaap Spies (2006-02-18)
- Didier Deshommes: some pyrex speedups implemented

matrix_over_field()

Return copy of this matrix, but with entries viewed as elements of the fraction field of the base ring (assuming it is defined).

EXAMPLES:

```
sage: A = MatrixSpace(IntegerRing(),2)([1,2,3,4])
sage: B = A.matrix_over_field()
sage: B
[1 2]
[3 4]
sage: B.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
```

matrix_space()

Return the ambient matrix space of self.

INPUT:

- nrows, ncols - (optional) number of rows and columns in returned matrix space.
- sparse - whether the returned matrix space uses sparse or dense matrices.

EXAMPLES:

```
sage: m = matrix(3, [1..9])
sage: m.matrix_space()
Full MatrixSpace of 3 by 3 dense matrices over Integer Ring
sage: m.matrix_space(ncols=2)
Full MatrixSpace of 3 by 2 dense matrices over Integer Ring
sage: m.matrix_space(1)
Full MatrixSpace of 1 by 3 dense matrices over Integer Ring
sage: m.matrix_space(1, 2, True)
Full MatrixSpace of 1 by 2 sparse matrices over Integer Ring
```

new_matrix()

Create a matrix in the parent of this matrix with the given number of rows, columns, etc. The default parameters are the same as for self.

INPUT:

These three variables get sent to matrix_space():

- nrows, ncols - number of rows and columns in returned matrix. If not specified, defaults to None and will give a matrix of the same size as self.

- `sparse` - whether returned matrix is sparse or not. Defaults to same value as self.

The remaining three variables (`coerce`, `entries`, and `copy`) are used by `sage.matrix.matrix_space.MatrixSpace()` to construct the new matrix.

Warning: This function called with no arguments returns the zero matrix of the same dimension and sparseness of self.

EXAMPLES:

sage: A = matrix(ZZ,2,2,[1,2,3,4]); A [1 2] [3 4] sage: A.new_matrix() [0 0] [0 0] sage: A.new_matrix(1,1) [0] sage: A.new_matrix(3,3).parent() Full MatrixSpace of 3 by 3 dense matrices over Integer Ring

```
sage: A = matrix(RR,2,3,[1.1,2.2,3.3,4.4,5.5,6.6]); A
[1.10000000000000 2.20000000000000 3.30000000000000]
[4.40000000000000 5.50000000000000 6.60000000000000]
sage: A.new_matrix()
[0.000000000000000 0.000000000000000 0.000000000000000]
[0.000000000000000 0.000000000000000 0.000000000000000]
sage: A.new_matrix().parent()
Full MatrixSpace of 2 by 3 dense matrices over Real Field with 53 bits of precision
```

numpy()

Return the Numpy matrix associated to this matrix.

INPUT:

- `dtype` - The desired data-type for the array. If not given, then the type will be determined as the minimum type required to hold the objects in the sequence.

EXAMPLES:

```
sage: a = matrix(3,range(12))
sage: a.numpy()
array([[0, 1, 2, 3],
       [4, 5, 6, 7],
       [8, 9, 10, 11]], dtype=object)
sage: a.numpy('f')
array([[  0.,   1.,   2.,   3.],
       [  4.,   5.,   6.,   7.],
       [  8.,   9.,  10.,  11.]], dtype=float32)
sage: a.numpy('d')
array([[  0.,   1.,   2.,   3.],
       [  4.,   5.,   6.,   7.],
       [  8.,   9.,  10.,  11.]])
sage: a.numpy('B')
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11]], dtype=uint8)
```

Type `numpy.typecodes` for a list of the possible typecodes:

```
sage: import numpy
sage: numpy.typecodes
{'All': '?bhilqpBHILQPfdgFDGSUVO', 'AllInteger': 'bBhHiIlLqQpP', 'AllFloat': 'fdgFDG', 'Unsi
```

row()

Return the `i`'th row of this matrix as a vector.

This row is a dense vector if and only if the matrix is a dense matrix.

INPUT:

- `i` - integer

- from_list - bool (default: False); if true, returns the i'th element of self.rows() (see rows()), which may be faster, but requires building a list of all rows the first time it is called after an entry of the matrix is changed.

EXAMPLES:

```
sage: a = matrix(2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: a.row(0)
(0, 1, 2)
sage: a.row(1)
(3, 4, 5)
sage: a.row(-1)  # last row
(3, 4, 5)
```

TESTS:

```
sage: a = matrix(2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: a.row(2)
...
IndexError: row index out of range
sage: a.row(-3)
...
IndexError: row index out of range
```

rows()

Return a list of the rows of self.

INPUT:

- copy - (default: True) if True, return a copy of the list of rows which is safe to change.

If self is sparse, returns rows as sparse vectors, and if self is dense returns them as dense vectors.

EXAMPLES:

```
sage: matrix(3, [1..9]).rows()
[(1, 2, 3), (4, 5, 6), (7, 8, 9)]
sage: matrix(RR, 2, [sqrt(2), pi, exp(1), 0]).rows()
[(1.41421356237310, 3.14159265358979), (2.71828182845905, 0.000000000000000)]
sage: matrix(RR, 0, 2, []).rows()
[]
sage: matrix(RR, 2, 0, []).rows()
[(), ()]
sage: m = matrix(RR, 3, 3, {(1,2): pi, (2, 2): -1, (0,1): sqrt(2)})
sage: parent(m.rows()[0])
Sparse vector space of dimension 3 over Real Field with 53 bits of precision
```

set_column()

Sets the entries of column col in self to be the entries of v.

EXAMPLES:

```
sage: A = matrix([[1,2],[3,4]]); A
[1 2]
[3 4]
sage: A.set_column(0, [0,0]); A
[0 2]
[0 4]
sage: A.set_column(1, [0,0]); A
[0 0]
```

```
[0 0]
sage: A.set_column(2, [0,0]); A
...
IndexError: index out of range

sage: A.set_column(0, [0,0,0])
...
ValueError: v must be of length 2
```

set_row()

Sets the entries of row `row` in self to be the entries of `v`.

EXAMPLES:

```
sage: A = matrix([[1,2],[3,4]]); A
[1 2]
[3 4]
sage: A.set_row(0, [0,0]); A
[0 0]
[3 4]
sage: A.set_row(1, [0,0]); A
[0 0]
[0 0]
sage: A.set_row(2, [0,0]); A
...
IndexError: index out of range

sage: A.set_row(0, [0,0,0])
...
ValueError: v must be of length 2
```

sparse_columns()

Return list of the sparse columns of self.

INPUT:

- **copy - (default: True) if True, return a copy so you can** modify it safely

EXAMPLES:

```
sage: a = matrix(2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: v = a.sparse_columns(); v
[(0, 3), (1, 4), (2, 5)]
sage: v[1].is_sparse()
True
```

sparse_matrix()

If this matrix is dense, return a sparse matrix with the same entries. If this matrix is sparse, return this matrix (not a copy).

Note: The definition of "dense" and "sparse" in Sage have nothing to do with the number of nonzero entries. Sparse and dense are properties of the underlying representation of the matrix.

EXAMPLES:

```
sage: A = MatrixSpace(QQ,2, sparse=False)([1,2,0,1])
sage: A.is_sparse()
False
sage: B = A.sparse_matrix()
sage: B.is_sparse()
True
```

```
sage: A
[1 2]
[0 1]
sage: B
[1 2]
[0 1]
sage: A*B
[1 4]
[0 1]
sage: A.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
sage: B.parent()
Full MatrixSpace of 2 by 2 sparse matrices over Rational Field
sage: (A*B).parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
sage: (B*A).parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
```

sparse_rows()

Return list of the sparse rows of self.

INPUT:

- **copy - (default: True) if True, return a copy so you can** modify it safely

EXAMPLES:

```
sage: m = Mat(ZZ,3,3,sparse=True)(range(9)); m
[0 1 2]
[3 4 5]
[6 7 8]
sage: v = m.sparse_rows(); v
[(0, 1, 2), (3, 4, 5), (6, 7, 8)]
sage: m.sparse_rows(copy=False) is m.sparse_rows(copy=False)
True
sage: v[1].is_sparse()
True
sage: m[0,0] = 10
sage: m.sparse_rows()
[(10, 1, 2), (3, 4, 5), (6, 7, 8)]
```

stack()

Return the augmented matrix self on top of other:

```
[ self  ]
[ other ]
```

EXAMPLES:

```
sage: M = Matrix(QQ, 2, 3, range(6))
sage: N = Matrix(QQ, 1, 3, [10,11,12])
sage: M.stack(N)
[ 0  1  2]
[ 3  4  5]
[10 11 12]
```

submatrix()

Return the matrix constructed from self using the specified range of rows and columns.

INPUT:

- `row`, `col` - index of the starting row and column. Indices start at zero.
- `nrows`, `ncols` - (optional) number of rows and columns to take. If not provided, take all rows below and all columns to the right of the starting entry.

SEE ALSO:

The functions `matrix_from_rows()`, `matrix_from_columns()`, and `matrix_from_rows_and_columns()` allow one to select arbitrary subsets of rows and/or columns.

EXAMPLES:

Take the 3×3 submatrix starting from entry (1,1) in a 4×4 matrix:

```
sage: m = matrix(4, [1..16])
sage: m.submatrix(1, 1)
[ 6  7  8]
[10 11 12]
[14 15 16]
```

Same thing, except take only two rows:

```
sage: m.submatrix(1, 1, 2)
[ 6  7  8]
[10 11 12]
```

And now take only one column:

```
sage: m.submatrix(1, 1, 2, 1)
[ 6]
[10]
```

You can take zero rows or columns if you want:

```
sage: m.submatrix(1, 1, 0)
[]
sage: parent(m.submatrix(1, 1, 0))
Full MatrixSpace of 0 by 3 dense matrices over Integer Ring
```

32.7 Base class for matrices, part 2

TESTS:

```
sage: m = matrix(ZZ['x'], 2, 3, [1..6])
sage: loads(dumps(m)) == m
True
```

class Matrix()

characteristic_polynomial()

Synonym for self.charpoly(...).

EXAMPLES:

```
sage: a = matrix(QQ, 2,2, [1,2,3,4]); a
[1 2]
[3 4]
sage: a.characteristic_polynomial('T')
T^2 - 5*T - 2
```

charpoly()

Return the characteristic polynomial of self, as a polynomial over the base ring.

ALGORITHM: Compute the Hessenberg form of the matrix and read off the characteristic polynomial from that.

If the base ring of the matrix is a number field, use PARI's charpoly instead.

The result is cached.

INPUT:

- `var` - a variable name (default: 'x')
- `algorithm` - string:
- `'hessenberg'` - default (use Hessenberg form of matrix)

EXAMPLES:

First a matrix over $\mathbf{Z}$:

```
sage: A = MatrixSpace(ZZ,2)( [1,2,  3,4] )
sage: f = A.charpoly('x')
sage: f
x^2 - 5*x - 2
sage: f.parent()
Univariate Polynomial Ring in x over Integer Ring
sage: f(A)
[0 0]
[0 0]
```

An example over $\mathbf{Q}$:

```
sage: A = MatrixSpace(QQ,3)(range(9))
sage: A.charpoly('x')
x^3 - 12*x^2 - 18*x
sage: A.trace()
12
sage: A.determinant()
0
```

We compute the characteristic polynomial of a matrix over the polynomial ring $\mathbf{Z}[a]$:

```
sage: R.<a> = PolynomialRing(ZZ)
sage: M = MatrixSpace(R,2)([a,1,  a,a+1]); M
[    a     1]
[    a a + 1]
sage: f = M.charpoly('x'); f
x^2 + (-2*a - 1)*x + a^2
sage: f.parent()
Univariate Polynomial Ring in x over Univariate Polynomial Ring in a over Integer Ring
sage: M.trace()
2*a + 1
sage: M.determinant()
a^2
```

We compute the characteristic polynomial of a matrix over the multi-variate polynomial ring $\mathbf{Z}[x, y]$:

```
sage: R.<x,y> = PolynomialRing(ZZ,2)
sage: A = MatrixSpace(R,2)([x, y, x^2, y^2])
sage: f = A.charpoly('x'); f
x^2 + (-y^2 - x)*x - x^2*y + x*y^2
```

It's a little difficult to distinguish the variables. To fix this, we temporarily view the indeterminate as Z:

```
sage: with localvars(f.parent(), 'Z'): print f
Z^2 + (-y^2 - x)*Z - x^2*y + x*y^2
```

We could also compute f in terms of Z from the start:

```
sage: A.charpoly('Z')
Z^2 + (-y^2 - x)*Z - x^2*y + x*y^2
```

Here is an example over a number field:

```
sage: x = QQ['x'].gen()
sage: K.<a> = NumberField(x^2 - 2)
sage: m = matrix(K, [[a-1, 2], [a, a+1]])
sage: m.charpoly('Z')
Z^2 - 2*a*Z - 2*a + 1
sage: m.charpoly('a')(m) == 0
True
```

TESTS:

```
sage: P.<a,b,c> = PolynomialRing(Rationals())
sage: u = MatrixSpace(P,3)([[0,0,a],[1,0,b],[0,1,c]])
sage: Q.<x> = PolynomialRing(P)
sage: u.charpoly('x')
x^3 - c*x^2 - b*x - a
```

cholesky_decomposition()

Return the Cholesky decomposition of `self`.

INPUT:

The input matrix must be:

- real, symmetric, and positive definite; or
- imaginary, Hermitian, and positive definite.

If not, a `ValueError` exception will be raised.

OUTPUT:

A lower triangular matrix L such that LL^t equals `self`.

ALGORITHM:

Calls the method `_cholesky_decomposition_`, which by default uses a standard recursion.

Warning: This implementation uses a standard recursion that is not known to be numerically stable.

Warning: It is potentially expensive to ensure that the input is positive definite. Therefore this is not checked and it is possible that the output matrix is *not* a valid Cholesky decomposition of `self`. An example of this is given in the tests below.

EXAMPLES:

Here is an example over the real double field; internally, this uses scipy:

```
sage: r = matrix(RDF, 5, 5, [ 0,0,0,0,1, 1,1,1,1,1, 16,8,4,2,1, 81,27,9,3,1, 256,64,16,4,1 ]
sage: m = r * r.transpose(); m
[    1.0     1.0     1.0     1.0     1.0]
[    1.0     5.0    31.0   121.0   341.0]
[    1.0    31.0   341.0  1555.0  4681.0]
[    1.0   121.0  1555.0  7381.0 22621.0]
[    1.0   341.0  4681.0 22621.0 69905.0]
sage: L = m.cholesky_decomposition(); L
[          1.0           0.0           0.0           0.0           0.0]
[          1.0           2.0           0.0           0.0           0.0]
[          1.0          15.0 10.7238052948           0.0           0.0]
[          1.0          60.0 60.9858144589 7.79297342371           0.0]
[          1.0         170.0 198.623524155 39.3665667796 1.72309958068]
sage: L.parent()
Full MatrixSpace of 5 by 5 dense matrices over Real Double Field
sage: L*L.transpose()
[ 1.0     1.0     1.0     1.0     1.0]
[ 1.0     5.0    31.0   121.0   341.0]
```

```
[ 1.0    31.0   341.0  1555.0  4681.0]
[ 1.0   121.0  1555.0  7381.0 22621.0]
[ 1.0   341.0  4681.0 22621.0 69905.0]
sage: ( L*L.transpose() - m ).norm(1) < 2^-30
True
```

Here is an example over a higher precision real field:

```
sage: r = matrix(RealField(100), 5, 5, [ 0,0,0,0,1, 1,1,1,1,1, 16,8,4,2,1, 81,27,9,3,1, 256,
sage: m = r * r.transpose()
sage: L = m.cholesky_decomposition()
sage: L.parent()
Full MatrixSpace of 5 by 5 dense matrices over Real Field with 100 bits of precision
sage: ( L*L.transpose() - m ).norm(1) < 2^-50
True
```

Here is a Hermitian example:

```
sage: r = matrix(CDF, 2, 2, [ 1, -2*I, 2*I, 6 ]); r
[   1.0 -2.0*I]
[ 2.0*I    6.0]
sage: r.eigenvalues()
[0.298437881284, 6.70156211872]
sage: ( r - r.conjugate().transpose() ).norm(1) < 1e-30
True
sage: L = r.cholesky_decomposition(); L
[          1.0             0]
[        2.0*I 1.41421356237]
sage: ( r - L*L.conjugate().transpose() ).norm(1) < 1e-30
True
sage: L.parent()
Full MatrixSpace of 2 by 2 dense matrices over Complex Double Field
```

TESTS:

The following examples are not positive definite:

```
sage: m = -identity_matrix(3).change_ring(RDF)
sage: m.cholesky_decomposition()
...
ValueError: The input matrix was not symmetric and positive definite

sage: m = -identity_matrix(2).change_ring(RealField(100))
sage: m.cholesky_decomposition()
...
ValueError: The input matrix was not symmetric and positive definite
```

Here is a large example over a higher precision complex field:

```
sage: r = MatrixSpace(ComplexField(100), 6, 6).random_element()
sage: m = r * r.conjugate().transpose()
sage: m.change_ring(CDF) # for display purposes
[                    2.5891918451    1.58308081508 - 0.93917354232*I    0.4508660242 - 0.8
[   1.58308081508 + 0.93917354232*I                      3.39096359127  -0.823614467666 - 0.
[   0.4508660242 + 0.898986215453*I  -0.823614467666 + 0.70698381556*I
[ -0.125366701515 + 1.32575360944*I   0.964188058124 + 1.80624774667*I  -1.61505575668 + 0.5
[ -0.161174433016 + 1.92791089094*I   0.884237835922 + 1.12339941545*I    1.16580777654 + 2.

sage: ( m - L*L.conjugate().transpose() ).norm(1) < 1e-20
True
sage: L.parent()
Full MatrixSpace of 6 by 6 dense matrices over Complex Field with 100 bits of precision
```

Here is an example that returns an incorrect answer, because the input is *not* positive definite:

```
sage: r = matrix(CDF, 2, 2, [ 1, -2*I, 2*I, 0 ]); r
[   1.0 -2.0*I]
[ 2.0*I      0]
sage: r.eigenvalues()
[2.56155281281, -1.56155281281]
sage: ( r - r.conjugate().transpose() ).norm(1) < 1e-30
True
sage: L = r.cholesky_decomposition(); L
[  1.0     0]
[2.0*I 2.0*I]
sage: L*L.conjugate().transpose()
[   1.0 -2.0*I]
[ 2.0*I    8.0]
```

column_module()

Return the free module over the base ring spanned by the columns of this matrix.

EXAMPLES:

```
sage: t = matrix(QQ, 3, range(9)); t
[0 1 2]
[3 4 5]
[6 7 8]
sage: t.column_module()
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1  0 -1]
[ 0  1  2]
```

column_space()

Return the vector space over the base ring spanned by the columns of this matrix.

EXAMPLES:

```
sage: M = MatrixSpace(QQ,3,3)
sage: A = M([1,9,-7,4/5,4,3,6,4,3])
sage: A.column_space()
Vector space of degree 3 and dimension 3 over Rational Field
Basis matrix:
[1 0 0]
[0 1 0]
[0 0 1]
sage: W = MatrixSpace(CC,2,2)
```

```
sage: B = W([1, 2+3*I,4+5*I,9]); B
[                      1.00000000000000 2.00000000000000 + 3.00000000000000*I]
[4.00000000000000 + 5.00000000000000*I                      9.00000000000000]
sage: B.column_space()
Vector space of degree 2 and dimension 2 over Complex Field with 53 bits of precision
Basis matrix:
[1.00000000000000                0]
[               0 1.00000000000000]
```

conjugate()

Return the conjugate of self, i.e. the matrix whose entries are the conjugates of the entries of self.

EXAMPLES:

```
sage: A = matrix(CDF, [[1+I,1],[0,2*I]])
sage: A.conjugate()
[1.0 - 1.0*I          1.0]
[           0      -2.0*I]
```

A matrix over a not-totally-real number field:

```
sage: K.<j> = NumberField(x^2+5)
sage: M = matrix(K, [[1+j,1], [0,2*j]])
sage: M.conjugate()
[-j + 1      1]
[     0   -2*j]
```

Conjugates work (trivially) for matrices over rings that embed canonically into the real numbers:

```
sage: M = random_matrix(ZZ, 2)
sage: M == M.conjugate()
True
sage: M = random_matrix(QQ, 3)
sage: M == M.conjugate()
True
sage: M = random_matrix(RR, 2)
sage: M == M.conjugate()
True
```

decomposition()

Returns the decomposition of the free module on which this matrix A acts from the right (i.e., the action is x goes to x A), along with whether this matrix acts irreducibly on each factor. The factors are guaranteed to be sorted in the same way as the corresponding factors of the characteristic polynomial.

Let A be the matrix acting from the on the vector space V of column vectors. Assume that A is square. This function computes maximal subspaces W_1, ..., W_n corresponding to Galois conjugacy classes of eigenvalues of A. More precisely, let $f(X)$ be the characteristic polynomial of A. This function computes the subspace $W_i = ker(g_(A)^n)$, where $g_i(X)$ is an irreducible factor of $f(X)$ and $g_i(X)$ exactly divides $f(X)$. If the optional parameter is_diagonalizable is True, then we let $W_i = ker(g(A))$, since then we know that $ker(g(A)) = ker(g(A)^n)$.

INPUT:

- `self` - a matrix
- `algorithm` - 'spin' (default): algorithm involves iterating the action of self on a vector. 'kernel': naively just compute $ker(f_i(A))$ for each factor f_i.
