Sage Reference Manual

Release 4.0.1

The Sage Development Team

June 06, 2009

CONTENTS

This is the manual for the Sage mathematical software system. Sage is free open source math software that supports research and teaching in algebra, geometry, number theory, cryptography, and related areas. Both the Sage development model and the technology in Sage itself are distinguished by an extremely strong emphasis on openness, community, cooperation, and collaboration: we are building the car, not reinventing the wheel.

This reference manual contains many examples that illustrate the usage of Sage. The examples are all tested with each release of Sage, and should produce exactly the same output as in this manual, except for line breaks.

The Sage command line is briefly described in *The Sage Command Line*, which lists the command line options. For more details about the command line, see the Sage tutorial.

The Sage graphical user interface is described in *The Sage Notebook*. This graphical user interface is unusual in that it operates via your web browser. It provides you with Sage worksheets that you can edit and evaluate, which contain scalable typeset mathematics and beautiful antialiased images.

Enjoy Sage!

CHAPTER

ONE

THE SAGE COMMAND LINE

The chapter lists the Sage command line options. For more details about how to use the Sage command line once it starts up, see the Sage tutorial and the documentation for IPython.

1.1 Attach a file to a running instance of Sage.

class Attach()

Attach a file to a running instance of Sage.

Note: `attach` is *not* a function and is not part of the Python language.

`load` is exactly the same as attach, but doesn't automatically reload a file when it changes.

You attach a file, e.g., `foo.sage` or `foo.py` or `foo.spyx`, to a running Sage session by typing

```
sage: attach foo.sage   # or foo.py   or foo.spyx  (not tested)
```

The contents of the file are then loaded, which means they are read into the running Sage session. For example, if `foo.sage` contains `x=5`, after attaching `foo.sage` the variable `x` will be set to 5. Moreover, any time you change `foo.sage`, the attached file will be re-read automatically (with no intervention on your part).

USAGE: `attach file1 file2 ...` - space-separated list of .py, .spyx, and .sage files.

EFFECT: Each file is read in and added to an internal list of watched files. The meaning of reading a file in depends on the file type:

- read in with no preparsing (so, e.g., `2^3` is 2 bit-xor 3),
- preparsed then the result is read in
- *not* preparsed. Compiled to a module `m` then `from m import *` is executed.

Type `attached_files()` for a list of all currently attached files. You can remove files from this list to stop them from being watched.

Note: `attach` is exactly the same as load, except it keeps track of the loaded file and automatically reloads it when it changes.

1.2 Interactively tracing execution of a command

trace(*code, preparse=True*)

Evaluate Sage code using the interactive tracer and return the result. The string `code` must be a valid expression enclosed in quotes (no assignments - the result of the expression is returned). In the Sage notebook this just raises a NotImplementedException.

INPUT:

- `code` - str
- `preparse` - bool (default: True); if True, run expression through the Sage preparser.

REMARKS: This function is extremely powerful! For example, if you want to step through each line of execution of, e.g., `factor(100)`, type

```
sage: trace("factor(100)")              # not tested
```

then at the (Pdb) prompt type `s` (or `step`), then press return over and over to step through every line of Python that is called in the course of the above computation. Type `?` at any time for help on how to use the debugger (e.g., `l` lists 11 lines around the current line; `bt` gives a back trace, etc.).

Setting a break point: If you have some code in a file and would like to drop into the debugger at a given point, put the following code at that point in the file:

```
import pdb; pdb.set_trace()
```

For an article on how to use the Python debuger, see http://www.onlamp.com/pub/a/python/2005/09/01/debugger.html

TESTS: The only real way to test this is via pexpect spawning a sage subprocess that uses IPython.

```
sage: import pexpect
sage: s = pexpect.spawn('sage')
sage: _ = s.sendline("trace('print factor(10)'); print 3+97")
sage: _ = s.sendline("s"); _ = s.sendline("c");
sage: _ = s.expect('100')
```

Seeing the ipdb prompt and the 2 * 5 in the output below is a strong indication that the trace command worked correctly.

```
sage: print s.before[s.before.find('---'):]
---...
ipdb> c
2 * 5
```

We test what happens in notebook embedded mode:

```
sage: sage.plot.plot.EMBEDDED_MODE = True
sage: trace('print factor(10)')
...
NotImplementedError: the trace command is not implemented in the Sage notebook; you must use the
```

1.3 Sage: Command Line Arguments

There are several flags you can pass to Sage via the command line:

- `-h, -?` Prints a help message.
- `-notebook` Starts the Sage notebook running in default mode. This does not open a browser; it just starts a Sage Notebook server running on http://localhost:8000 (or a subsequent port if that port is not available). Pressing {Control-c} stops the server.
- `-i [packages]` Installs the given Sage packages. If a package is listed at http://modular.math.washington.edu/sage/packages/optional/ and not available in your current directory, then Sage will try to download the package and install it.
- `-optional` Lists all optional packages that can be downloaded.

- `-t <files|dir>` Tests examples in .py, .pyx, .sage or .tex files.
- `-testall` Tests all examples in Sage.
- `-upgrade` Downloads the latest non-optional Sage packages from http://modular.math.washington.edu/sage/packages/standard/, then builds and installs them. In many cases this requires that your computer has the necessary software development tools (listed in the installation documentation). Optional packages have to upgraded manually using `sage -i`. (There are no binary packages yet.)
- `file1.sage file2.sage file.py ...` Starts Sage, compiles any .sage files to .py files, and runs files.
- `-advanced` Displays additional options that can be passed to Sage.

CHAPTER

TWO

THE SAGE NOTEBOOK

2.1 The Sage Notebook object

class Notebook (*dir, system=None, pretty_print=False, show_debug=False, address='localhost', port=8000, secure=True, server_pool=, []*)

DIR()

Return the absolute path to the directory that contains the Sage Notebook directory.

add_to_history(*input_text*)

add_to_user_history(*entry, username*)

add_user(*username, password, email, account_type='user', force=False*)

INPUT:

- `username` - the username
- `password` - the password
- `email` - the email address
- `account_type` - one of 'user', 'admin', or 'guest'
- `force` - bool

If the method get_accounts return False then user can only be added if force=True

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('Mark', 'password', '', force=True)sage:
nb.user('Mark')
Mark
sage: nb.add_user('Sarah', 'password', '')
Traceback (most recent call last):
ValueError: creating new accounts disabled.
sage: nb.set_accounts(True)
sage: nb.add_user('Sarah', 'password', '')sage:
nb.user('Sarah')
Sarah
```

backup_directory()

change_password(*username, password*)

INPUT:

- `username` - the username
- `password` - the password to change the user's password to

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('Mark', 'password', '', force=True)sage:
nb.user('Mark').password()
'aajfMKNH1hTm2'
sage: nb.change_password('Mark', 'different_password')
sage: nb.user('Mark').password()
'aaTlXok5npQME'
```

change_worksheet_key(*old_key, new_key*)

color()

conf()

copy_worksheet(*ws, owner*)

create_default_users(*passwd*)

Create the default users for a notebook.

INPUT:

- `passwd` - a string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.create_default_users('password')
Creating default users.
sage: list(sorted(nb.users().iteritems()))
[('_sage_', _sage_), ('admin', admin), ('guest', guest), ('pub', pub)]
sage: list(sorted(nb.passwords().iteritems()))
[('_sage_', 'aaQSqAReePlq6'), ('admin', 'aajfMKNH1hTm2'), ('guest', 'aaQSqAReePlq6'), ('pub'
sage: nb.create_default_users('newpassword')
Creating default users.
WARNING: User 'pub' already exists -- and is now being replaced.
WARNING: User '_sage_' already exists -- and is now being replaced.
WARNING: User 'guest' already exists -- and is now being replaced.
WARNING: User 'admin' already exists -- and is now being replaced.
sage: list(sorted(nb.passwords().iteritems()))
[('_sage_', 'aaQSqAReePlq6'), ('admin', 'aajH86zjeUSDY'), ('guest', 'aaQSqAReePlq6'), ('pub'
```

create_new_worksheet(*worksheet_name, username, docbrowser=False, add_to_list=True*)

create_new_worksheet_from_history(*name, username, maxlen=None*)

create_user_with_same_password(*user, other_user*)

INPUT:

- `user` - a string
- `other_user` - a string

OUTPUT: Changes password of `user` to that of `other_user`.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('bob', 'an**d', 'bob@gmail.com', force=True)
sage: nb.user('bob').password()
'aa4Q6Jbx/MiUs'
sage: nb.add_user('mary', 'ccd', 'mary@gmail.com', force=True)
sage: nb.user('mary').password()
'aaxr0gcWJMXKU'
sage: nb.create_user_with_same_password('bob', 'mary')
sage: nb.user('bob').password() == nb.user('mary').password()
True
```

default_user()
Return a default login name that the user will see when confronted with the Sage notebook login page.
OUTPUT: string
Currently this returns 'admin' if that is the *only* user. Otherwise it returns the string ''.
EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.create_default_users('password')
Creating default users.
sage: nb.default_user()
'admin'
sage: nb.add_user('AnotherUser', 'password', '', force=True)sage:
nb.default_user()
''
```

del_user(*username*)
Deletes the given user
EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('Mark', 'password', '', force=True)sage:
nb.user('Mark')
Mark
sage: nb.del_user('Mark')
sage: nb.user('Mark')
Traceback (most recent call last):
KeyError: "no user 'Mark'"
```

delete()
Delete all files related to this notebook.
This is used for doctesting mainly. This command is obviously *VERY* dangerous to use on a notebook you actually care about. You could easily lose all data.
EXAMPLES:

```
sage: tmp = tmp_dir()
sage: nb = sage.server.notebook.notebook.Notebook(tmp)
sage: sorted(os.listdir(tmp))
['backups', 'nb.sobj', 'objects', 'worksheets']
sage: nb.delete()
```

Now the directory is gone.

```
sage: os.listdir(tmp)
...
OSError: [Errno 2] No such file or directory: '...
```

delete_doc_browser_worksheets()

delete_worksheet(*filename*)
Delete the given worksheet and remove its name from the worksheet list.

deleted_worksheets()

directory()

empty_trash(*username*)
Empty the trash for the given user.
INPUT:

- `username` - a string

This empties the trash for the given user and cleans up all files associated with the worksheets that are in the trash.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.new_worksheet_with_title_from_text('Sage', owner='sage')
sage: W.move_to_trash('sage')
sage: nb.worksheet_names()
['sage/0']
sage: nb.empty_trash('sage')
sage: nb.worksheet_names()
[]
```

export_worksheet(*worksheet_filename, output_filename, verbose=True*)

Export a worksheet with given directory filenmae to output_filename.

INPUT:

- `worksheet_filename` - string
- `output_filename` - string
- `verbose` - bool (default: True) if True print some the tar command used to extract the sws file.

OUTPUT: creates a file on the filesystem

get_accounts()

Return `__accounts`

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.get_accounts()
False
sage: nb.set_accounts(True)
sage: nb.get_accounts()
True
```

get_all_worksheets()

get_server()

get_ulimit()

get_worksheet_names_with_collaborator(*user*)

get_worksheet_names_with_viewer(*user*)

get_worksheet_with_filename(*filename*)

Get the worksheet with given filename. If there is no such worksheet, raise a `KeyError`.

INPUT: string OUTPUT: a worksheet or KeyError

get_worksheet_with_name(*name*)

get_worksheets_with_collaborator(*user*)

get_worksheets_with_owner(*owner*)

get_worksheets_with_owner_that_are_viewable_by_user(*owner, user*)

get_worksheets_with_viewer(*user*)

history()

history_count()

history_count_inc()

history_html()

history_text()

history_with_start(*start*)

html(*worksheet_filename=None, username='guest', show_debug=False, admin=False*)

html_afterpublish_window(*worksheet, username, addr, dtime*)
Return the html code for a page dedicated to worksheet publishing after the publication of the given worksheet.

INPUT: worksheet - instance of Worksheet username - string addr - string dtime - instance of time.struct_time

html_banner()

html_banner_and_control(*user, entries*)

html_beforepublish_window(*worksheet, username*)
Return the html code for a page dedicated to worksheet publishing prior to the publication of the given worksheet.

INPUT: worksheet - instance of Worksheet username - string

html_debug_window()

html_doc(*username*)

html_download_or_delete_datafile(*ws, username, filename*)

html_edit_window(*worksheet, username*)
Return a window for editing `worksheet`.

INPUT:

- `worksheet` - a worksheet

html_notebook_settings()

html_plain_text_window(*worksheet, username*)
Return a window that displays a plain text version of the worksheet

INPUT:

- `worksheet` - a worksheet
- `username` - name of the user

html_pretty_print_check_form_element(*ws*)

html_settings()

html_share(*worksheet, username*)

html_slide_controls()

html_specific_revision(*username, ws, rev*)

html_system_select_form_element(*ws*)

html_topbar(*user, pub=False*)

html_upload_data_window(*ws, username*)

html_user_control(*user, entries*)

html_user_settings(*username*)

html_worksheet_page_template(*worksheet, username, title, select=None, backwards=False*)

html_worksheet_revision_list(*username, worksheet*)

html_worksheet_settings(*ws, username*)

html_worksheet_topbar(*worksheet, select=None, username='guest', backwards=False*)

import_worksheet(*filename, owner*)
Upload the worksheet with name `filename` and make it have the given owner.

INPUT:

- `filename` - a string

- `owner` - a string

OUTPUT:

- `worksheet` - a newly created worksheet

EXAMPLES: We create a notebook and import a plain text worksheet into it.

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: name = tmp_filename() + '.txt'
sage: open(name,'w').write('foo\n{{{\n2+3\n}}}')
sage: W = nb.import_worksheet(name, 'admin')
```

W is our newly-created worksheet, with the 2+3 cell in it:

```
sage: W.name()
'foo'
sage: W.cell_list()
[Cell 0; in=2+3, out=]
```

list_window_javascript(*worksheet_filenames*)

max_history_length()

migrate_old()

Migrate all old worksheets, i.e., ones with no owner, to `/pub`.

new_worksheet_with_title_from_text(*text, owner*)

number_of_backups()

object_directory()

object_list_html()

objects()

passwords()

Return the username:password dictionary.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.create_default_users('password')
Creating default users.
sage: nb.add_user('Mark', 'password', '', force=True)sage:
list(sorted(nb.passwords().iteritems()))
[('Mark', 'aajfMKNH1hTm2'), ('_sage_', 'aaQSqAReePlq6'), ('admin', 'aajfMKNH1hTm2'), ('guest
```

plain_text_worksheet_html(*name, prompts=True*)

pretty_print(*username=None*)

publish_worksheet(*worksheet, username*)

Publish the given worksheet.

This creates a new worksheet in the `pub` directory with the same contents as `worksheet`.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('Mark','password','',force=True)sage:
W = nb.new_worksheet_with_title_from_text('First steps', owner='Mark')
sage: nb.worksheet_names()
['Mark/0']
sage: nb.publish_worksheet(nb.get_worksheet_with_filename('Mark/0'), 'Mark')
<BLANKLINE>
[Cell 0; in=, out=]
sage: sorted(nb.worksheet_names())
['Mark/0', 'pub/0']
```

quit()

quit_idle_worksheet_processes()

save(*filename=None, verbose=False*)

scratch_worksheet()

server_pool()

set_accounts(*value*)

Changes `__accounts` to `value`

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.get_accounts()
False
sage: nb.set_accounts(True)
sage: nb.get_accounts()
True
sage: nb.set_accounts(False)
sage: nb.get_accounts()
False
```

set_color(*color*)

set_debug(*show_debug*)

set_directory(*dir*)

set_not_computing()

set_pretty_print(*pretty_print*)

set_server_pool(*servers*)

set_system(*system*)

set_ulimit(*ulimit*)

system(*username=None*)

user(*username*)

Return an instance of the User class given the username of a user in a notebook.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.create_default_users('password')
Creating default users.
sage: nb.user('admin')
admin
sage: nb.user('admin')._User__email
''
sage: nb.user('admin')._User__password
'aajfMKNH1hTm2'
```

user_conf(*username*)

Return a user's configuration.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.create_default_users('password')
Creating default users.
sage: config = nb.user_conf('admin')
sage: config['max_history_length']
500
sage: config['default_system']
```

```
'sage'
sage: config['autosave_interval']
180
sage: config['default_pretty_print']
False
```

user_exists(*username*)

Return whether or not a user exists given a username.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.create_default_users('password')
Creating default users.
sage: nb.user_exists('admin')
True
sage: nb.user_exists('pub')
True
sage: nb.user_exists('mark')
False
sage: nb.user_exists('guest')
True
```

user_history(*username*)

user_history_text(*username, maxlen=None*)

user_is_admin(*user*)

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('Administrator', 'password', '', 'admin', True)sage:
nb.add_user('RegularUser', 'password', '', 'user', True)sage:
nb.user_is_admin('Administrator')
True
sage: nb.user_is_admin('RegularUser')
False
```

user_is_guest(*username*)

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.create_default_users('password')
Creating default users.
sage: nb.user_is_guest('guest')
True
sage: nb.user_is_guest('admin')
False
```

user_list()

Return list of user objects.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.create_default_users('password')
Creating default users.
sage: sorted(nb.user_list(), key=lambda k: k.username())
[_sage_, admin, guest, pub]
```

usernames()

Return list of usernames.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.create_default_users('password')
Creating default users.
sage: sorted(nb.usernames())
['_sage_', 'admin', 'guest', 'pub']
```

users()

Return dictionary of users in a notebook.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.create_default_users('password')
Creating default users.
sage: list(sorted(nb.users().iteritems()))
[('_sage_', _sage_), ('admin', admin), ('guest', guest), ('pub', pub)]
```

valid_login_names()

Return list of users that can be signed in.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.create_default_users('password')
Creating default users.
sage: nb.valid_login_names()
['admin']
sage: nb.add_user('Mark', 'password', '', force=True)sage:
nb.add_user('Sarah', 'password', '', force=True)sage:
nb.add_user('David', 'password', '', force=True)sage:
sorted(nb.valid_login_names())
['David', 'Mark', 'Sarah', 'admin']
```

worksheet_directory()

worksheet_html(*filename, do_print=False*)

worksheet_list_for_public(*username, sort='last_edited', reverse=False, search=None*)

worksheet_list_for_user(*user, typ='active', sort='last_edited', reverse=False, search=None*)

worksheet_names()

Return a list of all the names of worksheets in this notebook.

OUTPUT: list of strings.

EXAMPLES: We make a new notebook with two users and two worksheets, then list their names:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.new_worksheet_with_title_from_text('Sage', owner='sage')
sage: nb.add_user('wstein','sage','wstein@sagemath.org',force=True)
sage: W2 = nb.new_worksheet_with_title_from_text('Elliptic Curves', owner='wstein')
sage: nb.worksheet_names()
['sage/0', 'wstein/0']
```

clean_name(*name*)

load_notebook(*dir, address=None, port=None, secure=None*)

Load the notebook from the given directory, or create one in that directory if one isn't already there.

INPUT:

- `dir` - a string that defines a directory name
- `address` - the address that the notebook server will listen on

- `port` - the port the server listens on
- `secure` - whether or not the notebook is secure

make_path_relative(*dir*)
If easy, replace the absolute path `dir` by a relative one.

sort_worksheet_list(*v, sort, reverse*)
INPUT:

- `sort` - 'last_edited', 'owner', 'rating', or 'name'
- `reverse` - if True, reverse the order of the sort.

2.2 A Cell.

A cell is a single input/output block. Worksheets are built out of a list of cells.

class Cell(*id, input, out, worksheet*)

cell_output_type()
Returns the cell output type.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.cell_output_type()
'wrap'
sage: C.set_cell_output_type('nowrap')
sage: C.cell_output_type()
'nowrap'
```

changed_input_text()
Returns the changed input text for the cell. If there was any changed input text, then it is reset to '' before this method returns.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.changed_input_text()
''
sage: C.set_changed_input_text('3+3')
sage: C.input_text()
'3+3'
sage: C.changed_input_text()
'3+3'
sage: C.changed_input_text()
''
sage: C.version()
0
```

cleaned_input_text()
Returns the input text with all of the percent directives removed. If the cell is interacting, then the interacting text is returned.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '%hide\n%maxima\n2+3', '5', None)
sage: C.cleaned_input_text()
'2+3'
```

computing()
Returns True if self is in its worksheet's queue.
EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = W.new_cell_after(0, "2^2")
sage: C.computing()
False

sage: import shutil; shutil.rmtree(nb.directory())
```

delete_files()
Deletes all of the files associated with this cell.
EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = sage.server.notebook.cell.Cell(0, 'plot(sin(x),0,5)', ", W)sage:
C.evaluate()
sage: W.check_comp(wait=9999)
('d', Cell 0; in=plot(sin(x),0,5), out=
<html><font color='black'><img src='cell://sage0.png'></font></html>
<BLANKLINE>
)
sage: C.files()
['sage0.png']
sage: C.delete_files()
sage: C.files()
[]
```

delete_output()
Delete all output in this cell.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None); C
Cell 0; in=2+3, out=5
sage: C.delete_output()
sage: C
Cell 0; in=2+3, out=
```

directory()
Returns the directory associated to self. If the directory doesn't already exist, then this method creates it.
EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', W)
sage: C.directory()
'.../worksheets/sage/0/cells/0'

sage: import shutil; shutil.rmtree(nb.directory())
```

doc_html(*wrap=None, div_wrap=True, do_print=False*)
Modified version of `self.html` for the doc browser. This is a hack and needs to be improved. The problem is how to get the documentation html to display nicely between the example cells. The type setting (jsMath formating) needs attention too.

edit_text(*ncols=0, prompts=False, max_out=None*)

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.edit_text()
'{{{id=0|\n2+3\n///\n5\n}}}'
```

evaluate(*introspect=False, time=None, username=None*)

INPUT:

- `username` - name of user doing the evaluation
- `time` - if True return time computation takes
- `introspect` - either False or a pair [before_cursor, after_cursor] of strings.

EXAMPLES: We create a notebook, worksheet, and cell and evaluate it in order to compute 3^5:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: W.edit_save('Sage\n{{{\n3^5\n}}}')
sage: C = W.cell_list()[0]; C
Cell 0; in=3^5, out=
sage: C.evaluate(username='sage')
sage: W.check_comp(wait=9999)
('d', Cell 0; in=3^5, out=
243
)
sage: C
Cell 0; in=3^5, out=
243

sage: import shutil; shutil.rmtree(nb.directory())
```

evaluated()

Return True if this cell has been successfully evaluated in a currently running session.

This is not about whether the output of the cell is valid given the input.

OUTPUT:

- `bool` - whether or not this cell has been evaluated in this session

EXAMPLES: We create a worksheet with a cell that has wrong output:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: W.edit_save('Sage\n{{{\n2+3\n///\n20\n}}}')
sage: C = W.cell_list()[0]
sage: C
Cell 0; in=2+3, out=
20
```

We re-evaluate that input cell:

```
sage: C.evaluate()
sage: W.check_comp(wait=9999)
('d', Cell 0; in=2+3, out=
5
)
```

Now the output is right:

```
sage: C
Cell 0; in=2+3, out=
5
```

And the cell is considered to have been evaluated.

```
sage: C.evaluated()
True
```

```
sage: import shutil; shutil.rmtree(nb.directory())
```

files()

Returns a list of all the files in self's directory.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = sage.server.notebook.cell.Cell(0, 'plot(sin(x),0,5)', '', W)sage:
C.evaluate()
sage: W.check_comp(wait=9999)
('d', Cell 0; in=plot(sin(x),0,5), out=
<html><font color='black'><img src='cell://sage0.png'></font></html>
<BLANKLINE>
)
sage: C.files()
['sage0.png']
```

```
sage: import shutil; shutil.rmtree(nb.directory())
```

files_html(*out*)

has_output()

Returns True if there is output for this cell.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.has_output()
True
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '', None)
sage: C.has_output()
False
```

html(*wrap=None, div_wrap=True, do_print=False*)

html_in(*do_print=False, ncols=80*)

Returns the HTML code for the input of this cell.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: print C.html_in()
<div class="insert_new_cell" id="insert_new_cell_0"...</a>
```

html_new_cell_after()

Returns the HTML code for inserting a new cell after self.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: print C.html_new_cell_after()
<div class="insert_new_cell" id="insert_new_cell_0">...
```

html_new_cell_before()
Returns the HTML code for inserting a new cell before self.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: print C.html_new_cell_before()
<div class="insert_new_cell" id="insert_new_cell_0">...
```

html_out(*ncols=0, do_print=False*)

id()
Returns the id of self.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.id()
0
```

input_text()
Returns self's input text.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.input_text()
'2+3'
```

interrupt()
Record that the calculation running in this cell was interrupted.
EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = W.new_cell_after(0, "2^2")
sage: C.interrupt()
sage: C.interrupted()
True
sage: C.evaluated()
False

sage: import shutil; shutil.rmtree(nb.directory())
```

interrupted()
Returns True if the evaluation of this cell has been interrupted.
EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = W.new_cell_after(0, "2^2")
sage: C.interrupt()
sage: C.interrupted()
True

sage: import shutil; shutil.rmtree(nb.directory())
```

introspect()
TODO: Figure out what the __introspect method is for and write a better doctest.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.introspect()
False
sage: C.set_introspect("a", "b")
sage: C.introspect()
['a', 'b']
```

introspect_html()

is_asap()

Return True if this is an asap cell, i.e., evaluation of it is done as soon as possible.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.is_asap()
False
sage: C.set_asap(True)
sage: C.is_asap()
True
```

is_auto_cell()

Returns True if self is an auto cell.

An auto cell is a cell that is automatically evaluated when the worksheet starts up.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.is_auto_cell()
False
sage: C = sage.server.notebook.cell.Cell(0, '#auto\n2+3', '5', None)
sage: C.is_auto_cell()
True
```

is_html()

Returns True if this is an HTML cell. An HTML cell whose system is 'html' and is typically specified by `%html`.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, "%html\nTest HTML", None, None)
sage: C.system()
'html'
sage: C.is_html()
True
sage: C = sage.server.notebook.cell.Cell(0, "Test HTML", None, None)
sage: C.is_html()
False
```

is_interacting()

Returns True

is_interactive_cell()

Return True if this cell contains the use of interact either as a function call or a decorator.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = W.new_cell_after(0, "@interact\ndef f(a=slider(0,10,1,5):\n    print a^2")
sage: C.is_interactive_cell()
True
sage: C = W.new_cell_after(C.id(), "2+2")
```

```
sage: C.is_interactive_cell()
False

sage: import shutil; shutil.rmtree(nb.directory())
```

is_last()

Returns True if self is the last cell in the worksheet.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = W.new_cell_after(0, "2^2"); C
Cell 1; in=2^2, out=
sage: C.is_last()
True
sage: C = W.get_cell_with_id(0)
sage: C.is_last()
False

sage: import shutil; shutil.rmtree(nb.directory())
```

is_no_output()

Return True if this is an no_output cell, i.e., a cell for which we don't care at all about the output.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.is_no_output()
False
sage: C.set_no_output(True)
sage: C.is_no_output()
True
```

next_id()

Returns the id of the next cell in the worksheet associated to self. If self is not in the worksheet or self is the last cell in the cell_list, then the id of the first cell is returned.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = W.new_cell_after(0, "2^2")
sage: C = W.get_cell_with_id(0)
sage: C.next_id()
1
sage: C = W.get_cell_with_id(1)
sage: C.next_id()
0

sage: import shutil; shutil.rmtree(nb.directory())
```

notebook()

Returns the notebook object associated to self.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', W)
```

```
sage: C.notebook() is nb
True

sage: import shutil; shutil.rmtree(nb.directory())
```

output_html()

output_text(*ncols=0, html=True, raw=False, allow_interact=True*)

parse_html(*s, ncols*)

parse_percent_directives()

Returns a string which consists of the input text of this cell with the percent directives at the top removed. As it's doing this, it computes a list of all the directives and which system (if any) the cell should be run under.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '%hide\n%maxima\n2+3', '5', None)
sage: C.parse_percent_directives()
'2+3'
sage: C.percent_directives()
['hide', 'maxima']
```

percent_directives()

Returns a list of all the percent directives that appear in this cell.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '%hide\n%maxima\n2+3', '5', None)
sage: C.percent_directives()
['hide', 'maxima']
```

plain_text(*ncols=0, prompts=True, max_out=None*)

Returns the plain text version of self.

TODO: Add more comprehensive doctests.

process_cell_urls(*x*)

sage()

TODO: Figure out what exactly this does.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.sage() is None
True
```

set_asap(*asap*)

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.is_asap()
False
sage: C.set_asap(True)
sage: C.is_asap()
True
```

set_cell_output_type(*typ='wrap'*)

Sets the cell output type.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.cell_output_type()
```

```
'wrap'
sage: C.set_cell_output_type('nowrap')
sage: C.cell_output_type()
'nowrap'
```

set_changed_input_text(*new_text*)

Note that this does not update the version of the cell. This is typically used for things like tab completion.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.set_changed_input_text('3+3')
sage: C.input_text()
'3+3'
sage: C.changed_input_text()
'3+3'
```

set_id(*id*)

Sets the id of self to id.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.set_id(2)
sage: C.id()
2
```

set_input_text(*input*)

Sets the input text of self to be the string input.

TODO: Add doctests for the code dealing with interact.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = W.new_cell_after(0, "2^2")
sage: C.evaluate()
sage: W.check_comp(wait=9999)
('d', Cell 1; in=2^2, out=
4
)
sage: C.version()
0

sage: C.set_input_text('3+3')
sage: C.input_text()
'3+3'
sage: C.evaluated()
False
sage: C.version()
1

sage: import shutil; shutil.rmtree(nb.directory())
```

set_introspect(*before_prompt, after_prompt*)

TODO: Figure out what the __introspect method is for and write a better doctest.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.set_introspect("a", "b")
```

```
sage: C.introspect()
['a', 'b']
```

set_introspect_html(*html, completing=False*)

set_is_html(*v*)

Sets whether or not this cell is an HTML cell.

This is called by check_for_system_switching in worksheet.py.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.is_html()
False
sage: C.set_is_html(True)
sage: C.is_html()
True
```

set_no_output(*no_output*)

Sets whether or not this is an no_output cell, i.e., a cell for which we don't care at all about the output.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.is_no_output()
False
sage: C.set_no_output(True)
sage: C.is_no_output()
True
```

set_output_text(*output, html, sage=None*)

set_worksheet(*worksheet, id=None*)

Sets the worksheet object of self to be worksheet and optionally changes the id of self.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: W = "worksheet object"
sage: C.set_worksheet(W)
sage: C.worksheet()
'worksheet object'
sage: C.set_worksheet(None, id=2)
sage: C.id()
2
```

stop_interacting()

system()

Returns the system used to evaluate this cell. The system is specified by a percent directive like '%maxima' at the top of a cell.

If no system is explicitly specified, then None is returned which tells the notebook to evaluate the cell using the worksheet's default system.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '%maxima\n2+3', '5', None)
sage: C.system()
'maxima'
sage: prefixes = ['%hide', '%time', '']
sage: cells = [sage.server.notebook.cell.Cell(0, '%s\n2+3'%prefix, '5', None) for prefix in
sage: [(C, C.system()) for C in cells if C.system() is not None]
[]
```

time()

Returns True if the time it takes to evaluate this cell should be printed.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.time()
False
sage: C = sage.server.notebook.cell.Cell(0, '%time\n2+3', '5', None)
sage: C.time()
True
```

unset_introspect()

TODO: Figure out what the __introspect method is for and write a better doctest.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.set_introspect("a", "b")
sage: C.introspect()
['a', 'b']
sage: C.unset_introspect()
sage: C.introspect()
False
```

update_html_output(*output=''*)

Update the list of files with html-style links or embeddings for this cell.

For interactive cells the html output section is always empty, mainly because there is no good way to distinguish content (e.g., images in the current directory) that goes into the interactive template and content that would go here.

url_to_self()

Returns a notebook URL for this cell.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', W)
sage: C.url_to_self()
'/home/sage/0/cells/0'
```

version()

Returns the version number of this cell.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.version()
0
sage: C.set_input_text('2+3')
sage: C.version()
1
```

word_wrap_cols()

Returns the number of columns for word wrapping. This defaults to 70, but the default setting for a notebook is 72.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.word_wrap_cols()
70
```

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', W)
sage: C.word_wrap_cols()
72

sage: import shutil; shutil.rmtree(nb.directory())
```

worksheet()

Returns the workseet associated to self.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', W)
sage: C.worksheet() is W
True

sage: import shutil; shutil.rmtree(nb.directory())
```

worksheet_filename()

Returns the filename of the worksheet associated to self.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', W)
sage: C.worksheet_filename()
'sage/0'

sage: import shutil; shutil.rmtree(nb.directory())
```

class **Cell_generic**()

delete_output()

Delete all output in this cell. This is not executed - it is an abstract function that must be overwritten in a derived class.

EXAMPLES: This function just raises a NotImplementedError, since it most be defined in derived class.

```
sage: C = sage.server.notebook.cell.Cell_generic()
sage: C.delete_output()
...
NotImplementedError
```

is_interactive_cell()

Returns True if this cell contains the use of interact either as a function call or a decorator.

EXAMPLES:

```
sage: from sage.server.notebook.cell import Cell_generic
sage: C = sage.server.notebook.cell.TextCell(0, '2+3', None)
sage: Cell_generic.is_interactive_cell(C)
False
```

class **ComputeCell**(*id, input, out, worksheet*)

cell_output_type()
Returns the cell output type.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.cell_output_type()
'wrap'
sage: C.set_cell_output_type('nowrap')
sage: C.cell_output_type()
'nowrap'
```

changed_input_text()
Returns the changed input text for the cell. If there was any changed input text, then it is reset to '' before this method returns.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.changed_input_text()
''
sage: C.set_changed_input_text('3+3')
sage: C.input_text()
'3+3'
sage: C.changed_input_text()
'3+3'
sage: C.changed_input_text()
''
sage: C.version()
0
```

cleaned_input_text()
Returns the input text with all of the percent directives removed. If the cell is interacting, then the interacting text is returned.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '%hide\n%maxima\n2+3', '5', None)
sage: C.cleaned_input_text()
'2+3'
```

computing()
Returns True if self is in its worksheet's queue.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = W.new_cell_after(0, "2^2")
sage: C.computing()
False

sage: import shutil; shutil.rmtree(nb.directory())
```

delete_files()
Deletes all of the files associated with this cell.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = sage.server.notebook.cell.Cell(0, 'plot(sin(x),0,5)', '', W)sage:
```

```
C.evaluate()
sage: W.check_comp(wait=9999)
('d', Cell 0; in=plot(sin(x),0,5), out=
<html><font color='black'><img src='cell://sage0.png'></font></html>
<BLANKLINE>
)
sage: C.files()
['sage0.png']
sage: C.delete_files()
sage: C.files()
[]
```

delete_output()
Delete all output in this cell.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None); C
Cell 0; in=2+3, out=5
sage: C.delete_output()
sage: C
Cell 0; in=2+3, out=
```

directory()
Returns the directory associated to self. If the directory doesn't already exist, then this method creates it.
EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', W)
sage: C.directory()
'.../worksheets/sage/0/cells/0'

sage: import shutil; shutil.rmtree(nb.directory())
```

doc_html(*wrap=None, div_wrap=True, do_print=False*)
Modified version of `self.html` for the doc browser. This is a hack and needs to be improved. The problem is how to get the documentation html to display nicely between the example cells. The type setting (jsMath formating) needs attention too.

edit_text(*ncols=0, prompts=False, max_out=None*)
EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.edit_text()
'{{{id=0|\n2+3\n///\n5\n}}}'
```

evaluate(*introspect=False, time=None, username=None*)
INPUT:

- `username` - name of user doing the evaluation
- `time` - if True return time computation takes
- `introspect` - either False or a pair [before_cursor, after_cursor] of strings.

EXAMPLES: We create a notebook, worksheet, and cell and evaluate it in order to compute 3^5:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: W.edit_save('Sage\n{{{\n3^5\n}}}')
```

```
sage: C = W.cell_list()[0]; C
Cell 0; in=3^5, out=
sage: C.evaluate(username='sage')
sage: W.check_comp(wait=9999)
('d', Cell 0; in=3^5, out=
243
)
sage: C
Cell 0; in=3^5, out=
243

sage: import shutil; shutil.rmtree(nb.directory())
```

evaluated()

Return True if this cell has been successfully evaluated in a currently running session. This is not about whether the output of the cell is valid given the input.

OUTPUT:

- `bool` - whether or not this cell has been evaluated in this session

EXAMPLES: We create a worksheet with a cell that has wrong output:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: W.edit_save('Sage\n{{{\n2+3\n///\n20\n}}}')
sage: C = W.cell_list()[0]
sage: C
Cell 0; in=2+3, out=
20
```

We re-evaluate that input cell:

```
sage: C.evaluate()
sage: W.check_comp(wait=9999)
('d', Cell 0; in=2+3, out=
5
)
```

Now the output is right:

```
sage: C
Cell 0; in=2+3, out=
5
```

And the cell is considered to have been evaluated.

```
sage: C.evaluated()
True

sage: import shutil; shutil.rmtree(nb.directory())
```

files()

Returns a list of all the files in self's directory.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = sage.server.notebook.cell.Cell(0, 'plot(sin(x),0,5)', '', W)sage:
C.evaluate()
sage: W.check_comp(wait=9999)
```

```
('d', Cell 0; in=plot(sin(x),0,5), out=
<html><font color='black'><img src='cell://sage0.png'></font></html>
<BLANKLINE>
)
sage: C.files()
['sage0.png']

sage: import shutil; shutil.rmtree(nb.directory())
```

files_html(*out*)

has_output()

Returns True if there is output for this cell.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.has_output()
True
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '', None)
sage: C.has_output()
False
```

html(*wrap=None, div_wrap=True, do_print=False*)

html_in(*do_print=False, ncols=80*)

Returns the HTML code for the input of this cell.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: print C.html_in()
<div class="insert_new_cell" id="insert_new_cell_0"...</a>
```

html_new_cell_after()

Returns the HTML code for inserting a new cell after self.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: print C.html_new_cell_after()
<div class="insert_new_cell" id="insert_new_cell_0">...
```

html_new_cell_before()

Returns the HTML code for inserting a new cell before self.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: print C.html_new_cell_before()
<div class="insert_new_cell" id="insert_new_cell_0">...
```

html_out(*ncols=0, do_print=False*)

id()

Returns the id of self.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.id()
0
```

input_text()

Returns self's input text.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.input_text()
'2+3'
```

interrupt()

Record that the calculation running in this cell was interrupted.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = W.new_cell_after(0, "2^2")
sage: C.interrupt()
sage: C.interrupted()
True
sage: C.evaluated()
False

sage: import shutil; shutil.rmtree(nb.directory())
```

interrupted()

Returns True if the evaluation of this cell has been interrupted.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = W.new_cell_after(0, "2^2")
sage: C.interrupt()
sage: C.interrupted()
True

sage: import shutil; shutil.rmtree(nb.directory())
```

introspect()

TODO: Figure out what the __introspect method is for and write a better doctest.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.introspect()
False
sage: C.set_introspect("a", "b")
sage: C.introspect()
['a', 'b']
```

introspect_html()

is_asap()

Return True if this is an asap cell, i.e., evaluation of it is done as soon as possible.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.is_asap()
False
sage: C.set_asap(True)
sage: C.is_asap()
True
```

is_auto_cell()

Returns True if self is an auto cell.

An auto cell is a cell that is automatically evaluated when the worksheet starts up.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.is_auto_cell()
False
sage: C = sage.server.notebook.cell.Cell(0, '#auto\n2+3', '5', None)
sage: C.is_auto_cell()
True
```

is_html()

Returns True if this is an HTML cell. An HTML cell whose system is 'html' and is typically specified by `%html`.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, "%html\nTest HTML", None, None)
sage: C.system()
'html'
sage: C.is_html()
True
sage: C = sage.server.notebook.cell.Cell(0, "Test HTML", None, None)
sage: C.is_html()
False
```

is_interacting()

Returns True

is_interactive_cell()

Return True if this cell contains the use of interact either as a function call or a decorator.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = W.new_cell_after(0, "@interact\ndef f(a=slider(0,10,1,5):\n    print a^2")
sage: C.is_interactive_cell()
True
sage: C = W.new_cell_after(C.id(), "2+2")
sage: C.is_interactive_cell()
False

sage: import shutil; shutil.rmtree(nb.directory())
```

is_last()

Returns True if self is the last cell in the worksheet.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = W.new_cell_after(0, "2^2"); C
Cell 1; in=2^2, out=
sage: C.is_last()
True
sage: C = W.get_cell_with_id(0)
sage: C.is_last()
False

sage: import shutil; shutil.rmtree(nb.directory())
```

is_no_output()

Return True if this is an no_output cell, i.e., a cell for which we don't care at all about the output.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.is_no_output()
False
sage: C.set_no_output(True)
sage: C.is_no_output()
True
```

next_id()

Returns the id of the next cell in the worksheet associated to self. If self is not in the worksheet or self is the last cell in the cell_list, then the id of the first cell is returned.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = W.new_cell_after(0, "2^2")
sage: C = W.get_cell_with_id(0)
sage: C.next_id()
1
sage: C = W.get_cell_with_id(1)
sage: C.next_id()
0

sage: import shutil; shutil.rmtree(nb.directory())
```

notebook()

Returns the notebook object associated to self.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', W)
sage: C.notebook() is nb
True

sage: import shutil; shutil.rmtree(nb.directory())
```

output_html()

output_text(*ncols=0, html=True, raw=False, allow_interact=True*)

parse_html(*s, ncols*)

parse_percent_directives()

Returns a string which consists of the input text of this cell with the percent directives at the top removed. As it's doing this, it computes a list of all the directives and which system (if any) the cell should be run under.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '%hide\n%maxima\n2+3', '5', None)
sage: C.parse_percent_directives()
'2+3'
sage: C.percent_directives()
['hide', 'maxima']
```

percent_directives()
Returns a list of all the percent directives that appear in this cell.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '%hide\n%maxima\n2+3', '5', None)
sage: C.percent_directives()
['hide', 'maxima']
```

plain_text(*ncols=0, prompts=True, max_out=None*)
Returns the plain text version of self.
TODO: Add more comprehensive doctests.

process_cell_urls(*x*)

sage()
TODO: Figure out what exactly this does.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.sage() is None
True
```

set_asap(*asap*)
EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.is_asap()
False
sage: C.set_asap(True)
sage: C.is_asap()
True
```

set_cell_output_type(*typ='wrap'*)
Sets the cell output type.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.cell_output_type()
'wrap'
sage: C.set_cell_output_type('nowrap')
sage: C.cell_output_type()
'nowrap'
```

set_changed_input_text(*new_text*)
Note that this does not update the version of the cell. This is typically used for things like tab completion.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.set_changed_input_text('3+3')
sage: C.input_text()
'3+3'
sage: C.changed_input_text()
'3+3'
```

set_id(*id*)
Sets the id of self to id.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.set_id(2)
```

```
sage: C.id()
2
```

set_input_text(*input*)

Sets the input text of self to be the string input.

TODO: Add doctests for the code dealing with interact.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = W.new_cell_after(0, "2^2")
sage: C.evaluate()
sage: W.check_comp(wait=9999)
('d', Cell 1; in=2^2, out=
4
)
sage: C.version()
0

sage: C.set_input_text('3+3')
sage: C.input_text()
'3+3'
sage: C.evaluated()
False
sage: C.version()
1

sage: import shutil; shutil.rmtree(nb.directory())
```

set_introspect(*before_prompt, after_prompt*)

TODO: Figure out what the __introspect method is for and write a better doctest.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.set_introspect("a", "b")
sage: C.introspect()
['a', 'b']
```

set_introspect_html(*html, completing=False*)

set_is_html(*v*)

Sets whether or not this cell is an HTML cell.

This is called by check_for_system_switching in worksheet.py.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.is_html()
False
sage: C.set_is_html(True)
sage: C.is_html()
True
```

set_no_output(*no_output*)

Sets whether or not this is an no_output cell, i.e., a cell for which we don't care at all about the output.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.is_no_output()
```

```
False
sage: C.set_no_output(True)
sage: C.is_no_output()
True
```

set_output_text(*output, html, sage=None*)

set_worksheet(*worksheet, id=None*)

Sets the worksheet object of self to be worksheet and optionally changes the id of self.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: W = "worksheet object"
sage: C.set_worksheet(W)
sage: C.worksheet()
'worksheet object'
sage: C.set_worksheet(None, id=2)
sage: C.id()
2
```

stop_interacting()

system()

Returns the system used to evaluate this cell. The system is specified by a percent directive like '%maxima' at the top of a cell.

If no system is explicitly specified, then None is returned which tells the notebook to evaluate the cell using the worksheet's default system.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '%maxima\n2+3', '5', None)
sage: C.system()
'maxima'
sage: prefixes = ['%hide', '%time', '']
sage: cells = [sage.server.notebook.cell.Cell(0, '%s\n2+3'%prefix, '5', None) for prefix in
sage: [(C, C.system()) for C in cells if C.system() is not None]
[]
```

time()

Returns True if the time it takes to evaluate this cell should be printed.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.time()
False
sage: C = sage.server.notebook.cell.Cell(0, '%time\n2+3', '5', None)
sage: C.time()
True
```

unset_introspect()

TODO: Figure out what the __introspect method is for and write a better doctest.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.set_introspect("a", "b")
sage: C.introspect()
['a', 'b']
sage: C.unset_introspect()
sage: C.introspect()
False
```

update_html_output(*output=''*)
Update the list of files with html-style links or embeddings for this cell.

For interactive cells the html output section is always empty, mainly because there is no good way to distinguish content (e.g., images in the current directory) that goes into the interactive template and content that would go here.

url_to_self()
Returns a notebook URL for this cell.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', W)
sage: C.url_to_self()
'/home/sage/0/cells/0'
```

version()
Returns the version number of this cell.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.version()
0
sage: C.set_input_text('2+3')
sage: C.version()
1
```

word_wrap_cols()
Returns the number of columns for word wrapping. This defaults to 70, but the default setting for a notebook is 72.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', None)
sage: C.word_wrap_cols()
70

sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', W)
sage: C.word_wrap_cols()
72

sage: import shutil; shutil.rmtree(nb.directory())
```

worksheet()
Returns the workseet associated to self.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', W)
sage: C.worksheet() is W
True

sage: import shutil; shutil.rmtree(nb.directory())
```

worksheet_filename()
Returns the filename of the worksheet associated to self.
EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: C = sage.server.notebook.cell.Cell(0, '2+3', '5', W)
sage: C.worksheet_filename()
'sage/0'

sage: import shutil; shutil.rmtree(nb.directory())
```

class TextCell(*id, text, worksheet*)

delete_output()
Delete all output in this cell. This does nothing since text cells have no output.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.TextCell(0, '2+3', None)
sage: C
TextCell 0: 2+3
sage: C.delete_output()
sage: C
TextCell 0: 2+3
```

edit_text()
EXAMPLES:

```
sage: C = sage.server.notebook.cell.TextCell(0, '2+3', None)
sage: C.edit_text()
'2+3'
```

html(*ncols=0, do_print=False, do_math_parse=True, editing=False*)
Returns an HTML version of self as a string.
INPUT:

- do_math_parse - bool (default: True) If True, call math_parse (defined in cell.py) on the html.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.TextCell(0, '2+3', None)
sage: C.html()
'<div class="text_cell" id="cell_text_0">2+3...'
sage: C.set_input_text("$2+3$")
sage: C.html(do_math_parse=True)
'<div class="text_cell" id="cell_text_0"><span class="math">2+3</span>...'
```

html_inner(*ncols=0, do_print=False, do_math_parse=True, editing=False*)
Returns an HTML version of the content of self as a string.
INPUT:

- do_math_parse - bool (default: True) If True, call math_parse (defined in cell.py) on the html.

EXAMPLES:

```
sage: C = sage.server.notebook.cell.TextCell(0, '2+3', None)
sage: C.html_inner()
'2+3...'
sage: C.set_input_text("$2+3$")
sage: C.html_inner(do_math_parse=True)
'<span class="math">2+3</span>...'
```

id()
EXAMPLES:

```
sage: C = sage.server.notebook.cell.TextCell(0, '2+3', None)
sage: C.id()
0
```

is_auto_cell()
EXAMPLES:

```
sage: C = sage.server.notebook.cell.TextCell(0, '2+3', None)
sage: C.is_auto_cell()
False
```

plain_text(*prompts=False*)
EXAMPLES:

```
sage: C = sage.server.notebook.cell.TextCell(0, '2+3', None)
sage: C.plain_text()
'2+3'
```

set_cell_output_type(*typ='wrap'*)
This does nothing for TextCells.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.TextCell(0, '2+3', None)
sage: C.set_cell_output_type("wrap")
```

set_input_text(*input_text*)
Sets the input text of self to be input_text.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.TextCell(0, '2+3', None)
sage: C
TextCell 0: 2+3
sage: C.set_input_text("3+2")
sage: C
TextCell 0: 3+2
```

set_worksheet(*worksheet, id=None*)
Sets the worksheet object of self to be worksheet and optionally changes the id of self.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.TextCell(0, '2+3', None)
sage: W = "worksheet object"
sage: C.set_worksheet(W)
sage: C.worksheet()
'worksheet object'
sage: C.set_worksheet(None, id=2)
sage: C.id()
2
```

worksheet()
Returns the worksheet object associated to self.
EXAMPLES:

```
sage: C = sage.server.notebook.cell.TextCell(0, '2+3', 'worksheet object')
sage: C.worksheet()
'worksheet object'
```

format_exception(*s0, ncols*)

Make it so excpetions don't appear expanded by default.

INPUT:

- `s0` - string
- `ncols` - integer

OUTPUT: string

If s0 contains "notracebacks" then this function always returns s0

EXAMPLES:

```
sage: sage.server.notebook.cell.format_exception(sage.server.notebook.cell.TRACEBACK,80)
'\nTraceback (click to the left for traceback)\n...\nTraceback (most recent call last):'
sage: sage.server.notebook.cell.format_exception(sage.server.notebook.cell.TRACEBACK + "notraceb
'Traceback (most recent call last):notracebacks'
```

number_of_rows(*txt, ncols*)

Returns the number of rows needed to display the string in txt if there are a maximum of ncols columns per row.

EXAMPLES:

```
sage: from sage.server.notebook.cell import number_of_rows
sage: s = "asdfasdf\nasdfasdf\n"
sage: number_of_rows(s, 8)
2
sage: number_of_rows(s, 5)
4
sage: number_of_rows(s, 4)
4
```

2.3 A Worksheet.

A worksheet is embedded in a webpage that is served by the Sage server. It is a linearly-ordered collections of numbered cells, where a cell is a single input/output block.

The worksheet module is responsible for running calculations in a worksheet, spawning Sage processes that do all of the actual work and are controlled via pexpect, and reporting on results of calculations. The state of the cells in a worksheet is stored on the filesystem (not in the notebook pickle sobj).

AUTHORS:

- William Stein

class Worksheet(*name, dirname, notebook_worksheet_directory, system, owner, docbrowser=False, pretty_print=False, auto_publish=False*)

DIR()

Return the absolute path to the directory that contains the Sage Notebook directory for the notebook that contains this worksheet.

OUTPUT: string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('A Test Worksheet', 'admin')
sage: W.DIR()    # random output
'/Users/was/.sage/temp/teragon_2.local/19129'
```

add_collaborator(*user*)

Add the given user as a collaborator on this worksheet.

INPUT:

- `user` - a string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('diophantus','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Collaborator test', 'admin')
sage: W.collaborators()
[]
sage: W.add_collaborator('diophantus')
sage: W.collaborators()
['diophantus']
```

add_viewer(*user*)

Add the given user as an allowed viewer of this worksheet.

INPUT:

- `user` - string (username)

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('diophantus','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Viewer test', 'admin')
sage: W.add_viewer('diophantus')
sage: W.viewers()
['diophantus']
```

append(*L*)

append_new_cell()

Create and append a new cell to the list of cells.

OUTPUT: a new empty cell

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Test Edit Save', 'admin')
sage: W
[Cell 0; in=, out=]
sage: W.append_new_cell()
Cell 1; in=, out=
sage: W
[Cell 0; in=, out=, Cell 1; in=, out=]
```

attach(*filename*)

attached_data_files()

Return a list of the filenames of files in the worksheet data directory.

OUTPUT: list of strings

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('A Test Worksheet', 'admin')
sage: W.attached_data_files()
[]
sage: open('%s/foo.data'%W.data_directory(),'w').close()
sage: W.attached_data_files()
['foo.data']
```

attached_files()

attached_html()

autosave(*username*)

best_completion(*s, word*)

cell_id_list()

Return a new list of the id's of cells in this worksheet.

OUTPUT: a new list

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Test Edit Save', 'admin')
```

Now we set the worksheet to have two cells with the default id of 0 and another with id 10.

```
sage: W.edit_save('Sage\n{{{\n2+3\n///\n5\n}}}\n{{{id=10|\n2+8\n///\n10\n}}}')
sage: W.cell_id_list()
[0, 10]
```

cell_list()

Return a reference to the list of the all the cells in this worksheet.

OUTPUT:

- `list` - a list of cells

Note: This function loads the cell list from disk (the file worksheet.txt) if it isn't available in memory.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Test Edit Save', 'admin')
sage: W.edit_save('Sage\n{{{\n2+3\n///\n5\n}}}\n{{{\n2+8\n///\n10\n}}}')
sage: v = W.cell_list(); v
[Cell 0; in=2+3, out=
5, Cell 1; in=2+8, out=
10]
sage: v[0]
Cell 0; in=2+3, out=
5
```

cells_directory()

Return the directory in which the cells of this worksheet are evaluated.

OUTPUT: string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('A Test Worksheet', 'admin')
sage: W.cells_directory()
'.../worksheets/admin/0/cells/'
```

check_cell(*id*)

Check the status on computation of the cell with given id.

INPUT:

- `id` - an integer

OUTPUT:

- `status` - a string, either 'd' (done) or 'w' (working)
- `cell` - the cell with given id

check_comp(*wait=0.20000000000000001*)

Check on currently computing cells in the queue.

INPUT:

- `wait` - float (default: 0.2); how long to wait for output.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: W.edit_save('Sage\n{{{\n3^20\n}}}')
sage: W.cell_list()[0].evaluate()
sage: W.check_comp()      # random output -- depends on computer speed
('d', Cell 0; in=3^20, out=
3486784401
)
sage: nb.delete()
```

check_for_system_switching(*input, cell*)

Check for input cells that start with `%foo`, where `foo` is an object with an eval method.

INPUT:

- `s` - a string of the code from the cell to be executed
- `C` - the cell object

EXAMPLES: First, we set up a new notebook and worksheet.

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
```

We first test running a native command in 'sage' mode and then a GAP cell within Sage mode.

```
sage: W.edit_save('Sage\nsystem:sage\n{{{\n2+3\n}}}\n\n{{{\n%gap\nSymmetricGroup(5)\n}}}')
sage: c0, c1 = W.cell_list()
sage: W.check_for_system_switching(c0.cleaned_input_text(), c0)
(False, '2+3')
sage: W.check_for_system_switching(c1.cleaned_input_text(), c1)
(True, "print _support_.syseval(gap, ur'''SymmetricGroup(5)''', '...')")

sage: c0.evaluate()
sage: W.check_comp()  #random output -- depends on the computer's speed
('d', Cell 0; in=2+3, out=
5
)
sage: c1.evaluate()
sage: W.check_comp()  #random output -- depends on the computer's speed
('d', Cell 1; in=%gap
SymmetricGroup(5), out=
Sym( [ 1 .. 5 ] )
)
```

Next, we run the same commands but from 'gap' mode.

```
sage: W.edit_save('Sage\nsystem:gap\n{{{\n%sage\n2+3\n}}}\n\n{{{\nSymmetricGroup(5)\n}}}')
sage: c0, c1 = W.cell_list()
sage: W.check_for_system_switching(c0.cleaned_input_text(), c0)
(False, '2+3')
sage: W.check_for_system_switching(c1.cleaned_input_text(), c1)
(True,
 "print _support_.syseval(gap, ur'''SymmetricGroup(5)''', '...')")
```

```
sage: c0.evaluate()
sage: W.check_comp()  #random output -- depends on the computer's speed
('d', Cell 0; in=%sage
2+3, out=
5
)
sage: c1.evaluate()
sage: W.check_comp()  #random output -- depends on the computer's speed
('d', Cell 1; in=SymmetricGroup(5), out=
Sym( [ 1 .. 5 ] )
)
```

clear()

clear_queue()

collaborator_names(*max=None*)

Returns a string of the non-owner collaborators on this worksheet.

INPUT:

- `max` - an integer. If this is specified, then only max number of collaborators are shown.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('test1', 'admin')
sage: C = W.collaborators(); C
[]
sage: C.append('sage')
sage: C.append('wstein')
sage: W.collaborator_names()
'sage, wstein'
sage: W.collaborator_names(max=1)
'sage, ...'
```

collaborators()

Return a (reference to the) list of the collaborators who can also view and modify this worksheet.

OUTPUT: list

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('test1', 'admin')
sage: C = W.collaborators(); C
[]
sage: C.append('sage')
sage: W.collaborators()
['sage']
```

completions_html(*id, s, cols=3*)

compute_cell_id_list()

compute_process_has_been_started()

Return True precisely if the compute process has been started, irregardless of whether or not it is currently churning away on a computation.

computing()

Return whether or not a cell is currently being run in the worksheet Sage process.

conf()

Return the configuration object for this worksheet, which is stored in an sobj in the worksheet directory.

OUTPUT: worksheet configuration object.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('test1', 'admin')
sage: W.conf()
Configuration: {}
```

cython_import(*cmd, cell*)

data_directory()

Return path to directory where worksheet data is stored.

OUTPUT: string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('A Test Worksheet', 'admin')
sage: W.data_directory()
'.../worksheets/admin/0/data/'
```

date_edited()

Returns the date the worksheet was last edited if already recorded otherwise the current local time is recorded and returned.

delete_all_output(*username*)

Delete all the output in all the worksheet cells.

INPUT:

- `username` - name of the user requesting the deletion.

EXAMPLES: We create a new notebook, user, and a worksheet with one cell.

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: W.edit_save('Sage\nsystem:sage\n{{{\n2+3\n///\n5\n}}}')
```

Notice that there is 1 cell with 5 in its output.

```
sage: W.cell_list()
[Cell 0; in=2+3, out=
5]
```

We now delete the output, observe that it is gone.

```
sage: W.delete_all_output('sage')
sage: W.cell_list()
[Cell 0; in=2+3, out=]
```

If an invalid user tries to delete all, a ValueError is raised.

```
sage: W.delete_all_output('hacker')
...
ValueError: user 'hacker' not allowed to edit this worksheet
```

Clean up.

```
sage: nb.delete()
```

delete_cell_input_files()

Delete all the files `code_%s.py` and `code_%s.spyx` that are created when evaluating cells. We do this when we first start the notebook to get rid of clutter.

delete_cell_with_id(*id*)

Remove the cell with given id and return the cell before it.

delete_cells_directory()

Delete the directory in which all the cell computations occur.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: W.edit_save('Sage\n{{{\n3^20\n}}}')
sage: sorted(os.listdir(W.directory()))
['snapshots', 'worksheet.txt']
sage: W.cell_list()[0].evaluate()
sage: sorted(os.listdir(W.directory()))
['cells', 'code', 'data', 'snapshots', 'worksheet.txt']
sage: W.delete_cells_directory()
sage: sorted(os.listdir(W.directory()))
['code', 'data', 'snapshots', 'worksheet.txt']
```

delete_notebook_specific_data()

Delete data from this worksheet this is specific to a certain notebook. This means deleting the attached files, collaborators, and viewers.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('hilbert','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('test1', 'admin')
sage: W.add_viewer('hilbert')
sage: W.delete_notebook_specific_data()
sage: W.viewers()
[]
sage: W.add_collaborator('hilbert')
sage: W.collaborators()
['admin', 'hilbert']
sage: W.delete_notebook_specific_data()
sage: W.collaborators()
['admin']
```

delete_user(*user*)

Delete a user from having any view or ownership of this worksheet.

INPUT:

- `user` - string; the name of a user

EXAMPLES: We create a notebook with 2 users and 1 worksheet that both view.

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('wstein','sage','wstein@sagemath.org',force=True)
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.new_worksheet_with_title_from_text('Sage', owner='sage')
sage: W.add_viewer('wstein')
sage: W.owner()
'sage'
sage: W.viewers()
['wstein']
```

We delete the sage user from the worksheet W. This makes wstein the new owner.

```
sage: W.delete_user('sage')
sage: W.viewers()
['wstein']
sage: W.owner()
'wstein'
```

Then we delete wstein from W, which makes the owner None:

```
sage: W.delete_user('wstein')
sage: W.owner() is None
True
sage: W.viewers()
[]
```

Finally, we clean up.

```
sage: nb.delete()
```

detach (*filename*)

directory()

Return the full path to the directory where this worksheet is stored.

OUTPUT: string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('A Test Worksheet', 'admin')
sage: W.directory()
'.../worksheets/admin/0'
```

do_sage_extensions_preparsing (*s, files_seen_so_far=, [], this_file=''*)

docbrowser()

Return True if this is a docbrowser worksheet.

OUTPUT: bool

EXAMPLES: We first create a standard worksheet for which docbrowser is of course False:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('test1', 'admin')
sage: W.docbrowser()
False
```

We create a worksheet for which docbrowser is True:

```
sage: W = nb.create_new_worksheet('docs', 'admin', docbrowser=True)
sage: W.docbrowser()
True
```

edit_save (*text, ignore_ids=False*)

Set the contents of this worksheet to the worksheet defined by the plain text string text, which should be a sequence of html and 's code blocks.

INPUT:

- `text` - a string
- `ignore_ids` - bool (default: False); if True ignore all the id's in the code block.

EXAMPLES: We create a new test notebook and a worksheet.

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test Edit Save', 'sage')
```

We set the contents of the worksheet using the edit_save command.

```
sage: W.edit_save('Sage\n{{{\n2+3\n///\n5\n}}}\n{{{\n2+8\n///\n10\n}}}')
sage: W
[Cell 0; in=2+3, out=
5, Cell 1; in=2+8, out=
10]
```

```
sage: W.name()
'Sage'
```

edit_text()
Returns a plain-text version of the worksheet with {{{}}} wiki-formatting, suitable for hand editing.

enqueue(*C, username=None, next=False*)
Queue up the cell C for evaluation in this worksheet.
INPUT:

- C - a Cell
- username - the name of the user that is evaluating this cell (mainly used for loging)

Note: If C.is_asap() is True, then we put C as close to the beginning of the queue as possible, but after all asap cells. Otherwise, C goes at the end of the queue.

eval_asap_no_output(*cmd, username=None*)

everyone_has_deleted_this_worksheet()
Return True if all users have deleted this worksheet, so we know we can safely purge it from disk.
OUTPUT: bool
EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: W.everyone_has_deleted_this_worksheet()
False
sage: W.move_to_trash('admin')
sage: W.everyone_has_deleted_this_worksheet()
True
```

filename()
Return the filename (really directory) where the files associated to this worksheet are stored.
EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('A Test Worksheet', 'admin')
sage: W.filename()
'admin/0'
sage: sorted(os.listdir(nb.directory() + '/worksheets/' + W.filename()))
['snapshots', 'worksheet.txt']
```

filename_without_owner()
Return the part of the worksheet filename after the last /, i.e., without any information about the owner of this worksheet.
EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('A Test Worksheet', 'admin')
sage: W.filename_without_owner()
'0'
sage: W.filename()
'admin/0'
```

get_cell_system(*cell*)
Returns the system that will run the input in cell. This defaults to worksheet's system if there is not one specifically given in the cell.
EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: W.edit_save('Sage\nsystem:sage\n{{{\n2+3\n}}}\n\n{{{\n%gap\nSymmetricGroup(5)\n}}}')
sage: c0, c1 = W.cell_list()
sage: W.get_cell_system(c0)
'sage'
sage: W.get_cell_system(c1)
'gap'
sage: W.edit_save('Sage\nsystem:gap\n{{{\n%sage\n2+3\n}}}\n\n{{{\nSymmetricGroup(5)\n}}}')
sage: c0, c1 = W.cell_list()
sage: W.get_cell_system(c0)
'sage'
sage: W.get_cell_system(c1)
'gap'
```

get_cell_with_id(*id*)

get_snapshot_text_filename(*name*)

has_published_version()

Return True if there is a published version of this worksheet.

OUTPUT: bool

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: P = nb.publish_worksheet(W, 'admin')
sage: P.has_published_version()
False
sage: W.has_published_version()
True
```

hide_all()

html(*include_title=True, do_print=False, confirm_before_leave=False, read_only=False*)

html_data_options_list()

html_file_menu()

html_menu()

html_ratings_info()

Return html that renders to give a summary of how this worksheet has been rated.

OUTPUT:

- `string` - a string of HTML as a bunch of table rows.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: W.rate(0, 'this lacks content', 'riemann')
sage: W.rate(3, 'this is great', 'hilbert')
sage: W.html_ratings_info()
'<tr><td>hilbert</td><td align=center>3</td><td>this is great</td></tr>\n<tr><td>riemann</td>
```

html_save_discard_buttons()

html_share_publish_buttons(*select=None, backwards=False*)

html_time_last_edited()

html_time_since_last_edited()

html_title(*username='guest'*)

html_worksheet_body(*do_print, publish=False*)

hunt_file(*filename*)

initialize_sage()

input_text()
Return text version of the input to the worksheet.

interrupt()
Interrupt all currently queued up calculations.

OUTPUT:

- `bool` - return True if no problems interrupting calculation return False if the Sage interpreter had to be restarted.

EXAMPLES: We create a worksheet and start a large factorization going:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: W.edit_save('Sage\n{{{\nfactor(2^997-1)\n}}}')
sage: W.cell_list()[0].evaluate()
```

It's running still

```
sage: W.check_comp()
('w', Cell 0; in=factor(2^997-1), out=...)
```

We interrupt it successfully.

```
sage: W.interrupt()          # random -- could fail on heavily loaded machine
True
```

Now we check and nothing is computing.

```
sage: W.check_comp()         # random -- could fail on heavily loaded machine
('e', None)
```

Clean up.

```
sage: nb.delete()
```

is_active(*user*)
Return True if this worksheet is active for the given user.

INPUT:

- `user` - string

OUTPUT: bool

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Active Test', 'admin')
sage: W.is_active('admin')
True
sage: W.move_to_archive('admin')
sage: W.is_active('admin')
False
```

is_archived(*user*)
Return True if this worksheet is archived for the given user.

INPUT:

- `user` - string

OUTPUT: bool

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Archived Test', 'admin')
sage: W.is_archived('admin')
False
sage: W.move_to_archive('admin')
sage: W.is_archived('admin')
True
```

is_auto_publish()

Returns boolean of "Is this worksheet set to be published automatically when saved?" if private variable "autopublish" is set otherwise False is returned and the variable is set to False.

is_doc_worksheet()

is_last_id_and_previous_is_nonempty(*id*)

is_owner(*username*)

is_published()

Return True if this worksheet is a published worksheet.

OUTPUT:

- `bool` - whether or not owner is 'pub'

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: W.is_published()
False
sage: W.set_owner('pub')
sage: W.is_published()
True
```

is_publisher(*username*)

Return True if username is the username of the publisher of this worksheet, assuming this worksheet was published.

INPUT:

- `username` - string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: P = nb.publish_worksheet(W, 'admin')
sage: P.is_publisher('hearst')
False
sage: P.is_publisher('admin')
True
```

is_rater(*username*)

Return True is the user with given username has rated this worksheet.

INPUT:

- `username` - string

OUTPUT: bool

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: W.rate(0, 'this lacks content', 'riemann')
sage: W.is_rater('admin')
False
sage: W.is_rater('riemann')
True
```

is_trashed(*user*)

Return True if this worksheet is in the trash for the given user.

INPUT:

- `user` - string

OUTPUT: bool

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Trash Test', 'admin')
sage: W.is_trashed('admin')
False
sage: W.move_to_trash('admin')
sage: W.is_trashed('admin')
True
```

javascript_confirm_before_leave()

javascript_for_being_active_worksheet()

javascript_for_jsmath_rendering()

last_compute_walltime()

last_edited()

last_to_edit()

limit_snapshots()

This routine will limit the number of snapshots of a worksheet, as specified by a hard-cioded value below.

Prior behavior was to allow unlimited numbers of snapshots and so this routine will not delete files created prior to this change.

This assumes snapshot names correspond to the `time.time()` method used to create base filenames in seconds in UTC time, and that there are no other extraneous files in the directory.

load_any_changed_attached_files(*s*)

Modify `s` by prepending any necessary load commands corresponding to attached files that have changed.

load_path()

move_out_of_trash(*user*)

Exactly the same as set_active(user).

INPUT:

- `user` - string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Active Test', 'admin')
sage: W.move_to_trash('admin')
sage: W.is_active('admin')
False
sage: W.move_out_of_trash('admin')
sage: W.is_active('admin')
True
```

move_to_archive(*user*)

Move this worksheet to be archived for the given user.

INPUT:

- `user` - string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Archive Test', 'admin')
sage: W.move_to_archive('admin')
sage: W.is_archived('admin')
True
```

move_to_trash(*user*)

Move this worksheet to the trash for the given user.

INPUT:

- `user` - string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Trash Test', 'admin')
sage: W.move_to_trash('admin')
sage: W.is_trashed('admin')
True
```

name()

Return the name of this worksheet.

OUTPUT: string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('A Test Worksheet', 'admin')
sage: W.name()
'A Test Worksheet'
```

new_cell_after(*id, input=''*)

Insert a new cell into the cell list after the cell with the given integer id.

INPUT:

- `id` - integer
- `input` - string

OUTPUT:

A new cell with the given input text (empty by default).

new_cell_before(*id, input=''*)

Insert a new cell into the cell list before the cell with the given integer id. If the id is not the id of any cell, inserts a new cell at the end of the cell list.

INPUT:

- `id` - integer
- `input` - string

OUTPUT:

A new cell with the given input text (empty by default).

new_text_cell_after(*id, input=''*)

Insert a new cell into the cell list after the cell with the given integer id. If the id is not the id of any cell, inserts a new cell at the end of the cell list.

INPUT:

- `id` - integer
- `input` - string

OUTPUT:

A new cell with the given input text (empty by default).

new_text_cell_before(*id, input=''*)

Insert a new cell into the cell list before the cell with the given integer id. If the id is not the id of any cell, inserts a new cell at the end of the cell list.

INPUT:

- `id` - integer
- `input` - string

OUTPUT:

A new cell with the given input text (empty by default).

next_block_id()

next_hidden_id()

notebook()

Return the notebook that contains this worksheet.

OUTPUT: a Notebook object.

EXAMPLES: This really returns the Notebook object that is set as a global variable of the twist module.

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('A Test Worksheet', 'admin')
sage: W.notebook()
<class 'sage.server.notebook.notebook.Notebook'>
sage: W.notebook() is sage.server.notebook.twist.notebook
True
```

owner()

ping(*username*)

plain_text(*prompts=False, banner=True*)

Return a plain-text version of the worksheet.

INPUT:

- `prompts` - if True format for inclusion in docstrings.

postprocess_output(*out, C*)

preparse(*s*)

preparse_input(*input, C*)

preparse_introspection_input(*input, C, introspect*)

preparse_nonswitched_input(*input*)

pretty_print()

Return True if output shold be pretty printed by default.

OUTPUT:

- `bool` - True of False

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('A Test Worksheet', 'admin')
sage: W.pretty_print()
False
sage: W.set_pretty_print('true')
sage: W.pretty_print()
True
```

published_version()
If this worksheet was published, return the published version of this worksheet. Otherwise, raise a ValueError.

OUTPUT: a worksheet (or raise a ValueError)

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: P = nb.publish_worksheet(W, 'admin')
sage: W.published_version() is P
True
```

publisher()
Return username of user that published this worksheet.

OUTPUT: string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: S = nb.publish_worksheet(W, 'admin')
sage: S.publisher()
'admin'
```

queue()

queue_id_list()

quit()

quit_if_idle(*timeout*)
Quit the worksheet process if it has been "idle" for more than `timeout` seconds, where idle is by definition that the worksheet has not reported back that it is actually computing. I.e., an ignored worksheet process (since the user closed their browser) is also considered idle, even if code is running.

rate(*x, comment, username*)
Set the rating on this worksheet by the given user to x and also set the given comment.

INPUT:

- `x` - integer
- `comment` - string
- `usename` - string

EXAMPLES: We create a worksheet and rate it, then look at the ratings.

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: W.rate(3, 'this is great', 'hilbert')
sage: W.ratings()
[('hilbert', 3, 'this is great')]
```

Note that only the last rating by a user counts:

```
sage: W.rate(1, 'this lacks content', 'riemann')
sage: W.rate(0, 'this lacks content', 'riemann')
sage: W.ratings()
[('hilbert', 3, 'this is great'), ('riemann', 0, 'this lacks content')]
```

rating()
Return overall aerage rating of self.

OUTPUT: float or the int -1 to mean "not rated"

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: W.rating()
-1
sage: W.rate(0, 'this lacks content', 'riemann')
sage: W.rate(3, 'this is great', 'hilbert')
sage: W.rating()
1.5
```

ratings()
Return all the ratings of this worksheet.
OUTPUT:
- `list` - a reference to the list of ratings.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: W.ratings()
[]
sage: W.rate(0, 'this lacks content', 'riemann')
sage: W.rate(3, 'this is great', 'hilbert')
sage: W.ratings()
[('riemann', 0, 'this lacks content'), ('hilbert', 3, 'this is great')]
```

record_edit(*user*)

reset_interact_state()
Reset the interact state of this worksheet.

restart_sage()
Restart Sage kernel.

revert_to_last_saved_state()

revert_to_snapshot(*name*)

sage()
Return a started up copy of Sage initialized for computations.
If this is a published worksheet, just return None, since published worksheets must not have any compute functionality.
OUTPUT: a Sage interface

satisfies_search(*search*)
Return True if all words in search are in the saved text of the worksheet.
INPUT: search is a string that describes a search query, i.e., a space-separated collections of words.
OUTPUT: True if the search is satisfied by self, i.e., all the words appear in the text version of self.

save()

save_snapshot(*user, E=None*)

set_active(*user*)
Set his worksheet to be active for the given user.
INPUT:
- `user` - string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Active Test', 'admin')
sage: W.move_to_archive('admin')
```

```
sage: W.is_active('admin')
False
sage: W.set_active('admin')
sage: W.is_active('admin')
True
```

set_auto_publish()
Sets the worksheet to be published automatically when the worksheet is saved if the worksheet isn't already set to this otherwise it is set not to.

set_cell_counter()

set_collaborators(*v*)
Set the list of collaborators to those listed in the list v of strings.

INPUT:

- v - a list of strings

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: nb.add_user('hilbert','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('test1', 'admin')
sage: W.set_collaborators(['sage', 'admin', 'hilbert', 'sage'])
```

Note that repeats are not added multiple times and admin - the owner - isn't added:

```
sage: W.collaborators()
['hilbert', 'sage']
```

set_filename(*filename*)
Set the worksheet filename (actually directory).

INPUT:

- filename - string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('A Test Worksheet', 'admin')
sage: W.filename()
'admin/0'
sage: W.set_filename('admin/10')
sage: W.filename()
'admin/10'
```

set_filename_without_owner(*nm*)
Set this worksheet filename (actually directory) by getting the owner from the pre-stored owner via `self.owner()`.

INPUT:

- nm - string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('A Test Worksheet', 'admin')
sage: W.filename()
'admin/0'
sage: W.set_filename_without_owner('5')
sage: W.filename()
'admin/5'
```

set_is_doc_worksheet(*value*)

set_name(*name*)

Set the name of this worksheet.

INPUT:

- `name` - string

EXAMPLES: We create a worksheet and change the name:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('A Test Worksheet', 'admin')
sage: W.set_name('A renamed worksheet')
sage: W.name()
'A renamed worksheet'
```

set_not_computing()

set_owner(*owner*)

set_pretty_print(*check='false'*)

Set whether or not output should be pretty printed by default.

INPUT:

- `check` - string (default: 'false'); either 'true' or 'false'.

Note: The reason the input is a string and lower case instead of a Python bool is because this gets called indirectory from javascript. (And, Jason Grout wrote this and didn't realize how unpythonic this design is - it should be redone to use True/False.)

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('A Test Worksheet', 'admin')
sage: W.set_pretty_print('false')
sage: W.pretty_print()
False
sage: W.set_pretty_print('true')
sage: W.pretty_print()
True
```

set_published_version(*filename*)

Set the published version of this worksheet to be the worksheet with given filename.

INPUT:

- `filename` - string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: P = nb.publish_worksheet(W, 'admin')  # indirect test
sage: W._Worksheet__published_version
'pub/0'
sage: W.set_published_version('pub/0')
```

set_system(*system='sage'*)

Set the math software system in which input is evaluated by default.

INPUT:

- `sysem` - string (default: 'sage')

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('A Test Worksheet', 'admin')
sage: W.set_system('magma')
sage: W.system()
'magma'
```

set_user_view(*user, x*)

Set the view on this worksheet for the given user.

INPUT:

- `user` - a string
- `x` - int, one of the variables ACTIVE, ARCHIVED, TRASH in worksheet.py

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: W.set_user_view('admin', sage.server.notebook.worksheet.ARCHIVED)
sage: W.user_view('admin') == sage.server.notebook.worksheet.ARCHIVED
True
```

set_worksheet_that_was_published(*W*)

Set the worksheet that was published to get self to W.

INPUT:

- `W` - a Worksheet

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: P = nb.publish_worksheet(W, 'admin')
sage: P.worksheet_that_was_published() is W
True
```

We fake things and make it look like P published itself:

```
sage: P.set_worksheet_that_was_published(P)
sage: P.worksheet_that_was_published() is P
True
```

show_all()

snapshot_data()

snapshot_directory()

start_next_comp()

synchro()

synchronize(*s*)

system()

Return the math software system in which by default all input to the notebook is evaluated.

OUTPUT: string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('A Test Worksheet', 'admin')
sage: W.system()
'sage'
sage: W.set_system('mathematica')
sage: W.system()
'mathematica'
```

time_idle()

time_since_last_edited()

truncated_name(*max=30*)

uncache_snapshot_data()

user_autosave_interval(*username*)

user_can_edit(*user*)

Return True if the user with given name is allowed to edit this worksheet.

INPUT:

- `user` - string

OUTPUT: bool

EXAMPLES: We create a notebook with one worksheet and two users.

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: nb.add_user('william', 'william', 'wstein@sagemath.org', force=True)
sage: W = nb.create_new_worksheet('Test', 'sage')
sage: W.user_can_edit('sage')
True
```

At first the user 'william' can't edit this worksheet:

```
sage: W.user_can_edit('william')
False
```

After adding 'william' as a collaborator he can edit the worksheet.

```
sage: W.add_collaborator('william')
sage: W.user_can_edit('william')
True
```

Clean up:

```
sage: nb.delete()
```

user_is_collaborator(*user*)

user_is_only_viewer(*user*)

user_is_viewer(*user*)

user_view(*user*)

Return the view that the given user has of this worksheet. If the user currently doesn't have a view set it to ACTIVE and return ACTIVE.

INPUT:

- `user` - a string

OUTPUT:

- `Python int` - one of ACTIVE, ARCHIVED, TRASH, which are defined in worksheet.py

EXAMPLES: We create a new worksheet and get the view, which is ACTIVE:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: W.user_view('admin')
1
sage: sage.server.notebook.worksheet.ACTIVE
1
```

Now for the admin user we move W to the archive:

```
sage: W.move_to_archive('admin')
```

The view is now archive.

```
sage: W.user_view('admin')
0
sage: sage.server.notebook.worksheet.ARCHIVED
0
```

For any other random viewer the view is set by default to ACTIVE.

```
sage: W.user_view('foo')
1
```

user_view_is (*user, x*)

Return True if the user view of user is x.

INPUT:

- `user` - a string
- `x` - int, one of the variables ACTIVE, ARCHIVED, TRASH in worksheet.py

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: W.user_view_is('admin', sage.server.notebook.worksheet.ARCHIVED)
False
sage: W.user_view_is('admin', sage.server.notebook.worksheet.ACTIVE)
True
```

viewer_names (*max=None*)

Returns a string of the non-owner viewers on this worksheet.

INPUT:

- `max` - an integer. If this is specified, then only max number of viewers are shown.

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('test1', 'admin')
sage: C = W.viewers(); C
[]
sage: C.append('sage')
sage: C.append('wstein')
sage: W.viewer_names()
'sage, wstein'
sage: W.viewer_names(max=1)
'sage, ...'
```

viewers ()

Return list of viewers of this worksheet.

OUTPUT:

- `list` - of string

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: nb.add_user('sage','sage','sage@sagemath.org',force=True)
sage: nb.add_user('hilbert','sage','sage@sagemath.org',force=True)
sage: W = nb.create_new_worksheet('test1', 'admin')
sage: W.add_viewer('hilbert')
sage: W.viewers()
```

```
['hilbert']
sage: W.add_viewer('sage')
sage: W.viewers()
['hilbert', 'sage']
```

warn_about_other_person_editing(*username, threshold*)

Check to see if another user besides username was the last to edit this worksheet during the last `threshold` seconds. If so, return True and that user name. If not, return False.

INPUT:

- `username` - user who would like to edit this file.
- `threshold` - number of seconds, so if there was no activity on this worksheet for this many seconds, then editing is considered safe.

worksheet_command(*cmd*)

worksheet_that_was_published()

Return the worksheet that was published to get this worksheet, if this worksheet was published. Otherwise just return this worksheet.

OUTPUT: Worksheet

EXAMPLES:

```
sage: nb = sage.server.notebook.notebook.Notebook(tmp_dir())
sage: W = nb.create_new_worksheet('Publish Test', 'admin')
sage: W.worksheet_that_was_published() is W
True

sage: S = nb.publish_worksheet(W, 'admin')
sage: S.worksheet_that_was_published() is S
False
sage: S.worksheet_that_was_published() is W
True
```

after_first_word(*s*)

Return everything after the first whitespace in the string s. Returns the empty string if there is nothing after the first whitespace.

INPUT:

- `s` - string

OUTPUT: a string

EXAMPLES:

```
sage: from sage.server.notebook.worksheet import after_first_word
sage: after_first_word("\%gap\n2+2\n")
'2+2\n'
sage: after_first_word("2+2")
''
```

convert_seconds_to_meaningful_time_span(*t*)

convert_time_to_string(*t*)

dictify(*s*)

INPUT:

- `s` - a string like 'in=5, out=7'

OUTPUT:

- `dict` - such as 'in':5, 'out':7

extract_first_compute_cell(*text*)
INPUT: a block of wiki-like marked up text OUTPUT:

- `meta` - meta information about the cell (as a dictionary)
- `input` - string, the input text
- `output` - string, the output text
- `end` - integer, first position after }}} in text.

extract_name(*text*)

extract_system(*text*)

extract_text_before_first_compute_cell(*text*)
OUTPUT: Everything in text up to the first {{{.

first_word(*s*)
Returns everything before the first whitespace in the string s. If there is no whitespace, then the entire string s is returned.

EXAMPLES:

```
sage: from sage.server.notebook.worksheet import first_word
sage: first_word("\%gap\n2+2\n")
'\\%gap'
sage: first_word("2+2")
'2+2'
```

format_completions_as_html(*cell_id, completions*)

ignore_prompts_and_output(*aString*)
Given a string s that defines an input block of code, if the first line begins in `sage:` (or >>>), strip out all lines that don't begin in either `sage:` (or >>>) or `...`, and remove all `sage:` (or >>>) and `...` from the beginning of the remaining lines.

TESTS:

```
sage: test1 = sage.server.notebook.worksheet.__internal_test1
sage: test1 == sage.server.notebook.worksheet.ignore_prompts_and_output(test1)
True

sage: test2 = sage.server.notebook.worksheet.__internal_test2
sage: sage.server.notebook.worksheet.ignore_prompts_and_output(test2)
'2 + 2\n'
```

init_sage_prestart(*server, ulimit*)
Set the module-scope variable _a_sage to an initialized sage server.

INPUT:

- `server, ulimit` - strings that are passed to the Sage pexpect interface constructor

EXAMPLES: The _a_sage variable is initially set to None:

```
sage: sage.server.notebook.worksheet._a_sage
```

We call init_sage_prestart and now _a_sage is a Sage instance:

```
sage: sage.server.notebook.worksheet.init_sage_prestart(None,None)
sage: sage.server.notebook.worksheet._a_sage
Sage
```

initialized_sage(*server, ulimit*)

Return one copy of a Sage compute process that has initialization code run.

INPUT:

- `server` - if sessions will be run via ssh on a remote account then this string specifies that account (passed on to the Sage pexpect interface).
- `ulimit` - string; passed to the ulimit command before running the subprocess

OUTPUT: a pexpect interface to a local or remote copy of Sage

EXAMPLES:

```
sage: S = sage.server.notebook.worksheet.initialized_sage(None,None)
sage: S
Sage
```

next_available_id(*v*)

Return smallest nonnegative integer not in v.

one_prestarted_sage(*server, ulimit*)

Return a Sage interface that has been initialized.

INPUT:

- `server, ulimit` - strings that are passed to the Sage pexpect interface constructor

OUTPUT: an interface to a running copy of Sage

If the global variable multisession is true, each call to one_prestarted_sage returns a new Sage compute instance. Otherwise it always returns the same instance.

EXAMPLES:

```
sage: sage.server.notebook.worksheet.one_prestarted_sage(None,None)
Sage
sage: sage.server.notebook.worksheet.multisession=False
sage: sage.server.notebook.worksheet.one_prestarted_sage(None,None) is sage.server.notebook.work
True
sage: sage.server.notebook.worksheet.multisession=True
```

split_search_string_into_keywords(*s*)

The point of this function is to allow for searches like this:

```
"ws 7" foo bar  Modular  '"the" end'
```

i.e., where search terms can be in quotes and the different quote types can be mixed.

INPUT:

- `s` - a string

OUTPUT:

- `list` - a list of strings

worksheet_filename(*name, owner*)

Return the relative directory name of this worksheet with given name and owner.

INPUT:

- `name` - string, which may have spaces and funny characters, which are replaced by underscores.
- `owner` - string, with no spaces or funny characters

OUTPUT: string

EXAMPLES:

```
sage: sage.server.notebook.worksheet.worksheet_filename('Example worksheet 3', 'sage10')
'sage10/Example_worksheet_3'
sage: sage.server.notebook.worksheet.worksheet_filename('Example#%&! work\sheet 3', 'sage10')
'sage10/Example_____work_sheet_3'
```

2.4 The Sage Notebook Twisted Web Server

TESTS: It is important that this file never be imported by default on startup by Sage, since it is very expensive, since importing Twisted is expensive. This doctests verifies that twist.py isn't imported on startup.

sage: os.system("sage -startuptime | grep twisted.web2 1>/dev/null") != 0 # !=0 means not found True

class AddWorksheet()

render(*ctx*)

class AdminToplevel(*cookie, username*)

userchild_conf()

userchild_home()

class AnonymousToplevel(*cookie, username*)

childFactory (*request, name*)

render (*ctx*)

class DocStatic ()

childFactory (*request, name*)

render (*ctx*)

class DownloadWorksheets (*username*)

render (*ctx*)

class EmptyTrash (*username*)

render (*ctx*)

Rendering this resource (1) empties the trash, and (2) returns a message.

EXAMPLES: We create a notebook with a worksheet, put it in the trash, then empty the trash by creating and rendering this worksheet.

```
sage: n = sage.server.notebook.notebook.Notebook('notebook-test')
sage: n.add_user('sage','sage','sage@sagemath.org',force=True)
sage: W = n.new_worksheet_with_title_from_text('Sage', owner='sage')
sage: W.move_to_trash('sage')
sage: n.worksheet_names()
['sage/0']
sage: sage.server.notebook.twist.notebook = n
sage: E = sage.server.notebook.twist.EmptyTrash('sage'); E
<sage.server.notebook.twist.EmptyTrash object at ...>
sage: E.render(None)
<twisted.web2.http.Response code=200, streamlen=...>
```

Finally we verify that the trashed worksheet is gone:

```
sage: n.worksheet_names()
[]
sage: n.delete()
```

class FailedToplevel (*info, problem, username=None*)

render (*ctx*)

class ForgotPassPage ()

render (*request*)

HTMLResponse (**args, **kwds*)

Returns an HTMLResponse object whose 'Content-Type' header has been set to 'text/html; charset=utf-8

EXAMPLES: sage: from sage.server.notebook.twist import HTMLResponse sage: response = HTMLResponse(stream='<html><head><title>Test</title></head><body>Test</body></html>') sage: re-

sponse.headers <Headers: Raw: {'content-type': ['text/html; charset=utf-8']} Parsed: {'content-type': <RecalcNeeded>}>

render(*ctx*)

class **Worksheet_datafile**(*name, username*)

render(*ctx*)

class **Worksheet_delete_all_output**(*name, username*)

render(*ctx*)

class **Worksheet_delete_cell**(*name, username*)
Deletes a notebook cell.

If there is only one cell left in a given worksheet, the request to delete that cell is ignored because there must be a least one cell at all times in a worksheet. (This requirement exists so other functions that evaluate relative to existing cells will still work, and so one can add new cells.)

render(*ctx*)

class **Worksheet_discard_and_quit**(*name, username*)
Save a snapshot of a worksheet and quit.

render(*ctx*)

class **Worksheet_do_upload_data**(*name, username*)

render(*ctx*)

class **Worksheet_download**(*name, username*)

childFactory(*request, name*)

class **Worksheet_edit**(*name, username*)
Return a window that allows the user to edit the text of the worksheet with the given filename.

render(*ctx*)

class **Worksheet_edit_published_page**(*name, username*)

render(*ctx*)

class **Worksheet_eval**(*name, username*)
Evaluate a worksheet cell.

If the request is not authorized (the requester did not enter the correct password for the given worksheet), then the request to evaluate or introspect the cell is ignored.

If the cell contains either 1 or 2 question marks at the end (not on a comment line), then this is interpreted as a request for either introspection to the documentation of the function, or the documentation of the function and the source code of the function respectively.

render(*ctx*)

class **Worksheet_hide_all**(*name, username*)

render(*ctx*)

class **Worksheet_input_settings**(*name, username*)

render(*ctx*)

class **Worksheet_interrupt**(*name, username*)

render(*ctx*)

class **Worksheet_introspect**(*name, username*)
Cell introspection. This is called when the user presses the tab key in the browser in order to introspect.

render(*ctx*)

class **Worksheet_invite_collab**(*name, username*)

render(*ctx*)

class **Worksheet_link_datafile**(*name, username*)

render(*ctx*)

class **Worksheet_new_cell_after**(*name, username*)
Adds a new cell after a given cell.

render(*ctx*)

class **Worksheet_new_cell_before**(*name, username*)
Adds a new cell before a given cell.

render(*ctx*)

class **Worksheet_new_text_cell_after**(*name, username*)
Adds a new text cell after a given cell.

render(*ctx*)

class **Worksheet_new_text_cell_before**(*name, username*)
Adds a new cell before a given cell.

render(*ctx*)

class **Worksheet_plain**(*name, username*)

render(*ctx*)

class **Worksheet_pretty_print**(*name, username*)

childFactory(*request, enable*)

class **Worksheet_print**(*name, username*)

render(*ctx*)

class **Worksheet_publish**(*name, username*)
This is a child resource of the Worksheet resource. It provides a frontend to the mangement of worksheet publication. This mangement functionality includes initializational of publication, re-publication, automated publication when a worksheet saved, and ending of publication.

render(*ctx*)

class **Worksheet_quit_sage**(*name, username*)

render(*ctx*)

class **Worksheet_rate**(*name, username*)

render(*ctx*)

class **Worksheet_rating_info**(*name, username*)

render(*ctx*)

class **Worksheet_rename**(*name, username*)

render(*ctx*)

class **Worksheet_restart_sage**(*name, username*)

render(*ctx*)

class **Worksheet_revert_to_last_saved_state**(*name, username*)

render(*ctx*)

class **Worksheet_revisions**(*name, username*)
Show a list of revisions of this worksheet.

render(*ctx*)

class **Worksheet_save**(*name, username*)
Save the contents of a worksheet after editing it in plain-text edit mode.

render(*ctx*)

class **Worksheet_save_and_close**(*name, username*)
Save a snapshot of a worksheet then quit it.

render(*ctx*)

class **Worksheet_save_and_quit**(*name, username*)
Save a snapshot of a worksheet and quit.

render(*ctx*)

class **Worksheet_save_snapshot**(*name, username*)
Save a snapshot of a worksheet.

render(*ctx*)

class **Worksheet_savedatafile**(*name, username*)

render(*ctx*)

class **Worksheet_set_cell_output_type**(*name, username*)
Set the output type of the cell.

This enables the type of output cell, such as to allowing wrapping for output that is very long.

render(*ctx*)

class **Worksheet_settings**(*name, username*)

render(*ctx*)

class **Worksheet_share**(*name, username*)

render(*ctx*)

class **Worksheet_show_all**(*name, username*)

render(*ctx*)

class **Worksheet_system**(*name, username*)

childFactory(*request, system*)

class **Worksheet_text**(*name, username*)
Return a window that allows the user to edit the text of the worksheet with the given filename.

render(*ctx*)

class **Worksheet_upload_data**(*name, username*)

render(*ctx*)

class **Worksheets**(*username*)

childFactory(*request, name*)

render(*ctx*)

class **WorksheetsAdmin**(*username*)

childFactory(*request, name*)

class **WorksheetsByUser**(*user, username*)

childFactory(*request, name*)

render(*ctx*)

render_list(*ctx*)

class **WorksheetsByUserAdmin**(*user, username*)

render(*ctx*)

do_passwords_match(*pass1, pass2*)
EXAMPLES:

```
sage: from sage.server.notebook.twist import do_passwords_match
sage: do_passwords_match('momcat', 'mothercat')
False
sage: do_passwords_match('mothercat', 'mothercat')
True
```

doc_worksheet()

encode_list(*v*)

extract_title(*html_page*)

gzip_handler(*request*)
Add gzip compression to the request if it makes sense.

init_updates()

is_valid_email(*email*)
from http://aspn.activestate.com/ASPN/Cookbook/Python/Recipe/65215

EXAMPLES:

```
sage: from sage.server.notebook.twist import is_valid_email
sage: is_valid_email('joe@washinton.gov')
True
sage: is_valid_email('joe.washington.gov')
False
```

is_valid_password(*password, username*)
Return True if and only if `password` is valid, i.e., is between 6 and 32 characters long, doesn't contain space(s), and doesn't contain `username`.

EXAMPLES:

```
sage: from sage.server.notebook.twist import is_valid_password
sage: is_valid_password('uip@un7!', None)
True
sage: is_valid_password('markusup89', None)
True
sage: is_valid_password('8u7', None)
False
sage: is_valid_password('fUmDagaz8LmtonAowjSe0Pvu9C5Gvr6eKcC6wsAT', None)
False
sage: is_valid_password('rrcF !u78!', None)
False
sage: is_valid_password('markusup89', 'markus')
False
```

is_valid_username(*username*)

Returns True if and only if `username` is valid, i.e., starts with a letter, is between 4 and 32 characters long, and contains only letters, numbers, underscores, and and one dot (.).

EXAMPLES:

```
sage: from sage.server.notebook.twist import is_valid_username
```

`username` must start with a letter

```
sage: is_valid_username('mark10')
True
sage: is_valid_username('10mark')
False
```

`username` must be between 4 and 32 characters long

```
sage: is_valid_username('bob')
False
sage: is_valid_username('I_love_computer_science_and_maths') #33 characters long
False
```

`username` must not have more than one dot (.)

```
sage: is_valid_username('david.andrews')
True
sage: is_valid_username('david.m.andrews')
False
sage: is_valid_username('math125.TA.5')
False
```

`username` must not have any spaces

```
sage: is_valid_username('David Andrews')
False
sage: is_valid_username('David M. Andrews')
False

sage: is_valid_username('sarah_andrews')
True

sage: is_valid_username('TA-1')
False
sage: is_valid_username('math125-TA')
False

sage: is_valid_username('dandrews@sagemath.org')
False
```

message(*msg, cont=None*)

notebook_idle_check()

notebook_save_check()

notebook_updates()

redirect(*url*)

render_worksheet_list(*args, pub, username*)
Returns a rendered worksheet listing.

INPUT:

- `args` - ctx.args where ctx is the dict passed into a resource's render method
- `pub` - boolean, True if this is a listing of public worksheets
- `username` - the user whose worksheets we are listing

OUTPUT: a string

set_cookie(*cookie*)

user_type(*username*)

word_wrap_cols()

worksheet_revision_publish(*worksheet, rev, username*)

worksheet_revision_revert(*worksheet, rev, username*)

2.5 Javascript (AJAX) Component of sage Notebook

Javascript (AJAX) Component of sage Notebook

AUTHORS:

- William Stein
- Tom Boothby
- Alex Clemesha

This file is one big raw triple-quoted string that contains a bunch of javascript. This javascript is inserted into the head of the notebook web page.

class JSKeyCode(*key, alt, ctrl, shift*)

js_test()

class JSKeyHandler()
This class is used to make javascript functions to check for specific keyevents.

add(*name, key='', alt=False, ctrl=False, shift=False*)
Similar to code{set_key(...)}, but this instead checks if there is an existing keycode by the specified name, and associates the specified key combination to that name in addition. This way, if different browsers don't catch one keycode, multiple keycodes can be assigned to the same test.

all_tests()
Builds all tests currently in the handler. Returns a string of javascript code which defines all functions.

set(*name, key='', alt=False, ctrl=False, shift=False*)
Add a named keycode to the handler. When built by code{all_tests()}, it can be called in javascript by code{key_<key_name>(event_object)}. The function returns true if the keycode numbered by the code{key} parameter was pressed with the appropriate modifier keys, false otherwise.

async_lib()

javascript()
Return javascript library for the Sage Notebook.

jmol_lib()

notebook_lib()

2.6 Customization of the Notebook

Customization of the Notebook

2.7 Sage Notebook CSS

Sage Notebook CSS

css(*color='default'*)

Return the CSS header used by the Sage Notebook.

INPUT:

- `color` - string or pair of html colors, e.g., 'gmail' 'grey' `('#ff0000', '#0000ff')`

EXAMPLES:

```
sage: import sage.server.notebook.css as c
sage: type(c.css())
<type 'str'>
```

2.8 Support for the Notebook (introspection and setup)

AUTHORS:

- William Stein (much of this code is from IPython).

completions(*s, globs, format=False, width=90, system='None'*)

Return a list of completions in the context of globs.

cython_import(*filename, verbose=False, compile_message=False, use_cache=False, create_local_c_file=True*)

INPUT:

- `filename` - name of a file that contains cython code

OUTPUT:

- `module` - the module that contains the compiled cython code.

Raises an `ImportError` exception if anything goes wrong.

cython_import_all(*filename, globals, verbose=False, compile_message=False, use_cache=False, create_local_c_file=True*)

INPUT:

- `filename` - name of a file that contains cython code

OUTPUT: changes globals using the attributes of the Cython module that do not begin with an underscore.

Raises an `ImportError` exception if anything goes wrong.

docstring(*obj_name, globs, system='sage'*)
Format `obj_name`'s docstring for printing in Sage notebook.

AUTHORS:

- William Stein: partly taken from IPython for use in Sage
- Nick Alexander: extensions

get_rightmost_identifier(*s*)

help(*obj*)
Display help on s.

Note: This a wrapper around the builtin help. If formats the output as HTML without word wrap, which looks better in the notebook.

INPUT:

- `s` - Python object, module, etc.

OUTPUT: prints out help about s; it's often more more extensive than foo?

TESTS:

```
sage: import numpy.linalg
sage: sage.server.support.help(numpy.linalg.norm)
<html><table notracebacks bgcolor="#386074" cellpadding=10 cellspacing=10><tr><td bgcolor="#f5f5
   <a target='_new' href='cell://docs-....html'>Click to open help window</a>&nbs
<br></font></tr></td></table></html>
```

init(*object_directory=None, globs={}*)
Initialize Sage for use with the web notebook interface.

load_session(*v, filename, state*)

save_session(*filename*)

setup_systems(*globs*)

source_code(*s, globs, system='sage'*)
Format obj's source code for printing in Sage notebook.

AUTHORS:

- William Stein: partly taken from IPython for use in Sage
- Nick Alexander: extensions

syseval(*system, cmd, dir=None*)

INPUT: **system – an object with an eval method that takes as input a cmd (a string), and two dictionaries:** sage_globals and locals.

dir – an otional directory to change to before calling system.eval.

OUTPUT: The output of system.eval is returned.

EXAMPLES: sage: from sage.misc.python import python sage: sage.server.support.syseval(python, '2+4/3') 3 '' sage: sage.server.support.syseval(python, 'import os; os.chdir(".")') '' sage: sage.server.support.syseval(python, 'import os; os.chdir(1,2,3)') Traceback (most recent call last): ... TypeError: chdir() takes exactly 1 argument (3 given) sage: sage.server.support.syseval(gap, "2+3") '5'

tabulate(*v, width=90, ncols=3*)

variables(*with_types=True*)

2.9 Sage Notebook: Introspection

TODO: - add support for grabbing source code from pyrex functions (even if not perfect is better than nothing). - png or mathml output format for docstring

introspect (*S, query, format='html'*)

Return introspection from a given query string.

INPUT:

- `S` - a Sage0 object, i.e., an interface to a running instance of Python with the Sage libraries loaded
- `query` - a string: - if has no '?' then return completion list - if begins or ends in one '?' return docstring - if begins or ends in '??' return source code
- `format` - (string) 'html', 'png', 'none' (only html is implemented right now!)

CHAPTER

THREE

SYMBOLIC CALCULUS

3.1 File: sage/symbolic/ring.pyx (starting at line 1)

class NumpyToSRMorphism()

class SymbolicRing()

Symbolic Ring, parent object for all symbolic expressions.

characteristic()

Return the characteristic of the symbolic ring, which is 0.

OUTPUT:

- a Sage integer

EXAMPLES:

```
sage: c = SR.characteristic(); c
0
sage: type(c)
<type 'sage.rings.integer.Integer'>
```

is_exact()

Return False, because there are approximate elements in the symbolic ring.

EXAMPLES:

```
sage: SR.is_exact()
False
```

Here is an inexact element.

```
sage: SR(1.9393)
1.93930000000000
```

is_field()

Returns True, since the symbolic expression ring is (for the most part) a field.

EXAMPLES:

```
sage: SR.is_field()
True
```

pi()

EXAMPLES:

```
sage: SR.pi() is pi
True
```

symbol()

EXAMPLES:

```
sage: SR.symbol("asdfasdfasdf")
asdfasdfasdf
```

var()

Return the symbolic variable defined by x as an element of the symbolic ring.

EXAMPLES:

```
sage: zz = SR.var('zz'); zz
zz
sage: type(zz)
<type 'sage.symbolic.expression.Expression'>
sage: t = SR.var('theta2'); t
theta2
```

wild()

Return the n-th wild-card for pattern matching and substitution.

INPUT:

- n - a nonnegative integer

OUTPUT:

- i^{th} wildcard expression

EXAMPLES:

```
sage: x,y = var('x,y')
sage: w0 = SR.wild(0); w1 = SR.wild(1)
sage: pattern = sin(x)*w0*w1^2; pattern
$0*$1^2*sin(x)
sage: f = atan(sin(x)*3*x^2); f
arctan(3*x^2*sin(x))
sage: f.has(pattern)
True
sage: f.subs(pattern == x^2)
arctan(x^2)
```

class **UnderscoreSageMorphism**()

is_SymbolicExpressionRing()

Returns True if *R* is the symbolic expression ring.

EXAMPLES:

```
sage: from sage.symbolic.ring import is_SymbolicExpressionRing
sage: is_SymbolicExpressionRing(ZZ)
False
sage: is_SymbolicExpressionRing(SR)
True
```

is_SymbolicVariable()

Returns True if x is a variable.

EXAMPLES:

```
sage: from sage.symbolic.ring import is_SymbolicVariable
sage: is_SymbolicVariable(x)
True
sage: is_SymbolicVariable(x+2)
False
```

the_SymbolicRing()
Return the unique symbolic ring object.

(This is mainly used for unpickling.)

EXAMPES:

```
sage: sage.symbolic.ring.the_SymbolicRing()
Symbolic Ring
sage: sage.symbolic.ring.the_SymbolicRing() is sage.symbolic.ring.the_SymbolicRing()
True
sage: sage.symbolic.ring.the_SymbolicRing() is SR
True
```

var()
EXAMPLES:

```
sage: from sage.symbolic.ring import var
sage: var("x y z")
(x, y, z)
sage: var("x,y,z")
(x, y, z)
sage: var("x , y , z")
(x, y, z)
sage: var("z")
z
```

3.2 Symbolic Expressions

RELATIONAL EXPRESSIONS:

We create a relational expression:

```
sage: x = var('x')
sage: eqn = (x-1)^2 <= x^2 - 2*x + 3
sage: eqn.subs(x == 5)
16 <= 18
```

Notice that squaring the relation squares both sides.

```
sage: eqn^2
(x - 1)^4 <= (x^2 - 2*x + 3)^2
sage: eqn.expand()
x^2 - 2*x + 1 <= x^2 - 2*x + 3
```

The can transform a true relational into a false one:

```
sage: eqn = SR(-5) < SR(-3); eqn
-5 < -3
sage: bool(eqn)
True
sage: eqn^2
25 < 9
sage: bool(eqn^2)
False
```

We can do arithmetic with relationals:

```
sage: e = x+1 <= x-2
sage: e + 2
x + 3 <= x
sage: e - 1
x <= x - 3
sage: e*(-1)
-x - 1 <= -x + 2
sage: (-2)*e
-2*x - 2 <= -2*x + 4
sage: e*5
5*x + 5 <= 5*x - 10
sage: e/5
1/5*x + 1/5 <= 1/5*x - 2/5
sage: 5/e
5/(x + 1) <= 5/(x - 2)
sage: e/(-2)
-1/2*x - 1/2 <= -1/2*x + 1
sage: -2/e
-2/(x + 1) <= -2/(x - 2)
```

We can even add together two relations, so long as the operators are the same:

```
sage: (x^3 + x <= x - 17)  + (-x <= x - 10)
x^3 <= 2*x - 27
```

Here they aren't:

```
sage: (x^3 + x <= x - 17)  + (-x >= x - 10)
...
TypeError: incompatible relations
```

ARBITRARY SAGE ELEMENTS:

You can work symbolically with any Sage datatype. This can lead to nonsense if the data type is strange, e.g., an element of a finite field (at present).

We mix Singular variables with symbolic variables:

```
sage: R.<u,v> = QQ[]
sage: var('a,b,c')
(a, b, c)
sage: expand((u + v + a + b + c)^2)
a^2 + 2*a*b + 2*a*c + 2*a*u + 2*a*v + b^2 + 2*b*c + 2*b*u + 2*b*v + c^2 + 2*c*u + 2*c*v + u^2 + 2*u*v
```

TESTS:

Test jacobian on pynac expressions. #5546

```
sage: var('x,y')
(x, y)
sage: f = x + y
sage: jacobian(f, [x,y])
[1 1]
```

Test if matrices work #5546

```
sage: var('x,y,z')
(x, y, z)
sage: M = matrix(2,2,[x,y,z,x])
sage: v = vector([x,y])
sage: M * v
(x^2 + y^2, x*y + x*z)
sage: v*M
(x^2 + y*z, 2*x*y)
```

class Expression()

Order()

Order, as in big oh notation.

OUTPUT: symbolic expression

EXAMPLES: sage: n = var('n') sage: (17*n^3).Order() Order(n^3)

add_to_both_sides()

Returns a relation obtained by adding x to both sides of this relation.

EXAMPLES:

```
sage: var('x y z')
(x, y, z)
sage: eqn = x^2 + y^2 + z^2 <= 1
sage: eqn.add_to_both_sides(-z^2)
x^2 + y^2 <= -z^2 + 1
sage: eqn.add_to_both_sides(I)
x^2 + y^2 + z^2 + I <= (I + 1)
```

arccos()

Return the arc cosine of self.

EXAMPLES:

```
sage: x.arccos()
arccos(x)
sage: SR(1).arccos()
0
sage: SR(1/2).arccos()
1/3*pi
sage: SR(0.4).arccos()
arccos(0.400000000000000)
```

Use .n() to get a numerical approximation:

```
sage: SR(0.4).arccos().n()
1.15927948072741
sage: plot(lambda x: SR(x).arccos(), -1,1)
```

arccosh()

Return the inverse hyperbolic cosine of self.

EXAMPLES:

```
sage: x.arccosh()
arccosh(x)
sage: SR(0).arccosh()
1/2*I*pi
sage: SR(1/2).arccosh()
arccosh(1/2)
```

```
sage: SR(CDF(1/2)).arccosh()
arccosh(0.5)
```

Use .n() to get a numerical approximation:

```
sage: SR(CDF(1/2)).arccosh().n()
1.0471975512*I
sage: maxima('acosh(0.5)')
1.047197551196598*%i
```

arcsin()

Return the arcsin of x, i.e., the number y between -pi and pi such that sin(y) == x.

EXAMPLES:

```
sage: x.arcsin()
arcsin(x)
sage: SR(0.5).arcsin()
arcsin(0.500000000000000)
```

Use .n() to get a numerical approximation:

```
sage: SR(0.5).arcsin().n()
0.523598775598299

sage: SR(0.999).arcsin()
arcsin(0.999000000000000)
sage: SR(-0.999).arcsin()
-arcsin(0.999000000000000)
sage: SR(0.999).arcsin().n()
1.52607123962616
```

arcsinh()

Return the inverse hyperbolic sine of self.

EXAMPLES:

```
sage: x.arcsinh()
arcsinh(x)
sage: SR(0).arcsinh()
0
sage: SR(1).arcsinh()
arcsinh(1)
sage: SR(1.0).arcsinh()
arcsinh(1.00000000000000)
```

Use .n() to get a numerical approximation:

```
sage: SR(1.0).arcsinh().n()
0.881373587019543
sage: maxima('asinh(1.0)')
0.881373587019543
```

Sage automatically applies certain identies:: sage: SR(3/2).arcsinh().cosh() 1/2*sqrt(13)

arctan()

Return the arc tangent of self.

EXAMPLES:

```
sage: x = var('x')
sage: x.arctan()
arctan(x)
sage: SR(1).arctan()
```

```
1/4*pi
sage: SR(1/2).arctan()
arctan(1/2)
sage: SR(0.5).arctan()
arctan(0.500000000000000)
```

Use .n() to get a numerical approximation:

```
sage: SR(0.5).arctan().n()
0.463647609000806
sage: plot(lambda x: SR(x).arctan(), -20,20)
```

arctan2()

Return the inverse of the 2-variable tan function on self and x.

EXAMPLES:

```
sage: var('x,y')
(x, y)
sage: x.arctan2(y)
arctan2(x, y)
sage: SR(1/2).arctan2(1/2)
1/4*pi
sage: maxima.eval('atan2(1/2,1/2)')
'%pi/4'

sage: SR(-0.7).arctan2(SR(-0.6))
-pi + arctan(1.16666666666667)
```

Use .n() to get a numerical approximation:

```
sage: SR(-0.7).arctan2(SR(-0.6)).n()
-2.27942259892257
```

TESTS:

We compare a bunch of different evaluation points between Sage and Maxima:

```
sage: float(SR(0.7).arctan2(0.6))
0.8621700546672264
sage: maxima('atan2(0.7,0.6)')
.862170054667226...
sage: float(SR(0.7).arctan2(-0.6))
2.2794225989225669
sage: maxima('atan2(0.7,-0.6)')
2.279422598922567
sage: float(SR(-0.7).arctan2(0.6))
-0.8621700546672264
sage: maxima('atan2(-0.7,0.6)')
-.862170054667226...
sage: float(SR(-0.7).arctan2(-0.6))
-2.2794225989225669
sage: maxima('atan2(-0.7,-0.6)')
-2.279422598922567
sage: float(SR(0).arctan2(-0.6))
3.1415926535897931
sage: maxima('atan2(0,-0.6)')
3.141592653589793
sage: float(SR(0).arctan2(0.6))
0.0
sage: maxima('atan2(0,0.6)')
0.0
```

```
sage: SR(0).arctan2(0)
0

sage: SR(I).arctan2(1)
arctan2(I, 1)
sage: SR(CDF(0,1)).arctan2(1)
arctan2(1.0*I, 1)
sage: SR(1).arctan2(CDF(0,1))
arctan2(1, 1.0*I)
```

arctanh()

Return the inverse hyperbolic tangent of self.

EXAMPLES:

```
sage: x.arctanh()
arctanh(x)
sage: SR(0).arctanh()
0
sage: SR(1/2).arctanh()
arctanh(1/2)
sage: SR(0.5).arctanh()
arctanh(0.500000000000000)
```

Use .n() to get a numerical approximation:

```
sage: SR(0.5).arctanh().n()
0.549306144334055
sage: SR(0.5).arctanh().tanh()
0.500000000000000
sage: maxima('atanh(0.5)')
.5493061443340...
```

args()

EXAMPLES:

```
sage: x,y = var('x,y')
sage: f = x + y
sage: f.arguments()
(x, y)

sage: g = f.function(x)
sage: g.arguments()
(x,)
```

arguments()

EXAMPLES:

```
sage: x,y = var('x,y')
sage: f = x + y
sage: f.arguments()
(x, y)

sage: g = f.function(x)
sage: g.arguments()
(x,)
```

assume()

Assume that this equation holds. This is relevant for symbolic integration, among other things.

EXAMPLES: We call the assume method to assume that $x > 2$:

```
sage: (x > 2).assume()
```

Bool returns True below if the inequality is *definitely* known to be True.

```
sage: bool(x > 0)
True
sage: bool(x < 0)
False
```

This may or may not be True, so bool returns False:

```
sage: bool(x > 3)
False
```

TESTS:

```
sage: v,c = var('v,c')
sage: assume(c != 0)
sage: integral((1+v^2/c^2)^3/(1-v^2/c^2)^(3/2),v)
-75/8*sqrt(c^2)*arcsin(sqrt(c^2)*v/c^2) - 17/8*v^3/(sqrt(-v^2/c^2 + 1)*c^2) - 1/4*v^5/(sqrt(
```

binomial()

Return binomial coefficient "self choose k".

OUTPUT: symbolic expression

EXAMPLES: sage: var('x, y') (x, y) sage: SR(5).binomial(SR(3)) 10 sage: x.binomial(SR(3)) 1/6*x^3 - 1/2*x^2 + 1/3*x sage: x.binomial(y) binomial(x,y)

coeff()

Returns the coefficient of s^n in this symoblic expression.

INPUT:

- s - expression
- n - integer, default 1

OUTPUT:

- coefficient of s^n

Sometimes it may be necessary to expand or factor first, since this is not done automatically.

EXAMPLES:

```
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + x/y + 2*sin(x*y)/x + 100
sage: f.collect(x)
x^3*sin(x*y) + (a + y + 1/y)*x + 2*sin(x*y)/x + 100
sage: f.coefficient(x,0)
100
sage: f.coefficient(x,-1)
2*sin(x*y)
sage: f.coefficient(x,1)
a + y + 1/y
sage: f.coefficient(x,2)
0
sage: f.coefficient(x,3)
sin(x*y)
sage: f.coefficient(x^3)
sin(x*y)
sage: f.coefficient(sin(x*y))
x^3 + 2/x
sage: f.collect(sin(x*y))
```

```
(x^3 + 2/x)*sin(x*y) + a*x + x*y + x/y + 100

sage: var('a, x, y, z')
(a, x, y, z)
sage: f = (a*sqrt(2))*x^2 + sin(y)*x^(1/2) + z^z
sage: f.coefficient(sin(y))
sqrt(x)
sage: f.coefficient(x^2)
sqrt(2)*a
sage: f.coefficient(x^(1/2))
sin(y)
sage: f.coefficient(1)
0
sage: f.coefficient(x, 0)
sqrt(x)*sin(y) + z^z
```

coefficient()

Returns the coefficient of s^n in this symoblic expression.

INPUT:

- s - expression
- n - integer, default 1

OUTPUT:

- coefficient of s^n

Sometimes it may be necessary to expand or factor first, since this is not done automatically.

EXAMPLES:

```
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + x/y + 2*sin(x*y)/x + 100
sage: f.collect(x)
x^3*sin(x*y) + (a + y + 1/y)*x + 2*sin(x*y)/x + 100
sage: f.coefficient(x,0)
100
sage: f.coefficient(x,-1)
2*sin(x*y)
sage: f.coefficient(x,1)
a + y + 1/y
sage: f.coefficient(x,2)
0
sage: f.coefficient(x,3)
sin(x*y)
sage: f.coefficient(x^3)
sin(x*y)
sage: f.coefficient(sin(x*y))
x^3 + 2/x
sage: f.collect(sin(x*y))
(x^3 + 2/x)*sin(x*y) + a*x + x*y + x/y + 100

sage: var('a, x, y, z')
(a, x, y, z)
sage: f = (a*sqrt(2))*x^2 + sin(y)*x^(1/2) + z^z
sage: f.coefficient(sin(y))
sqrt(x)
sage: f.coefficient(x^2)
sqrt(2)*a
```

```
sage: f.coefficient(x^(1/2))
sin(y)
sage: f.coefficient(1)
0
sage: f.coefficient(x, 0)
sqrt(x)*sin(y) + z^z
```

coefficients()

Coefficients of this symbolic expression as a polynomial in x.

INPUT:

- x - optional variable

OUTPUT:

- A list of pairs (expr, n), where expr is a symbolic expression and n is a power.

EXAMPLES:

```
sage: var('x, y, a')
(x, y, a)
sage: p = x^3 - (x-3)*(x^2+x) + 1
sage: p.coefficients()
[[1, 0], [3, 1], [2, 2]]
sage: p = expand((x-a*sqrt(2))^2 + x + 1); p
-2*sqrt(2)*a*x + 2*a^2 + x^2 + x + 1
sage: p.coefficients(a)
[[x^2 + x + 1, 0], [-2*sqrt(2)*x, 1], [2, 2]]
sage: p.coefficients(x)
[[2*a^2 + 1, 0], [-2*sqrt(2)*a + 1, 1], [1, 2]]
```

A polynomial with wacky exponents:

```
sage: p = (17/3*a)*x^(3/2) + x*y + 1/x + x^x
sage: p.coefficients(x)
[[1, -1], [x^x, 0], [y, 1], [17/3*a, 3/2]]
```

coeffs()

Coefficients of this symbolic expression as a polynomial in x.

INPUT:

- x - optional variable

OUTPUT:

- A list of pairs (expr, n), where expr is a symbolic expression and n is a power.

EXAMPLES:

```
sage: var('x, y, a')
(x, y, a)
sage: p = x^3 - (x-3)*(x^2+x) + 1
sage: p.coefficients()
[[1, 0], [3, 1], [2, 2]]
sage: p = expand((x-a*sqrt(2))^2 + x + 1); p
-2*sqrt(2)*a*x + 2*a^2 + x^2 + x + 1
sage: p.coefficients(a)
[[x^2 + x + 1, 0], [-2*sqrt(2)*x, 1], [2, 2]]
sage: p.coefficients(x)
[[2*a^2 + 1, 0], [-2*sqrt(2)*a + 1, 1], [1, 2]]
```

A polynomial with wacky exponents:

```
sage: p = (17/3*a)*x^(3/2) + x*y + 1/x + x^x
sage: p.coefficients(x)
[[1, -1], [x^x, 0], [y, 1], [17/3*a, 3/2]]
```

collect()

INPUT:

- s - a symbol

OUTPUT:

- expression

EXAMPLES:

```
sage: var('x,y,z')
(x, y, z)
sage: f = 4*x*y + x*z + 20*y^2 + 21*y*z + 4*z^2 + x^2*y^2*z^2
sage: f.collect(x)
x^2*y^2*z^2 + (4*y + z)*x + 20*y^2 + 21*y*z + 4*z^2
sage: f.collect(y)
(x^2*z^2 + 20)*y^2 + (4*x + 21*z)*y + x*z + 4*z^2
sage: f.collect(z)
(x^2*y^2 + 4)*z^2 + (x + 21*y)*z + 4*x*y + 20*y^2
```

collect_common_factors()

EXAMPLES:

```
sage: var('x')
x
sage: (x/(x^2 + x)).collect_common_factors()
1/(x + 1)
```

combine()

Returns a simplified version of this symbolic expression by combining all terms with the same denominator into a single term.

EXAMPLES:

```
sage: var('x, y, a, b, c')
(x, y, a, b, c)
sage: f = x*(x-1)/(x^2 - 7) + y^2/(x^2-7) + 1/(x+1) + b/a + c/a; f
(x - 1)*x/(x^2 - 7) + y^2/(x^2 - 7) + b/a + c/a + 1/(x + 1)
sage: f.combine()
((x - 1)*x + y^2)/(x^2 - 7) + (b + c)/a + 1/(x + 1)
```

conjugate()

Return the complex conjugate of this symbolic expression.

EXAMPLES:

```
sage: a = 1 + 2*I
sage: a.conjugate()
-2*I + 1
sage: a = sqrt(2) + 3^(1/3)*I; a
sqrt(2) + I*3^(1/3)
sage: a.conjugate()
sqrt(2) - I*3^(1/3)

sage: SR(CDF.0).conjugate()
-1.0*I
sage: x.conjugate()
conjugate(x)
```

```
sage: SR(RDF(1.5)).conjugate()
1.5
sage: SR(float(1.5)).conjugate()
1.50000000000000
sage: SR(I).conjugate()
-I
sage: ( 1+I  + (2-3*I)*x).conjugate()
(3*I + 2)*conjugate(x) - I + 1
```

cos()

Return the cosine of self.

EXAMPLES:

```
sage: var('x, y')
(x, y)
sage: cos(x^2 + y^2)
cos(x^2 + y^2)
sage: cos(sage.symbolic.constants.pi)
-1
sage: cos(SR(1))
cos(1)
sage: cos(SR(RealField(150)(1)))
0.540302305868139717400936607442976603732310420
```

In order to get a numeric approximation use .n():

```
sage: SR(RR(1)).cos().n()
0.540302305868140
sage: SR(float(1)).cos().n()
0.540302305868140
```

cosh()

Return cosh of self.

We have $sinh(x) = (e^{x} + e^{-x})/2$.

EXAMPLES:

```
sage: x.cosh()
cosh(x)
sage: SR(1).cosh()
cosh(1)
sage: SR(0).cosh()
1
sage: SR(1.0).cosh()
cosh(1.00000000000000)
```

Use .n() to get a numerical approximation:

```
sage: SR(1.0).cosh().n()
1.54308063481524
sage: maxima('cosh(1.0)')
1.543080634815244
sage: SR(1.0000000000000000000000000).cosh()
cosh(1.0000000000000000000000000)
sage: SR(1).cosh().n(90)
1.54308063481524377847790560
sage: SR(RIF(1)).cosh()
cosh(1)
sage: SR(RIF(1)).cosh().n()
1.543080634815244?
```

csgn()

Return the sign of self, which is -1 if self < 0, 0 if self == 0, and 1 if self > 0, or unevaluated when self is a nonconstant symbolic expression.

It can be somewhat arbitrary when self is not real.

EXAMPLES: sage: x = var('x') sage: SR(-2).csgn() -1 sage: SR(0.0).csgn() 0 sage: SR(10).csgn() 1 sage: x.csgn() csgn(x) sage: SR(CDF.0).csgn() 1 sage: SR(I).csgn() 1

default_variable()

Return the default variable, which is by definition the first variable in self, or x is there are no variables in self. The result is cached.

EXAMPLES:

```
sage: sqrt(2).default_variable()
x
sage: x, theta, a = var('x, theta, a')
sage: f = x^2 + theta^3 - a^x
sage: f.default_variable()
a
```

Note that this is the first *variable*, not the first *argument*:

```
sage: f(theta, a, x) = a + theta^3
sage: f.default_variable()
a
sage: f.variables()
(a, theta)
sage: f.arguments()
(theta, a, x)
```

degree()

Return the exponent of the highest nonnegative power of s in self.

OUTPUT:

- an integer >= 0.

EXAMPLES:

```
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y^10 + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + 2*sin(x*y)/x + x/y^10 + 100
sage: f.degree(x)
3
sage: f.degree(y)
1
sage: f.degree(sin(x*y))
1
sage: (x^-3+y).degree(x)
0
```

denominator()

Returns the denominator of this symbolic expression. If the expression is not a quotient, then this will just return 1.

EXAMPLES:

```
sage: x, y, z, theta = var('x, y, z, theta')
sage: f = (sqrt(x) + sqrt(y) + sqrt(z))/(x^10 - y^10 - sqrt(theta))
sage: f.denominator()
sqrt(theta) - x^10 + y^10
```

```
sage: y = var('y')
sage: g = x + y/(x + 2); g
x + y/(x + 2)
sage: g.numerator()
x + y/(x + 2)
sage: g.denominator()
1
```

derivative()

Returns the derivative of this expressions with respect to the variables supplied in args.

Multiple variables and iteration counts may be supplied; see documentation for the global derivative() function for more details.

See Also:

_derivative()

EXAMPLES:

```
sage: var("x y")
(x, y)
sage: t = (x^2+y)^2
sage: t.derivative(x)
4*(x^2 + y)*x
sage: t.derivative(x, 2)
12*x^2 + 4*y
sage: t.derivative(x, 2, y)
4
sage: t.derivative(y)
2*x^2 + 2*y

sage: t = sin(x+y^2)*tan(x*y)
sage: t.derivative(x)
(tan(x*y)^2 + 1)*y*sin(y^2 + x) + cos(y^2 + x)*tan(x*y)
sage: t.derivative(y)
(tan(x*y)^2 + 1)*x*sin(y^2 + x) + 2*y*cos(y^2 + x)*tan(x*y)

sage: h = sin(x)/cos(x)
sage: derivative(h,x,x,x)
6*sin(x)^4/cos(x)^4 + 8*sin(x)^2/cos(x)^2 + 2
sage: derivative(h,x,3)
6*sin(x)^4/cos(x)^4 + 8*sin(x)^2/cos(x)^2 + 2

sage: var('x, y')
(x, y)
sage: u = (sin(x) + cos(y))*(cos(x) - sin(y))
sage: derivative(u,x,y)
sin(x)*sin(y) - cos(x)*cos(y)
sage: f = ((x^2+1)/(x^2-1))^(1/4)
sage: g = derivative(f, x); g # this is a complex expression
1/2*(x/(x^2 - 1) - (x^2 + 1)*x/(x^2 - 1)^2)/((x^2 + 1)/(x^2 - 1))^(3/4)
sage: g.factor()
-x/((x^2 - 1)^(5/4)*(x^2 + 1)^(3/4))

sage: y = var('y')
sage: f = y^(sin(x))
sage: derivative(f, x)
y^sin(x)*log(y)*cos(x)
```

```
sage: g(x) = sqrt(5-2*x)
sage: g_3 = derivative(g, x, 3); g_3(2)
-3

sage: f = x*e^(-x)
sage: derivative(f, 100)
x*e^(-x) - 100*e^(-x)

sage: g = 1/(sqrt((x^2-1)*(x+5)^6))
sage: derivative(g, x)
-((x + 5)^6*x + 3*(x + 5)^5*(x^2 - 1))/((x + 5)^6*(x^2 - 1))^(3/2)
```

TESTS:

```
sage: t.derivative()
...
ValueError: No differentiation variable specified.
```

diff()

Returns the derivative of this expressions with respect to the variables supplied in args.

Multiple variables and iteration counts may be supplied; see documentation for the global derivative() function for more details.

See Also:

_derivative()

EXAMPLES:

```
sage: var("x y")
(x, y)
sage: t = (x^2+y)^2
sage: t.derivative(x)
4*(x^2 + y)*x
sage: t.derivative(x, 2)
12*x^2 + 4*y
sage: t.derivative(x, 2, y)
4
sage: t.derivative(y)
2*x^2 + 2*y

sage: t = sin(x+y^2)*tan(x*y)
sage: t.derivative(x)
(tan(x*y)^2 + 1)*y*sin(y^2 + x) + cos(y^2 + x)*tan(x*y)
sage: t.derivative(y)
(tan(x*y)^2 + 1)*x*sin(y^2 + x) + 2*y*cos(y^2 + x)*tan(x*y)

sage: h = sin(x)/cos(x)
sage: derivative(h,x,x,x)
6*sin(x)^4/cos(x)^4 + 8*sin(x)^2/cos(x)^2 + 2

sage: g(x) = sqrt(5-2*x)
sage: g_3 = derivative(g, x, 3); g_3(2)
-3

sage: f = x*e^(-x)
sage: derivative(f, 100)
x*e^(-x) - 100*e^(-x)

sage: g = 1/(sqrt((x^2-1)*(x+5)^6))
sage: derivative(g, x)
-((x + 5)^6*x + 3*(x + 5)^5*(x^2 - 1))/((x + 5)^6*(x^2 - 1))^(3/2)
```

TESTS:

```
sage: t.derivative()
...
ValueError: No differentiation variable specified.
```

differentiate()

Returns the derivative of this expressions with respect to the variables supplied in args.

Multiple variables and iteration counts may be supplied; see documentation for the global derivative() function for more details.

See Also:

_derivative()

EXAMPLES:

```
sage: var("x y")
(x, y)
sage: t = (x^2+y)^2
sage: t.derivative(x)
4*(x^2 + y)*x
sage: t.derivative(x, 2)
12*x^2 + 4*y
sage: t.derivative(x, 2, y)
4
sage: t.derivative(y)
2*x^2 + 2*y

sage: t = sin(x+y^2)*tan(x*y)
sage: t.derivative(x)
(tan(x*y)^2 + 1)*y*sin(y^2 + x) + cos(y^2 + x)*tan(x*y)
sage: t.derivative(y)
(tan(x*y)^2 + 1)*x*sin(y^2 + x) + 2*y*cos(y^2 + x)*tan(x*y)

sage: h = sin(x)/cos(x)
sage: derivative(h,x,x,x)
6*sin(x)^4/cos(x)^4 + 8*sin(x)^2/cos(x)^2 + 2
sage: derivative(h,x,3)
6*sin(x)^4/cos(x)^4 + 8*sin(x)^2/cos(x)^2 + 2
```

```
sage: var('x, y')
(x, y)
sage: u = (sin(x) + cos(y))*(cos(x) - sin(y))
sage: derivative(u,x,y)
sin(x)*sin(y) - cos(x)*cos(y)
sage: f = ((x^2+1)/(x^2-1))^(1/4)
sage: g = derivative(f, x); g # this is a complex expression
1/2*(x/(x^2 - 1) - (x^2 + 1)*x/(x^2 - 1)^2)/((x^2 + 1)/(x^2 - 1))^(3/4)
sage: g.factor()
-x/((x^2 - 1)^(5/4)*(x^2 + 1)^(3/4))

sage: y = var('y')
sage: f = y^(sin(x))
sage: derivative(f, x)
y^sin(x)*log(y)*cos(x)

sage: g(x) = sqrt(5-2*x)
sage: g_3 = derivative(g, x, 3); g_3(2)
-3

sage: f = x*e^(-x)
sage: derivative(f, 100)
x*e^(-x) - 100*e^(-x)

sage: g = 1/(sqrt((x^2-1)*(x+5)^6))
sage: derivative(g, x)
-((x + 5)^6*x + 3*(x + 5)^5*(x^2 - 1))/((x + 5)^6*(x^2 - 1))^(3/2)
```

TESTS:

```
sage: t.derivative()
...
ValueError: No differentiation variable specified.
```

divide_both_sides()

Returns a relation obtained by dividing both sides of this relation by *x*.

Note: The *checksign* keyword argument is currently ignored and is included for backward compatibility reasons only.

EXAMPLES:

```
sage: theta = var('theta')
sage: eqn =   (x^3 + theta < sin(x*theta))
sage: eqn.divide_both_sides(theta, checksign=False)
(x^3 + theta)/theta < sin(theta*x)/theta
sage: eqn.divide_both_sides(theta)
(x^3 + theta)/theta < sin(theta*x)/theta
sage: eqn/theta
(x^3 + theta)/theta < sin(theta*x)/theta
```

exp()

Return exponential function of self, i.e., e to the power of self.

EXAMPLES:

```
sage: x.exp()
e^x
sage: SR(0).exp()
1
sage: SR(1/2).exp()
e^(1/2)
```

```
sage: SR(0.5).exp()
e^0.500000000000000
sage: (pi*I).exp()
-1
```

Use .n() to get a numerical approximation:

```
sage: SR(0.5).exp().n()
1.64872127070013
sage: math.exp(0.5)
1.6487212707001282

sage: SR(0.5).exp().log()
0.500000000000000
```

exp_simplify()

Simplifies this symbolic expression, which can contain logs, exponentials, and radicals, by converting it into a form which is canonical over a large class of expressions and a given ordering of variables

DETAILS: This uses the Maxima radcan() command. From the Maxima documentation: "All functionally equivalent forms are mapped into a unique form. For a somewhat larger class of expressions, produces a regular form. Two equivalent expressions in this class do not necessarily have the same appearance, but their difference can be simplified by radcan to zero. For some expressions radcan is quite time consuming. This is the cost of exploring certain relationships among the components of the expression for simplifications based on factoring and partial fraction expansions of exponents."

ALIAS: radical_simplify, simplify_radical, simplify_log, log_simplify, exp_simplify, simplify_exp are all the same

EXAMPLES:

```
sage: var('x,y,a')
(x, y, a)

sage: f = log(x*y)
sage: f.simplify_radical()
log(x) + log(y)

sage: f = (log(x+x^2)-log(x))^a/log(1+x)^(a/2)
sage: f.simplify_radical()
log(x + 1)^(1/2*a)

sage: f = (e^x-1)/(1+e^(x/2))
sage: f.simplify_exp()
e^(1/2*x) - 1
```

expand()

Expand this symbolic expression. Products of sums and exponentiated sums are multiplied out, numerators of rational expressions which are sums are split into their respective terms, and multiplications are distributed over addition at all levels.

EXAMPLES:

We expand the expression $(x-y)^5$ using both method and functional notation.

```
sage: x,y = var('x,y')
sage: a = (x-y)^5
sage: a.expand()
x^5 - 5*x^4*y + 10*x^3*y^2 - 10*x^2*y^3 + 5*x*y^4 - y^5
sage: expand(a)
x^5 - 5*x^4*y + 10*x^3*y^2 - 10*x^2*y^3 + 5*x*y^4 - y^5
```

We expand some other expressions:

```
sage: expand((x-1)^3/(y-1))
x^3/(y - 1) - 3*x^2/(y - 1) + 3*x/(y - 1) - 1/(y - 1)
sage: expand((x+sin((x+y)^2))^2)
x^2 + 2*x*sin((x + y)^2) + sin((x + y)^2)^2
```

We can expand individual sides of a relation:

```
sage: a = (16*x-13)^2 == (3*x+5)^2/2
sage: a.expand()
256*x^2 - 416*x + 169 == 9/2*x^2 + 15*x + 25/2
sage: a.expand('left')
256*x^2 - 416*x + 169 == 1/2*(3*x + 5)^2
sage: a.expand('right')
(16*x - 13)^2 == 9/2*x^2 + 15*x + 25/2
```

TESTS:

sage: var('x,y') (x, y) sage: ((x + (2/3)*y)^3).expand() x^3 + 2*x^2*y + 4/3*x*y^2 + 8/27*y^3 sage: expand((x*sin(x) - cos(y)/x)^2) x^2*sin(x)^2 - 2*sin(x)*cos(y) + cos(y)^2/x^2 sage: f = (x-y)*(x+y); f (x - y)*(x + y) sage: f.expand() x^2 - y^2

expand_rational()

Expand this symbolic expression. Products of sums and exponentiated sums are multiplied out, numerators of rational expressions which are sums are split into their respective terms, and multiplications are distributed over addition at all levels.

EXAMPLES:

We expand the expression $(x-y)^5$ using both method and functional notation.

```
sage: x,y = var('x,y')
sage: a = (x-y)^5
sage: a.expand()
x^5 - 5*x^4*y + 10*x^3*y^2 - 10*x^2*y^3 + 5*x*y^4 - y^5
sage: expand(a)
x^5 - 5*x^4*y + 10*x^3*y^2 - 10*x^2*y^3 + 5*x*y^4 - y^5
```

We expand some other expressions:

```
sage: expand((x-1)^3/(y-1))
x^3/(y - 1) - 3*x^2/(y - 1) + 3*x/(y - 1) - 1/(y - 1)
sage: expand((x+sin((x+y)^2))^2)
x^2 + 2*x*sin((x + y)^2) + sin((x + y)^2)^2
```

We can expand individual sides of a relation:

```
sage: a = (16*x-13)^2 == (3*x+5)^2/2
sage: a.expand()
256*x^2 - 416*x + 169 == 9/2*x^2 + 15*x + 25/2
sage: a.expand('left')
256*x^2 - 416*x + 169 == 1/2*(3*x + 5)^2
sage: a.expand('right')
(16*x - 13)^2 == 9/2*x^2 + 15*x + 25/2
```

TESTS:

sage: var('x,y') (x, y) sage: ((x + (2/3)*y)^3).expand() x^3 + 2*x^2*y + 4/3*x*y^2 + 8/27*y^3 sage: expand((x*sin(x) - cos(y)/x)^2) x^2*sin(x)^2 - 2*sin(x)*cos(y) + cos(y)^2/x^2 sage: f = (x-y)*(x+y); f (x - y)*(x + y) sage: f.expand() x^2 - y^2

expand_trig()

Expands trigonometric and hyperbolic functions of sums of angles and of multiple angles occurring in self. For best results, self should already be expanded.

INPUT:

- `full` - (default: False) To enhance user control of simplification, this function expands only one level at a time by default, expanding sums of angles or multiple angles. To obtain full expansion into sines and cosines immediately, set the optional parameter full to True.
- `half_angles` - (default: False) If True, causes half-angles to be simplified away.
- `plus` - (default: True) Controls the sum rule; expansion of sums (e.g. 'sin(x + y)') will take place only if plus is True.
- `times` - (default: True) Controls the product rule, expansion of products (e.g. sin(2*x)) will take place only if times is True.

OUTPUT: a symbolic expression

EXAMPLES:

```
sage: sin(5*x).expand_trig()
sin(x)^5 - 10*sin(x)^3*cos(x)^2 + 5*sin(x)*cos(x)^4
sage: cos(2*x + var('y')).expand_trig()
-sin(2*x)*sin(y) + cos(2*x)*cos(y)
```

We illustrate various options to this function:

```
sage: f = sin(sin(3*cos(2*x))*x)
sage: f.expand_trig()
sin(-(sin(cos(2*x))^3 - 3*sin(cos(2*x))*cos(cos(2*x))^2)*x)
sage: f.expand_trig(full=True)
sin(((sin(sin(x)^2)*cos(cos(x)^2) - sin(cos(x)^2)*cos(sin(x)^2))^3 - 3*(sin(sin(x)^2)*cos(co
sage: sin(2*x).expand_trig(times=False)
sin(2*x)
sage: sin(2*x).expand_trig(times=True)
2*sin(x)*cos(x)
sage: sin(2 + x).expand_trig(plus=False)
sin(x + 2)
sage: sin(2 + x).expand_trig(plus=True)
sin(2)*cos(x) + sin(x)*cos(2)
sage: sin(x/2).expand_trig(half_angles=False)
sin(1/2*x)
sage: sin(x/2).expand_trig(half_angles=True)
1/2*sqrt(-cos(x) + 1)*sqrt(2)
```

ALIASES:

`trig_expand()` and `expand_trig()` are the same

`factor`()

Factors self, containing any number of variables or functions, into factors irreducible over the integers.

INPUT:

- `self` - a symbolic expression
- `dontfactor` - list (default: []), a list of variables with respect to which factoring is not to occur. Factoring also will not take place with respect to any variables which are less important (using the variable ordering assumed for CRE form) than those on the 'dontfactor' list.

EXAMPLES:

```
sage: x,y,z = var('x, y, z')
sage: (x^3-y^3).factor()
(x - y)*(x^2 + x*y + y^2)
sage: factor(-8*y - 4*x + z^2*(2*y + x))
(z - 2)*(z + 2)*(x + 2*y)
sage: f = -1 - 2*x - x^2 + y^2 + 2*x*y^2 + x^2*y^2
sage: F = factor(f/(36*(1 + 2*y + y^2)), dontfactor=[x]); F
1/36*(y - 1)*(x^2 + 2*x + 1)/(y + 1)
```

If you are factoring a polynomial with rational coefficients (and dontfactor is empty) the factorization is done using Singular instead of Maxima, so the following is very fast instead of dreadfully slow:

```
sage: var('x,y')
(x, y)
sage: (x^99 + y^99).factor()
(x + y)*(x^2 - x*y + y^2)*(x^6 - x^3*y^3 + y^6)*...
```

factor_list()

Returns a list of the factors of self, as computed by the factor command.

INPUT:

- self - a symbolic expression
- dontfactor - see docs for factor()

Note: If you already have a factored expression and just want to get at the individual factors, use _factor_list() instead.

EXAMPLES:

```
sage: var('x, y, z')
(x, y, z)
sage: f = x^3-y^3
sage: f.factor()
(x - y)*(x^2 + x*y + y^2)
```

Notice that the -1 factor is separated out:

```
sage: f.factor_list()
[(x - y, 1), (x^2 + x*y + y^2, 1)]
```

We factor a fairly straightforward expression:

```
sage: factor(-8*y - 4*x + z^2*(2*y + x)).factor_list()
[(z - 2, 1), (z + 2, 1), (x + 2*y, 1)]
```

A more complicated example:

```
sage: var('x, u, v')
(x, u, v)
sage: f = expand((2*u*v^2-v^2-4*u^3)^2 * (-u)^3 * (x-sin(x))^3)
sage: f.factor()
-(x - sin(x))^3*(4*u^3 - 2*u*v^2 + v^2)^2*u^3
sage: g = f.factor_list(); g
[(x - sin(x), 3), (4*u^3 - 2*u*v^2 + v^2, 2), (u, 3), (-1, 1)]
```

This function also works for quotients:

```
sage: f = -1 - 2*x - x^2 + y^2 + 2*x*y^2 + x^2*y^2
sage: g = f/(36*(1 + 2*y + y^2)); g
1/36*(x^2*y^2 + 2*x*y^2 - x^2 + y^2 - 2*x - 1)/(y^2 + 2*y + 1)
sage: g.factor(dontfactor=[x])
1/36*(y - 1)*(x^2 + 2*x + 1)/(y + 1)
sage: g.factor_list(dontfactor=[x])
[(y - 1, 1), (y + 1, -1), (x^2 + 2*x + 1, 1), (1/36, 1)]
```

This example also illustrates that the exponents do not have to be integers:

```
sage: f = x^(2*sin(x)) * (x-1)^(sqrt(2)*x); f
(x - 1)^(sqrt(2)*x)*x^(2*sin(x))
sage: f.factor_list()
[(x - 1, sqrt(2)*x), (x, 2*sin(x))]
```

factorial()

Return the factorial of self.

OUTPUT: symbolic expression

EXAMPLES: sage: var('x, y') (x, y) sage: SR(5).factorial() 120 sage: x.factorial() factorial(x) sage: (x^2+y^3).factorial() factorial(x^2 + y^3)

find()

Find all occurences of the given pattern in this expression.

Note that once a subexpression matches the pattern, the search doesn't extend to subexpressions of it.

EXAMPLES:

```
sage: var('x,y,z,a,b')
(x, y, z, a, b)
sage: w0 = SR.wild(0); w1 = SR.wild(1)

sage: (sin(x)*sin(y)).find(sin(w0))
[sin(x), sin(y)]

sage: ((sin(x)+sin(y))*(a+b)).expand().find(sin(w0))
[sin(x), sin(y)]

sage: (1+x+x^2+x^3).find(x)
[x]
sage: (1+x+x^2+x^3).find(x^w0)
[x^3, x^2]

sage: (1+x+x^2+x^3).find(y)
[]

# subexpressions of a match are not listed
sage: ((x^y)^z).find(w0^w1)
[(x^y)^z]
```

find_maximum_on_interval()

Numerically find the maximum of the expression `self` on the interval [a,b] (or [b,a]) along with the point at which the maximum is attained.

See the documentation for `self.find_minimum_on_interval` for more details.

EXAMPLES:

```
sage: f = x*cos(x)
sage: f.find_maximum_on_interval(0,5)
(0.5610963381910451, 0.8603335890...)
sage: f.find_maximum_on_interval(0,5, tol=0.1, maxfun=10)
(0.561090323458081..., 0.857926501456...)
```

find_minimum_on_interval()

Numerically find the minimum of the expression `self` on the interval [a,b] (or [b,a]) and the point at which it attains that minimum. Note that `self` must be a function of (at most) one variable.

INPUT:

- `var` - variable (default: first variable in self)
- `a,b` - endpoints of interval on which to minimize self.
- `tol` - the convergence tolerance
- `maxfun` - maximum function evaluations

OUTPUT:

- `minval` - (float) the minimum value that self takes on in the interval [a,b]
- `x` - (float) the point at which self takes on the minimum value

EXAMPLES:

```
sage: f = x*cos(x)
sage: f.find_minimum_on_interval(1, 5)
(-3.288371395590..., 3.4256184695...)
sage: f.find_minimum_on_interval(1, 5, tol=1e-3)
(-3.288371361890..., 3.4257507903...)
sage: f.find_minimum_on_interval(1, 5, tol=1e-2, maxfun=10)
(-3.288370845983..., 3.4250840220...)
sage: show(f.plot(0, 20))
sage: f.find_minimum_on_interval(1, 15)
(-9.477294259479..., 9.5293344109...)
```

ALGORITHM:

Uses `scipy.optimize.fminbound` which uses Brent's method.

AUTHORS:

- William Stein (2007-12-07)

find_root()

Numerically find a root of self on the closed interval [a,b] (or [b,a]) if possible, where self is a function in the one variable.

INPUT:

- `a, b` - endpoints of the interval
- `var` - optional variable
- `xtol, rtol` - the routine converges when a root is known to lie within xtol of the value return. Should be = 0. The routine modifies this to take into account the relative precision of doubles.
- `maxiter` - integer; if convergence is not achieved in maxiter iterations, an error is raised. Must be = 0.
- `full_output` - bool (default: False), if True, also return object that contains information about convergence.

EXAMPLES:

Note that in this example both f(-2) and f(3) are positive, yet we still find a root in that interval:

```
sage: f = x^2 - 1
sage: f.find_root(-2, 3)
1.0
sage: f.find_root(-2, 3, x)
1.0
sage: z, result = f.find_root(-2, 3, full_output=True)
sage: result.converged
True
sage: result.flag
'converged'
sage: result.function_calls
11
sage: result.iterations
10
sage: result.root
1.0
```

More examples:

```
sage: (sin(x) + exp(x)).find_root(-10, 10)
-0.588532743981862...
sage: sin(x).find_root(-1,1)
0.0
sage: (1/tan(x)).find_root(3,3.5)
3.1415926535...
```

An example with a square root:

```
sage: f = 1 + x + sqrt(x+2); f.find_root(-2,10)
-1.6180339887498949
```

Some examples that Ted Kosan came up with:

```
sage: t = var('t')
sage: v = 0.004*(9600*e^(-(1200*t)) - 2400*e^(-(300*t)))
sage: v.find_root(0, 0.002)
0.001540327067911417...

sage: a = .004*(8*e^(-(300*t)) - 8*e^(-(1200*t)))*(720000*e^(-(300*t)) - 11520000*e^(-(1200*
```

There is a 0 very close to the origin:

```
sage: show(plot(a, 0, .002), xmin=0, xmax=.002)
```

Using solve does not work to find it:

```
sage: a.solve(t)
[]
```

However `find_root` works beautifully:

```
sage: a.find_root(0,0.002)
0.0004110514049349...
```

We illustrate that root finding is only implemented in one dimension:

```
sage: x, y = var('x,y')
sage: (x-y).find_root(-2,2)
...
NotImplementedError: root finding currently only implemented in 1 dimension.
```

TESTS:

Test the special case that failed for the first attempt to fix #3980:

```
sage: t = var('t')
sage: find_root(1/t - x,0,2)
...
NotImplementedError: root finding currently only implemented in 1 dimension.
```

forget()

Forget the given constraint.

EXAMPLES:

```
sage: var('x,y')
(x, y)
sage: forget()
sage: assume(x>0, y < 2)
sage: assumptions()
[x > 0, y < 2]
sage: forget(y < 2)
sage: assumptions()
[x > 0]
```

full_simplify()

Applies simplify_trig, simplify_rational, and simplify_radical to self (in that order).

ALIAS: simplfy_full and full_simplify are the same.

EXAMPLES:

```
sage: a = log(8)/log(2)
sage: a.simplify_full()
3

sage: f = sin(x)^2 + cos(x)^2
sage: f.simplify_full()
1

sage: f = sin(x/(x^2 + x))
sage: f.simplify_full()
sin(1/(x + 1))
```

function()

Return a callable symbolic expression with the given variables.

EXAMPLES:

We will use several symbolic variables in the examples below:

```
sage: var('x, y, z, t, a, w, n')
(x, y, z, t, a, w, n)

sage: u = sin(x) + x*cos(y)
sage: g = u.function(x,y)
sage: g(x,y)
x*cos(y) + sin(x)
sage: g(t,z)
t*cos(z) + sin(t)
sage: g(x^2, x^y)
x^2*cos(x^y) + sin(x^2)

sage: f = (x^2 + sin(a*w)).function(a,x,w); f
(a, x, w) |--> x^2 + sin(a*w)
sage: f(1,2,3)
sin(3) + 4
```

Using the `function()` method we can obtain the above function f, but viewed as a function of different variables:

```
sage: h = f.function(w,a); h
(w, a) |--> x^2 + sin(a*w)
```

This notation also works:

```
sage: h(w,a) = f
sage: h
(w, a) |--> x^2 + sin(a*w)
```

You can even make a symbolic expression f into a function by writing `f(x,y) = f`:

```
sage: f = x^n + y^n; f
x^n + y^n
sage: f(x,y) = f
sage: f
(x, y) |--> x^n + y^n
sage: f(2,3)
2^n + 3^n
```

gamma()

Return the Gamma function evaluated at self.

EXAMPLES: sage: x = var('x') sage: x.gamma() gamma(x) sage: SR(2).gamma() 1 sage: SR(10).gamma() 362880 sage: SR(10.0r).gamma() gamma(10.0000000000000)

Use .n() to get a numerical approximation:

```
sage: SR(10.0r).gamma().n()
362880.000000000
sage: SR(CDF(1,1)).gamma()
gamma(1.0 + 1.0*I)
sage: SR(CDF(1,1)).gamma().n()
0.498015668118 - 0.154949828302*I

sage: gp('gamma(1+I)') # 32-bit
0.49801566811835604271369111746219809195 - 0.15494982830181068512495513048388660520*I

sage: gp('gamma(1+I)') # 64-bit
0.49801566811835604271369111746219809195 - 0.15494982830181068512495513048388660520*I

sage: set_verbose(-1); plot(lambda x: SR(x).gamma(), -6,4).show(ymin=-3,ymax=3)
```

gcd()

Return the gcd of self and b, which must be integers or polynomials over the rational numbers.

TODO: I tried the massive gcd from http://trac.sagemath.org/sage_trac/ticket/694 on Ginac dies after about 10 seconds. Singular easily does that GCD now. Since Ginac only handles poly gcd over QQ, we should change ginac itself to use Singular.

EXAMPLES:

```
sage: var('x,y')
(x, y)
sage: SR(10).gcd(SR(15))
5
sage: (x^3 - 1).gcd(x-1)
x - 1
sage: (x^3 - 1).gcd(x^2+x+1)
x^2 + x + 1
sage: (x^3 - sage.symbolic.constants.pi).gcd(x-sage.symbolic.constants.pi)
...
RuntimeError: gcd: arguments must be polynomials over the rationals
sage: gcd(x^3 - y^3, x-y)
-x + y
sage: gcd(x^100-y^100, x^10-y^10)
-x^10 + y^10
sage: gcd(expand( (x^2+17*x+3/7*y)*(x^5 - 17*y + 2/3) ), expand((x^13+17*x+3/7*y)*(x^5 - 17*
1/7*x^5 - 17/7*y + 2/21
```

gradient()

Compute the gradient of a symbolic function.

This function returns a vector whose components are the derivatives of the original function with respect to the arguments of the original function. Alternatively, you can specify the variables as a list.

EXAMPLES:

```
sage: x,y = var('x y')
sage: f = x^2+y^2
sage: f.gradient()
(2*x, 2*y)
sage: g(x,y) = x^2+y^2
sage: g.gradient()
((x, y) |--> 2*x, (x, y) |--> 2*y)
sage: n = var('n')
sage: f(x,y) = x^n+y^n
sage: f.gradient()
((x, y) |--> n*x^(n - 1), (x, y) |--> n*y^(n - 1))
```

```
sage: f.gradient([y,x])
((x, y) |--> n*y^(n - 1), (x, y) |--> n*x^(n - 1))
```

has()

EXAMPLES:

```
sage: var('x,y,a'); w0 = SR.wild(); w1 = SR.wild()
(x, y, a)
sage: (x*sin(x + y + 2*a)).has(y)
True
```

Here "x+y" is not a subexpression of "x+y+2*a" (which has the subexpressions "x", "y" and "2*a"):

```
sage: (x*sin(x + y + 2*a)).has(x+y)
False
sage: (x*sin(x + y + 2*a)).has(x + y + w0)
True
```

The following fails because "2*(x+y)" automatically gets converted to "2*x+2*y" of which "x+y" is not a subexpression:

```
sage: (x*sin(2*(x+y) + 2*a)).has(x+y)
False
```

Although x^1==x and x^0==1, neither "x" nor "1" are actually of the form "x^something":

```
sage: (x+1).has(x^w0)
False
```

Here is another possible pitfall, where the first expression matches because the term "-x" has the form "(-1)*x" in GiNaC. To check whether a polynomial contains a linear term you should use the coeff() function instead.

```
sage: (4*x^2 - x + 3).has(w0*x)
True
sage: (4*x^2 + x + 3).has(w0*x)
False
sage: (4*x^2 + x + 3).has(x)
True
sage: (4*x^2 - x + 3).coeff(x,1)
-1
sage: (4*x^2 + x + 3).coeff(x,1)
1
```

hessian()

Compute the hessian of a function. This returns a matrix components are the 2nd partial derivatives of the original function.

EXAMPLES:

```
sage: x,y = var('x y')
sage: f = x^2+y^2
sage: f.hessian()
[2 0]
[0 2]
sage: g(x,y) = x^2+y^2
sage: g.hessian()
[(x, y) |--> 2 (x, y) |--> 0]
[(x, y) |--> 0 (x, y) |--> 2]
```

imag()

Return the imaginary part of this symbolic expression.

EXAMPLES:

```
sage: sqrt(-2).imag_part()
sqrt(2)
```

We simplify $\ln(\exp(z))$ to z for $-\pi < \mathrm{Im}(z) <= \pi$:

```
sage: z = var('z')
sage: f = log(exp(z))
sage: assume(-pi < imag(z))
sage: assume(imag(z) <= pi)
sage: f
log(e^z)
sage: f.simplify()
z
sage: forget()
```

A more symbolic example:

```
sage: var('a, b')
(a, b)
sage: f = log(a + b*I)
sage: f.imag_part()
arctan2(real_part(b) + imag_part(a), real_part(a) - imag_part(b))
```

TESTS:

```
sage: x = var('x')
sage: x.imag_part()
imag_part(x)
sage: SR(2+3*I).imag_part()
3
sage: SR(CC(2,3)).imag_part()
3.00000000000000
sage: SR(CDF(2,3)).imag_part()
3.0
```

imag_part()

Return the imaginary part of this symbolic expression.

EXAMPLES:

```
sage: sqrt(-2).imag_part()
sqrt(2)
```

We simplify $\ln(\exp(z))$ to z for $-\pi < \mathrm{Im}(z) <= \pi$:

```
sage: z = var('z')
sage: f = log(exp(z))
sage: assume(-pi < imag(z))
sage: assume(imag(z) <= pi)
sage: f
log(e^z)
sage: f.simplify()
z
sage: forget()
```

A more symbolic example:

```
sage: var('a, b')
(a, b)
sage: f = log(a + b*I)
sage: f.imag_part()
arctan2(real_part(b) + imag_part(a), real_part(a) - imag_part(b))
```

TESTS:

```
sage: x = var('x')
sage: x.imag_part()
imag_part(x)
sage: SR(2+3*I).imag_part()
3
sage: SR(CC(2,3)).imag_part()
3.00000000000000
sage: SR(CDF(2,3)).imag_part()
3.0
```

integral()

Compute the integral of self. Please see sage.calculus.calculus.integral for more details.

EXAMPLES:

```
sage: sin(x).integral(x,0,3)
-cos(3) + 1
sage: sin(x).integral(x)
-cos(x)
```

integrate()

Compute the integral of self. Please see sage.calculus.calculus.integral for more details.

EXAMPLES:

```
sage: sin(x).integral(x,0,3)
-cos(3) + 1
sage: sin(x).integral(x)
-cos(x)
```

inverse_laplace()

Return inverse Laplace transform of self. See sage.calculus.calculus.inverse_laplace

EXAMPLES:

```
sage: var('w, m')
(w, m)
sage: f = (1/(w^2+10)).inverse_laplace(w, m); f
1/10*sqrt(10)*sin(sqrt(10)*m)
```

is_polynomial()

Return True if self is a polynomial in the given variable.

EXAMPLES:

```
sage: var('x,y,z')
(x, y, z)
sage: t = x^2 + y; t
x^2 + y
sage: t.is_polynomial(x)
True
sage: t.is_polynomial(y)
True
sage: t.is_polynomial(z)
True

sage: t = sin(x) + y; t
y + sin(x)
sage: t.is_polynomial(x)
False
sage: t.is_polynomial(y)
True
```

```
sage: t.is_polynomial(sin(x))
True
```

is_relational()
Return True if self is a relational expression.
EXAMPLES:

```
sage: x = var('x')
sage: eqn = (x-1)^2 == x^2 - 2*x + 3
sage: eqn.is_relational()
True
sage: sin(x).is_relational()
False
```

is_unit()
Return True if this expression is a unit of the symbolic ring.
EXAMPLES:

```
sage: SR(1).is_unit()
True
sage: SR(-1).is_unit()
True
sage: SR(0).is_unit()
False
```

iterator()
Return an iterator over the arguments of this expression.
EXAMPLES:

```
sage: x,y,z = var('x,y,z')
sage: list((x+y+z).iterator())
[x, y, z]
sage: list((x*y*z).iterator())
[x, y, z]
sage: list((x^y*z*(x+y)).iterator())
[x + y, x^y, z]
```

laplace()
Return Lapalace transform of self. See sage.calculus.calculus.laplace
EXAMPLES:

```
sage: var('x,s,z')
(x, s, z)
sage: (z + exp(x)).laplace(x, s)
z/s + 1/(s - 1)
```

leading_coeff()
Return the leading coefficient of s in self.
EXAMPLES:

```
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + x/y + 2*sin(x*y)/x + 100
sage: f.leading_coefficient(x)
sin(x*y)
sage: f.leading_coefficient(y)
x
```

```
sage: f.leading_coefficient(sin(x*y))
x^3 + 2/x
```

leading_coefficient()

Return the leading coefficient of s in self.

EXAMPLES:

```
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + x/y + 2*sin(x*y)/x + 100
sage: f.leading_coefficient(x)
sin(x*y)
sage: f.leading_coefficient(y)
x
sage: f.leading_coefficient(sin(x*y))
x^3 + 2/x
```

left()

If self is a relational expression, return the left hand side of the relation. Otherwise, raise a ValueError.

EXAMPLES:

```
sage: x = var('x')
sage: eqn = (x-1)^2 == x^2 - 2*x + 3
sage: eqn.left_hand_side()
(x - 1)^2
sage: eqn.lhs()
(x - 1)^2
sage: eqn.left()
(x - 1)^2
```

left_hand_side()

If self is a relational expression, return the left hand side of the relation. Otherwise, raise a ValueError.

EXAMPLES:

```
sage: x = var('x')
sage: eqn = (x-1)^2 == x^2 - 2*x + 3
sage: eqn.left_hand_side()
(x - 1)^2
sage: eqn.lhs()
(x - 1)^2
sage: eqn.left()
(x - 1)^2
```

lgamma()

Return the log-gamma function evaluated at self. This is the logarithm of gamma of self, where gamma is a complex function such that gamma(n) equals factorial(n-1).

EXAMPLES: sage: x = var('x') sage: x.lgamma() lgamma(x) sage: SR(2).lgamma() 0 sage: SR(5).lgamma() log(24) sage: SR(5-1).factorial().log() log(24) sage: set_verbose(-1); plot(lambda x: SR(x).lgamma(), -7,8, plot_points=1000).show() sage: math.exp(0.5) 1.6487212707001282 sage: plot(lambda x: (SR(x).exp() - SR(-x).exp())/2 - SR(x).sinh(), -1, 1)

lhs()

If self is a relational expression, return the left hand side of the relation. Otherwise, raise a ValueError.

EXAMPLES:

```
sage: x = var('x')
sage: eqn = (x-1)^2 == x^2 - 2*x + 3
```

```
sage: eqn.left_hand_side()
(x - 1)^2
sage: eqn.lhs()
(x - 1)^2
sage: eqn.left()
(x - 1)^2
```

limit()

Return a symbolic limit. See sage.calculus.calculus.limit

EXAMPLES:

```
sage: (sin(x)/x).limit(x=0)
1
```

log()

Return the logarithm of self.

EXAMPLES:

```
sage: x, y = var('x, y')
sage: x.log()
log(x)
sage: (x^y + y^x).log()
log(x^y + y^x)
sage: SR(0).log()
...
RuntimeError: log_eval(): log(0)
sage: SR(1).log()
0
sage: SR(1/2).log()
log(1/2)
sage: SR(0.5).log()
log(0.500000000000000)
```

Use .n() to get a numerical approximation:

```
sage: SR(0.5).log().n()
-0.693147180559945
sage: SR(0.5).log().exp()
0.500000000000000
sage: math.log(0.5)
-0.69314718055994529
sage: plot(lambda x: SR(x).log(), 0.1,10)
```

log_simplify()

Simplifies this symbolic expression, which can contain logs, exponentials, and radicals, by converting it into a form which is canonical over a large class of expressions and a given ordering of variables

DETAILS: This uses the Maxima radcan() command. From the Maxima documentation: "All functionally equivalent forms are mapped into a unique form. For a somewhat larger class of expressions, produces a regular form. Two equivalent expressions in this class do not necessarily have the same appearance, but their difference can be simplified by radcan to zero. For some expressions radcan is quite time consuming. This is the cost of exploring certain relationships among the components of the expression for simplifications based on factoring and partial fraction expansions of exponents."

ALIAS: radical_simplify, simplify_radical, simplify_log, log_simplify, exp_simplify, simplify_exp are all the same

EXAMPLES:

```
sage: var('x,y,a')
(x, y, a)
```

```
sage: f = log(x*y)
sage: f.simplify_radical()
log(x) + log(y)

sage: f = (log(x+x^2)-log(x))^a/log(1+x)^(a/2)
sage: f.simplify_radical()
log(x + 1)^(1/2*a)

sage: f = (e^x-1)/(1+e^(x/2))
sage: f.simplify_exp()
e^(1/2*x) - 1
```

low_degree()

Return the exponent of the lowest nonpositive power of s in self.

OUTPUT:

- an integer <= 0.

EXAMPLES:

```
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y^10 + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + 2*sin(x*y)/x + x/y^10 + 100
sage: f.low_degree(x)
-1
sage: f.low_degree(y)
-10
sage: f.low_degree(sin(x*y))
0
sage: (x^3+y).low_degree(x)
0
```

match()

See http://www.ginac.de/tutorial/Pattern-matching-and-advanced-substitutions.html

EXAMPLES:

```
sage: var('x,y,z,a,b,c,d,e,f')
(x, y, z, a, b, c, d, e, f)
sage: w0 = SR.wild(0); w1 = SR.wild(1); w2 = SR.wild(2)
sage: ((x+y)^a).match((x+y)^a)
True
sage: ((x+y)^a).match((x+y)^b)
False
sage: ((x+y)^a).match(w0^w1)
True
sage: ((x+y)^a).match(w0^w0)
False
sage: ((x+y)^(x+y)).match(w0^w0)
True
sage: ((a+b)*(a+c)).match((a+w0)*(a+w1))
True
sage: ((a+b)*(a+c)).match((w0+b)*(w0+c))
True
sage: ((a+b)*(a+c)).match((w0+w1)*(w0+w2))     # surprising?
False
sage: (a*(x+y)+a*z+b).match(a*w0+w1)
True
sage: (a+b+c+d+e+f).match(c)
False
```

```
sage: (a+b+c+d+e+f).has(c)
True
sage: (a+b+c+d+e+f).match(c+w0)
True
sage: (a+b+c+d+e+f).match(c+e+w0)
True
sage: (a+b).match(a+b+w0)
True
sage: (a*b^2).match(a^w0*b^w1)
False
sage: (a*b^2).match(a*b^w1)
True
sage: (x*x.arctan2(x^2)).match(w0*w0.arctan2(w0^2))
True
```

minpoly()

Return the minimal polynomial of this symbolic expression.

EXAMPLES:

```
sage: golden_ratio.minpoly()
x^2 - x - 1
```

multiply_both_sides()

Returns a relation obtained by multiplying both sides of this relation by x.

Note: The *checksign* keyword argument is currently ignored and is included for backward compatibility reasons only.

EXAMPLES:

```
sage: var('x,y'); f = x + 3 < y - 2
(x, y)
sage: f.multiply_both_sides(7)
7*x + 21 < 7*y - 14
sage: f.multiply_both_sides(-1/2)
-1/2*x - 3/2 < -1/2*y + 1
sage: f*(-2/3)
-2/3*x - 2 < -2/3*y + 4/3
sage: f*(-pi)
-(x + 3)*pi < -(y - 2)*pi
```

Since the direction of the inequality never changes when doing arithmetic with equations, you can multiply or divide the equation by a quantity with unknown sign:

```
sage: f*(1+I)
(I + 1)*x + 3*I + 3 < (I + 1)*y - 2*I - 2
sage: f = sqrt(2) + x == y^3
sage: f.multiply_both_sides(I)
I*x + I*sqrt(2) == I*y^3
sage: f.multiply_both_sides(-1)
-x - sqrt(2) == -y^3
```

Note that the direction of the following inequalities is not reversed:

```
sage: (x^3 + 1 > 2*sqrt(3)) * (-1)
-x^3 - 1 > -2*sqrt(3)
sage: (x^3 + 1 >= 2*sqrt(3)) * (-1)
-x^3 - 1 >= -2*sqrt(3)
sage: (x^3 + 1 <= 2*sqrt(3)) * (-1)
-x^3 - 1 <= -2*sqrt(3)
```

n()

Return a numerical approximation this symbolic expression as either a real or complex number with at least the requested number of bits or digits of precision.

EXAMPLES:

```
sage: sin(x).subs(x=5).n()
-0.958924274663138
sage: sin(x).subs(x=5).n(100)
-0.95892427466313846889315440616
sage: sin(x).subs(x=5).n(digits=50)
-0.95892427466313846889315440615599397335246154396460
sage: zeta(x).subs(x=2).numerical_approx(digits=50)
1.6449340668482264364724151666460251892189499012068

sage: cos(3).numerical_approx(200)
-0.98999249660044545727157279473126130239367909661558832881409
sage: numerical_approx(cos(3), digits=10)
-0.9899924966
sage: (i + 1).numerical_approx(32)
1.00000000 + 1.00000000*I
sage: (pi + e + sqrt(2)).numerical_approx(100)
7.2740880444219335226246195788
```

TESTS:

We test the evaluation of different infinities available in pynac:

```
sage: t = x - oo; t
-Infinity
sage: t.n()
-infinity
sage: t = x + oo; t
+Infinity
sage: t.n()
+infinity
sage: t = x - unsigned_infinity; t
Infinity
sage: t.n()
+infinity
```

nintegral()

Compute the numerical integral of self. Please see sage.calculus.calculus.nintegral for more details.

EXAMPLES:

```
sage: sin(x).nintegral(x,0,3)
(1.989992496600..., 2.209335488557...e-14, 21, 0)
```

nintegrate()

Compute the numerical integral of self. Please see sage.calculus.calculus.nintegral for more details.

EXAMPLES:

```
sage: sin(x).nintegral(x,0,3)
(1.989992496600..., 2.209335488557...e-14, 21, 0)
```

nops()

Returns the number of arguments of this expression.

EXAMPLES:

```
sage: var('a,b,c,x,y')
(a, b, c, x, y)
sage: a.number_of_operands()
0
sage: (a^2 + b^2 + (x+y)^2).number_of_operands()
3
sage: (a^2).number_of_operands()
2
sage: (a*b^2*c).number_of_operands()
3
```

norm()

The complex norm of this symbolic expression, i.e., the expression times its complex conjugate.

EXAMPLES:

```
sage: a = 1 + 2*I
sage: a.norm()
5
sage: a = sqrt(2) + 3^(1/3)*I; a
sqrt(2) + I*3^(1/3)
sage: a.norm()
3^(2/3) + 2
sage: CDF(a).norm()
4.08008382305
sage: CDF(a.norm())
4.08008382305
```

number_of_arguments()

EXAMPLES:

```
sage: x,y = var('x,y')
sage: f = x + y
sage: f.number_of_arguments()
2

sage: g = f.function(x)
sage: g.number_of_arguments()
1

sage: x,y,z = var('x,y,z')
sage: (x+y).number_of_arguments()
2
sage: (x+1).number_of_arguments()
1
sage: (sin(x)+1).number_of_arguments()
1
sage: (sin(z)+x+y).number_of_arguments()
3
sage: (sin(x+y)).number_of_arguments()
2

sage: ( 2^(8/9) - 2^(1/9) )(x-1)
...
ValueError: the number of arguments must be less than or equal to 0
```

number_of_operands()

Returns the number of arguments of this expression.

EXAMPLES:

```
sage: var('a,b,c,x,y')
(a, b, c, x, y)
sage: a.number_of_operands()
0
sage: (a^2 + b^2 + (x+y)^2).number_of_operands()
3
sage: (a^2).number_of_operands()
2
sage: (a*b^2*c).number_of_operands()
3
```

numerator()

Returns the numerator of this symbolic expression. If the expression is not a quotient, then this will return the expression itself.

EXAMPLES:

```
sage: a, x, y = var('a,x,y')
sage: f = x*(x-a)/((x^2 - y)*(x-a)); f
x/(x^2 - y)
sage: f.numerator()
x
sage: f.denominator()
x^2 - y

sage: y = var('y')
sage: g = x + y/(x + 2); g
x + y/(x + 2)
sage: g.numerator()
x + y/(x + 2)
sage: g.denominator()
1
```

numerical_approx()

Return a numerical approximation this symbolic expression as either a real or complex number with at least the requested number of bits or digits of precision.

EXAMPLES:

```
sage: sin(x).subs(x=5).n()
-0.958924274663138
sage: sin(x).subs(x=5).n(100)
-0.95892427466313846889315440616
sage: sin(x).subs(x=5).n(digits=50)
-0.95892427466313846889315440615599397335246154396460
sage: zeta(x).subs(x=2).numerical_approx(digits=50)
1.6449340668482264364724151666460251892189499012068

sage: cos(3).numerical_approx(200)
-0.98999249660044545727157279473126130239367909661558832881409
sage: numerical_approx(cos(3), digits=10)
-0.9899924966
sage: (i + 1).numerical_approx(32)
1.00000000 + 1.00000000*I
sage: (pi + e + sqrt(2)).numerical_approx(100)
7.2740880444219335226246195788
```

TESTS:

We test the evaluation of different infinities available in pynac:

```
sage: t = x - oo; t
-Infinity
sage: t.n()
-infinity
sage: t = x + oo; t
+Infinity
sage: t.n()
+infinity
sage: t = x - unsigned_infinity; t
Infinity
sage: t.n()
+infinity
```

operands()

Returns a list containing the operands of this expression.

EXAMPLES:

```
sage: var('a,b,c,x,y')
(a, b, c, x, y)
sage: (a^2 + b^2 + (x+y)^2).operands()
[(x + y)^2, a^2, b^2]
sage: (a^2).operands()
[a, 2]
sage: (a*b^2*c).operands()
[a, b^2, c]
```

operator()

Returns the topmost operator in this expression.

EXAMPLES:

```
sage: x,y,z = var('x,y,z')
sage: (x+y).operator()
<built-in function add>
sage: (x^y).operator()
<built-in function pow>
sage: (x^y * z).operator()
<built-in function mul>
sage: (x < y).operator()
<built-in function lt>

sage: abs(x).operator()
abs
sage: r = gamma(x).operator(); type(r)
<class 'sage.functions.other.Function_gamma'>

sage: from sage.symbolic.function import function
sage: psi = function('psi', 1)
sage: psi(x).operator()
psi

sage: r = psi(x).operator()
sage: r == psi
True

sage: f = function('f', 1, conjugate_func=lambda x: 2*x)
sage: nf = f(x).operator()
sage: nf(x).conjugate()
2*x
```

```
sage: f = function('f')
sage: a = f(x).diff(x); a
D[0](f)(x)
sage: a.operator()
D[0](f)
```

TESTS: sage: (x <= y).operator() <built-in function le> sage: (x == y).operator() <built-in function eq> sage: (x != y).operator() <built-in function ne> sage: (x > y).operator() <built-in function gt> sage: (x >= y).operator() <built-in function ge>

partial_fraction()

Return the partial fraction expansion of `self` with respect to the given variable.

INPUT:

- `var` - variable name or string (default: first variable)

OUTPUT: Symbolic expression

EXAMPLES:

```
sage: f = x^2/(x+1)^3
sage: f.partial_fraction()
1/(x + 1) - 2/(x + 1)^2 + 1/(x + 1)^3
sage: f.partial_fraction()
1/(x + 1) - 2/(x + 1)^2 + 1/(x + 1)^3
```

Notice that the first variable in the expression is used by default:

```
sage: y = var('y')
sage: f = y^2/(y+1)^3
sage: f.partial_fraction()
1/(y + 1) - 2/(y + 1)^2 + 1/(y + 1)^3

sage: f = y^2/(y+1)^3 + x/(x-1)^3
sage: f.partial_fraction()
y^2/(y^3 + 3*y^2 + 3*y + 1) + 1/(x - 1)^2 + 1/(x - 1)^3
```

You can explicitly specify which variable is used:

```
sage: f.partial_fraction(y)
x/(x^3 - 3*x^2 + 3*x - 1) + 1/(y + 1) - 2/(y + 1)^2 + 1/(y + 1)^3
```

plot()

Plot a symbolic expression. All arguments are passed onto the standard plot command.

EXAMPLES:

This displays a straight line:

```
sage: sin(2).plot((x,0,3))
```

This draws a red oscillatory curve:

```
sage: sin(x^2).plot((x,0,2*pi), rgbcolor=(1,0,0))
```

Another plot using the variable theta:

```
sage: var('theta')
theta
sage: (cos(theta) - erf(theta)).plot((theta,-2*pi,2*pi))
```

A very thick green plot with a frame:

```
sage: sin(x).plot((x,-4*pi, 4*pi), thickness=20, rgbcolor=(0,0.7,0)).show(frame=True)
```

You can embed 2d plots in 3d space as follows:

```
sage: plot(sin(x^2), (x,-pi, pi), thickness=2).plot3d(z = 1)
```

A more complicated family:

```
sage: G = sum([plot(sin(n*x), (x,-2*pi, 2*pi)).plot3d(z=n) for n in [0,0.1,..1]])
sage: G.show(frame_aspect_ratio=[1,1,1/2])
```

A plot involving the floor function:

```
sage: plot(1.0 - x * floor(1/x), (x,0.00001,1.0))
```

Sage used to allow symbolic functions with "no arguments"; this no longer works:

```
sage: plot(2*sin, -4, 4)
...
TypeError: unsupported operand parent(s) for '*': 'Integer Ring' and '<class 'sage.functions
```

You should evaluate the function first:

```
sage: plot(2*sin(x), -4, 4)
```

TESTS:

```
sage: f(x) = x*(1 - x)
sage: plot(f,0,1)
```

poly()

Express this symbolic expression as a polynomial in x. If this is not a polynomial in x, then some coefficients may be functions of x.

Warning: This is different from `polynomial()` which returns a Sage polynomial over a given base ring.

EXAMPLES:

```
sage: var('a, x')
(a, x)
sage: p = expand((x-a*sqrt(2))^2 + x + 1); p
-2*sqrt(2)*a*x + 2*a^2 + x^2 + x + 1
sage: p.poly(a)
-2*sqrt(2)*a*x + 2*a^2 + x^2 + x + 1
sage: bool(expand(p.poly(a)) == p)
True
sage: p.poly(x)
-(2*sqrt(2)*a - 1)*x + 2*a^2 + x^2 + 1
```

polynomial()

Return this symbolic expression as an algebraic polynomial over the given base ring, if possible.

The point of this function is that it converts purely symbolic polynomials into optimised algebraic polynomials over a given base ring.

Warning: This is different from meth:*poly* which is used to rewrite self as a polynomial in terms of one of the variables.

INPUT:

- `base_ring` - a ring

EXAMPLES:

```
sage: f = x^2 -2/3*x + 1
sage: f.polynomial(QQ)
x^2 - 2/3*x + 1
```

```
sage: f.polynomial(GF(19))
x^2 + 12*x + 1
```

Polynomials can be useful for getting the coefficients of an expression:

```
sage: g = 6*x^2 - 5
sage: g.coefficients()
[[-5, 0], [6, 2]]
sage: g.polynomial(QQ).list()
[-5, 0, 6]
sage: g.polynomial(QQ).dict()
{0: -5, 2: 6}

sage: f = x^2*e + x + pi/e
sage: f.polynomial(RDF)
2.71828182846*x^2 + 1.0*x + 1.15572734979
sage: g = f.polynomial(RR); g
2.71828182845905*x^2 + 1.00000000000000*x + 1.15572734979092
sage: g.parent()
Univariate Polynomial Ring in x over Real Field with 53 bits of precision
sage: f.polynomial(RealField(100))
2.7182818284590452353602874714*x^2 + 1.0000000000000000000000000000*x + 1.1557273497909217
sage: f.polynomial(CDF)
2.71828182846*x^2 + 1.0*x + 1.15572734979
sage: f.polynomial(CC)
2.71828182845905*x^2 + 1.00000000000000*x + 1.15572734979092
```

We coerce a multivariate polynomial with complex symbolic coefficients:

```
sage: x, y, n = var('x, y, n')
sage: f = pi^3*x - y^2*e - I; f
pi^3*x - y^2*e - I
sage: f.polynomial(CDF)
(-2.71828182846)*y^2 + 31.0062766803*x - 1.0*I
sage: f.polynomial(CC)
(-2.71828182845905)*y^2 + 31.0062766802998*x - 1.00000000000000*I
sage: f.polynomial(ComplexField(70))
(-2.7182818284590452354)*y^2 + 31.006276680299820175*x - 1.0000000000000000000*I
```

Another polynomial:

```
sage: f = sum((e*I)^n*x^n for n in range(5)); f
x^4*e^4 - I*x^3*e^3 - x^2*e^2 + I*x*e + 1
sage: f.polynomial(CDF)
54.5981500331*x^4 - 20.0855369232*I*x^3 - 7.38905609893*x^2 + 2.71828182846*I*x + 1.0
sage: f.polynomial(CC)
54.5981500331442*x^4 - 20.0855369231877*I*x^3 - 7.38905609893065*x^2 + 2.71828182845905*I*x
```

A multivariate polynomial over a finite field:

```
sage: f = (3*x^5 - 5*y^5)^7; f
(3*x^5 - 5*y^5)^7
sage: g = f.polynomial(GF(7)); g
3*x^35 + 2*y^35
sage: parent(g)
Multivariate Polynomial Ring in x, y over Finite Field of size 7
```

power_series()

Return algebraic power series associated to this symbolic expression, which must be a polynomial in one variable, with coefficients coercible to the base ring.

The power series is truncated one more than the degree.

EXAMPLES:

```
sage: theta = var('theta')
sage: f = theta^3 + (1/3)*theta - 17/3
sage: g = f.power_series(QQ); g
-17/3 + 1/3*theta + theta^3 + O(theta^4)
sage: g^3
-4913/27 + 289/9*theta - 17/9*theta^2 + 2602/27*theta^3 + O(theta^4)
sage: g.parent()
Power Series Ring in theta over Rational Field
```

pyobject()

Get the underlying Python object corresponding to this expression, assuming this expression is a single numerical value. Otherwise, a TypeError is raised.

EXAMPLES:

```
sage: var('x')
x
sage: b = -17/3
sage: a = SR(b)
sage: a.pyobject()
-17/3
sage: a.pyobject() is b
True
```

radical_simplify()

Simplifies this symbolic expression, which can contain logs, exponentials, and radicals, by converting it into a form which is canonical over a large class of expressions and a given ordering of variables

DETAILS: This uses the Maxima radcan() command. From the Maxima documentation: "All functionally equivalent forms are mapped into a unique form. For a somewhat larger class of expressions, produces a regular form. Two equivalent expressions in this class do not necessarily have the same appearance, but their difference can be simplified by radcan to zero. For some expressions radcan is quite time consuming. This is the cost of exploring certain relationships among the components of the expression for simplifications based on factoring and partial fraction expansions of exponents."

ALIAS: radical_simplify, simplify_radical, simplify_log, log_simplify, exp_simplify, simplify_exp are all the same

EXAMPLES:

```
sage: var('x,y,a')
(x, y, a)

sage: f = log(x*y)
sage: f.simplify_radical()
log(x) + log(y)

sage: f = (log(x+x^2)-log(x))^a/log(1+x)^(a/2)
sage: f.simplify_radical()
log(x + 1)^(1/2*a)

sage: f = (e^x-1)/(1+e^(x/2))
sage: f.simplify_exp()
e^(1/2*x) - 1
```

rational_expand()

Expand this symbolic expression. Products of sums and exponentiated sums are multiplied out, numerators of rational expressions which are sums are split into their respective terms, and multiplications are distributed over addition at all levels.

EXAMPLES:

We expand the expression $(x-y)^5$ using both method and functional notation.

```
sage: x,y = var('x,y')
sage: a = (x-y)^5
sage: a.expand()
x^5 - 5*x^4*y + 10*x^3*y^2 - 10*x^2*y^3 + 5*x*y^4 - y^5
sage: expand(a)
x^5 - 5*x^4*y + 10*x^3*y^2 - 10*x^2*y^3 + 5*x*y^4 - y^5
```

We expand some other expressions:

```
sage: expand((x-1)^3/(y-1))
x^3/(y - 1) - 3*x^2/(y - 1) + 3*x/(y - 1) - 1/(y - 1)
sage: expand((x+sin((x+y)^2))^2)
x^2 + 2*x*sin((x + y)^2) + sin((x + y)^2)^2
```

We can expand individual sides of a relation:

```
sage: a = (16*x-13)^2 == (3*x+5)^2/2
sage: a.expand()
256*x^2 - 416*x + 169 == 9/2*x^2 + 15*x + 25/2
sage: a.expand('left')
256*x^2 - 416*x + 169 == 1/2*(3*x + 5)^2
sage: a.expand('right')
(16*x - 13)^2 == 9/2*x^2 + 15*x + 25/2
```

TESTS:

sage: var('x,y') (x, y) sage: ((x + (2/3)*y)^3).expand() x^3 + 2*x^2*y + 4/3*x*y^2 + 8/27*y^3 sage: expand((x*sin(x) - cos(y)/x)^2) x^2*sin(x)^2 - 2*sin(x)*cos(y) + cos(y)^2/x^2 sage: f = (x-y)*(x+y); f (x - y)*(x + y) sage: f.expand() x^2 - y^2

rational_simplify()

Simplify by expanding repeatedly rational expressions.

ALIAS: rational_simplify and simplify_rational are the same

EXAMPLES:

```
sage: f = sin(x/(x^2 + x))
sage: f
sin(x/(x^2 + x))
sage: f.simplify_rational()
sin(1/(x + 1))

sage: f = ((x - 1)^(3/2) - (x + 1)*sqrt(x - 1))/sqrt((x - 1)*(x + 1)); f
((x - 1)^(3/2) - sqrt(x - 1)*(x + 1))/sqrt((x - 1)*(x + 1))
sage: f.simplify_rational()
-2*sqrt(x - 1)/sqrt(x^2 - 1)
```

real()

Return the real part of this symbolic expression.

EXAMPLES:

```
sage: x = var('x')
sage: x.real_part()
real_part(x)
sage: SR(2+3*I).real_part()
2
sage: SR(CDF(2,3)).real_part()
2.0
sage: SR(CC(2,3)).real_part()
2.00000000000000
```

```
sage: f = log(x)
sage: f.real_part()
log(abs(x))
```

real_part()

Return the real part of this symbolic expression.

EXAMPLES:

```
sage: x = var('x')
sage: x.real_part()
real_part(x)
sage: SR(2+3*I).real_part()
2
sage: SR(CDF(2,3)).real_part()
2.0
sage: SR(CC(2,3)).real_part()
2.00000000000000

sage: f = log(x)
sage: f.real_part()
log(abs(x))
```

rhs()

If self is a relational expression, return the right hand side of the relation. Otherwise, raise a ValueError.

EXAMPLES:

```
sage: x = var('x')
sage: eqn = (x-1)^2 <= x^2 - 2*x + 3
sage: eqn.right_hand_side()
x^2 - 2*x + 3
sage: eqn.rhs()
x^2 - 2*x + 3
sage: eqn.right()
x^2 - 2*x + 3
```

right()

If self is a relational expression, return the right hand side of the relation. Otherwise, raise a ValueError.

EXAMPLES:

```
sage: x = var('x')
sage: eqn = (x-1)^2 <= x^2 - 2*x + 3
sage: eqn.right_hand_side()
x^2 - 2*x + 3
sage: eqn.rhs()
x^2 - 2*x + 3
sage: eqn.right()
x^2 - 2*x + 3
```

right_hand_side()

If self is a relational expression, return the right hand side of the relation. Otherwise, raise a ValueError.

EXAMPLES:

```
sage: x = var('x')
sage: eqn = (x-1)^2 <= x^2 - 2*x + 3
sage: eqn.right_hand_side()
x^2 - 2*x + 3
sage: eqn.rhs()
x^2 - 2*x + 3
```

```
sage: eqn.right()
x^2 - 2*x + 3
```

roots()

Returns roots of `self` that can be found exactly, possibly with multiplicities. Not all roots are guaranteed to be found.

Warning: This is *not* a numerical solver - use `find_root` to solve for self == 0 numerically on an interval.

INPUT:

- `x` - variable to view the function in terms of (use default variable if not given)
- `explicit_solutions` - bool (default True); require that roots be explicit rather than implicit
- `multiplicities` - bool (default True); when True, return multiplicities
- `ring` - a ring (default None): if not None, convert self to a polynomial over ring and find roots over ring

OUTPUT:

list of pairs (root, multiplicity) or list of roots

If there are infinitely many roots, e.g., a function like $\sin(x)$, only one is returned.

EXAMPLES:

```
sage: var('x, a')
(x, a)
```

A simple example:

```
sage: ((x^2-1)^2).roots()
[(-1, 2), (1, 2)]
sage: ((x^2-1)^2).roots(multiplicities=False)
[-1, 1]
```

A complicated example.

```
sage: f = expand((x^2 - 1)^3*(x^2 + 1)*(x-a)); f
-a*x^8 + x^9 + 2*a*x^6 - 2*x^7 - 2*a*x^2 + 2*x^3 + a - x
```

The default variable is a, since it is the first in alphabetical order:

```
sage: f.roots()
[(x, 1)]
```

As a polynomial in a, x is indeed a root:

```
sage: f.poly(a)
x^9 - 2*x^7 + 2*x^3 - (x^8 - 2*x^6 + 2*x^2 - 1)*a - x
sage: f(a=x)
0
```

The roots in terms of x are what we expect:

```
sage: f.roots(x)
[(a, 1), (-I, 1), (I, 1), (1, 3), (-1, 3)]
```

Only one root of $\sin(x) = 0$ is given:

```
sage: f = sin(x)
sage: f.roots(x)
[(0, 1)]
```

We derive the roots of a general quadratic polynomial:

```
sage: var('a,b,c,x')
(a, b, c, x)
sage: (a*x^2 + b*x + c).roots(x)
[(-1/2*(b + sqrt(-4*a*c + b^2))/a, 1), (-1/2*(b - sqrt(-4*a*c + b^2))/a, 1)]
```

By default, all the roots are required to be explicit rather than implicit. To get implicit roots, pass `explicit_solutions=False` to `.roots()`

```
sage: var('x')
x
sage: f = x^(1/9) + (2^(8/9) - 2^(1/9))*(x - 1) - x^(8/9)
sage: f.roots()
...
RuntimeError: no explicit roots found
sage: f.roots(explicit_solutions=False)
[((2^(8/9) - 2^(1/9) + x^(8/9) - x^(1/9))/(2^(8/9) - 2^(1/9)), 1)]
```

Another example, but involving a degree 5 poly whose roots don't get computed explicitly:

```
sage: f = x^5 + x^3 + 17*x + 1
sage: f.roots()
...
RuntimeError: no explicit roots found
sage: f.roots(explicit_solutions=False)
[(x^5 + x^3 + 17*x + 1, 1)]
sage: f.roots(explicit_solutions=False, multiplicities=False)
[x^5 + x^3 + 17*x + 1]
```

Now let's find some roots over different rings:

```
sage: f.roots(ring=CC)
[(-0.0588115223184495, 1), (-1.331099917875... - 1.52241655183732*I, 1), (-1.331099917875...
sage: (2.5*f).roots(ring=RR)
[(-0.058811522318449..., 1)]
sage: f.roots(ring=CC, multiplicities=False)
[-0.0588115223184495, -1.331099917875... - 1.52241655183732*I, -1.331099917875... + 1.522416
sage: f.roots(ring=QQ)
[]
sage: f.roots(ring=QQbar, multiplicities=False)
[-0.05881152231844944?, -1.331099917875796? - 1.522416551837318?*I, -1.331099917875796? + 1.
```

Root finding over finite fields:

```
sage: f.roots(ring=GF(7^2, 'a'))
[(3, 1), (4*a + 6, 2), (3*a + 3, 2)]
```

TESTS:

```
sage: (sqrt(3) * f).roots(ring=QQ)
...
TypeError: unable to convert sqrt(3) to a rational
```

series()

Return the power series expansion of self in terms of the variable symbol to the given order.

INPUT:

- `symbol` - a variable
- `order` - an integer

OUTPUT:

- a power series

To truncate the power series and obtain a normal expression, use the truncate command.

EXAMPLES:

We expand a polynomial in x about 0, about 1, and also truncate it back to a polynomial:

```
sage: var('x,y')
(x, y)
sage: f = (x^3 - sin(y)*x^2 - 5*x + 3); f
x^3 - x^2*sin(y) - 5*x + 3
sage: g = f.series(x, 4); g
3 + (-5)*x + (-sin(y))*x^2 + 1*x^3
sage: g.truncate()
x^3 - x^2*sin(y) - 5*x + 3
sage: g = f.series(x==1, 4); g
(-sin(y) - 1) + (-2*sin(y) - 2)*(x - 1) + (-sin(y) + 3)*(x - 1)^2 + 1*(x - 1)^3
sage: h = g.truncate(); h
-(sin(y) - 3)*(x - 1)^2 + (x - 1)^3 - 2*(sin(y) + 1)*(x - 1) - sin(y) - 1
sage: h.expand()
x^3 - x^2*sin(y) - 5*x + 3
```

We computer another series expansion of an analytic function:

```
sage: f = sin(x)/x^2
sage: f.series(x,7)
1*x^(-1) + (-1/6)*x + 1/120*x^3 + (-1/5040)*x^5 + Order(x^7)
sage: f.series(x==1,3)
(sin(1)) + (-2*sin(1) + cos(1))*(x - 1) + (5/2*sin(1) - 2*cos(1))*(x - 1)^2 + Order((x - 1)^
sage: f.series(x==1,3).truncate().expand()
5/2*x^2*sin(1) - 2*x^2*cos(1) - 7*x*sin(1) + 5*x*cos(1) + 11/2*sin(1) - 3*cos(1)
```

Following the GiNaC tutorial, we use John Machin's amazing formula $\pi = 16\tan^{-1}(1/5) - 4\tan^{-1}(1/239)$ to compute digits of π. We expand the arc tangent around 0 and insert the fractions 1/5 and 1/239.

```
sage: x = var('x')
sage: f = atan(x).series(x, 10); f
1*x + (-1/3)*x^3 + 1/5*x^5 + (-1/7)*x^7 + 1/9*x^9 + Order(x^10)
sage: float(16*f.subs(x==1/5) - 4*f.subs(x==1/239))
3.1415926824043994
```

show()

Show this symbolic expression, i.e., typeset it nicely.

EXAMPLES:

```
sage: (x^2 + 1).show()
x^{2}  + 1
```

simplify()

Returns a simplified version of this symbolic expression.

Note: Currently, this does just sends the expression to Maxima and converts it back to Sage.

See Also:

simplify_full(), simplify_trig(), simplify_rational(), simplify_radical()

EXAMPLES:

```
sage: a = var('a'); f = x*sin(2)/(x^a); f
x*sin(2)/x^a
sage: f.simplify()
x^(-a + 1)*sin(2)
```

simplify_exp()

Simplifies this symbolic expression, which can contain logs, exponentials, and radicals, by converting it

into a form which is canonical over a large class of expressions and a given ordering of variables

DETAILS: This uses the Maxima radcan() command. From the Maxima documentation: "All functionally equivalent forms are mapped into a unique form. For a somewhat larger class of expressions, produces a regular form. Two equivalent expressions in this class do not necessarily have the same appearance, but their difference can be simplified by radcan to zero. For some expressions radcan is quite time consuming. This is the cost of exploring certain relationships among the components of the expression for simplifications based on factoring and partial fraction expansions of exponents."

ALIAS: radical_simplify, simplify_radical, simplify_log, log_simplify, exp_simplify, simplify_exp are all the same

EXAMPLES:

```
sage: var('x,y,a')
(x, y, a)

sage: f = log(x*y)
sage: f.simplify_radical()
log(x) + log(y)

sage: f = (log(x+x^2)-log(x))^a/log(1+x)^(a/2)
sage: f.simplify_radical()
log(x + 1)^(1/2*a)

sage: f = (e^x-1)/(1+e^(x/2))
sage: f.simplify_exp()
e^(1/2*x) - 1
```

simplify_full()

Applies simplify_trig, simplify_rational, and simplify_radical to self (in that order).

ALIAS: simplfy_full and full_simplify are the same.

EXAMPLES:

```
sage: a = log(8)/log(2)
sage: a.simplify_full()
3

sage: f = sin(x)^2 + cos(x)^2
sage: f.simplify_full()
1

sage: f = sin(x/(x^2 + x))
sage: f.simplify_full()
sin(1/(x + 1))
```

simplify_log()

Simplifies this symbolic expression, which can contain logs, exponentials, and radicals, by converting it into a form which is canonical over a large class of expressions and a given ordering of variables

DETAILS: This uses the Maxima radcan() command. From the Maxima documentation: "All functionally equivalent forms are mapped into a unique form. For a somewhat larger class of expressions, produces a regular form. Two equivalent expressions in this class do not necessarily have the same appearance, but their difference can be simplified by radcan to zero. For some expressions radcan is quite time consuming. This is the cost of exploring certain relationships among the components of the expression for simplifications based on factoring and partial fraction expansions of exponents."

ALIAS: radical_simplify, simplify_radical, simplify_log, log_simplify, exp_simplify, simplify_exp are all the same

EXAMPLES:

```
sage: var('x,y,a')
(x, y, a)

sage: f = log(x*y)
sage: f.simplify_radical()
log(x) + log(y)

sage: f = (log(x+x^2)-log(x))^a/log(1+x)^(a/2)
sage: f.simplify_radical()
log(x + 1)^(1/2*a)

sage: f = (e^x-1)/(1+e^(x/2))
sage: f.simplify_exp()
e^(1/2*x) - 1
```

simplify_radical()

Simplifies this symbolic expression, which can contain logs, exponentials, and radicals, by converting it into a form which is canonical over a large class of expressions and a given ordering of variables

DETAILS: This uses the Maxima radcan() command. From the Maxima documentation: "All functionally equivalent forms are mapped into a unique form. For a somewhat larger class of expressions, produces a regular form. Two equivalent expressions in this class do not necessarily have the same appearance, but their difference can be simplified by radcan to zero. For some expressions radcan is quite time consuming. This is the cost of exploring certain relationships among the components of the expression for simplifications based on factoring and partial fraction expansions of exponents."

ALIAS: radical_simplify, simplify_radical, simplify_log, log_simplify, exp_simplify, simplify_exp are all the same

EXAMPLES:

```
sage: var('x,y,a')
(x, y, a)

sage: f = log(x*y)
sage: f.simplify_radical()
log(x) + log(y)

sage: f = (log(x+x^2)-log(x))^a/log(1+x)^(a/2)
sage: f.simplify_radical()
log(x + 1)^(1/2*a)

sage: f = (e^x-1)/(1+e^(x/2))
sage: f.simplify_exp()
e^(1/2*x) - 1
```

simplify_rational()

Simplify by expanding repeatedly rational expressions.

ALIAS: rational_simplify and simplify_rational are the same

EXAMPLES:

```
sage: f = sin(x/(x^2 + x))
sage: f
sin(x/(x^2 + x))
sage: f.simplify_rational()
sin(1/(x + 1))

sage: f = ((x - 1)^(3/2) - (x + 1)*sqrt(x - 1))/sqrt((x - 1)*(x + 1)); f
((x - 1)^(3/2) - sqrt(x - 1)*(x + 1))/sqrt((x - 1)*(x + 1))
```

```
sage: f.simplify_rational()
-2*sqrt(x - 1)/sqrt(x^2 - 1)
```

simplify_trig()

First expands using trig_expand, then employs the identities $\sin(x)^2 + \cos(x)^2 = 1$ and $\cosh(x)^2 - \sin(x)^2 = 1$ to simplify expressions containing tan, sec, etc., to sin, cos, sinh, cosh.

ALIAS: trig_simplify and simplify_trig are the same

EXAMPLES:

```
sage: f = sin(x)^2 + cos(x)^2; f
sin(x)^2 + cos(x)^2
sage: f.simplify()
sin(x)^2 + cos(x)^2
sage: f.simplify_trig()
1
```

sin()

EXAMPLES:

```
sage: var('x, y')
(x, y)
sage: sin(x^2 + y^2)
sin(x^2 + y^2)
sage: sin(sage.symbolic.constants.pi)
0
sage: sin(SR(1))
sin(1)
sage: sin(SR(RealField(150)(1)))
0.84147098480789650665250232163029899962256306
```

sinh()

Return sinh of self.

We have $sinh(x) = (e^{x} - e^{-x})/2$.

EXAMPLES:

```
sage: x.sinh()
sinh(x)
sage: SR(1).sinh()
sinh(1)
sage: SR(0).sinh()
0
sage: SR(1.0).sinh()
sinh(1.00000000000000)
```

Use .n() to get a numerical approximation:

```
sage: SR(1.0).sinh().n()
1.17520119364380
sage: maxima('sinh(1.0)')
1.175201193643801

sinh(1.0000000000000000000000000)
sage: SR(1).sinh().n(90)
1.17520119364380145688238193
sage: SR(RIF(1)).sinh()
sinh(1)
sage: SR(RIF(1)).sinh().n()
1.175201193643802?
```

solve()

Analytically solve the equation `self == 0` for the variable x.

> **Warning:** This is not a numerical solver - use `find_root` to solve for self == 0 numerically on an interval.

INPUT:

- `x` - variable to solve for
- `multiplicities` - bool (default: False); if True, return corresponding multiplicities.
- **`explicit_solutions` - bool; if True, require that all** solutions returned be explicit (rather than implicit)

EXAMPLES:

```
sage: z = var('z')
sage: (z^5 - 1).solve(z)
[z == e^(2/5*I*pi), z == e^(4/5*I*pi), z == e^(-4/5*I*pi), z == e^(-2/5*I*pi), z == 1]

sage: var('Q')
Q
sage: solve(Q*sqrt(Q^2 + 2) - 1,Q)
[Q == 1/sqrt(-sqrt(2) + 1), Q == 1/sqrt(sqrt(2) + 1)]
```

sqrt()

EXAMPLES: sage: var('x, y') (x, y) sage: SR(2).sqrt() sqrt(2) sage: (x^2+y^2).sqrt() sqrt(x^2 + y^2) sage: (x^2).sqrt() sqrt(x^2)

step()

Return the value of the Heaviside step function, which is 0 for negative x, 1/2 for 0, and 1 for positive x.

EXAMPLES:

```
sage: x = var('x')
sage: SR(1.5).step()
1
sage: SR(0).step()
1/2
sage: SR(-1/2).step()
0
sage: SR(float(-1)).step()
0
```

subs()

EXAMPLES:

```
sage: var('x,y,z,a,b,c,d,e,f')
(x, y, z, a, b, c, d, e, f)
sage: w0 = SR.wild(0); w1 = SR.wild(1)
sage: t = a^2 + b^2 + (x+y)^3

# substitute with keyword arguments (works only with symbols)
sage: t.subs(a=c)
(x + y)^3 + b^2 + c^2

# substitute with a dictionary argument
sage: t.subs({a^2: c})
(x + y)^3 + b^2 + c

sage: t.subs({w0^2: w0^3})
(x + y)^3 + a^3 + b^3
```

```
# substitute with a relational expression
sage: t.subs(w0^2 == w0^3)
(x + y)^3 + a^3 + b^3

sage: t.subs(w0==w0^2)
(x^2 + y^2)^18 + a^16 + b^16

# more than one keyword argument is accepted
sage: t.subs(a=b, b=c)
(x + y)^3 + b^2 + c^2

# using keyword arguments with a dictionary is allowed
sage: t.subs({a:b}, b=c)
(x + y)^3 + b^2 + c^2

# in this case keyword arguments override the dictionary
sage: t.subs({a:b}, a=c)
(x + y)^3 + b^2 + c^2

sage: t.subs({a:b, b:c})
(x + y)^3 + b^2 + c^2
```

TESTS: # no arguments return the same expression sage: t.subs() (x + y)^3 + a^2 + b^2
similarly for an empty dictionary argument sage: t.subs({}) (x + y)^3 + a^2 + b^2
non keyword or dictionary argument returns error sage: t.subs(5) Traceback (most recent call last): ... TypeError: subs takes either a set of keyword arguments, a dictionary, or a symbolic relational expression
substitutions with infinity sage: (x/y).subs(y=oo) 0 sage: (x/y).subs(x=oo) +Infinity sage: (x*y).subs(x=oo) +Infinity sage: (x^y).subs(x=oo) Traceback (most recent call last): ... RuntimeError: power::eval(): pow(Infinity, x) for non numeric x is not defined. sage: (x^y).subs(y=oo) Traceback (most recent call last): ... RuntimeError: power::eval(): pow(x, Infinity) for non numeric x is not defined. sage: (x+y).subs(x=oo) +Infinity sage: (x-y).subs(y=oo) -Infinity sage: gamma(x).subs(x=-1) Infinity sage: 1/gamma(x).subs(x=-1) 0

subs_expr()

Given a dictionary of key:value pairs, substitute all occurrences of key for value in self. The substitutions can also be given as a number of symbolic equalities key == value; see the examples.

> **Warning:** This is a formal pattern substitution, which may or may not have any mathematical meaning. The exact rules used at present in Sage are determined by Maxima's subst command. Sometimes patterns are not replaced even though one would think they should be - see examples below.

EXAMPLES:

```
sage: f = x^2 + 1
sage: f.subs_expr(x^2 == x)
x + 1

sage: var('x,y,z'); f = x^3 + y^2 + z
(x, y, z)
sage: f.subs_expr(x^3 == y^2, z == 1)
2*y^2 + 1
```

Or the same thing giving the substitutions as a dictionary:

```
sage: f.subs_expr({x^3:y^2, z:1})
2*y^2 + 1
```

```
sage: f = x^2 + x^4
sage: f.subs_expr(x^2 == x)
x^4 + x
sage: f = cos(x^2) + sin(x^2)
sage: f.subs_expr(x^2 == x)
sin(x) + cos(x)

sage: f(x,y,t) = cos(x) + sin(y) + x^2 + y^2 + t
sage: f.subs_expr(y^2 == t)
(x, y, t) |--> x^2 + 2*t + sin(y) + cos(x)
```

The following seems really weird, but it *is* what Maple does:

```
sage: f.subs_expr(x^2 + y^2 == t)
(x, y, t) |--> x^2 + y^2 + t + sin(y) + cos(x)
sage: maple.eval('subs(x^2 + y^2 = t, cos(x) + sin(y) + x^2 + y^2 + t)')          # optional
'cos(x)+sin(y)+x^2+y^2+t'
sage: maxima.quit()
sage: maxima.eval('cos(x) + sin(y) + x^2 + y^2 + t, x^2 + y^2 = t')
'sin(y)+y^2+cos(x)+x^2+t'
```

Actually Mathematica does something that makes more sense:

```
sage: mathematica.eval('Cos[x] + Sin[y] + x^2 + y^2 + t /. x^2 + y^2 -> t')       # optional
2 t + Cos[x] + Sin[y]
```

substitute()

EXAMPLES:

```
sage: var('x,y,z,a,b,c,d,e,f')
(x, y, z, a, b, c, d, e, f)
sage: w0 = SR.wild(0); w1 = SR.wild(1)
sage: t = a^2 + b^2 + (x+y)^3

# substitute with keyword arguments (works only with symbols)
sage: t.subs(a=c)
(x + y)^3 + b^2 + c^2

# substitute with a dictionary argument
sage: t.subs({a^2: c})
(x + y)^3 + b^2 + c

sage: t.subs({w0^2: w0^3})
(x + y)^3 + a^3 + b^3

# substitute with a relational expression
sage: t.subs(w0^2 == w0^3)
(x + y)^3 + a^3 + b^3

sage: t.subs(w0==w0^2)
(x^2 + y^2)^18 + a^16 + b^16

# more than one keyword argument is accepted
sage: t.subs(a=b, b=c)
(x + y)^3 + b^2 + c^2

# using keyword arguments with a dictionary is allowed
sage: t.subs({a:b}, b=c)
(x + y)^3 + b^2 + c^2
```

```
# in this case keyword arguments override the dictionary
sage: t.subs({a:b}, a=c)
(x + y)^3 + b^2 + c^2

sage: t.subs({a:b, b:c})
(x + y)^3 + b^2 + c^2
```

TESTS: # no arguments return the same expression sage: t.subs() (x + y)^3 + a^2 + b^2
similarly for an empty dictionary argument sage: t.subs({}) (x + y)^3 + a^2 + b^2
non keyword or dictionary argument returns error sage: t.subs(5) Traceback (most recent call last): ... TypeError: subs takes either a set of keyword arguments, a dictionary, or a symbolic relational expression
substitutions with infinity sage: (x/y).subs(y=oo) 0 sage: (x/y).subs(x=oo) +Infinity sage: (x*y).subs(x=oo) +Infinity sage: (x^y).subs(x=oo) Traceback (most recent call last): ... RuntimeError: power::eval(): pow(Infinity, x) for non numeric x is not defined. sage: (x^y).subs(y=oo) Traceback (most recent call last): ... RuntimeError: power::eval(): pow(x, Infinity) for non numeric x is not defined. sage: (x+y).subs(x=oo) +Infinity sage: (x-y).subs(y=oo) -Infinity sage: gamma(x).subs(x=-1) Infinity sage: 1/gamma(x).subs(x=-1) 0

substitute_expression()

Given a dictionary of key:value pairs, substitute all occurrences of key for value in self. The substitutions can also be given as a number of symbolic equalities key == value; see the examples.

> **Warning:** This is a formal pattern substitution, which may or may not have any mathematical meaning. The exact rules used at present in Sage are determined by Maxima's subst command. Sometimes patterns are not replaced even though one would think they should be - see examples below.

EXAMPLES:

```
sage: f = x^2 + 1
sage: f.subs_expr(x^2 == x)
x + 1

sage: var('x,y,z'); f = x^3 + y^2 + z
(x, y, z)
sage: f.subs_expr(x^3 == y^2, z == 1)
2*y^2 + 1
```

Or the same thing giving the substitutions as a dictionary:

```
sage: f.subs_expr({x^3:y^2, z:1})
2*y^2 + 1

sage: f = x^2 + x^4
sage: f.subs_expr(x^2 == x)
x^4 + x
sage: f = cos(x^2) + sin(x^2)
sage: f.subs_expr(x^2 == x)
sin(x) + cos(x)

sage: f(x,y,t) = cos(x) + sin(y) + x^2 + y^2 + t
sage: f.subs_expr(y^2 == t)
(x, y, t) |--> x^2 + 2*t + sin(y) + cos(x)
```

The following seems really weird, but it *is* what Maple does:

```
sage: f.subs_expr(x^2 + y^2 == t)
(x, y, t) |--> x^2 + y^2 + t + sin(y) + cos(x)
sage: maple.eval('subs(x^2 + y^2 = t, cos(x) + sin(y) + x^2 + y^2 + t)')          # optional
```

```
'cos(x)+sin(y)+x^2+y^2+t'
sage: maxima.quit()
sage: maxima.eval('cos(x) + sin(y) + x^2 + y^2 + t, x^2 + y^2 = t')
'sin(y)+y^2+cos(x)+x^2+t'
```

Actually Mathematica does something that makes more sense:

```
sage: mathematica.eval('Cos[x] + Sin[y] + x^2 + y^2 + t /. x^2 + y^2 -> t')       # optional
2 t + Cos[x] + Sin[y]
```

substitute_function()

Returns this symbolic expressions all occurrences of the function *original* replaced with the function *new*.

EXAMPLES:

```
sage: x,y = var('x,y')
sage: clear_functions()
sage: foo = function('foo'); bar = function('bar')
sage: f = foo(x) + 1/foo(pi*y)
sage: f.substitute_function(foo, bar)
1/bar(pi*y) + bar(x)
```

subtract_from_both_sides()

Returns a relation obtained by subtracting *x* from both sides of this relation.

EXAMPLES:

```
sage: eqn = x*sin(x)*sqrt(3) + sqrt(2) > cos(sin(x))
sage: eqn.subtract_from_both_sides(sqrt(2))
sqrt(3)*x*sin(x) > -sqrt(2) + cos(sin(x))
sage: eqn.subtract_from_both_sides(cos(sin(x)))
sqrt(3)*x*sin(x) + sqrt(2) - cos(sin(x)) > 0
```

tan()

EXAMPLES:

```
sage: var('x, y')
(x, y)
sage: tan(x^2 + y^2)
tan(x^2 + y^2)
sage: tan(sage.symbolic.constants.pi/2)
...
ValueError: simple pole at 1/2*pi
sage: tan(SR(1))
tan(1)
sage: tan(SR(RealField(150)(1)))
1.5574077246549022305069748074583601730872508
```

tanh()

Return tanh of self.

We have $ anh(x) = sinh(x) / cosh(x)$.

EXAMPLES:

```
sage: x.tanh()
tanh(x)
sage: SR(1).tanh()
tanh(1)
sage: SR(0).tanh()
0
sage: SR(1.0).tanh()
tanh(1.00000000000000)
```

Use .n() to get a numerical approximation:

```
sage: SR(1.0).tanh().n()
0.761594155955765
sage: maxima('tanh(1.0)')
.7615941559557649
sage: plot(lambda x: SR(x).tanh(), -1, 1)
```

taylor()

Expands this symbolic expression in a truncated Taylor or Laurent series in the variable v around the point a, containing terms through $(x-a)^n$.

INPUT:

- v - variable
- a - number
- n - integer

EXAMPLES:

```
sage: var('a, x, z')
(a, x, z)
sage: taylor(a*log(z), z, 2, 3)
1/24*(z - 2)^3*a - 1/8*(z - 2)^2*a + 1/2*(z - 2)*a + a*log(2)
sage: taylor(sqrt (sin(x) + a*x + 1), x, 0, 3)
1/48*(3*a^3 + 9*a^2 + 9*a - 1)*x^3 - 1/8*(a^2 + 2*a + 1)*x^2 + 1/2*(a + 1)*x + 1
sage: taylor (sqrt (x + 1), x, 0, 5)
7/256*x^5 - 5/128*x^4 + 1/16*x^3 - 1/8*x^2 + 1/2*x + 1
sage: taylor (1/log (x + 1), x, 0, 3)
-19/720*x^3 + 1/24*x^2 - 1/12*x + 1/x + 1/2
sage: taylor (cos(x) - sec(x), x, 0, 5)
-1/6*x^4 - x^2
sage: taylor ((cos(x) - sec(x))^3, x, 0, 9)
-1/2*x^8 - x^6
sage: taylor (1/(cos(x) - sec(x))^3, x, 0, 5)
-15377/7983360*x^4 - 6767/604800*x^2 + 11/120/x^2 + 1/2/x^4 - 1/x^6 - 347/15120
```

test_relation()

Test this relation at several random values, attempting to find a contradiction. If this relation has no variables, it will also test this relation after casting into the domain.

Because the interval fields never return false positives, we can be assured that if True or False is returned (and proof is False) then the answer is correct.

INPUT:

```
ntests -- (default 20) the number of iterations to run
domain -- (optional) the domain from which to draw the random values
          defaults to CIF for equality testing and RIF for
          order testing
proof --  (default True) if False and the domain is an interval field,
          regard overlapping (potentially equal) intervals as equal,
          and return True if all tests succeeded.
```

OUTPUT:

```
True - this relation holds in the domain and has no variables
False - a contradiction was found
NotImplemented - no contradiction found
```

EXAMPLES:

```
sage: (3 < pi).test_relation()
True
```

```
sage: (0 >= pi).test_relation()
False
sage: (exp(pi) - pi).n()
19.9990999791895
sage: (exp(pi) - pi == 20).test_relation()
False
sage: (sin(x)^2 + cos(x)^2 == 1).test_relation()
NotImplemented
sage: (sin(x)^2 + cos(x)^2 == 1).test_relation(proof=False)
True
sage: (x == 1).test_relation()
False
sage: var('x,y')
(x, y)
sage: (x < y).test_relation()
False
```

TESTS:

```
sage: all_relations = [op for name, op in sorted(operator.__dict__.items()) if len(name) ==
sage: all_relations
[<built-in function eq>, <built-in function ge>, <built-in function gt>, <built-in function
sage: [op(3, pi).test_relation() for op in all_relations]
[False, False, False, True, True, True]
sage: [op(pi, pi).test_relation() for op in all_relations]
[True, True, False, True, False, False]

sage: s = 'some_very_long_variable_name_which_will_definitely_collide_if_we_use_a_reasonable
sage: t1, t2 = var(','.join([s+'1',s+'2']))
sage: (t1 == t2).test_relation()
False
```

trailing_coeff()

Return the trailing coefficient of s in self, i.e., the coefficient of the smallest power of s in self.

EXAMPLES:

```
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + x/y + 2*sin(x*y)/x + 100
sage: f.trailing_coefficient(x)
2*sin(x*y)
sage: f.trailing_coefficient(y)
x
sage: f.trailing_coefficient(sin(x*y))
a*x + x*y + x/y + 100
```

trailing_coefficient()

Return the trailing coefficient of s in self, i.e., the coefficient of the smallest power of s in self.

EXAMPLES:

```
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + x/y + 2*sin(x*y)/x + 100
sage: f.trailing_coefficient(x)
2*sin(x*y)
sage: f.trailing_coefficient(y)
x
```

```
sage: f.trailing_coefficient(sin(x*y))
a*x + x*y + x/y + 100
```

trig_expand()

Expands trigonometric and hyperbolic functions of sums of angles and of multiple angles occurring in self. For best results, self should already be expanded.

INPUT:

- full - (default: False) To enhance user control of simplification, this function expands only one level at a time by default, expanding sums of angles or multiple angles. To obtain full expansion into sines and cosines immediately, set the optional parameter full to True.
- half_angles - (default: False) If True, causes half-angles to be simplified away.
- plus - (default: True) Controls the sum rule; expansion of sums (e.g. 'sin(x + y)') will take place only if plus is True.
- times - (default: True) Controls the product rule, expansion of products (e.g. sin(2*x)) will take place only if times is True.

OUTPUT: a symbolic expression

EXAMPLES:

```
sage: sin(5*x).expand_trig()
sin(x)^5 - 10*sin(x)^3*cos(x)^2 + 5*sin(x)*cos(x)^4
sage: cos(2*x + var('y')).expand_trig()
-sin(2*x)*sin(y) + cos(2*x)*cos(y)
```

We illustrate various options to this function:

```
sage: f = sin(sin(3*cos(2*x))*x)
sage: f.expand_trig()
sin(-(sin(cos(2*x))^3 - 3*sin(cos(2*x))*cos(cos(2*x))^2)*x)
sage: f.expand_trig(full=True)
sin(((sin(sin(x)^2)*cos(cos(x)^2) - sin(cos(x)^2)*cos(sin(x)^2))^3 - 3*(sin(sin(x)^2)*cos(co
sage: sin(2*x).expand_trig(times=False)
sin(2*x)
sage: sin(2*x).expand_trig(times=True)
2*sin(x)*cos(x)
sage: sin(2 + x).expand_trig(plus=False)
sin(x + 2)
sage: sin(2 + x).expand_trig(plus=True)
sin(2)*cos(x) + sin(x)*cos(2)
sage: sin(x/2).expand_trig(half_angles=False)
sin(1/2*x)
sage: sin(x/2).expand_trig(half_angles=True)
1/2*sqrt(-cos(x) + 1)*sqrt(2)
```

ALIASES:

trig_expand() and expand_trig() are the same

trig_simplify()

First expands using trig_expand, then employs the identities $\sin(x)^2 + \cos(x)^2 = 1$ and $\cosh(x)^2 - \sin(x)^2 = 1$ to simplify expressions containing tan, sec, etc., to sin, cos, sinh, cosh.

ALIAS: trig_simplify and simplify_trig are the same

EXAMPLES:

```
sage: f = sin(x)^2 + cos(x)^2; f
sin(x)^2 + cos(x)^2
sage: f.simplify()
sin(x)^2 + cos(x)^2
```

```
sage: f.simplify_trig()
1
```

truncate()

Given a power series or expression, return the corresponding expression without the big oh.

INPUT:

- a series as output by the series command

OUTPUT:

- expression

EXAMPLES:

```
sage: f = sin(x)/x^2
sage: f.truncate()
sin(x)/x^2
sage: f.series(x,7)
1*x^(-1) + (-1/6)*x + 1/120*x^3 + (-1/5040)*x^5 + Order(x^7)
sage: f.series(x,7).truncate()
-1/5040*x^5 + 1/120*x^3 - 1/6*x + 1/x
sage: f.series(x==1,3).truncate().expand()
5/2*x^2*sin(1) - 2*x^2*cos(1) - 7*x*sin(1) + 5*x*cos(1) + 11/2*sin(1) - 3*cos(1)
```

variables()

Return sorted list of variables that occur in this expression.

EXAMPLES:

```
sage: (x,y,z) = var('x,y,z')
sage: (x+y).variables()
(x, y)
sage: (2*x).variables()
(x,)
sage: (x^y).variables()
(x, y)
sage: sin(x+y^z).variables()
(x, y, z)
```

zeta()

EXAMPLES:

```
sage: x, y = var('x, y')
sage: (x/y).zeta()
zeta(x/y)
sage: SR(2).zeta()
1/6*pi^2
sage: SR(3).zeta()
zeta(3)
sage: SR(CDF(0,1)).zeta()
zeta(1.0*I)
sage: SR(CDF(0,1)).zeta().n()
0.00330022368532 - 0.418155449141*I
sage: CDF(0,1).zeta()
0.00330022368532 - 0.418155449141*I
sage: plot(lambda x: SR(x).zeta(), -10,10).show(ymin=-3,ymax=3)
```

TESTS:

```
sage: t = SR(1).zeta(); t
zeta(1)
```

```
sage: t.n()
+infinity
```

class **ExpressionIterator**()

next()
x.next() -> the next value, or raise StopIteration

is_Expression()
Retruns True if *x* is a symbolic Expression.

EXAMPLES:

```
sage: from sage.symbolic.expression import is_Expression
sage: is_Expression(x)
True
sage: is_Expression(2)
False
sage: is_Expression(SR(2))
True
```

is_SymbolicEquation()
Returns True if *x* is a symbolic equation.

EXAMPLES:

The following two examples are symbolic equations:

```
sage: from sage.symbolic.expression import is_SymbolicEquation
sage: is_SymbolicEquation(sin(x) == x)
True
sage: is_SymbolicEquation(sin(x) < x)
True
sage: is_SymbolicEquation(x)
False
```

This is not, since `2==3` evaluates to the boolean `False`:

```
sage: is_SymbolicEquation(2 == 3)
False
```

However here since both 2 and 3 are coerced to be symbolic, we obtain a symbolic equation:

```
sage: is_SymbolicEquation(SR(2) == SR(3))
True
```

3.3 Symbolic Equations and Inequalities.

Sage can solve symbolic equations and express inequalities. For example, we derive the quadratic formula as follows:

```
sage: a,b,c = var('a,b,c')
sage: qe = (a*x^2 + b*x + c == 0)
sage: qe
a*x^2 + b*x + c == 0
sage: print solve(qe, x)
[
x == -1/2*(b + sqrt(-4*a*c + b^2))/a,
```

```
x == -1/2*(b - sqrt(-4*a*c + b^2))/a
]
```

3.3.1 The operator, left hand side, and right hand side

Operators:

```
sage: eqn = x^3 + 2/3 >= x - pi
sage: eqn.operator()
<built-in function ge>
sage: (x^3 + 2/3 < x - pi).operator()
<built-in function lt>
sage: (x^3 + 2/3 == x - pi).operator()
<built-in function eq>
```

Left hand side:

```
sage: eqn = x^3 + 2/3 >= x - pi
sage: eqn.lhs()
x^3 + 2/3
sage: eqn.left()
x^3 + 2/3
sage: eqn.left_hand_side()
x^3 + 2/3
```

Right hand side:

```
sage: (x + sqrt(2) >= sqrt(3) + 5/2).right()
sqrt(3) + 5/2
sage: (x + sqrt(2) >= sqrt(3) + 5/2).rhs()
sqrt(3) + 5/2
sage: (x + sqrt(2) >= sqrt(3) + 5/2).right_hand_side()
sqrt(3) + 5/2
```

3.3.2 Arithmetic

Add two symbolic equations:

```
sage: var('a,b')
(a, b)
sage: m = 144 == -10 * a + b
sage: n = 136 == 10 * a + b
sage: m + n
280 == 2*b
sage: int(-144) + m
0 == -10*a + b - 144
```

Subtract two symbolic equations:

```
sage: var('a,b')
(a, b)
sage: m = 144 == 20 * a + b
sage: n = 136 == 10 * a + b
```

```
sage: m - n
8 == 10*a
sage: int(144) - m
0 == -20*a - b + 144
```

Multiply two symbolic equations:

```
sage: x = var('x')
sage: m = x == 5*x + 1
sage: n = sin(x) == sin(x+2*pi)
sage: m * n
x*sin(x) == (5*x + 1)*sin(2*pi + x)
sage: m = 2*x == 3*x^2 - 5
sage: int(-1) * m
-2*x == -3*x^2 + 5
```

Divide two symbolic equations:

```
sage: x = var('x')
sage: m = x == 5*x + 1
sage: n = sin(x) == sin(x+2*pi)
sage: m/n
x/sin(x) == (5*x + 1)/sin(2*pi + x)
sage: m = x != 5*x + 1
sage: n = sin(x) != sin(x+2*pi)
sage: m/n
x/sin(x) != (5*x + 1)/sin(2*pi + x)
```

3.3.3 Substitution

Substitution into relations:

```
sage: x, a = var('x, a')
sage: eq = (x^3 + a == sin(x/a)); eq
x^3 + a == sin(x/a)
sage: eq.substitute(x=5*x)
125*x^3 + a == sin(5*x/a)
sage: eq.substitute(a=1)
x^3 + 1 == sin(x)
sage: eq.substitute(a=x)
x^3 + x == sin(1)
sage: eq.substitute(a=x, x=1)
x + 1 == sin(1/x)
sage: eq.substitute({a:x, x:1})
x + 1 == sin(1/x)
```

3.3.4 Solving

We can solve equations:

```
sage: x = var('x')
sage: S = solve(x^3 - 1 == 0, x)
sage: S
```

```
[x == 1/2*I*sqrt(3) - 1/2, x == -1/2*I*sqrt(3) - 1/2, x == 1]
sage: S[0]
x == 1/2*I*sqrt(3) - 1/2
sage: S[0].right()
1/2*I*sqrt(3) - 1/2
sage: S = solve(x^3 - 1 == 0, x, solution_dict=True)
sage: S
[{x: 1/2*I*sqrt(3) - 1/2}, {x: -1/2*I*sqrt(3) - 1/2}, {x: 1}]
sage: z = 5
sage: solve(z^2 == sqrt(3),z)
...
TypeError: 5 is not a valid variable.
```

We illustrate finding multiplicities of solutions:

```
sage: f = (x-1)^5*(x^2+1)
sage: solve(f == 0, x)
[x == -I, x == I, x == 1]
sage: solve(f == 0, x, multiplicities=True)
([x == -I, x == I, x == 1], [1, 1, 5])
```

We can numerically find roots of equations:

```
sage: (x == sin(x)).find_root(-2,2)
0.0
sage: (x^5 + 3*x + 2 == 0).find_root(-2,2,x)
-0.63283452024215225
sage: (cos(x) == sin(x)).find_root(10,20)
19.634954084936208
```

We illustrate some valid error conditions:

```
sage: (cos(x) != sin(x)).find_root(10,20)
...
ValueError: Symbolic equation must be an equality.
sage: (SR(3)==SR(2)).find_root(-1,1)
...
RuntimeError: no zero in the interval, since constant expression is not 0.
```

There must be at most one variable:

```
sage: x, y = var('x,y')
sage: (x == y).find_root(-2,2)
...
NotImplementedError: root finding currently only implemented in 1 dimension.
```

3.3.5 Assumptions

Forgetting assumptions:

```
sage: var('x,y')
(x, y)
sage: forget() #Clear assumptions
sage: assume(x>0, y < 2)
```

```
sage: assumptions()
[x > 0, y < 2]
sage: (y < 2).forget()
sage: assumptions()
[x > 0]
```

3.3.6 Miscellaneous

Conversion to Maxima:

```
sage: x = var('x')
sage: eq = (x^(3/5) >= pi^2 + e^i)
sage: eq._maxima_init_()
'(x)^(3/5) >= ((%pi)^(2))+(exp(0+%i*1))'
sage: e1 = x^3 + x == sin(2*x)
sage: z = e1._maxima_()
sage: z.parent() is sage.calculus.calculus.maxima
True
sage: z = e1._maxima_(maxima)
sage: z.parent() is maxima
True
sage: z = maxima(e1)
sage: z.parent() is maxima
True
```

Conversion to Maple:

```
sage: x = var('x')
sage: eq = (x == 2)
sage: eq._maple_init_()
'x = 2'
```

Comparison:

```
sage: x = var('x')
sage: (x>0) == (x>0)
True
sage: (x>0) == (x>1)
False
sage: (x>0) != (x>1)
True
```

Variables appearing in the relation:

```
sage: var('x,y,z,w')
(x, y, z, w)
sage: f =  (x+y+w) == (x^2 - y^2 - z^3);   f
w + x + y == x^2 - y^2 - z^3
sage: f.variables()
(w, x, y, z)
```

LaTeX output:

```
sage: latex(x^(3/5) >= pi)
x^{\frac{3}{5}}  \geq  \pi
```

3.3.7 More Examples

```
sage: x,y,a = var('x,y,a')
sage: f = x^2 + y^2 == 1
sage: f.solve(x)
[x == -sqrt(-y^2 + 1), x == sqrt(-y^2 + 1)]
```

```
sage: f = x^5 + a
sage: solve(f==0,x)
[x == (-a)^(1/5)*e^(2/5*I*pi), x == (-a)^(1/5)*e^(4/5*I*pi), x == (-a)^(1/5)*e^(-4/5*I*pi), x == (-a
```

You can also do arithmetic with inequalities, as illustrated below:

```
sage: var('x y')
(x, y)
sage: f = x + 3 == y - 2
sage: f
x + 3 == y - 2
sage: g = f - 3; g
x == y - 5
sage: h =  x^3 + sqrt(2) == x*y*sin(x)
sage: h
sqrt(2) + x^3 == x*y*sin(x)
sage: h - sqrt(2)
x^3 == x*y*sin(x) - sqrt(2)
sage: h + f
x + sqrt(2) + x^3 + 3 == x*y*sin(x) + y - 2
sage: f = x + 3 < y - 2
sage: g = 2 < x+10
sage: f - g
x + 1 < -x + y - 12
sage: f + g
x + 5 < x + y + 8
sage: f*(-1)
-x - 3 < -y + 2
```

TESTS:

We test serializing symbolic equations:

```
sage: eqn = x^3 + 2/3 >= x
sage: loads(dumps(eqn))
x^3 + 2/3 >= x
sage: loads(dumps(eqn)) == eqn
True
```

AUTHORS:

- Bobby Moretti: initial version (based on a trick that Robert Bradshaw suggested).
- William Stein: second version
- William Stein (2007-07-16): added arithmetic with symbolic equations

solve (*f, *args, **kwds*)
Algebraically solve an equation of system of equations for given variables.

INPUT:

- `f` - equation or system of equations (given by a list or tuple)
- `*args` - variables to solve for.
- `solution_dict = True` - return a list of dictionaries containing the solutions.

EXAMPLES:

```
sage: x, y = var('x, y')
sage: solve([x+y==6, x-y==4], x, y)
[[x == 5, y == 1]]
sage: solve([x^2+y^2 == 1, y^2 == x^3 + x + 1], x, y)
[[x == -1/2*I*sqrt(3) - 1/2, y == -1/2*sqrt(-I*sqrt(3) + 3)*sqrt(2)],
 [x == -1/2*I*sqrt(3) - 1/2, y == 1/2*sqrt(-I*sqrt(3) + 3)*sqrt(2)],
 [x == 1/2*I*sqrt(3) - 1/2, y == -1/2*sqrt(I*sqrt(3) + 3)*sqrt(2)],
 [x == 1/2*I*sqrt(3) - 1/2, y == 1/2*sqrt(I*sqrt(3) + 3)*sqrt(2)],
 [x == 0, y == -1],
 [x == 0, y == 1]]
sage: solutions=solve([x^2+y^2 == 1, y^2 == x^3 + x + 1], x, y, solution_dict=True)
sage: for solution in solutions: print solution[x].n(digits=3), ",", solution[y].n(digits=3)
-0.500 - 0.866*I , -1.27 + 0.341*I
-0.500 - 0.866*I , 1.27 - 0.341*I
-0.500 + 0.866*I , -1.27 - 0.341*I
-0.500 + 0.866*I , 1.27 + 0.341*I
0.000 , -1.00
0.000 , 1.00
sage: z = 5
sage: solve([8*z + y == 3, -z +7*y == 0],y,z)
...
TypeError: 5 is not a valid variable.
```

If `True` appears in the list of equations it is ignored, and if `False` appears in the list then no solutions are returned. E.g., note that the first `3==3` evaluates to `True`, not to a symbolic equation.

```
sage: solve([3==3, 1.00000000000000*x^3 == 0], x)
[x == 0]
sage: solve([1.00000000000000*x^3 == 0], x)
[x == 0]
```

Here, the first equation evaluates to `False`, so there are no solutions:

```
sage: solve([1==3, 1.00000000000000*x^3 == 0], x)
[]

sage: var('s,j,b,m,g')
(s, j, b, m, g)
sage: sys = [ m*(1-s) - b*s*j, b*s*j-g*j ];
sage: solve(sys,s,j)
[[s == 1, j == 0], [s == g/b, j == (b - g)*m/(b*g)]]
sage: solve(sys,(s,j))
[[s == 1, j == 0], [s == g/b, j == (b - g)*m/(b*g)]]
sage: solve(sys,[s,j])
[[s == 1, j == 0], [s == g/b, j == (b - g)*m/(b*g)]]
```

solve_mod(*eqns, modulus, solution_dict=False*)

Return all solutions to an equation or list of equations modulo the given integer modulus. Each equation must involve only polynomials in 1 or many variables.

By default the solutions are returned as n-tuples, where n is the number of variables appearing anywhere in the given equations. The variables are in alphabetical order.

INPUT:

- `eqns` - equation or list of equations
- `modulus` - an integer
- `solution_dict` - (default: False) if True, return a list of dictionaries containing the solutions.

EXAMPLES:

```
sage: var('x,y')
(x, y)
sage: solve_mod([x^2 + 2 == x, x^2 + y == y^2], 14)
[(4, 2), (4, 6), (4, 9), (4, 13)]
sage: solve_mod([x^2 == 1, 4*x  == 11], 15)
[(14,)]
```

Fermat's equation modulo 3 with exponent 5:

```
sage: var('x,y,z')
(x, y, z)
sage: solve_mod([x^5 + y^5 == z^5], 3)
[(0, 0, 0), (0, 1, 1), (0, 2, 2), (1, 0, 1), (1, 1, 2), (1, 2, 0), (2, 0, 2), (2, 1, 0), (2, 2,
```

We can solve with respect to a bigger modulus if it consists only of small prime factors:

```
sage: [d] = solve_mod([5*x + y == 3, 2*x - 3*y == 9], 3*5*7*11*19*23*29, solution_dict = True)
sage: d[x]
12915279
sage: d[y]
8610183
```

We solve an simple equation modulo 2:

```
sage: x,y = var('x,y')
sage: solve_mod([x == y], 2)
[(0, 0), (1, 1)]
```

Warning: The current implementation splits the modulus into prime powers, then naively enumerates all possible solutions and finally combines the solution using the Chinese Remainder Theorem. The interface is good, but the algorithm is horrible if the modulus has some larger prime factors! Sage {does} have the ability to do something much faster in certain cases at least by using Groebner basis, linear algebra techniques, etc. But for a lot of toy problems this function as is might be useful. At least it establishes an interface.

solve_mod_enumerate(*eqns, modulus*)

Return all solutions to an equation or list of equations modulo the given integer modulus. Each equation must involve only polynomials in 1 or many variables.

The solutions are returned as n-tuples, where n is the number of variables appearing anywhere in the given equations. The variables are in alphabetical order.

INPUT:

- `eqns` - equation or list of equations
- `modulus` - an integer

EXAMPLES:

```
sage: var('x,y')
(x, y)
sage: solve_mod([x^2 + 2 == x, x^2 + y == y^2], 14)
[(4, 2), (4, 6), (4, 9), (4, 13)]
sage: solve_mod([x^2 == 1, 4*x  == 11], 15)
[(14,)]
```

Fermat's equation modulo 3 with exponent 5:

```
sage: var('x,y,z')
(x, y, z)
sage: solve_mod([x^5 + y^5 == z^5], 3)
[(0, 0, 0), (0, 1, 1), (0, 2, 2), (1, 0, 1), (1, 1, 2), (1, 2, 0), (2, 0, 2), (2, 1, 0), (2, 2,
```

We solve an simple equation modulo 2:

```
sage: x,y = var('x,y')
sage: solve_mod([x == y], 2)
[(0, 0), (1, 1)]
```

Warning: Currently this naively enumerates all possible solutions. The interface is good, but the algorithm is horrible if the modulus is at all large! Sage *does* have the ability to do something much faster in certain cases at least by using the Chinese Remainder Theorem, Groebner basis, linear algebra techniques, etc. But for a lot of toy problems this function as is might be useful. At the very least, it establishes an interface.

string_to_list_of_solutions(*s*)

Used internally by the symbolic solve command to convert the output of Maxima's solve command to a list of solutions in Sage's symbolic package.

EXAMPLES:

We derive the (monic) quadratic formula:

```
sage: var('x,a,b')
(x, a, b)
sage: solve(x^2 + a*x + b == 0, x)
[x == -1/2*a - 1/2*sqrt(a^2 - 4*b), x == -1/2*a + 1/2*sqrt(a^2 - 4*b)]
```

Behind the scenes when the above is evaluated the function `string_to_list_of_solutions()` is called with input the string *s* below:

```
sage: s = '[x=-(sqrt(a^2-4*b)+a)/2,x=(sqrt(a^2-4*b)-a)/2]'
sage: sage.symbolic.relation.string_to_list_of_solutions(s)
 [x == -1/2*a - 1/2*sqrt(a^2 - 4*b), x == -1/2*a + 1/2*sqrt(a^2 - 4*b)]
```

test_relation_maxima(*relation*)

Return True if this (in)equality is definitely true. Return False if it is false or the algorithm for testing (in)equality is inconclusive.

EXAMPLES:

```
sage: from sage.symbolic.relation import test_relation_maxima
sage: k = var('k')
sage: pol = 1/(k-1) - 1/k -1/k/(k-1);
sage: test_relation_maxima(pol == 0)
True
sage: f = sin(x)^2 + cos(x)^2 - 1
sage: test_relation_maxima(f == 0)
```

```
True
sage: test_relation_maxima( x == x )
True
sage: test_relation_maxima( x != x )
False
sage: test_relation_maxima( x > x )
False
sage: test_relation_maxima( x^2 > x )
False
sage: test_relation_maxima( x + 2 > x )
True
sage: test_relation_maxima( x - 2 > x )
False
```

3.4 Symbolic Computation.

AUTHORS:

- Bobby Moretti and William Stein (2006-2007)

The Sage calculus module is loosely based on the Sage Enhancement Proposal found at: http://www.sagemath.org:9001/CalculusSEP.

EXAMPLES:

The basic units of the calculus package are symbolic expressions which are elements of the symbolic expression ring (SR). To create a symbolic variable object in Sage, use the `var()` function, whose argument is the text of that variable. Note that Sage is intelligent about LaTeXing variable names.

```
sage: x1 = var('x1'); x1
x1
sage: latex(x1)
x_{1}
sage: theta = var('theta'); theta
theta
sage: latex(theta)
\theta
```

Sage predefines `x` to be a global indeterminate. Thus the following works:

```
sage: x^2
x^2
sage: type(x)
<type 'sage.symbolic.expression.Expression'>
```

More complicated expressions in Sage can be built up using ordinary arithmetic. The following are valid, and follow the rules of Python arithmetic: (The '=' operator represents assignment, and not equality)

```
sage: var('x,y,z')
(x, y, z)
sage: f = x + y + z/(2*sin(y*z/55))
sage: g = f^f; g
(x + y + 1/2*z/sin(1/55*y*z))^(x + y + 1/2*z/sin(1/55*y*z))
```

Differentiation and integration are available, but behind the scenes through maxima:

```
sage: f = sin(x)/cos(2*y)
sage: f.derivative(y)
2*sin(x)*sin(2*y)/cos(2*y)^2
sage: g = f.integral(x); g
-cos(x)/cos(2*y)
```

Note that these methods require an explicit variable name. If none is given, Sage will try to find one for you.

```
sage: f = sin(x); f.derivative()
cos(x)
```

However when this is ambiguous, Sage will raise an exception:

```
sage: f = sin(x+y); f.derivative()
...
ValueError: No differentiation variable specified.
```

Substitution works similarly. We can substitute with a python dict:

```
sage: f = sin(x*y - z)
sage: f({x: var('t'), y: z})
sin(t*z - z)
```

Also we can substitute with keywords:

```
sage: f = sin(x*y - z)
sage: f(x = t, y = z)
sin(t*z - z)
```

It was formerly the case that if there was no ambiguity of variable names, we didn't have to specify them; that still works for the moment, but the behavior is deprecated:

```
sage: f = sin(x)
sage: f(y)
doctest:...: DeprecationWarning: Substitution using function-call syntax and unnamed arguments is dep
sin(y)
sage: f(pi)
0
```

However if there is ambiguity, we should explicitly state what variables we're substituting for:

```
sage: f = sin(2*pi*x/y)
sage: f(x=4)
sin(8*pi/y)
```

We can also make a `CallableSymbolicExpression`, which is a `SymbolicExpression` that is a function of specified variables in a fixed order. Each `SymbolicExpression` has a `function(...)` method that is used to create a `CallableSymbolicExpression`, as illustrated below:

```
sage: u = log((2-x)/(y+5))
sage: f = u.function(x, y); f
(x, y) |--> log(-(x - 2)/(y + 5))
```

There is an easier way of creating a `CallableSymbolicExpression`, which relies on the Sage preparser.

```
sage: f(x,y) = log(x)*cos(y); f
(x, y) |--> log(x)*cos(y)
```

Then we have fixed an order of variables and there is no ambiguity substituting or evaluating:

```
sage: f(x,y) = log((2-x)/(y+5))
sage: f(7,t)
log(-5/(t + 5))
```

Some further examples:

```
sage: f = 5*sin(x)
sage: f
5*sin(x)
sage: f(x=2)
5*sin(2)
sage: f(x=pi)
0
sage: float(f(x=pi))
0.0
```

Another example:

```
sage: f = integrate(1/sqrt(9+x^2), x); f
arcsinh(1/3*x)
sage: f(x=3)
arcsinh(1)
sage: f.derivative(x)
1/3/sqrt(1/9*x^2 + 1)
```

We compute the length of the parabola from 0 to 2:

```
sage: x = var('x')
sage: y = x^2
sage: dy = derivative(y,x)
sage: z = integral(sqrt(1 + dy^2), x, 0, 2)
sage: z
sqrt(17) + 1/4*arcsinh(4)
sage: n(z,200)
4.6467837624329358733826155674904591885104869874232887508703
sage: float(z)
4.6467837624329356
```

We test pickling:

```
sage: x, y = var('x,y')
sage: f = -sqrt(pi)*(x^3 + sin(x/cos(y)))
sage: bool(loads(dumps(f)) == f)
True
```

Coercion examples:

We coerce various symbolic expressions into the complex numbers:

```
sage: CC(I)
1.00000000000000*I
sage: CC(2*I)
2.00000000000000*I
sage: ComplexField(200)(2*I)
2.0000000000000000000000000000000000000000000000000000000000*I
sage: ComplexField(200)(sin(I))
1.1752011936438014568823818505956008151557179813340958702296*I
sage: f = sin(I) + cos(I/2); f
sin(I) + cos(1/2*I)
sage: CC(f)
1.12762596520638 + 1.17520119364380*I
sage: ComplexField(200)(f)
1.1276259652063807852262251614026720125478471180986674836290 + 1.1752011936438014568823818505956008151
sage: ComplexField(100)(f)
1.1276259652063807852262251614 + 1.1752011936438014568823818506*I
```

We illustrate construction of an inverse sum where each denominator has a new variable name:

```
sage: f = sum(1/var('n%s'%i)^i for i in range(10))
sage: f
1/n1 + 1/n2^2 + 1/n3^3 + 1/n4^4 + 1/n5^5 + 1/n6^6 + 1/n7^7 + 1/n8^8 + 1/n9^9 + 1
```

Note that after calling var, the variables are immediately available for use:

```
sage: (n1 + n2)^5
(n1 + n2)^5
```

We can, of course, substitute:

```
sage: f(n9=9,n7=n6)
1/n1 + 1/n2^2 + 1/n3^3 + 1/n4^4 + 1/n5^5 + 1/n6^6 + 1/n6^7 + 1/n8^8 + 387420490/387420489
```

TESTS:

Substitution:

```
sage: f = x
sage: f(x=5)
5
```

Simplifying expressions involving scientific notation:

```
sage: k = var('k')
sage: a0 = 2e-06; a1 = 12
sage: c = a1 + a0*k; c
(2.00000000000000e-6)*k + 12
sage: sqrt(c)
sqrt((2.00000000000000e-6)*k + 12)
sage: sqrt(c^3)
sqrt(((2.00000000000000e-6)*k + 12)^3)
```

The symbolic Calculus package uses its own copy of maxima for simplification, etc., which is separate from the default system-wide version:

```
sage: maxima.eval('[x,y]: [1,2]')
'[1,2]'
sage: maxima.eval('expand((x+y)^3)')
'27'
```

If the copy of maxima used by the symbolic calculus package were the same as the default one, then the following would return 27, which would be very confusing indeed!

```
sage: x, y = var('x,y')
sage: expand((x+y)^3)
x^3 + 3*x^2*y + 3*x*y^2 + y^3
```

Set x to be 5 in maxima:

```
sage: maxima('x: 5')
5
sage: maxima('x + x + %pi')
%pi+10
```

This simplification is done using maxima (behind the scenes):

```
sage: x + x + pi
 pi + 2*x
```

Note that x is still x, since the maxima used by the calculus package is different than the one in the interactive interpreter.

Check to see that the problem with the variables method mentioned in Trac ticket #3779 is actually fixed:

```
sage: f = function('F',x)
sage: diff(f*SR(1),x)
D[0](F)(x)
```

clear_functions()

Clear all user-defined functions from the symbol tables.

EXAMPLES:

```
sage: f = function('foo')
sage: id_f1 = id(f)
sage: id_f1 == id(function('foo'))
True
sage: clear_functions()
sage: id_f1 == id(function('foo'))
False
```

dummy_diff(**args*)

This function is called when 'diff' appears in a Maxima string.

EXAMPLES:

```
sage: from sage.calculus.calculus import dummy_diff
sage: x,y = var('x,y')
sage: dummy_diff(sin(x*y), x, SR(2), y, SR(1))
-x*y^2*cos(x*y) - 2*y*sin(x*y)
```

Here the function is used implicitly:

```
sage: a = var('a')
sage: f = function('cr', a)
sage: g = f.diff(a); g
D[0](cr)(a)
```

dummy_limit(**args*)

This function is called to create formal wrappers of limits that Maxima can't compute:

EXAMPLES:

```
sage: a = lim(exp(x^2)*(1-erf(x)), x=infinity); a
limit(-e^(x^2)*erf(x) + e^(x^2), x, +Infinity)
sage: a = sage.calculus.calculus.dummy_limit(sin(x)/x, x, 0);a
limit(sin(x)/x, x, 0)
```

function(*s, *args*)

Create a formal symbolic function with the name *s*.

EXAMPLES:

```
sage: var('a, b')
(a, b)
sage: f = function('cr', a)
sage: g = f.diff(a).integral(b)
sage: g
b*D[0](cr)(a)
```

In Sage 4.0, you need to use `substitute_function()` to replace all occurrences of a function with another:

```
sage: g.substitute_function(cr, cos)
-b*sin(a)

sage: g.substitute_function(cr, (sin(x) + cos(x)).function(x))
-(sin(a) - cos(a))*b
```

In Sage 4.0, basic arithmetic with unevaluated functions is no longer supported:

```
sage: x = var('x')
sage: f = function('f')
sage: 2*f
...
TypeError: unsupported operand parent(s) for '*': 'Integer Ring' and '<type 'sage.symbolic.funct
```

You now need to evaluate the function in order to do the arithmetic:

```
sage: 2*f(x)
2*f(x)
```

integral(*expression, v=None, a=None, b=None, algorithm='maxima'*)

Returns the indefinite integral with respect to the variable v, ignoring the constant of integration. Or, if endpoints a and b are specified, returns the definite integral over the interval $[a, b]$.

If `self` has only one variable, then it returns the integral with respect to that variable.

INPUT:

- `v` - (optional) a variable or variable name
- `a` - (optional) lower endpoint of definite integral

- b - (optional) upper endpoint of definite integral
- algorithm - (default: 'maxima') one of
  - 'maxima' - use maxima (the default)
  - 'sympy' - use sympy (also in Sage)
  - 'mathematica_free' - use http://integrals.wolfram.com/

EXAMPLES:

```
sage: x = var('x')
sage: h = sin(x)/(cos(x))^2
sage: h.integral(x)
1/cos(x)

sage: f = x^2/(x+1)^3
sage: f.integral()
1/2*(4*x + 3)/(x^2 + 2*x + 1) + log(x + 1)

sage: f = x*cos(x^2)
sage: f.integral(x, 0, sqrt(pi))
0
sage: f.integral(a=-pi, b=pi)
0

sage: f(x) = sin(x)
sage: f.integral(x, 0, pi/2)
1
```

The variable and endpoints are both optional:

```
sage: integral(sin(x))
-cos(x)
sage: integral(sin(x), var('y'))
y*sin(x)
sage: integral(sin(x), pi, 2*pi)
-2
sage: integral(sin(x), var('y'), pi, 2*pi)
pi*sin(x)
```

Constraints are sometimes needed:

```
sage: var('x, n')
(x, n)
sage: integral(x^n,x)
...
TypeError: Computation failed since Maxima requested additional constraints (try the command 'as
Is  n+1  zero or nonzero?
sage: assume(n > 0)
sage: integral(x^n,x)
x^(n + 1)/(n + 1)
sage: forget()
```

Usually the constraints are of sign, but others are possible:

```
sage: assume(n==-1)
sage: integral(x^n,x)
log(x)
```

Note that an exception is raised when a definite integral is divergent.

```
sage: forget()

sage: integrate(1/x^3,x,0,1)
...
ValueError: Integral is divergent.
sage: integrate(1/x^3,x,-1,3)
...
ValueError: Integral is divergent.
```

Note: Above, putting assume(n == -1) does not yield the right behavior.

The examples in the Maxima documentation:

```
sage: var('x, y, z, b')
(x, y, z, b)
sage: integral(sin(x)^3)
1/3*cos(x)^3 - cos(x)
sage: integral(x/sqrt(b^2-x^2))
x*log(2*b + 2*sqrt(b^2 - x^2))
sage: integral(x/sqrt(b^2-x^2), x)
-sqrt(b^2 - x^2)
sage: integral(cos(x)^2 * exp(x), x, 0, pi)
3/5*e^pi - 3/5
sage: integral(x^2 * exp(-x^2), x, -oo, oo)
1/2*sqrt(pi)
```

We integrate the same function in both Mathematica and Sage (via Maxima):

```
sage: _ = var('x, y, z')
sage: f = sin(x^2) + y^z
sage: g = mathematica(f)                              # optional  -- requires mathematica
sage: print g                                         # optional -- requires mathematica
          z        2
         y  + Sin[x ]
sage: print g.Integrate(x)                            # optional -- requires mathematica
             z        Pi                 2
          x y  + Sqrt[--] FresnelS[Sqrt[--] x]
                   2                  Pi
sage: print f.integral(x)
y^z*x + 1/8*((I - 1)*sqrt(2)*erf((1/2*I - 1/2)*sqrt(2)*x) + (I + 1)*sqrt(2)*erf((1/2*I + 1/2)*sq
```

Alternatively, just use algorithm='mathematica_free' to integrate via Mathematica over the internet (deos NOT require a mathematica license!):

```
sage: _ = var('x, y, z')
sage: f = sin(x^2) + y^z
sage: f.integrate(algorithm="mathematica_free")       # optional -- requires internet
sqrt(pi)*sqrt(1/2)*fresnels(sqrt(2)*x/sqrt(pi)) + y^z*x
```

We can also use Sympy:

```
sage: _ = var('x, y, z')
sage: (x^y-z).integrate(y)
-y*z + x^y/log(x)
sage: (x^y-z).integrate(y,algorithm="sympy")
-y*z + x^y/log(x)
```

We integrate the above function in maple now:

```
sage: g = maple(f); g                                  # optional -- requires maple
sin(x^2)+y^z
sage: g.integrate(x)                                   # optional -- requires maple
1/2*2^(1/2)*Pi^(1/2)*FresnelS(2^(1/2)/Pi^(1/2)*x)+y^z*x
```

We next integrate a function with no closed form integral. Notice that the answer comes back as an expression that contains an integral itself.

```
sage: A = integral(1/ ((x-4) * (x^3+2*x+1)), x); A
1/73*log(x - 4) - 1/73*integrate((x^2 + 4*x + 18)/(x^3 + 2*x + 1), x)
```

We now show that floats are not converted to rationals automatically since we by default have keepfloat: true in maxima.

```
sage: integral(e^(-x^2),x, 0, 0.1)
0.0562314580091*sqrt(pi)
```

ALIASES: integral() and integrate() are the same.

EXAMPLES: Here is example where we have to use assume:

```
sage: a,b = var('a,b')
sage: integrate(1/(x^3 *(a+b*x)^(1/3)), x)
...
TypeError: Computation failed since Maxima requested additional constraints (try the command 'as
Is  a  positive or negative?
```

So we just assume that $a > 0$ and the integral works:

```
sage: assume(a>0)
sage: integrate(1/(x^3 *(a+b*x)^(1/3)), x)
2/9*sqrt(3)*b^2*arctan(1/3*(2*(b*x + a)^(1/3) + a^(1/3))*sqrt(3)/a^(1/3))/a^(7/3) + 2/9*b^2*log(
```

TESTS:

The following integral was broken prior to Maxima 5.15.0 - see #3013

```
sage: integrate(sin(x)*cos(10*x)*log(x))
1/18*log(x)*cos(9*x) - 1/22*log(x)*cos(11*x) - 1/18*integrate(cos(9*x)/x, x) + 1/22*integrate(cc
```

It is no longer possible to use certain functions without an explicit variable. Instead, evaluate the function at a variable, and then take the integral:

```
sage: integrate(sin)
...
TypeError

sage: integrate(sin(x))
-cos(x)
sage: integrate(sin(x), 0, 1)
-cos(1) + 1
```

integrate(*expression, v=None, a=None, b=None, algorithm='maxima'*)

Returns the indefinite integral with respect to the variable v, ignoring the constant of integration. Or, if endpoints a and b are specified, returns the definite integral over the interval $[a, b]$.

If `self` has only one variable, then it returns the integral with respect to that variable.

INPUT:

- v - (optional) a variable or variable name
- a - (optional) lower endpoint of definite integral
- b - (optional) upper endpoint of definite integral
- algorithm - (default: 'maxima') one of
  - 'maxima' - use maxima (the default)
  - 'sympy' - use sympy (also in Sage)
  - 'mathematica_free' - use http://integrals.wolfram.com/

EXAMPLES:

```
sage: x = var('x')
sage: h = sin(x)/(cos(x))^2
sage: h.integral(x)
1/cos(x)

sage: f = x^2/(x+1)^3
sage: f.integral()
1/2*(4*x + 3)/(x^2 + 2*x + 1) + log(x + 1)

sage: f = x*cos(x^2)
sage: f.integral(x, 0, sqrt(pi))
0
sage: f.integral(a=-pi, b=pi)
0

sage: f(x) = sin(x)
sage: f.integral(x, 0, pi/2)
1
```

The variable and endpoints are both optional:

```
sage: integral(sin(x))
-cos(x)
sage: integral(sin(x), var('y'))
y*sin(x)
sage: integral(sin(x), pi, 2*pi)
-2
sage: integral(sin(x), var('y'), pi, 2*pi)
pi*sin(x)
```

Constraints are sometimes needed:

```
sage: var('x, n')
(x, n)
sage: integral(x^n,x)
...
TypeError: Computation failed since Maxima requested additional constraints (try the command 'as
Is  n+1  zero or nonzero?
sage: assume(n > 0)
sage: integral(x^n,x)
x^(n + 1)/(n + 1)
sage: forget()
```

Usually the constraints are of sign, but others are possible:

```
sage: assume(n==-1)
sage: integral(x^n,x)
log(x)
```

Note that an exception is raised when a definite integral is divergent.

```
sage: forget()

sage: integrate(1/x^3,x,0,1)
...
ValueError: Integral is divergent.
sage: integrate(1/x^3,x,-1,3)
...
ValueError: Integral is divergent.
```

Note: Above, putting assume(n == -1) does not yield the right behavior.

The examples in the Maxima documentation:

```
sage: var('x, y, z, b')
(x, y, z, b)
sage: integral(sin(x)^3)
1/3*cos(x)^3 - cos(x)
sage: integral(x/sqrt(b^2-x^2))
x*log(2*b + 2*sqrt(b^2 - x^2))
sage: integral(x/sqrt(b^2-x^2), x)
-sqrt(b^2 - x^2)
sage: integral(cos(x)^2 * exp(x), x, 0, pi)
3/5*e^pi - 3/5
sage: integral(x^2 * exp(-x^2), x, -oo, oo)
1/2*sqrt(pi)
```

We integrate the same function in both Mathematica and Sage (via Maxima):

```
sage: _ = var('x, y, z')
sage: f = sin(x^2) + y^z
sage: g = mathematica(f)                              # optional  -- requires mathematica
sage: print g                                         # optional -- requires mathematica
          z        2
         y  + Sin[x ]
sage: print g.Integrate(x)                            # optional -- requires mathematica
            z        Pi                 2
         x y  + Sqrt[--] FresnelS[Sqrt[--] x]
                     2                  Pi
sage: print f.integral(x)
y^z*x + 1/8*((I - 1)*sqrt(2)*erf((1/2*I - 1/2)*sqrt(2)*x) + (I + 1)*sqrt(2)*erf((1/2*I + 1/2)*sq
```

Alternatively, just use algorithm='mathematica_free' to integrate via Mathematica over the internet (deos NOT require a mathematica license!):

```
sage: _ = var('x, y, z')
sage: f = sin(x^2) + y^z
sage: f.integrate(algorithm="mathematica_free")       # optional -- requires internet
sqrt(pi)*sqrt(1/2)*fresnels(sqrt(2)*x/sqrt(pi)) + y^z*x
```

We can also use Sympy:

```
sage: _ = var('x, y, z')
sage: (x^y-z).integrate(y)
-y*z + x^y/log(x)
sage: (x^y-z).integrate(y,algorithm="sympy")
-y*z + x^y/log(x)
```

We integrate the above function in maple now:

```
sage: g = maple(f); g                                  # optional -- requires maple
sin(x^2)+y^z
sage: g.integrate(x)                                   # optional -- requires maple
1/2*2^(1/2)*Pi^(1/2)*FresnelS(2^(1/2)/Pi^(1/2)*x)+y^z*x
```

We next integrate a function with no closed form integral. Notice that the answer comes back as an expression that contains an integral itself.

```
sage: A = integral(1/ ((x-4) * (x^3+2*x+1)), x); A
1/73*log(x - 4) - 1/73*integrate((x^2 + 4*x + 18)/(x^3 + 2*x + 1), x)
```

We now show that floats are not converted to rationals automatically since we by default have keepfloat: true in maxima.

```
sage: integral(e^(-x^2),x, 0, 0.1)
0.0562314580091*sqrt(pi)
```

ALIASES: integral() and integrate() are the same.

EXAMPLES: Here is example where we have to use assume:

```
sage: a,b = var('a,b')
sage: integrate(1/(x^3 *(a+b*x)^(1/3)), x)
...
TypeError: Computation failed since Maxima requested additional constraints (try the command 'as
Is  a  positive or negative?
```

So we just assume that $a > 0$ and the integral works:

```
sage: assume(a>0)
sage: integrate(1/(x^3 *(a+b*x)^(1/3)), x)
2/9*sqrt(3)*b^2*arctan(1/3*(2*(b*x + a)^(1/3) + a^(1/3))*sqrt(3)/a^(1/3))/a^(7/3) + 2/9*b^2*log(
```

TESTS:

The following integral was broken prior to Maxima 5.15.0 - see #3013

```
sage: integrate(sin(x)*cos(10*x)*log(x))
1/18*log(x)*cos(9*x) - 1/22*log(x)*cos(11*x) - 1/18*integrate(cos(9*x)/x, x) + 1/22*integrate(co
```

It is no longer possible to use certain functions without an explicit variable. Instead, evaluate the function at a variable, and then take the integral:

```
sage: integrate(sin)
...
TypeError

sage: integrate(sin(x))
-cos(x)
sage: integrate(sin(x), 0, 1)
-cos(1) + 1
```

inverse_laplace(*ex, t, s*)

Attempts to compute the inverse Laplace transform of `self` with respect to the variable t and transform parameter s. If this function cannot find a solution, a formal function is returned.

The function that is returned may be be viewed as a function of s.

DEFINITION: The inverse Laplace transform of a function $F(s)$, is the function $f(t)$ defined by

$$F(s) = \frac{1}{2\pi i}\int_{\gamma-i\infty}^{\gamma+i\infty} e^{st}F(s)dt,$$

where γ is chosen so that the contour path of integration is in the region of convergence of $F(s)$.

EXAMPLES:

```
sage: var('w, m')
(w, m)
sage: f = (1/(w^2+10)).inverse_laplace(w, m); f
1/10*sqrt(10)*sin(sqrt(10)*m)
sage: laplace(f, m, w)
1/(w^2 + 10)

sage: f(t) = t*cos(t)
sage: s = var('s')
sage: L = laplace(f, t, s); L
t |--> 2*s^2/(s^2 + 1)^2 - 1/(s^2 + 1)
sage: inverse_laplace(L, s, t)
t |--> t*cos(t)
sage: inverse_laplace(1/(s^3+1), s, t)
1/3*(sqrt(3)*sin(1/2*sqrt(3)*t) - cos(1/2*sqrt(3)*t))*e^(1/2*t) + 1/3*e^(-t)
```

No explicit inverse Laplace transform, so one is returned formally as a function `ilt`:

```
sage: inverse_laplace(cos(s), s, t)
ilt(cos(s), s, t)
```

laplace(*ex, t, s*)

Attempts to compute and return the Laplace transform of `self` with respect to the variable t and transform parameter s. If this function cannot find a solution, a formal function is returned.

The function that is returned may be be viewed as a function of s.

DEFINITION: The Laplace transform of a function $f(t)$, defined for all real numbers $t \geq 0$, is the function $F(s)$ defined by

$$F(s) = \int_0^\infty e^{-st}f(t)dt.$$

EXAMPLES: We compute a few Laplace transforms:

```
sage: var('x, s, z, t, t0')
(x, s, z, t, t0)
sage: sin(x).laplace(x, s)
1/(s^2 + 1)
sage: (z + exp(x)).laplace(x, s)
z/s + 1/(s - 1)
sage: log(t/t0).laplace(t, s)
 -(euler_gamma + log(s) + log(t0))/s
```

We do a formal calculation:

```
sage: f = function('f', x)
sage: g = f.diff(x); g
D[0](f)(x)
sage: g.laplace(x, s)
s*laplace(f(x), x, s) - f(0)
```

EXAMPLE: A BATTLE BETWEEN the X-women and the Y-men (by David Joyner): Solve

$$x' = -16y, x(0) = 270, y' = -x + 1, y(0) = 90.$$

This models a fight between two sides, the "X-women" and the "Y-men", where the X-women have 270 initially and the Y-men have 90, but the Y-men are better at fighting, because of the higher factor of "-16" vs "-1", and also get an occasional reinforcement, because of the "+1" term.

```
sage: var('t')
t
sage: t = var('t')
sage: x = function('x', t)
sage: y = function('y', t)
sage: de1 = x.diff(t) + 16*y
sage: de2 = y.diff(t) + x - 1
sage: de1.laplace(t, s)
s*laplace(x(t), t, s) + 16*laplace(y(t), t, s) - x(0)
sage: de2.laplace(t, s)
s*laplace(y(t), t, s) - 1/s + laplace(x(t), t, s) - y(0)
```

Next we form the augmented matrix of the above system:

```
sage: A = matrix([[s, 16, 270],[1, s, 90+1/s]])
sage: E = A.echelon_form()
sage: xt = E[0,2].inverse_laplace(s,t)
sage: yt = E[1,2].inverse_laplace(s,t)
sage: xt
629/2*e^(-4*t) - 91/2*e^(4*t) + 1
sage: yt
629/8*e^(-4*t) + 91/8*e^(4*t)
sage: p1 = plot(xt,0,1/2,rgbcolor=(1,0,0))
sage: p2 = plot(yt,0,1/2,rgbcolor=(0,1,0))
sage: (p1+p2).save()
```

Another example:

```
sage: var('a,s,t')
(a, s, t)
sage: f = exp (2*t + a) * sin(t) * t; f
t*e^(a + 2*t)*sin(t)
sage: L = laplace(f, t, s); L
2*(s - 2)*e^a/(s^2 - 4*s + 5)^2
sage: inverse_laplace(L, s, t)
t*e^(a + 2*t)*sin(t)
```

Unable to compute solution:

```
sage: laplace(1/s, s, t)
laplace(1/s, s, t)
```

lim(*ex, dir=None, taylor=False, algorithm='maxima', **argv*)

Return the limit as the variable v approaches a from the given direction.

```
expr.limit(x = a)
expr.limit(x = a, dir='above')
```

INPUT:

- `dir` - (default: None); dir may have the value 'plus' (or 'above') for a limit from above, 'minus' (or 'below') for a limit from below, or may be omitted (implying a two-sided limit is to be computed).
- `taylor` - (default: False); if True, use Taylor series, which allows more integrals to be computed (but may also crash in some obscure cases due to bugs in Maxima).
- `**argv` - 1 named parameter

Note: The output may also use 'und' (undefined), 'ind' (indefinite but bounded), and 'infinity' (complex infinity).

EXAMPLES:

```
sage: x = var('x')
sage: f = (1+1/x)^x
sage: f.limit(x = oo)
e
sage: f.limit(x = 5)
7776/3125
sage: f.limit(x = 1.2)
2.06961575467...
sage: f.limit(x = I, taylor=True)
(-I + 1)^I
sage: f(x=1.2)
2.0696157546720...
sage: f(x=I)
(-I + 1)^I
sage: CDF(f(x=I))
2.06287223508 + 0.74500706218*I
sage: CDF(f.limit(x = I))
2.06287223508 + 0.74500706218*I
```

More examples:

```
sage: limit(x*log(x), x = 0, dir='above')
0
sage: lim((x+1)^(1/x),x = 0)
e
sage: lim(e^x/x, x = oo)
+Infinity
sage: lim(e^x/x, x = -oo)
0
sage: lim(-e^x/x, x = oo)
-Infinity
sage: lim((cos(x))/(x^2), x = 0)
+Infinity
sage: lim(sqrt(x^2+1) - x, x = oo)
0
sage: lim(x^2/(sec(x)-1), x=0)
2
sage: lim(cos(x)/(cos(x)-1), x=0)
-Infinity
sage: lim(x*sin(1/x), x=0)
0
```

```
sage: f = log(log(x))/log(x)
sage: forget(); assume(x<-2); lim(f, x=0, taylor=True)
limit(log(log(x))/log(x), x, 0)
```

Here ind means "indefinite but bounded":

```
sage: lim(sin(1/x), x = 0)
ind
```

limit (*ex, dir=None, taylor=False, algorithm='maxima', **argv*)

Return the limit as the variable v approaches a from the given direction.

```
expr.limit(x = a)
expr.limit(x = a, dir='above')
```

INPUT:

- `dir` - (default: None); dir may have the value 'plus' (or 'above') for a limit from above, 'minus' (or 'below') for a limit from below, or may be omitted (implying a two-sided limit is to be computed).
- `taylor` - (default: False); if True, use Taylor series, which allows more integrals to be computed (but may also crash in some obscure cases due to bugs in Maxima).
- `**argv` - 1 named parameter

Note: The output may also use 'und' (undefined), 'ind' (indefinite but bounded), and 'infinity' (complex infinity).

EXAMPLES:

```
sage: x = var('x')
sage: f = (1+1/x)^x
sage: f.limit(x = oo)
e
sage: f.limit(x = 5)
7776/3125
sage: f.limit(x = 1.2)
2.06961575467...
sage: f.limit(x = I, taylor=True)
(-I + 1)^I
sage: f(x=1.2)
2.0696157546720...
sage: f(x=I)
(-I + 1)^I
sage: CDF(f(x=I))
2.06287223508 + 0.74500706218*I
sage: CDF(f.limit(x = I))
2.06287223508 + 0.74500706218*I
```

More examples:

```
sage: limit(x*log(x), x = 0, dir='above')
0
sage: lim((x+1)^(1/x),x = 0)
e
sage: lim(e^x/x, x = oo)
+Infinity
sage: lim(e^x/x, x = -oo)
0
sage: lim(-e^x/x, x = oo)
```

```
-Infinity
sage: lim((cos(x))/(x^2), x = 0)
+Infinity
sage: lim(sqrt(x^2+1) - x, x = oo)
0
sage: lim(x^2/(sec(x)-1), x=0)
2
sage: lim(cos(x)/(cos(x)-1), x=0)
-Infinity
sage: lim(x*sin(1/x), x=0)
0
```

```
sage: f = log(log(x))/log(x)
sage: forget(); assume(x<-2); lim(f, x=0, taylor=True)
limit(log(log(x))/log(x), x, 0)
```

Here ind means "indefinite but bounded":

```
sage: lim(sin(1/x), x = 0)
ind
```

mapped_opts(*v*)

Used internally when creating a string of options to pass to Maxima.

INPUT:

- v - an object

OUTPUT: a string.

The main use of this is to turn Python bools into lower case strings.

EXAMPLES:

```
sage: sage.calculus.calculus.mapped_opts(True)
'true'
sage: sage.calculus.calculus.mapped_opts(False)
'false'
sage: sage.calculus.calculus.mapped_opts('bar')
'bar'
```

maxima_options(***kwds*)

Used internally to create a string of options to pass to Maxima.

EXAMPLES:

```
sage: sage.calculus.calculus.maxima_options(an_option=True, another=False, foo='bar')
'an_option=true,foo=bar,another=false'
```

minpoly(*ex, var='x', algorithm=None, bits=None, degree=None, epsilon=0*)

Return the minimal polynomial of self, if possible.

INPUT:

- var - polynomial variable name (default 'x')
- algorithm - 'algebraic' or 'numerical' (default both, algebraic first)
- bits - the number of bits to use in numerical approx
- degree - the expected algebraic degree

- `epsilon` - return without error as long as f(self) epsilon, in the case that the result cannot be proven.

  All of the above parameters are optional, with epsilon=0, bits and degree tested up to 1000 and 24 by default respectively. The numerical algorithm will be faster if bits and/or degree are given explicitly. The algebraic algorithm ignores the last three parameters.

OUTPUT: The minimal polynomial of self. If the numerical algorithm is used then it is proved symbolically when epsilon=0 (default).

If the minimal polynomial could not be found, two distinct kinds of errors are raised. If no reasonable candidate was found with the given bit/degree parameters, a `ValueError` will be raised. If a reasonable candidate was found but (perhaps due to limits in the underlying symbolic package) was unable to be proved correct, a `NotImplementedError` will be raised.

ALGORITHM: Two distinct algorithms are used, depending on the algorithm parameter. By default, the algebraic algorithm is attempted first, then the numerical one.

Algebraic: Attempt to evaluate this expression in QQbar, using cyclotomic fields to resolve exponential and trig functions at rational multiples of pi, field extensions to handle roots and rational exponents, and computing compositums to represent the full expression as an element of a number field where the minimal polynomial can be computed exactly. The bits, degree, and epsilon parameters are ignored.

Numerical: Computes a numerical approximation of `self` and use PARI's algdep to get a candidate minpoly f. If $f($`self`$)$, evaluated to a higher precision, is close enough to 0 then evaluate $f($`self`$)$ symbolically, attempting to prove vanishing. If this fails, and `epsilon` is non-zero, return f if and only if $f($`self`$) <$ `epsilon`. Otherwise raise a `ValueError` (if no suitable candidate was found) or a `NotImplementedError` (if a likely candidate was found but could not be proved correct).

EXAMPLES: First some simple examples:

```
sage: sqrt(2).minpoly()
x^2 - 2
sage: minpoly(2^(1/3))
x^3 - 2
sage: minpoly(sqrt(2) + sqrt(-1))
x^4 - 2*x^2 + 9
sage: minpoly(sqrt(2)-3^(1/3))
x^6 - 6*x^4 + 6*x^3 + 12*x^2 + 36*x + 1
```

Works with trig and exponential functions too.

```
sage: sin(pi/3).minpoly()
x^2 - 3/4
sage: sin(pi/7).minpoly()
x^6 - 7/4*x^4 + 7/8*x^2 - 7/64
sage: minpoly(exp(I*pi/17))
x^16 - x^15 + x^14 - x^13 + x^12 - x^11 + x^10 - x^9 + x^8 - x^7 + x^6 - x^5 + x^4 - x^3 + x^2 -
```

Here we verify it gives the same result as the abstract number field.

```
sage: (sqrt(2) + sqrt(3) + sqrt(6)).minpoly()
x^4 - 22*x^2 - 48*x - 23
sage: K.<a,b> = NumberField([x^2-2, x^2-3])
sage: (a+b+a*b).absolute_minpoly()
x^4 - 22*x^2 - 48*x - 23
```

Here we solve a cubic and then recover it from its complicated radical expansion.

```
sage: f = x^3 - x + 1
sage: a = f.solve(x)[0].rhs(); a
-1/2*(I*sqrt(3) + 1)*(1/18*sqrt(3)*sqrt(23) - 1/2)^(1/3) - 1/6*(-I*sqrt(3) + 1)/(1/18*sqrt(3)*sq
```

```
sage: a.minpoly()
x^3 - x + 1
```

Note that simplification may be necessary to see that the minimal polynomial is correct.

```
sage: a = sqrt(2)+sqrt(3)+sqrt(5)
sage: f = a.minpoly(); f
x^8 - 40*x^6 + 352*x^4 - 960*x^2 + 576
sage: f(a)
((((sqrt(2) + sqrt(3) + sqrt(5))^2 - 40)*(sqrt(2) + sqrt(3) + sqrt(5))^2 + 352)*(sqrt(2) + sqrt(
sage: f(a).expand()
0
```

Here we show use of the `epsilon` parameter. That this result is actually exact can be shown using the addition formula for sin, but maxima is unable to see that.

```
sage: a = sin(pi/5)
sage: a.minpoly(algorithm='numerical')
...
NotImplementedError: Could not prove minimal polynomial x^4 - 5/4*x^2 + 5/16 (epsilon 0.00000000
sage: f = a.minpoly(algorithm='numerical', epsilon=1e-100); f
x^4 - 5/4*x^2 + 5/16
sage: f(a).numerical_approx(100)
0.00000000000000000000000000000
```

The degree must be high enough (default tops out at 24).

```
sage: a = sqrt(3) + sqrt(2)
sage: a.minpoly(algorithm='numerical', bits=100, degree=3)
...
ValueError: Could not find minimal polynomial (100 bits, degree 3).
sage: a.minpoly(algorithm='numerical', bits=100, degree=10)
x^4 - 10*x^2 + 1
```

There is a difference between algorithm='algebraic' and algorithm='numerical':

```
sage: cos(pi/22).minpoly(algorithm='algebraic')
x^10 - 11/4*x^8 + 11/4*x^6 - 77/64*x^4 + 55/256*x^2 - 11/1024
sage: cos(pi/22).minpoly(algorithm='numerical')
Traceback (most recent call last):
NotImplementedError: Could not prove minimal polynomial x^10 - 11/4*x^8 + 11/4*x^6 - 77/64*x^4 +
```

Sometimes it fails.

```
sage: sin(1).minpoly()
...
ValueError: Could not find minimal polynomial (1000 bits, degree 24).
```

Note: Failure to produce a minimal polynomial does not necessarily indicate that this number is transcendental.

nintegral (*ex, x, a, b, desired_relative_error='1e-8', maximum_num_subintervals=200*)

Return a floating point machine precision numerical approximation to the integral of `self` from a to b, computed using floating point arithmetic via maxima.

INPUT:

- x - variable to integrate with respect to
- a - lower endpoint of integration
- b - upper endpoint of integration
- desired_relative_error - (default: '1e-8') the desired relative error
- maximum_num_subintervals - (default: 200) maxima number of subintervals

OUTPUT:

- float: approximation to the integral
- float: estimated absolute error of the approximation
- the number of integrand evaluations
- an error code:
  - 0 - no problems were encountered
  - 1 - too many subintervals were done
  - 2 - excessive roundoff error
  - 3 - extremely bad integrand behavior
  - 4 - failed to converge
  - 5 - integral is probably divergent or slowly convergent
  - 6 - the input is invalid

ALIAS: nintegrate is the same as nintegral

REMARK: There is also a function numerical_integral that implements numerical integration using the GSL C library. It is potentially much faster and applies to arbitrary user defined functions.

Also, there are limits to the precision to which Maxima can compute the integral to due to limitations in quadpack.

```
sage: f = x
sage: f = f.nintegral(x,0,1,1e-14)
...
ValueError: Maxima (via quadpack) cannot compute the integral to that precision
```

EXAMPLES:

```
sage: f(x) = exp(-sqrt(x))
sage: f.nintegral(x, 0, 1)
(0.52848223531423055, 4.163...e-11, 231, 0)
```

We can also use the numerical_integral function, which calls the GSL C library.

```
sage: numerical_integral(f, 0, 1)
(0.52848223225314706, 6.83928460...e-07)
```

Note that in exotic cases where floating point evaluation of the expression leads to the wrong value, then the output can be completely wrong:

```
sage: f = exp(pi*sqrt(163)) - 262537412640768744
```

Despite appearance, f is really very close to 0, but one gets a nonzero value since the definition of float(f) is that it makes all constants inside the expression floats, then evaluates each function and each arithmetic operation using float arithmetic:

```
sage: float(f)
-480.0
```

Computing to higher precision we see the truth:

```
sage: f.n(200)
-7.4992740280181431112064614366622348652078895136533593355718e-13
sage: f.n(300)
-7.4992740280181431112064614366266300913729246258962178935209506618170909557568196396710300
```

Now numerically integrating, we see why the answer is wrong:

```
sage: f.nintegrate(x,0,1)
(-480.00000000000011, 5.3290705182007538e-12, 21, 0)
```

It is just because every floating point evaluation of return -480.0 in floating point.

Important note: using GP/PARI one can compute numerical integrals to high precision:

```
sage: gp.eval('intnum(x=17,42,exp(-x^2)*log(x))')
'2.5657285005610514829173563961304785900 E-127'    # 64-bit
sage: old_prec = gp.set_real_precision(50)
sage: gp.eval('intnum(x=17,42,exp(-x^2)*log(x))')
'2.5657285005610514829173563961304785900147709554020 E-127'
sage: gp.set_real_precision(old_prec)
57
```

Note that the input function above is a string in PARI syntax.

nintegrate(*ex, x, a, b, desired_relative_error='1e-8', maximum_num_subintervals=200*)

Return a floating point machine precision numerical approximation to the integral of `self` from a to b, computed using floating point arithmetic via maxima.

INPUT:

- `x` - variable to integrate with respect to
- `a` - lower endpoint of integration
- `b` - upper endpoint of integration
- `desired_relative_error` - (default: '1e-8') the desired relative error
- `maximum_num_subintervals` - (default: 200) maxima number of subintervals

OUTPUT:

- float: approximation to the integral
- float: estimated absolute error of the approximation
- the number of integrand evaluations
- an error code:
  - `0` - no problems were encountered
  - `1` - too many subintervals were done
  - `2` - excessive roundoff error
  - `3` - extremely bad integrand behavior
  - `4` - failed to converge
  - `5` - integral is probably divergent or slowly convergent
  - `6` - the input is invalid

ALIAS: nintegrate is the same as nintegral

sage: old_prec = gp.set_real_precision(50)
sage: gp.eval('intnum(x=17,42,exp(-x^2)*log(x))')
'2.5657285005610514829173563961304785900147709554020 E-127'
sage: gp.set_real_precision(old_prec)
57
```

Note that the input function above is a string in PARI syntax.

symbolic_expression_from_maxima_element(*x, maxima=Maxima*)

Given an element of the calculus copy of the Maxima interface, create the corresponding Sage symbolic expression.

EXAMPLES:

```
sage: a = sage.calculus.calculus.maxima('x^(sqrt(y)+%pi) + sin(%e + %pi)')
sage: sage.calculus.calculus.symbolic_expression_from_maxima_element(a)
x^(pi + sqrt(y)) - sin(e)
sage: var('x, y')
(x, y)
sage: v = sage.calculus.calculus.maxima.vandermonde_matrix([x, y, 1/2])
sage: sage.calculus.calculus.symbolic_expression_from_maxima_element(v)
[  1   x x^2]
[  1   y y^2]
[  1 1/2 1/4]
```

symbolic_expression_from_maxima_string(*x, equals_sub=False, maxima=Maxima*)

Given a string representation of a Maxima expression, parse it and return the corresponding Sage symbolic expression.

INPUT:

- `x` - a string
- `equals_sub` - (default: False) if True, replace '=' by '==' in self
- `maxima` - (default: the calculus package's Maxima) the Maxima interpreter to use.

EXAMPLES:

```
sage: sage.calculus.calculus.symbolic_expression_from_maxima_string('x^%e + %e^%pi + %i + sin(0)')
x^e + e^pi + I
```

symbolic_expression_from_string(*s, syms=None, accept_sequence=False*)

var_cmp(*x, y*)

Return comparison of the two variables x and y, which is just the comparison of the underlying string representations of the variables. This is used internally by the Calculus package.

INPUT:

- `x, y` - symbolic variables

OUTPUT: Python integer; either -1, 0, or 1.

EXAMPLES:

```
sage: sage.calculus.calculus.var_cmp(x,x)
0
sage: sage.calculus.calculus.var_cmp(x,var('z'))
-1
sage: sage.calculus.calculus.var_cmp(x,var('a'))
1
```

3.5 Functional notation support for common calculus methods.

EXAMPLES: We illustrate each of the calculus functional functions.

```
sage: simplify(x - x)
0
sage: a = var('a')
sage: derivative(x^a + sin(x), x)
a*x^(a - 1) + cos(x)
sage: diff(x^a + sin(x), x)
a*x^(a - 1) + cos(x)
sage: derivative(x^a + sin(x), x)
a*x^(a - 1) + cos(x)
sage: integral(a*x*sin(x), x)
-(x*cos(x) - sin(x))*a
sage: integrate(a*x*sin(x), x)
-(x*cos(x) - sin(x))*a
sage: limit(a*sin(x)/x, x=0)
a
sage: taylor(a*sin(x)/x, x, 0, 4)
1/120*a*x^4 - 1/6*a*x^2 + a
sage: expand( (x-a)^3 )
-a^3 + 3*a^2*x - 3*a*x^2 + x^3
sage: laplace( e^(x+a), x, a)
e^a/(a - 1)
sage: inverse_laplace( e^a/(a-1), x, a)
ilt(e^a/(a - 1), x, a)
```

derivative (*f, *args, **kwds*)

The derivative of f.

Repeated differentiation is supported by the syntax given in the examples below.

ALIAS: diff

EXAMPLES: We differentiate a callable symbolic function:

```
sage: f(x,y) = x*y + sin(x^2) + e^(-x)
sage: f
(x, y) |--> x*y + e^(-x) + sin(x^2)
sage: derivative(f, x)
(x, y) |--> 2*x*cos(x^2) + y - e^(-x)
sage: derivative(f, y)
(x, y) |--> x
```

We differentiate a polynomial:

```
sage: t = polygen(QQ, 't')
sage: f = (1-t)^5; f
-t^5 + 5*t^4 - 10*t^3 + 10*t^2 - 5*t + 1
sage: derivative(f)
-5*t^4 + 20*t^3 - 30*t^2 + 20*t - 5
sage: derivative(f, t)
-5*t^4 + 20*t^3 - 30*t^2 + 20*t - 5
sage: derivative(f, t, t)
-20*t^3 + 60*t^2 - 60*t + 20
sage: derivative(f, t, 2)
-20*t^3 + 60*t^2 - 60*t + 20
sage: derivative(f, 2)
-20*t^3 + 60*t^2 - 60*t + 20
```

We differentiate a symbolic expression:

```
sage: var('a x')
(a, x)
sage: f = exp(sin(a - x^2))/x
sage: derivative(f, x)
-2*e^(sin(-x^2 + a))*cos(-x^2 + a) - e^(sin(-x^2 + a))/x^2
sage: derivative(f, a)
e^(sin(-x^2 + a))*cos(-x^2 + a)/x
```

Syntax for repeated differentiation:

```
sage: R.<u, v> = PolynomialRing(QQ)
sage: f = u^4*v^5
sage: derivative(f, u)
4*u^3*v^5
sage: f.derivative(u)   # can always use method notation too
4*u^3*v^5

sage: derivative(f, u, u)
12*u^2*v^5
sage: derivative(f, u, u, u)
24*u*v^5
sage: derivative(f, u, 3)
24*u*v^5

sage: derivative(f, u, v)
20*u^3*v^4
sage: derivative(f, u, 2, v)
60*u^2*v^4
sage: derivative(f, u, v, 2)
80*u^3*v^3
sage: derivative(f, [u, v, v])
80*u^3*v^3
```

diff (*f, *args, **kwds*)

The derivative of f.

Repeated differentiation is supported by the syntax given in the examples below.

ALIAS: diff

EXAMPLES: We differentiate a callable symbolic function:

```
sage: f(x,y) = x*y + sin(x^2) + e^(-x)
sage: f
(x, y) |--> x*y + e^(-x) + sin(x^2)
sage: derivative(f, x)
(x, y) |--> 2*x*cos(x^2) + y - e^(-x)
sage: derivative(f, y)
(x, y) |--> x
```

We differentiate a polynomial:

```
sage: t = polygen(QQ, 't')
sage: f = (1-t)^5; f
-t^5 + 5*t^4 - 10*t^3 + 10*t^2 - 5*t + 1
sage: derivative(f)
-5*t^4 + 20*t^3 - 30*t^2 + 20*t - 5
sage: derivative(f, t)
```

```
-5*t^4 + 20*t^3 - 30*t^2 + 20*t - 5
sage: derivative(f, t, t)
-20*t^3 + 60*t^2 - 60*t + 20
sage: derivative(f, t, 2)
-20*t^3 + 60*t^2 - 60*t + 20
sage: derivative(f, 2)
-20*t^3 + 60*t^2 - 60*t + 20
```

We differentiate a symbolic expression:

```
sage: var('a x')
(a, x)
sage: f = exp(sin(a - x^2))/x
sage: derivative(f, x)
-2*e^(sin(-x^2 + a))*cos(-x^2 + a) - e^(sin(-x^2 + a))/x^2
sage: derivative(f, a)
e^(sin(-x^2 + a))*cos(-x^2 + a)/x
```

Syntax for repeated differentiation:

```
sage: R.<u, v> = PolynomialRing(QQ)
sage: f = u^4*v^5
sage: derivative(f, u)
4*u^3*v^5
sage: f.derivative(u)   # can always use method notation too
4*u^3*v^5

sage: derivative(f, u, u)
12*u^2*v^5
sage: derivative(f, u, u, u)

sage: derivative(f, u, v)
20*u^3*v^4
sage: derivative(f, u, 2, v)
60*u^2*v^4
sage: derivative(f, u, v, 2)
80*u^3*v^3
sage: derivative(f, [u, v, v])
80*u^3*v^3
```

expand(*x, *args, **kwds*)

EXAMPLES:

```
sage: a = (x-1)*(x^2 - 1); a
(x - 1)*(x^2 - 1)
sage: expand(a)
x^3 - x^2 - x + 1
```

You can also use expand on polynomial, integer, and other factorizations:

```
sage: x = polygen(ZZ)
sage: F = factor(x^12 - 1); F
(x - 1) * (x + 1) * (x^2 - x + 1) * (x^2 + 1) * (x^2 + x + 1) * (x^4 - x^2 + 1)
sage: expand(F)
```

```
x^12 - 1
sage: F.expand()
x^12 - 1
sage: F = factor(2007); F
3^2 * 223
sage: expand(F)
2007
```

Note: If you want to compute the expanded form of a polynomial arithmetic operation quickly and the coefficients of the polynomial all lie in some ring, e.g., the integers, it is vastly faster to create a polynomial ring and do the arithmetic there.

```
sage: x = polygen(ZZ)       # polynomial over a given base ring.
sage: f = sum(x^n for n in range(5))
sage: f*f                   # much faster, even if the degree is huge
x^8 + 2*x^7 + 3*x^6 + 4*x^5 + 5*x^4 + 4*x^3 + 3*x^2 + 2*x + 1
```

TESTS:

```
sage: t1 = (sqrt(3)-3)*(sqrt(3)+1)/6;
sage: tt1 = -1/sqrt(3);
sage: t2 = sqrt(3)/6;
sage: float(t1)
-0.577350269189625...
sage: float(tt1)
-0.577350269189625...
sage: float(t2)
0.28867513459481287
sage: float(expand(t1 + t2))
-0.288675134594812...
sage: float(expand(tt1 + t2))
-0.288675134594812...
```

integral (*f, *args, **kwds*)

The integral of f.

EXAMPLES:

```
sage: integral(sin(x), x)
-cos(x)
sage: integral(sin(x)^2, x, pi, 123*pi/2)
121/4*pi
sage: integral( sin(x), x, 0, pi)
2
```

We integrate a symbolic function:

```
sage: f(x,y,z) = x*y/z + sin(z)
sage: integral(f, z)
(x, y, z) |--> x*y*log(z) - cos(z)
```

```
sage: var('a,b')
(a, b)
sage: assume(b-a>0)
sage: integral( sin(x), x, a, b)
cos(a) - cos(b)
sage: forget()
```

```
sage: integral(x/(x^3-1), x)
1/3*sqrt(3)*arctan(1/3*(2*x + 1)*sqrt(3)) + 1/3*log(x - 1) - 1/6*log(x^2 + x + 1)

sage: integral( exp(-x^2), x )
1/2*sqrt(pi)*erf(x)
```

We define the Gaussian, plot and integrate it numerically and symbolically:

```
sage: f(x) = 1/(sqrt(2*pi)) * e^(-x^2/2)
sage: P = plot(f, -4, 4, hue=0.8, thickness=2)
sage: P.show(ymin=0, ymax=0.4)
sage: numerical_integral(f, -4, 4)                    # random output
(0.99993665751633376, 1.1101527003413533e-14)
sage: integrate(f, x)
x |--> 1/2*erf(1/2*sqrt(2)*x)
```

You can have Sage calculate multiple integrals. For example, consider the function $exp(y^2)$ on the region between the lines $x = y$, $x = 1$, and $y = 0$. We find the value of the integral on this region using the command:

```
sage: area = integral(integral(exp(y^2),x,0,y),y,0,1); area
1/2*e - 1/2
sage: float(area)
0.85914091422952255
```

We compute the line integral of $\sin(x)$ along the arc of the curve $x = y^4$ from $(1, -1)$ to $(1, 1)$:

```
sage: t = var('t')
sage: (x,y) = (t^4,t)
sage: (dx,dy) = (diff(x,t), diff(y,t))
sage: integral(sin(x)*dx, t,-1, 1)
0
sage: restore('x,y')    # restore the symbolic variables x and y
```

Sage is unable to do anything with the following integral:

```
sage: integral( exp(-x^2)*log(x), x )
integrate(e^(-x^2)*log(x), x)
```

Sage does not know how to compute this integral either:

```
sage: integral( exp(-x^2)*ln(x), x, 0, oo)
integrate(e^(-x^2)*log(x), x, 0, +Infinity)
```

This definite integral is easy:

```
sage: integral( ln(x)/x, x, 1, 2)
1/2*log(2)^2
```

Sage can't do this elliptic integral (yet):

```
sage: integral(1/sqrt(2*t^4 - 3*t^2 - 2), t, 2, 3)
integrate(1/sqrt(2*t^4 - 3*t^2 - 2), t, 2, 3)
```

A double integral:

```
sage: y = var('y')
sage: integral(integral(x*y^2, x, 0, y), y, -2, 2)
32/5
```

This illustrates using assumptions:

```
sage: integral(abs(x), x, 0, 5)
25/2
sage: integral(abs(x), x, 0, a)
integrate(abs(x), x, 0, a)
sage: assume(a>0)
sage: integral(abs(x), x, 0, a)
1/2*a^2
sage: forget()       # forget the assumptions.
```

We integrate and differentiate a huge mess:

```
sage: f = (x^2-1+3*(1+x^2)^(1/3))/(1+x^2)^(2/3)*x/(x^2+2)^2
sage: g = integral(f, x)
sage: h = f - diff(g, x)
```

```
sage: [float(h(i)) for i in range(5)] #random

[0.0,
 -1.1102230246251565e-16,
 -5.5511151231257827e-17,
 -5.5511151231257827e-17,
 -6.9388939039072284e-17]
sage: h.factor()
0
sage: bool(h == 0)
True
```

integrate(*f, *args, **kwds*)

The integral of f.

EXAMPLES:

```
sage: integral(sin(x), x)
-cos(x)
sage: integral(sin(x)^2, x, pi, 123*pi/2)
121/4*pi
sage: integral( sin(x), x, 0, pi)
2
```

We integrate a symbolic function:

```
sage: f(x,y,z) = x*y/z + sin(z)
sage: integral(f, z)
(x, y, z) |--> x*y*log(z) - cos(z)
```

```
sage: var('a,b')
(a, b)
sage: assume(b-a>0)
sage: integral( sin(x), x, a, b)
cos(a) - cos(b)
sage: forget()
```

```
sage: integral(x/(x^3-1), x)
1/3*sqrt(3)*arctan(1/3*(2*x + 1)*sqrt(3)) + 1/3*log(x - 1) - 1/6*log(x^2 + x + 1)
```

```
sage: integral( exp(-x^2), x )
1/2*sqrt(pi)*erf(x)
```

We define the Gaussian, plot and integrate it numerically and symbolically:

```
sage: f(x) = 1/(sqrt(2*pi)) * e^(-x^2/2)
sage: P = plot(f, -4, 4, hue=0.8, thickness=2)
sage: P.show(ymin=0, ymax=0.4)
sage: numerical_integral(f, -4, 4)                    # random output
(0.99993665751633376, 1.1101527003413533e-14)
sage: integrate(f, x)
x |--> 1/2*erf(1/2*sqrt(2)*x)
```

You can have Sage calculate multiple integrals. For example, consider the function $exp(y^2)$ on the region between the lines $x = y$, $x = 1$, and $y = 0$. We find the value of the integral on this region using the command:

```
sage: area = integral(integral(exp(y^2),x,0,y),y,0,1); area
1/2*e - 1/2
sage: float(area)
0.85914091422952255
```

We compute the line integral of $\sin(x)$ along the arc of the curve $x = y^4$ from $(1, -1)$ to $(1, 1)$:

```
sage: t = var('t')
sage: (x,y) = (t^4,t)
sage: (dx,dy) = (diff(x,t), diff(y,t))
sage: integral(sin(x)*dx, t,-1, 1)
0
sage: restore('x,y')    # restore the symbolic variables x and y
```

Sage is unable to do anything with the following integral:

```
sage: integral( exp(-x^2)*log(x), x )
integrate(e^(-x^2)*log(x), x)
```

Sage does not know how to compute this integral either:

```
sage: integral( exp(-x^2)*ln(x), x, 0, oo)
integrate(e^(-x^2)*log(x), x, 0, +Infinity)
```

This definite integral is easy:

```
sage: integral( ln(x)/x, x, 1, 2)
1/2*log(2)^2
```

Sage can't do this elliptic integral (yet):

```
sage: integral(1/sqrt(2*t^4 - 3*t^2 - 2), t, 2, 3)
integrate(1/sqrt(2*t^4 - 3*t^2 - 2), t, 2, 3)
```

A double integral:

```
sage: y = var('y')
sage: integral(integral(x*y^2, x, 0, y), y, -2, 2)
32/5
```

This illustrates using assumptions:

```
sage: integral(abs(x), x, 0, 5)
25/2
sage: integral(abs(x), x, 0, a)
integrate(abs(x), x, 0, a)
sage: assume(a>0)
sage: integral(abs(x), x, 0, a)
1/2*a^2
sage: forget()       # forget the assumptions.
```

We integrate and differentiate a huge mess:

```
sage: f = (x^2-1+3*(1+x^2)^(1/3))/(1+x^2)^(2/3)*x/(x^2+2)^2
sage: g = integral(f, x)
sage: h = f - diff(g, x)
```

```
sage: [float(h(i)) for i in range(5)] #random

[0.0,
 -1.1102230246251565e-16,
 -5.5511151231257827e-17,
 -5.5511151231257827e-17,
 -6.9388939039072284e-17]
sage: h.factor()
0
sage: bool(h == 0)
True
```

lim(*f, dir=None, taylor=False, **argv*)

Return the limit as the variable v approaches a from the given direction.

```
limit(expr, x = a)
limit(expr, x = a, dir='above')
```

INPUT:

- `dir` - (default: None); dir may have the value 'plus' (or 'above') for a limit from above, 'minus' (or 'below') for a limit from below, or may be omitted (implying a two-sided limit is to be computed).
- `taylor` - (default: False); if True, use Taylor series, which allows more integrals to be computed (but may also crash in some obscure cases due to bugs in Maxima).
- `\*\*argv` - 1 named parameter

ALIAS: You can also use lim instead of limit.

EXAMPLES:

```
sage: limit(sin(x)/x, x=0)
1
sage: limit(exp(x), x=oo)
+Infinity
sage: lim(exp(x), x=-oo)
0
```

```
sage: lim(1/x, x=0)
und
sage: limit(sqrt(x^2+x+1)+x, taylor=True, x=-oo)
-1/2
sage: limit((tan(sin(x)) - sin(tan(x)))/x^7, taylor=True, x=0)
1/30
```

Sage does not know how to do this limit (which is 0), so it returns it unevaluated:

```
sage: lim(exp(x^2)*(1-erf(x)), x=infinity)
limit(-e^(x^2)*erf(x) + e^(x^2), x, +Infinity)
```

limit (*f, dir=None, taylor=False, **argv*)

Return the limit as the variable v approaches a from the given direction.

```
limit(expr, x = a)
limit(expr, x = a, dir='above')
```

INPUT:

- `dir` - (default: None); dir may have the value 'plus' (or 'above') for a limit from above, 'minus' (or 'below') for a limit from below, or may be omitted (implying a two-sided limit is to be computed).
- `taylor` - (default: False); if True, use Taylor series, which allows more integrals to be computed (but may also crash in some obscure cases due to bugs in Maxima).
- `\*\*argv` - 1 named parameter

ALIAS: You can also use lim instead of limit.

EXAMPLES:

```
sage: limit(sin(x)/x, x=0)
1
sage: limit(exp(x), x=oo)
+Infinity
sage: lim(exp(x), x=-oo)
0
sage: lim(1/x, x=0)
und
sage: limit(sqrt(x^2+x+1)+x, taylor=True, x=-oo)
-1/2
sage: limit((tan(sin(x)) - sin(tan(x)))/x^7, taylor=True, x=0)
1/30
```

Sage does not know how to do this limit (which is 0), so it returns it unevaluated:

```
sage: lim(exp(x^2)*(1-erf(x)), x=infinity)
limit(-e^(x^2)*erf(x) + e^(x^2), x, +Infinity)
```

simplify (*f*)

Simplify the expression f.

EXAMPLES: We simplify the expression $i + x - x$.

```
sage: f = I + x - x; simplify(f)
I
```

In fact, printing f yields the same thing - i.e., the simplified form.

taylor (*f, v, a, n*)

Expands self in a truncated Taylor or Laurent series in the variable v around the point a, containing terms through $(x-a)^n$.

INPUT:

- v - variable
- a - number
- n - integer

EXAMPLES:

```
sage: var('x,k,n')
(x, k, n)
sage: taylor (sqrt (1 - k^2*sin(x)^2), x, 0, 6)
-1/720*(45*k^6 - 60*k^4 + 16*k^2)*x^6 - 1/24*(3*k^4 - 4*k^2)*x^4 - 1/2*k^2*x^2 + 1
sage: taylor ((x + 1)^n, x, 0, 4)
1/24*(n^4 - 6*n^3 + 11*n^2 - 6*n)*x^4 + 1/6*(n^3 - 3*n^2 + 2*n)*x^3 + 1/2*(n^2 - n)*x^2 + n*x +
```

3.6 A Sample Session using Sympy

In this first part, we do all of the examples in the Sympy tutorial (http://code.google.com/p/sympy/wiki/Tutorial), but using Sage instead of Sympy.

```
sage: a = Rational((1,2))
sage: a
1/2
sage: a*2
1
sage: Rational(2)^50 / Rational(10)^50
1/888178419700125232338905334472656 25
sage: 1.0/2
0.500000000000000
sage: 1/2
1/2
sage: pi^2
pi^2
sage: float(pi)
3.1415926535897931
sage: RealField(200)(pi)
3.14159265358979323846264338327950288419716939937510582097 49
sage: float(pi + exp(1))
5.85987448204883...
sage: oo != 2
True

sage: var('x y')
(x, y)
sage: x + y + x - y
2*x
sage: (x+y)^2
(x + y)^2
sage: ((x+y)^2).expand()
x^2 + 2*x*y + y^2
sage: ((x+y)^2).subs(x=1)
```

```
(y + 1)^2
sage: ((x+y)^2).subs(x=y)
4*y^2

sage: limit(sin(x)/x, x=0)
1
sage: limit(x, x=oo)
+Infinity
sage: limit((5^x + 3^x)^(1/x), x=oo)
5

sage: diff(sin(x), x)
cos(x)
sage: diff(sin(2*x), x)
2*cos(2*x)
sage: diff(tan(x), x)
tan(x)^2 + 1
sage: limit((tan(x+y) - tan(x))/y, y=0)
cos(x)^(-2)
sage: diff(sin(2*x), x, 1)
2*cos(2*x)
sage: diff(sin(2*x), x, 2)
-4*sin(2*x)
sage: diff(sin(2*x), x, 3)
-8*cos(2*x)

sage: cos(x).taylor(x,0,10)
-1/3628800*x^10 + 1/40320*x^8 - 1/720*x^6 + 1/24*x^4 - 1/2*x^2 + 1
sage: (1/cos(x)).taylor(x,0,10)
50521/3628800*x^10 + 277/8064*x^8 + 61/720*x^6 + 5/24*x^4 + 1/2*x^2 + 1

sage: matrix([[1,0], [0,1]])
[1 0]
[0 1]
sage: var('x y')
(x, y)
sage: A = matrix([[1,x], [y,1]])
sage: A
[1 x]
[y 1]
sage: A^2
[x*y + 1     2*x]
[    2*y x*y + 1]
sage: R.<x,y> = QQ[]
sage: A = matrix([[1,x], [y,1]])
sage: print A^10
[x^5*y^5 + 45*x^4*y^4 + 210*x^3*y^3 + 210*x^2*y^2 + 45*x*y + 1     10*x^5*y^4 + 120*x^4*y^3 + 252*x^
[    10*x^4*y^5 + 120*x^3*y^4 + 252*x^2*y^3 + 120*x*y^2 + 10*y x^5*y^5 + 45*x^4*y^4 + 210*x^3*y^3 + 2
sage: var('x y')
(x, y)
```

And here are some actual tests of sympy:

```
sage: from sympy import Symbol, cos, sympify, pprint
sage: from sympy.abc import x

sage: e = sympify(1)/cos(x)**3; e
cos(x)**(-3)
sage: f = e.series(x, 0, 10); f
1 + 3*x**2/2 + 11*x**4/8 + 241*x**6/240 + 8651*x**8/13440 + O(x**10)
```

And the pretty-printer:

```
sage: pprint(e)
       1
    -------
       3
    cos (x)
sage: pprint(f)
           2       4         6          8
        3*x    11*x    241*x    8651*x
    1 + ---- + ----- + ------ + ------- + O(x**10)
         2       8       240       13440
```

And the functionality to convert from sympy format to Sage format:

```
sage: e._sage_()
cos(x)^(-3)
sage: e._sage_().taylor(x._sage_(), 0, 8)
8651/13440*x^8 + 241/240*x^6 + 11/8*x^4 + 3/2*x^2 + 1
sage: f._sage_()
8651/13440*x^8 + 241/240*x^6 + 11/8*x^4 + 3/2*x^2 + 1
```

Mixing SymPy with Sage:

```
sage: import sympy
sage: sympy.sympify(var("y"))+sympy.Symbol("x")
x + y
sage: o = var("omega")
sage: s = sympy.Symbol("x")
sage: t1 = s + o
sage: t2 = o + s
sage: type(t1)
<class 'sympy.core.add.Add'>
sage: type(t2)
<type 'sage.symbolic.expression.Expression'>
sage: t1, t2
(omega + x, omega + x)
sage: e=sympy.sin(var("y"))+sage.all.cos(sympy.Symbol("x"))
sage: type(e)
<class 'sympy.core.add.Add'>
sage: e
cos(x) + sin(y)
sage: e=e._sage_()
sage: type(e)
<type 'sage.symbolic.expression.Expression'>
sage: e
sin(y) + cos(x)
sage: e = sage.all.cos(var("y")**3)**4+var("x")**2
```

```
sage: e = e._sympy_()
sage: e
x**2 + cos(y**3)**4
```

```
sage: a = sympy.Matrix([1, 2, 3])
sage: a[1]
2
```

```
sage: sympify(1.5)
1.50000000000000
sage: sympify(2)
2
sage: sympify(-2)
-2
```

3.7 Calculus Tests and Examples.

Compute the Christoffel symbol.

```
sage: var('r t theta phi')
(r, t, theta, phi)
sage: m = matrix(SR, [[(1-1/r),0,0,0],[0,-(1-1/r)^(-1),0,0],[0,0,-r^2,0],[0,0,0,-r^2*(sin(theta))^2]]
sage: print m
[          -1/r + 1                   0                   0                   0]
[                 0        1/(1/r - 1)                   0                   0]
[                 0                   0              -r^2                   0]
[                 0                   0                   0 -r^2*sin(theta)^2]
```

```
sage: def christoffel(i,j,k,vars,g):
...       s = 0
...       ginv = g^(-1)
...       for l in range(g.nrows()):
...           s = s + (1/2)*ginv[k,l]*(g[j,l].diff(vars[i])+g[i,l].diff(vars[j])-g[i,j].diff(vars[l]))
...       return s
```

```
sage: christoffel(3,3,2, [t,r,theta,phi], m)
-sin(theta)*cos(theta)
sage: X = christoffel(1,1,1,[t,r,theta,phi],m)
sage: X
 1/2/((1/r - 1)*r^2)
sage: X.rational_simplify()
 -1/2/(r^2 - r)
```

Some basic things:

```
sage: f(x,y) = x^3 + sinh(1/y)
sage: f
(x, y) |--> x^3 + sinh(1/y)
sage: f^3
(x, y) |--> (x^3 + sinh(1/y))^3
sage: (f^3).expand()
(x, y) |--> x^9 + 3*x^6*sinh(1/y) + 3*x^3*sinh(1/y)^2 + sinh(1/y)^3
```

A polynomial over a symbolic base ring:

```
sage: R = SR[x]
sage: f = R([1/sqrt(2), 1/(4*sqrt(2))])
sage: f
1/8*sqrt(2)*x + 1/2*sqrt(2)
sage: -f
-1/8*sqrt(2)*x - 1/2*sqrt(2)
sage: (-f).degree()
1
```

A big product. Notice that simplifying simplifies the product further:

```
sage: A = exp(I*pi/5)
sage: b = A*A*A*A*A*A*A*A*A*A
sage: b
1
```

We check a statement made at the beginning of Friedlander and Joshi's book on Distributions:

```
sage: f(x) = sin(x^2)
sage: g(x) = cos(x) + x^3
sage: u = f(x+t) + g(x-t)
sage: u
-(t - x)^3 + sin((t + x)^2) + cos(-t + x)
sage: u.diff(t,2) - u.diff(x,2)
0
```

Restoring variables after they have been turned into functions:

```
sage: x = function('x')
sage: type(x)
<type 'sage.symbolic.function.SFunction'>
sage: x(2/3)
x(2/3)
sage: restore('x')
sage: sin(x).variables()
(x,)
```

MATHEMATICA: Some examples of integration and differentiation taken from some Mathematica docs:

```
sage: var('x n a')
(x, n, a)
sage: diff(x^n, x)        # the output looks funny, but is correct
n*x^(n - 1)
sage: diff(x^2 * log(x+a), x)
2*x*log(a + x) + x^2/(a + x)
sage: derivative(arctan(x), x)
1/(x^2 + 1)
sage: derivative(x^n, x, 3)
(n - 2)*(n - 1)*n*x^(n - 3)
sage: derivative( function('f')(x), x)
D[0](f)(x)
sage: diff( 2*x*f(x^2), x)
4*x^2*D[0](f)(x^2) + 2*f(x^2)
sage: integrate( 1/(x^4 - a^4), x)
1/4*log(-a + x)/a^3 - 1/4*log(a + x)/a^3 - 1/2*arctan(x/a)/a^3
```

```
sage: expand(integrate(log(1-x^2), x))
x*log(-x^2 + 1) - 2*x - log(x - 1) + log(x + 1)
sage: integrate(log(1-x^2)/x, x)
log(-x^2 + 1)*log(x) + 1/2*polylog2(-x^2 + 1)
sage: integrate(exp(1-x^2),x)
1/2*sqrt(pi)*e*erf(x)
sage: integrate(sin(x^2),x)
1/8*((I - 1)*sqrt(2)*erf((1/2*I - 1/2)*sqrt(2)*x) + (I + 1)*sqrt(2)*erf((1/2*I + 1/2)*sqrt(2)*x))*sqr

sage: integrate((1-x^2)^n,x)
integrate((-x^2 + 1)^n, x)
sage: integrate(x^x,x)
integrate(x^x, x)
sage: integrate(1/(x^3+1),x)
1/3*sqrt(3)*arctan(1/3*(2*x - 1)*sqrt(3)) + 1/3*log(x + 1) - 1/6*log(x^2 - x + 1)
sage: integrate(1/(x^3+1), x, 0, 1)
1/9*pi*sqrt(3) + 1/3*log(2)

sage: forget()
sage: c = var('c')
sage: assume(c > 0)
sage: integrate(exp(-c*x^2), x, -oo, oo)
sqrt(pi)/sqrt(c)
sage: forget()
```

The following are a bunch of examples of integrals that Mathematica can do, but Sage currently can't do:

```
sage: integrate(sqrt(x + sqrt(x)), x)     # todo -- mathematica can do this
integrate(sqrt(x + sqrt(x)), x)
sage: integrate(log(x)*exp(-x^2))         # todo -- mathematica can do this
integrate(e^(-x^2)*log(x), x)
```

Todo - Mathematica can do this and gets $\pi^2/15$.

```
sage: integrate(log(1+sqrt(1+4*x)/2)/x, x, 0, 1)  # not tested
[boom!]
Integral is divergent

sage: integrate(ceil(x^2 + floor(x)), x, 0, 5)     # todo: mathematica can do this
integrate(ceil(x^2) + floor(x), x, 0, 5)
```

MAPLE: The basic differentiation and integration examples in the Maple documentation:

```
sage: diff(sin(x), x)
cos(x)
sage: diff(sin(x), y)
0
sage: diff(sin(x), x, 3)
-cos(x)
sage: diff(x*sin(cos(x)), x)
-x*sin(x)*cos(cos(x)) + sin(cos(x))
sage: diff(tan(x), x)
tan(x)^2 + 1
sage: f = function('f'); f
f
```

```
sage: diff(f(x), x)
D[0](f)(x)
sage: diff(f(x,y), x, y)
D[0, 1](f)(x, y)
sage: diff(f(x,y), x, y) - diff(f(x,y), y, x)
0
sage: g = function('g')
sage: var('x y z')
(x, y, z)
sage: diff(g(x,y,z), x,z,z)
D[0, 2, 2](g)(x, y, z)
sage: integrate(sin(x), x)
-cos(x)
sage: integrate(sin(x), x, 0, pi)
2

sage: var('a b')
(a, b)
sage: assume(b-a>0)      # annoying -- maple doesn't require this...
sage: print integrate(sin(x), x, a, b)
                               cos(a) - cos(b)
sage: forget()

sage: integrate( x/(x^3-1), x)
1/3*sqrt(3)*arctan(1/3*(2*x + 1)*sqrt(3)) + 1/3*log(x - 1) - 1/6*log(x^2 + x + 1)
sage: integrate(exp(-x^2), x)
1/2*sqrt(pi)*erf(x)
sage: integrate(exp(-x^2)*log(x), x)       # todo: maple can compute this exactly.
integrate(e^(-x^2)*log(x), x)
sage: f = exp(-x^2)*log(x)
sage: f.nintegral(x, 0, 999)
(-0.87005772672831..., 7.5584...e-10, 567, 0)
sage: integral(1/sqrt(2*t^4 - 3*t^2 - 2), t, 2, 3)      # todo: maple can do this
integrate(1/sqrt(2*t^4 - 3*t^2 - 2), t, 2, 3)
sage: integral(integral(x*y^2, x, 0, y), y, -2, 2)
32/5
```

We verify several standard differentiation rules:

```
sage: function('f, g')
(f, g)
sage: diff(f(t)*g(t),t)
D[0](f)(t)*g(t) + f(t)*D[0](g)(t)
sage: diff(f(t)/g(t), t)
D[0](f)(t)/g(t) - f(t)*D[0](g)(t)/g(t)^2
sage: diff(f(t) + g(t), t)
D[0](f)(t) + D[0](g)(t)
sage: diff(c*f(t), t)
c*D[0](f)(t)
```

3.8 Conversion of symbolic expressions to other types

This module provides routines for converting new symbolic expressions to other types. Primarily, it provides a class `Converter` which will walk the expression tree and make calls to methods overridden by subclasses.

class AlgebraicConverter(*field*)

arithmetic(*ex, operator*)

Convert a symbolic expression to an algebraic number.

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import AlgebraicConverter
sage: f = 2^(1/2)
sage: a = AlgebraicConverter(QQbar)
sage: a.arithmetic(f, f.operator())
1.414213562373095?
```

composition(*ex, operator*)

Coerce to an algebraic number.

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import AlgebraicConverter
sage: a = AlgebraicConverter(QQbar)
sage: a.composition(exp(I*pi/3), exp)
0.500000000000000? + 0.866025403784439?*I
sage: a.composition(sin(pi/5), sin)
0.5877852522924731? + 0.?e-18*I
```

pyobject(*ex, obj*)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import AlgebraicConverter
sage: a = AlgebraicConverter(QQbar)
sage: f = SR(2)
sage: a.pyobject(f, f.pyobject())
2
sage: _.parent()
Algebraic Field
```

class Converter(*use_fake_div=False*)

arithmetic(*ex, operator*)

The input to this method is a symbolic expression and the infix operator corresponding to that expression. Typically, one will convert all of the arguments and then perform the operation afterward.

TESTS:

```
sage: from sage.symbolic.expression_conversions import Converter
sage: f = x + 2
sage: Converter().arithmetic(f, f.operator())
...
NotImplementedError: arithmetic
```

composition(*ex, operator*)

The input to this method is a symbolic expression and its operator. This method will get called when you have a symbolic function application.

TESTS:

```
sage: from sage.symbolic.expression_conversions import Converter
sage: f = sin(2)
sage: Converter().composition(f, f.operator())
```

```
...
NotImplementedError: composition
```

derivative(*ex, operator*)

The input to this method is a symbolic expression which corresponds to a relation.

TESTS:

```
sage: from sage.symbolic.expression_conversions import Converter
sage: a = function('f', x).diff(x); a
D[0](f)(x)
sage: Converter().derivative(a, a.operator())
...
NotImplementedError: derivative
```

get_fake_div(*ex*)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import Converter
sage: c = Converter(use_fake_div=True)
sage: c.get_fake_div(sin(x)/x)
FakeExpression([sin(x), x], <built-in function div>)
sage: c.get_fake_div(-1*sin(x))
FakeExpression([sin(x)], <built-in function neg>)
sage: c.get_fake_div(-x)
FakeExpression([x], <built-in function neg>)
sage: c.get_fake_div((2*x^3+2*x-1)/((x-2)*(x+1)))
FakeExpression([2*x^3 + 2*x - 1, FakeExpression([x - 2, x + 1], <built-in function mul>)], <
```

pyobject(*ex, obj*)

The input to this method is the result of calling `pyobject()` on a symbolic expression.

Note: Note that if a constant such as `pi` is encountered in the expression tree, its corresponding pyobject which is an instance of `sage.symbolic.constants.Pi` will be passed into this method. One cannot do arithmetic using such an object.

TESTS:

```
sage: from sage.symbolic.expression_conversions import Converter
sage: f = SR(1)
sage: Converter().pyobject(f, f.pyobject())
...
NotImplementedError: pyobject
```

relation(*ex, operator*)

The input to this method is a symbolic expression which corresponds to a relation.

TESTS:

```
sage: from sage.symbolic.expression_conversions import Converter
sage: import operator
sage: Converter().relation(x==3, operator.eq)
...
NotImplementedError: relation
sage: Converter().relation(x==3, operator.lt)
...
NotImplementedError: relation
```

symbol(*ex*)

The input to this method is a symbolic expression which corresponds to a single variable. For example, this method could be used to return a generator for a polynomial ring.

TESTS:

```
sage: from sage.symbolic.expression_conversions import Converter
sage: Converter().symbol(x)
...
NotImplementedError: symbol
```

class FakeExpression(*operands, operator*)

Pynac represents x/y as xy^{-1}. Often, tree-walkers would prefer to see divisions instead of multiplications and negative exponents. To allow for this (since Pynac internally doesn't have division at all), there is a possibility to pass use_fake_div=True; this will rewrite an Expression into a mixture of Expression and FakeExpression nodes, where the FakeExpression nodes are used to represent divisions. These nodes are intended to act sufficiently like Expression nodes that tree-walkers won't care about the difference.

operands()

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import FakeExpression
sage: import operator; x,y = var('x,y')
sage: f = FakeExpression([x, y], operator.div)
sage: f.operands()
[x, y]
```

operator()

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import FakeExpression
sage: import operator; x,y = var('x,y')
sage: f = FakeExpression([x, y], operator.div)
sage: f.operator()
<built-in function div>
```

pyobject()

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import FakeExpression
sage: import operator; x,y = var('x,y')
sage: f = FakeExpression([x, y], operator.div)
sage: f.pyobject()
...
TypeError: self must be a numeric expression
```

class FastCallableConverter(*ex, etb*)

arithmetic(*ex, operator*)

EXAMPLES:

```
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
sage: etb = ExpressionTreeBuilder(vars=['x','y'])
sage: var('x,y')
(x, y)
sage: (x+y)._fast_callable_(etb)
add(v_0, v_1)
sage: (-x)._fast_callable_(etb)
neg(v_0)
sage: (x+y+x^2)._fast_callable_(etb)
add(add(ipow(v_0, 2), v_0), v_1)
```

TESTS:

```
sage: etb = ExpressionTreeBuilder(vars=['x'], domain=RDF)
sage: (x^7)._fast_callable_(etb)
ipow(v_0, 7)
```

composition(*ex, function*)

Given an ExpressionTreeBuilder, return an Expression representing this value.

EXAMPLES:

```
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
sage: etb = ExpressionTreeBuilder(vars=['x','y'])
sage: x,y = var('x,y')
sage: sin(sqrt(x+y))._fast_callable_(etb)
sin(sqrt(add(v_0, v_1)))
```

pyobject(*ex, obj*)

EXAMPLES:

```
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
sage: etb = ExpressionTreeBuilder(vars=['x'])
sage: pi._fast_callable_(etb)
pi
sage: etb = ExpressionTreeBuilder(vars=['x'], domain=RDF)
sage: pi._fast_callable_(etb)
3.14159265359
```

relation(*ex, operator*)

EXAMPLES:

```
sage: ff = fast_callable(x == 2, vars=['x'])
sage: ff(2)
0
sage: ff(4)
2
sage: ff = fast_callable(x < 2, vars=['x'])
...
NotImplementedError
```

symbol(*ex*)

Given an ExpressionTreeBuilder, return an Expression representing this value.

EXAMPLES:

```
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
sage: etb = ExpressionTreeBuilder(vars=['x','y'])
sage: x, y, z = var('x,y,z')
sage: x._fast_callable_(etb)
v_0
sage: y._fast_callable_(etb)
v_1
sage: z._fast_callable_(etb)
...
ValueError: Variable 'z' not found
```

class **FastFloatConverter**(*ex, *vars*)

arithmetic(*ex, operator*)

EXAMPLES:

```
sage: x,y = var('x,y')
sage: f = x*x-y
```

```
sage: ff = f._fast_float_('x','y')
sage: ff(2,3)
1.0

sage: a = x + 2*y
sage: f = a._fast_float_('x', 'y')
sage: f(1,0)
1.0
sage: f(0,1)
2.0

sage: f = sqrt(x)._fast_float_('x'); f.op_list()
['load 0', 'call sqrt(1)']

sage: f = (1/2*x)._fast_float_('x'); f.op_list()
['load 0', 'push 0.5', 'mul']
```

composition(*ex, operator*)

EXAMPLES:

```
sage: f = sqrt(x)._fast_float_('x')
sage: f(2)
1.41421356237309...
sage: y = var('y')
sage: f = sqrt(x+y)._fast_float_('x', 'y')
sage: f(1,1)
1.41421356237309...

sage: f = sqrt(x+2*y)._fast_float_('x', 'y')
sage: f(2,0)
1.41421356237309...
sage: f(0,1)
1.41421356237309...
```

pyobject(*ex, obj*)

EXAMPLES:

```
sage: f = SR(2)._fast_float_()
sage: f(3)
2.0
```

relation(*ex, operator*)

EXAMPLES:

```
sage: ff = fast_float(x == 2, 'x')
sage: ff(2)
0.0
sage: ff(4)
2.0
sage: ff = fast_float(x < 2, 'x')
...
NotImplementedError
```

symbol(*ex*)

EXAMPLES:

```
sage: f = x._fast_float_('x', 'y')
sage: f(1,2)
1.0
sage: f = x._fast_float_('y', 'x')
```

```
sage: f(1,2)
2.0
```

class **InterfaceInit**(*interface*)

arithmetic(*ex, operator*)
EXAMPLES:

```
sage: import operator
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: m.arithmetic(x+2, operator.add)
'(x)+(2)'
```

composition(*ex, operator*)
EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: m.composition(sin(x), sin)
'sin(x)'
sage: m.composition(ceil(x), ceil)
'ceiling(x)'

sage: m = InterfaceInit(mathematica)
sage: m.composition(sin(x), sin)
'Sin[x]'
```

derivative(*ex, operator*)
EXAMPLES:

```
sage: import operator
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: a = function('f', x).diff(x); a
D[0](f)(x)
sage: print m.derivative(a, a.operator())
diff('f(x), x, 1)
sage: b = function('f', x).diff(x).diff(x)
sage: print m.derivative(b, b.operator())
diff('f(x), x, 2)
```

pyobject(*ex, obj*)
EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: ii = InterfaceInit(gp)
sage: f = 2+I
sage: ii.pyobject(f, f.pyobject())
'I + 2'

sage: ii.pyobject(SR(2), 2)
'2'

sage: ii.pyobject(pi, pi.pyobject())
'Pi'
```

relation(*ex, operator*)
EXAMPLES:

```
sage: import operator
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: m.relation(x==3, operator.eq)
'x = 3'
sage: m.relation(x==3, operator.lt)
'x < 3'
```

symbol(*ex*)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: m.symbol(x)
'x'
```

class **PolynomialConverter**(*ex, base_ring=None, ring=None*)

arithmetic(*ex, operator*)

EXAMPLES:

```
sage: import operator
sage: from sage.symbolic.expression_conversions import PolynomialConverter

sage: x, y = var('x, y')
sage: p = PolynomialConverter(x, base_ring=RR)
sage: p.arithmetic(pi+e, operator.add)
5.85987448204884
sage: p.arithmetic(x^2, operator.pow)
1.00000000000000*x^2

sage: p = PolynomialConverter(x+y, base_ring=RR)
sage: p.arithmetic(x*y+y^2, operator.add)
x*y + y^2
```

composition(*ex, operator*)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import PolynomialConverter
sage: a = sin(2)
sage: p = PolynomialConverter(a*x, base_ring=RR)
sage: p.composition(a, a.operator())
0.909297426825682
```

pyobject(*ex, obj*)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import PolynomialConverter
sage: p = PolynomialConverter(x, base_ring=QQ)
sage: f = SR(2)
sage: p.pyobject(f, f.pyobject())
2
sage: _.parent()
Rational Field
```

relation(*ex, op*)

EXAMPLES:

```
sage: import operator
sage: from sage.symbolic.expression_conversions import PolynomialConverter
```

```
sage: x, y = var('x, y')
sage: p = PolynomialConverter(x, base_ring=RR)

sage: p.relation(x==3, operator.eq)
1.00000000000000*x - 3.00000000000000
sage: p.relation(x==3, operator.lt)
...
ValueError: Unable to represent as a polynomial

sage: p = PolynomialConverter(x - y, base_ring=QQ)
sage: p.relation(x^2 - y^3 + 1 == x^3, operator.eq)
-x^3 - y^3 + x^2 + 1
```

symbol(*ex*)

Returns a variable in the polynomial ring.

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import PolynomialConverter
sage: p = PolynomialConverter(x, base_ring=QQ)
sage: p.symbol(x)
x
sage: _.parent()
Univariate Polynomial Ring in x over Rational Field
```

class **RingConverter**(*R*, *subs_dict=None*)

arithmetic(*ex*, *operator*)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import RingConverter
sage: P.<z> = ZZ[]
sage: R = RingConverter(P, subs_dict={x:z})
sage: a = 2*x^2 + x + 3
sage: R(a)
2*z^2 + z + 3
```

composition(*ex*, *operator*)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import RingConverter
sage: R = RingConverter(RIF)
sage: R(cos(2))
-0.4161468365471424?
```

pyobject(*ex*, *obj*)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import RingConverter
sage: R = RingConverter(RIF)
sage: R(SR(5/2))
2.5000000000000000?
```

symbol(*ex*)

All symbols appearing in the expression must appear in *subs_dict* in order for the conversion to be successful.

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import RingConverter
sage: R = RingConverter(RIF, subs_dict={x:2})
sage: R(x+pi)
5.141592653589794?

sage: R = RingConverter(RIF)
sage: R(x+pi)
...
TypeError
```

class SubstituteFunction (*ex, original, new*)

arithmetic (*ex, operator*)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import SubstituteFunction
sage: foo = function('foo'); bar = function('bar')
sage: s = SubstituteFunction(foo(x), foo, bar)
sage: f = x*foo(x) + pi/foo(x)
sage: s.arithmetic(f, f.operator())
x*bar(x) + pi/bar(x)
```

composition (*ex, operator*)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import SubstituteFunction
sage: foo = function('foo'); bar = function('bar')
sage: s = SubstituteFunction(foo(x), foo, bar)
sage: f = foo(x)
sage: s.composition(f, f.operator())
bar(x)
sage: f = foo(foo(x))
sage: s.composition(f, f.operator())
bar(bar(x))
sage: f = sin(foo(x))
sage: s.composition(f, f.operator())
sin(bar(x))
sage: f = foo(sin(x))
sage: s.composition(f, f.operator())
bar(sin(x))
```

derivative (*ex, operator*)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import SubstituteFunction
sage: foo = function('foo'); bar = function('bar')
sage: s = SubstituteFunction(foo(x), foo, bar)
sage: f = foo(x).diff(x)
sage: s.derivative(f, f.operator())
D[0](bar)(x)
```

pyobject (*ex, obj*)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import SubstituteFunction
sage: foo = function('foo'); bar = function('bar')
sage: s = SubstituteFunction(foo(x), foo, bar)
sage: f = SR(2)
sage: s.pyobject(f, f.pyobject())
```

```
2
sage: _.parent()
Symbolic Ring
```

relation(*ex, operator*)
EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import SubstituteFunction
sage: foo = function('foo'); bar = function('bar')
sage: s = SubstituteFunction(foo(x), foo, bar)
sage: eq = foo(x) == x
sage: s.relation(eq, eq.operator())
bar(x) == x
```

symbol(*ex*)
EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import SubstituteFunction
sage: foo = function('foo'); bar = function('bar')
sage: s = SubstituteFunction(foo(x), foo, bar)
sage: s.symbol(x)
x
```

class **SympyConverter**(*use_fake_div=False*)
Converts any expression to SymPy.

EXAMPLE:

```
sage: import sympy
sage: var('x,y')
(x, y)
sage: f = exp(x^2) - arcsin(pi+x)/y
sage: f._sympy_()
-asin(pi + x)/y + exp(x**2)
sage: _._sage_()
-arcsin(pi + x)/y + e^(x^2)

sage: sympy.sympify(x) # indirect doctest
x
```

arithmetic(*ex, operator*)
EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import SympyConverter
sage: s = SympyConverter()
sage: f = x + 2
sage: s.arithmetic(f, f.operator())
2 + x
```

composition(*ex, operator*)
EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import SympyConverter
sage: s = SympyConverter()
sage: f = sin(2)
sage: s.composition(f, f.operator())
sin(2)
sage: type(_)
sin
sage: f = arcsin(2)
```

```
sage: s.composition(f, f.operator())
asin(2)
```

pyobject(*ex*, *obj*)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import SympyConverter
sage: s = SympyConverter()
sage: f = SR(2)
sage: s.pyobject(f, f.pyobject())
2
sage: type(_)
<class 'sympy.core.numbers.Integer'>
```

symbol(*ex*)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import SympyConverter
sage: s = SympyConverter()
sage: s.symbol(x)
x
sage: type(_)
<class 'sympy.core.symbol.Symbol'>
```

algebraic(*ex*, *field*)

Returns the symbolic expression *ex* as a element of the algebraic field *field*.

EXAMPLES:

```
sage: a = SR(5/6)
sage: AA(a)
5/6
sage: type(AA(a))
<class 'sage.rings.qqbar.AlgebraicReal'>
sage: QQbar(a)
5/6
sage: type(QQbar(a))
<class 'sage.rings.qqbar.AlgebraicNumber'>
sage: QQbar(i)
1*I
sage: AA(golden_ratio)
1.618033988749895?
sage: QQbar(golden_ratio)
1.618033988749895?
sage: QQbar(sin(pi/3))
0.866025403784439?

sage: QQbar(sqrt(2) + sqrt(8))
4.242640687119285?
sage: AA(sqrt(2)) ^ 4) == 4
True
sage: AA(-golden_ratio)
-1.618033988749895?
sage: QQbar((2*I)^(1/2))
1 + 1*I
sage: QQbar(e^(pi*I/3))
0.500000000000000? + 0.866025403784439?*I

sage: AA(x*sin(0))
```

```
0
sage: QQbar(x*sin(0))
0
```

fast_callable(*ex, etb*)

Given an ExpressionTreeBuilder *etb*, return an Expression representing the symbolic expression *ex*.

EXAMPLES:

```
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
sage: etb = ExpressionTreeBuilder(vars=['x','y'])
sage: x,y = var('x,y')
sage: f = y+2*x^2
sage: f._fast_callable_(etb)
add(mul(ipow(v_0, 2), 2), v_1)

sage: f = (2*x^3+2*x-1)/((x-2)*(x+1))
sage: f._fast_callable_(etb)
div(add(add(mul(ipow(v_0, 3), 2), mul(v_0, 2)), -1), mul(add(v_0, -2), add(v_0, 1)))
```

fast_float(*ex, *vars*)

Returns an object which provides fast floating point evaluation of the symbolic expression *ex*.

See `sage.ext.fast_eval` for more information.

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import fast_float
sage: f = sqrt(x+1)
sage: ff = fast_float(f, 'x')
sage: ff(1.0)
1.4142135623730951
```

polynomial(*ex, base_ring=None, ring=None*)

Returns a polynomial from the symbolic expression *ex*. Either a base ring *base_ring* or a polynomial ring *ring* can be specified for the parent of result. If just a base ring is given, then the variables of the base ring will be the variables of the expression *ex*.

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import polynomial
sage: f = x^2 + 2
sage: polynomial(f, base_ring=QQ)
x^2 + 2
sage: _.parent()
Univariate Polynomial Ring in x over Rational Field

sage: polynomial(f, ring=QQ['x,y'])
x^2 + 2
sage: _.parent()
Multivariate Polynomial Ring in x, y over Rational Field

sage: x, y = var('x, y')
sage: polynomial(x + y^2, ring=QQ['x,y'])
y^2 + x
sage: _.parent()
Multivariate Polynomial Ring in x, y over Rational Field
```

The polynomials can have arbitrary (constant) coefficients so long as they coerce into the base ring:

```
sage: polynomial(2^sin(2)*x^2 + exp(3), base_ring=RR)
1.87813065119873*x^2 + 20.0855369231877
```

3.9 Further examples from Wester's paper

These are all the problems at http://yacas.sourceforge.net/essaysmanual.html

They come from the 1994 paper "Review of CAS mathematical capabilities", by Michael Wester, who put forward 123 problems that a reasonable computer algebra system should be able to solve and tested the then current versions of various commercial CAS on this list. Sage can do most of the problems natively now, i.e., with no explicit calls to maxima or other systems.

```
sage: factorial(50)
30414093201713378043612608166064768844377641568960512000000000000
sage: factor(factorial(50))
2^47 * 3^22 * 5^12 * 7^8 * 11^4 * 13^3 * 17^2 * 19^2 * 23^2 * 29 * 31 * 37 * 41 * 43 * 47
```

```
sage: # 1/2+...+1/10 = 4861/2520
sage: sum(1/n for n in range(2,10+1)) == 4861/2520
True
```

```
sage: # Evaluate  e^(Pi*Sqrt(163)) to 50 decimal digits
sage: a = e^(pi*sqrt(163)); a
e^(pi*sqrt(163))
sage: print RealField(150)(a)

```

CHAPTER

FOUR

2D GRAPHICS

4.1 2D Plotting

Sage provides extensive 2D plotting functionality. The underlying rendering is done using the matplotlib Python library.

The following graphics primitives are supported:

- arrow - an arrow from a min point to a max point.
- circle - a circle with given radius
- disk - a filled disk (i.e. a sector or wedge of a circle)
- line - a line determined by a sequence of points (this need not be straight!)
- point - a point
- text - some text
- polygon - a filled polygon

The following plotting functions are supported:

- plot - plot of a function or other Sage object (e.g., elliptic curve).
- parametric_plot
- polar_plot
- list_plot
- bar_chart
- contour_plot
- plot_vector_field
- matrix_plot
- graphics_array

The following miscellaneous Graphics functions are included:

- Graphics

- is_Graphics
- rgbcolor
- hue

Type ? after each primitive in Sage for help and examples.

EXAMPLES: We construct a plot involving several graphics objects:

```
sage: G = plot(cos, -5, 5, thickness=5, rgbcolor=(0.5,1,0.5))
sage: P = polygon([[1,2], [5,6], [5,0]], rgbcolor=(1,0,0))
sage: P   # show it
```

We draw a circle and a curve:

```
sage: circle((1,1), 1) + plot(x^2, (0,5))
```

Notice that the above circle is not round, because the aspect ratio of the coordinate system is not 1:1. The `aspect_ratio` option to show allows us to fix this:

```
sage: show(circle((1,1), 1) + plot(x^2, (0,5)), aspect_ratio=1)
```

With an aspect ratio of 2 the circle is squashed half way down (it looks twice as wide as it does tall):

```
sage: show(circle((1,1), 1) + plot(x^2, (0,5)), aspect_ratio=2)
```

Use figsize to set the actual aspect ratio of the rendered image (i.e., of the frame). For example, this image is twice as many pixels wide as it is tall:

```
sage: show(circle((1,1), 1) + plot(x^2, (0,5)), figsize=[8,4])
```

Next we construct the reflection of the above polygon about the y-axis by iterating over the list of first-coordinates of the first graphic element of P (which is the actual Polygon; note that P is a Graphics object, which consists of a single polygon):

```
sage: Q = polygon([(-x,y) for x,y in P[0]], rgbcolor=(0,0,1))
sage: Q   # show it
```

We combine together different graphics objects using "+":

```
sage: H = G + P + Q
sage: print H
Graphics object consisting of 3 graphics primitives
sage: type(H)
<class 'sage.plot.plot.Graphics'>
sage: H[1]
Polygon defined by 3 points
sage: list(H[1])
[(1.0, 2.0), (5.0, 6.0), (5.0, 0.0)]
sage: H       # show it
```

We can put text in a graph:

```
sage: L = [[cos(pi*i/100)^3,sin(pi*i/100)] for i in range(200)]
sage: p = line(L, rgbcolor=(1/4,1/8,3/4))
sage: t = text('A Bulb', (1.5, 0.25))
sage: x = text('x axis', (1.5,-0.2))
sage: y = text('y axis', (0.4,0.9))
sage: g = p+t+x+y
sage: g.show(xmin=-1.5, xmax=2, ymin=-1, ymax=1)
```

We plot the Riemann zeta function along the critical line and see the first few zeros:

```
sage: i = CDF.0      # define i this way for maximum speed.
sage: p1 = plot(lambda t: arg(zeta(0.5+t*i)), 1,27,rgbcolor=(0.8,0,0))
sage: p2 = plot(lambda t: abs(zeta(0.5+t*i)), 1,27,rgbcolor=hue(0.7))
sage: print p1 + p2
Graphics object consisting of 2 graphics primitives
sage: p1 + p2    # display it
```

Many concentric circles shrinking toward the origin:

```
sage: show(sum(circle((i,0), i, hue=sin(i/10)) for i in [10,9.9,..,0]), aspect_ratio=1)
```

Here is a pretty graph:

```
sage: g = Graphics()
sage: for i in range(60):
...     p = polygon([(i*cos(i),i*sin(i)), (0,i), (i,0)],\
...                 rgbcolor=hue(i/40+0.4), alpha=0.2)
...     g = g + p
...
sage: g.show(dpi=200, axes=False)
```

Another graph:

```
sage: x = var('x')
sage: P = plot(sin(x)/x, -4,4, rgbcolor=(0,0,1)) + \
...       plot(x*cos(x), -4,4, rgbcolor=(1,0,0)) + \
...       plot(tan(x),-4,4,rgbcolor=(0,1,0))
...
sage: P.show(ymin=-pi,ymax=pi)
```

PYX EXAMPLES: These are some examples of plots similar to some of the plots in the PyX (http://pyx.sourceforge.net) documentation:

Symbolline:

```
sage: y(x) = x*sin(x^2)
sage: v = [(x, y(x)) for x in [-3,-2.95,..,3]]
sage: show(points(v, rgbcolor=(0.2,0.6, 0.1), pointsize=30) + plot(spline(v), -3.1, 3))
```

Cycliclink:

```
sage: x = var('x')
sage: g1 = plot(cos(20*x)*exp(-2*x), 0, 1)
sage: g2 = plot(2*exp(-30*x) - exp(-3*x), 0, 1)
sage: show(graphics_array([g1, g2], 2, 1), xmin=0)
```

Pi Axis: In the PyX manual, the point of this example is to show labeling the X-axis using rational multiples of Pi. Sage currently has no support for controlling how the ticks on the x and y axes are labeled, so this is really a bad example:

```
sage: g1 = plot(sin(x), 0, 2*pi)
sage: g2 = plot(cos(x), 0, 2*pi, linestyle = "--")
sage: g1 + g2     # show their sum
```

An illustration of integration:

```
sage: f(x) = (x-3)*(x-5)*(x-7)+40
sage: P = line([(2,0),(2,f(2))], rgbcolor=(0,0,0))
sage: P += line([(8,0),(8,f(8))], rgbcolor=(0,0,0))
sage: P += polygon([(2,0),(2,f(2))] + [(x, f(x)) for x in [2,2.1,..,8]] + [(8,0),(2,0)],  rgbcolor=(
sage: P += text("$\\int_{a}^b f(x) dx$", (5, 20), fontsize=16, rgbcolor=(0,0,0))
sage: P += plot(f, 1, 8.5, thickness=3)
sage: P     # show the result
```

NUMERICAL PLOTTING:

Sage also provides 2D plotting with an interface that is a likely very familiar to people doing numerical computation. For example,

```
sage: from pylab import *
sage: t = arange(0.0, 2.0, 0.01)
sage: s = sin(2*pi*t)
sage: P = plot(t, s, linewidth=1.0)
sage: xl = xlabel('time (s)')
sage: yl = ylabel('voltage (mV)')
sage: t = title('About as simple as it gets, folks')
sage: grid(True)
sage: savefig('sage.png')
```

Since the above overwrites many Sage plotting functions, we reset the state of Sage, so that the examples below work!

```
sage: reset()
```

See http://matplotlib.sourceforge.net for complete documentation about how to use Matplotlib.

TESTS: We test dumping and loading a plot.

```
sage: p = plot(sin(x), (x, 0,2*pi))
sage: Q = loads(dumps(p))
```

AUTHORS:

- Alex Clemesha and William Stein (2006-04-10): initial version
- David Joyner: examples
- Alex Clemesha (2006-05-04) major update
- Willaim Stein (2006-05-29): fine tuning, bug fixes, better server integration
- William Stein (2006-07-01): misc polish
- Alex Clemesha (2006-09-29): added contour_plot, frame axes, misc polishing

- Robert Miller (2006-10-30): tuning, NetworkX primitive
- Alex Clemesha (2006-11-25): added plot_vector_field, matrix_plot, arrow, bar_chart, Axes class usage (see axes.py)
- Bobby Moretti and William Stein (2008-01): Change plot to specify ranges using the (varname, min, max) notation.
- William Stein (2008-01-19): raised the documentation coverage from a miserable 12 percent to a 'wopping' 35 percent, and fixed and clarified numerous small issues.

class Graphics()

The Graphics object is an empty list of graphics objects It is useful to use this object when intializing a for loop where different graphics object will be added to the empty object.

EXAMPLES:

```
sage: G = Graphics(); print G
Graphics object consisting of 0 graphics primitives
sage: c = circle((1,1), 1)
sage: G+=c; print G
Graphics object consisting of 1 graphics primitive
```

Here we make a graphic of embedded isosceles triangles, coloring each one with a different color as we go:

```
sage: h=10; c=0.4; p=0.1;
sage: G = Graphics()
sage: for x in srange(1,h+1):
...         l = [[0,x*sqrt(3)],[-x/2,-x*sqrt(3)/2],[x/2,-x*sqrt(3)/2],[0,x*sqrt(3)]]
...         G+=line(l,rgbcolor=hue(c + p*(x/h)))
sage: G.show(figsize=[5,5])
```

add_primitive(*primitive*)

Adds a primitive to this graphics object.

aspect_ratio()

Get the current aspect ratio.

OUTPUT: either None if the aspect ratio hasn't been set or a positive float

EXAMPLES:

```
sage: P = circle((1,1), 1)
sage: P.aspect_ratio() is None
True
sage: P.set_aspect_ratio(2)
sage: P.aspect_ratio()
2.0
```

axes(*show=None*)

Set whether or not the x and y axes are shown by default.

INPUT:

- `show` - bool

If called with no input, return the current axes setting.

EXAMPLES:

```
sage: L = line([(1,2), (3,-4), (2, 5), (1,2)])
```

By default the axes are displayed.

```
sage: L.axes()
True
```

But we turn them off, and verify that they are off

```
sage: L.axes(False)
sage: L.axes()
False
```

Displaying L now shows a triangle but no axes.

```
sage: L
```

axes_color(*c=None*)

Set the axes color.

If called with no input, return the current axes_color setting.

INPUT:

- c - an rgb color 3-tuple, where each tuple entry is a float between 0 and 1

EXAMPLES: We create a line, which has like everything a default axes color of black.

```
sage: L = line([(1,2), (3,-4), (2, 5), (1,2)])
sage: L.axes_color()
(0, 0, 0)
```

We change the axes color to red and verify the change.

```
sage: L.axes_color((1,0,0))
sage: L.axes_color()
(1.0, 0.0, 0.0)
```

When we display the plot, we'll see a blue triangle and bright red axes.

```
sage: L
```

axes_label_color(*c=None*)

Set the color of the axes labels.

The axes labels are placed at the edge of the x and y axes, and are not on by default (use the `axes_labels` command to set them; see the example below). This function just changes their color.

INPUT:

- c - an rgb 3-tuple of numbers between 0 and 1

If called with no input, return the current axes_label_color setting.

EXAMPLES: We create a plot, which by default has axes label color black.

```
sage: p = plot(sin, (-1,1))
sage: p.axes_label_color()
(0, 0, 0)
```

We change the labels to be red, and confirm this:

```
sage: p.axes_label_color((1,0,0))
sage: p.axes_label_color()
(1.0, 0.0, 0.0)
```

We set labels, since otherwise we won't see anything.

```
sage: p.axes_labels(['$x$ axis', '$y$ axis'])
```

In the plot below, notice that the labels are red:

```
sage: p
```

axes_labels(*l=None*)

Set the axes labels.

INPUT:

- `l` - (default: None) a list of two strings or None

OUTPUT: a 2-tuple of strings

If l is None, returns the current `axes_labels`, which is itself by default None. The default labels are both empty.

EXAMPLES: We create a plot and put x and y axes labels on it.

```
sage: p = plot(sin(x), (x, 0, 10))
sage: p.axes_labels(['x','y'])
sage: p.axes_labels()
('x', 'y')
```

Now when you plot p, you see x and y axes labels:

```
sage: p
```

axes_range(*xmin=None, xmax=None, ymin=None, ymax=None*)

Set the ranges of the x and y axes.

INPUT:

- `xmin, xmax, ymin, ymax` - floats

EXAMPLES:

```
sage: L = line([(1,2), (3,-4), (2, 5), (1,2)])
sage: L.set_axes_range(-1, 20, 0, 2)
sage: d = L.get_axes_range()
sage: d['xmin'], d['xmax'], d['ymin'], d['ymax']
(-1.0, 20.0, 0.0, 2.0)
```

axes_width(*w=None*)

Set the axes width. Use this to draw a plot with really fat or really thin axes.

INPUT:

- `w` - a float

If called with no input, return the current `axes_width` setting.

EXAMPLE: We create a plot, see the default axes width (with funny Python float rounding), then reset the width to 10 (very fat).

```
sage: p = plot(cos, (-3,3))
sage: p.axes_width()
0.80000000000000004
sage: p.axes_width(10)
sage: p.axes_width()
10.0
```

Finally we plot the result, which is a graph with very fat axes.

```
sage: p
```

fontsize(*s=None*)

Set the font size of axes labels and tick marks.

INPUT:

- `s` - integer, a font size in points.

If called with no input, return the current fontsize.

EXAMPLES:

```
sage: L = line([(1,2), (3,-4), (2, 5), (1,2)])
sage: L.fontsize()
10
sage: L.fontsize(20)
sage: L.fontsize()
20
```

All the numbers on the axes will be very large in this plot:

```
sage: L
```

get_axes_range()

Returns a dictionary of the range of the axes for this graphics object. This is fall back to the ranges in get_minmax_data() for any value which the user has not explicitly set.

> **Warning:** Changing the dictionary returned by this function does not change the axes range for this object. To do that, use the set_axes_range() method.

EXAMPLES:

```
sage: L = line([(1,2), (3,-4), (2, 5), (1,2)])
sage: list(sorted(L.get_axes_range().items()))
[('xmax', 3.0), ('xmin', 1.0), ('ymax', 5.0), ('ymin', -4.0)]
sage: L.set_axes_range(xmin=-1)
sage: list(sorted(L.get_axes_range().items()))
[('xmax', 3.0), ('xmin', -1.0), ('ymax', 5.0), ('ymin', -4.0)]
```

get_minmax_data()

Return a dictionary whose keys give the xmin, xmax, ymin, and ymax data for this graphic.

> **Warning:** The returned dictionary is mutable, but changing it does not change the xmin/xmax/ymin/ymax data. The minmax data is a function of the primitives which make up this Graphics object. To change the range of the axes, call methods xmin(), xmax(), ymin(), ymax(), or set_axes_range().

EXAMPLES:

```
sage: g = line([(-1,1), (3,2)])
sage: list(sorted(g.get_minmax_data().items()))
[('xmax', 3.0), ('xmin', -1.0), ('ymax', 2.0), ('ymin', 1.0)]
```

Note that changing ymax doesn't change the output of get_minmax_data:

```
sage: g.ymax(10)
sage: list(sorted(g.get_minmax_data().items()))
[('xmax', 3.0), ('xmin', -1.0), ('ymax', 2.0), ('ymin', 1.0)]
```

plot(**args, **kwds*)

Draw a 2d plot this graphics object, which just returns this object since this is already a 2d graphics object.

EXAMPLES:

```
sage: S = circle((0,0), 2)
sage: S.plot() is S
True
```

plot3d(*z=0, **kwds*)

Returns an embedding of this 2D plot into the xy-plane of 3D space, as a 3D plot object. An optional parameter z can be given to specify the z-coordinate.

EXAMPLES:

```
sage: sum([plot(z*sin(x), 0, 10).plot3d(z) for z in range(6)]) #long
```

save(*filename=None, xmin=None, xmax=None, ymin=None, ymax=None, figsize=(6, 3.7082039324993699), figure=None, sub=None, savenow=True, dpi=100, axes=None, axes_labels=None, fontsize=None, frame=False, verify=True, aspect_ratio=None, gridlines=None, gridlinesstyle=None, vgridlinesstyle=None, hgridlinesstyle=None*)

Save the graphics to an image file of type: PNG, PS, EPS, SVG, SOBJ, depending on the file extension you give the filename. Extension types can be: `.png`, `.ps`, `.eps`, `.svg`, and `.sobj` (for a Sage object you can load later).

EXAMPLES:

```
sage: c = circle((1,1),1,rgbcolor=(1,0,0))
sage: c.show(xmin=-1,xmax=3,ymin=-1,ymax=3)
```

To correct the apect ratio of certain graphics, it is necessary to show with a '`figsize`' of square dimensions.

```
sage: c.show(figsize=[5,5],xmin=-1,xmax=3,ymin=-1,ymax=3)

sage: point((-1,1),pointsize=30, rgbcolor=(1,0,0))
```

set_aspect_ratio(*ratio*)

Set the aspect ratio.

INPUT:

- `ratio` - a positive real number

EXAMPLES: We create a plot of a circle, and it doesn't look quite round:

```
sage: P = circle((1,1), 1); P
```

So we set the aspect ratio and now it is round:

```
sage: P.set_aspect_ratio(1)
sage: P
```

Note that the aspect ratio is inherited upon addition (which takes the max of aspect ratios of objects whose aspect ratio has been set):

```
sage: P + circle((0,0), 0.5)            # still square
```

In the following example, both plots produce a circle that looks twice as wide as tall:

```
sage: Q = circle((0,0), 0.5); Q.set_aspect_ratio(2)
sage: P + Q
sage: Q + P
```

set_axes_range(*xmin=None, xmax=None, ymin=None, ymax=None*)

Set the ranges of the x and y axes.

INPUT:

- `xmin, xmax, ymin, ymax` - floats

EXAMPLES:

```
sage: L = line([(1,2), (3,-4), (2, 5), (1,2)])
sage: L.set_axes_range(-1, 20, 0, 2)
sage: d = L.get_axes_range()
sage: d['xmin'], d['xmax'], d['ymin'], d['ymax']
(-1.0, 20.0, 0.0, 2.0)
```

show(*xmin=None, xmax=None, ymin=None, ymax=None, figsize=(6, 3.7082039324993699), filename=None, dpi=100, axes=None, axes_labels=None, frame=False, fontsize=None, aspect_ratio=None, gridlines=None, gridlinesstyle=None, vgridlinesstyle=None, hgridlinesstyle=None, linkmode=False*)

Show this graphics image with the default image viewer.

OPTIONAL INPUT:

- `filename` - (default: None) string
- `dpi` - dots per inch
- `figsize` - [width, height]
- `aspect_ratio` - the perceived width divided by the perceived height. If the aspect ratio is set to 1, circles will look round. If it is set to 2 they will look twice as wide as they are tall. This is the aspect_ratio of the image, not of the frame that contains it. If you want to set the aspect ratio of the frame, use figsize.
- `axes` - (default: True)
- `axes_labels` - (default: None) list (or tuple) of two strings; the first is used as the label for the horizontal axis, and the second for the vertical axis.
- `fontsize` - (default: current setting – 10) positive integer; used for axes labels; if you make this very large, you may have to increase figsize to see all labels.
- `frame` - (default: False) draw a frame around the image
- `gridlines` - (default: None) can be any of the following:
  - None, False: do not add grid lines.
  - True, "automatic", "major": add grid lines at major ticks of the axes.
  - "minor": add grid at major and minor ticks.
  - [xlist,ylist]: a tuple or list containing two elements, where xlist (or ylist) can be any of the following.
    - None, False: don't add horizontal (or vertical) lines.
    - True, "automatic", "major": add horizontal (or vertical) grid lines at the major ticks of the axes.
    - "minor": add horizontal (or vertical) grid lines at major and minor ticks of axes.
    - an iterable yielding numbers n or pairs (n,opts), where n is the coordinate of the line and opt is a dictionary of MATPLOTLIB options for rendering the line.
- `gridlinesstyle, hgridlinesstyle, vgridlinesstyle` - (default: None) a dictionary of MATPLOTLIB options for the rendering of the grid lines, the horizontal grid lines or the vertical grid lines, respectively.
- **`linkmode` - (default: False) If True a string containing a link** to the produced file is returned.

EXAMPLES:

```
sage: c = circle((1,1), 1, rgbcolor=(1,0,0))
sage: c.show(xmin=-1, xmax=3, ymin=-1, ymax=3)
```

To correct the apect ratio of certain graphics, it is necessary to show with a '`figsize`' of square dimensions.

```
sage: c.show(figsize=[5,5], xmin=-1, xmax=3, ymin=-1, ymax=3)
```

You can turn off the drawing of the axes:

```
sage: show(plot(sin,-4,4), axes=False)
```

You can also label the axes:

```
sage: show(plot(sin,-4,4), axes_labels=('x','y'))
```

You can turn on the drawing of a frame around the plots:

```
sage: show(plot(sin,-4,4), frame=True)
```

Add grid lines at the major ticks of the axes.

```
sage: c = circle((0,0), 1)
sage: c.show(gridlines=True)
sage: c.show(gridlines="automatic")
sage: c.show(gridlines="major")
```

Add grid lines at the major and minor ticks of the axes.

```
sage: u,v = var('u v')
sage: f = exp(-(u^2+v^2))
sage: p = plot_vector_field(f.gradient(), (u,-2,2), (v,-2,2))
sage: p.show(gridlines="minor")
```

Add only horizontal or vertical grid lines.

```
sage: p = plot(sin,-10,20)
sage: p.show(gridlines=[None, "automatic"])
sage: p.show(gridlines=["minor", False])
```

Add grid lines at specific positions (using lists/tuples).

```
sage: x, y = var('x, y')
sage: p = implicit_plot((y^2-x^2)*(x-1)*(2*x-3)-4*(x^2+y^2-2*x)^2,              ...
sage: p.show(gridlines=[[1,0],[-1,0,1]])
```

Add grid lines at specific positions (using iterators).

```
sage: def maple_leaf(t):
...     return (100/(100+(t-pi/2)^8))*(2-sin(7*t)-cos(30*t)/2)
sage: p = polar_plot(maple_leaf, -pi/4, 3*pi/2, rgbcolor="red",plot_points=1000) #long
sage: p.show(gridlines=( [-3,-2.75,..,3], xrange(-1,5,2) )) #long
```

Add grid lines at specific positions (using functions).

```
sage: y = x^5 + 4*x^4 - 10*x^3 - 40*x^2 + 9*x + 36
sage: p = plot(y, -4.1, 1.1)
sage: xlines = lambda a,b: [z for z,m in y.roots()]
sage: p.show(gridlines=[xlines, [0]], frame=True, axes=False)
```

Change the style of all the grid lines.

```
sage: b = bar_chart([-3,5,-6,11], rgbcolor=(1,0,0))
sage: b.show(gridlines=([-1,-0.5,..,4],True),              ...     gridlinesstyle=dict(color=
```

Change the style of the horizontal or vertical grid lines separately.

```
sage: p = polar_plot(2 + 2*cos(x), 0, 2*pi, rgbcolor=hue(0.3))
sage: p.show(gridlines=True,              ...     hgridlinesstyle=dict(color="orange", linewi
```

Change the style of each grid line individually.

```
sage: x, y = var('x, y')
sage: p = implicit_plot((y^2-x^2)*(x-1)*(2*x-3)-4*(x^2+y^2-2*x)^2,              ...
sage: p.show(gridlines=(
...     [
...      (1,{"color":"red","linestyle":":"}),
...      (0,{"color":"blue","linestyle":"--"})
...     ],
...     [
...      (-1,{"rgbcolor":"red","linestyle":":"}),
...      (0,{"color":"blue","linestyle":"--"}),
```

```
...       (1,{"rgbcolor":"red","linestyle":":"}),
...      ]
...      ),
...      gridlinesstyle=dict(marker='x',rgbcolor="black"))
```

Grid lines can be added to contour plots.

```
sage: f = sin(x^2 + y^2)*cos(x)*sin(y)
sage: c = contour_plot(f, (x, -4, 4), (y, -4, 4), plot_points=100)
sage: c.show(gridlines=True, gridlinesstyle={'linestyle':':','linewidth':1, 'rgbcolor':'red'
```

Grid lines can be added to matrix plots.

```
sage: M = MatrixSpace(QQ,10).random_element()
sage: matrix_plot(M).show(gridlines=True)
```

tick_label_color(*c=None*)

Set the color of the axes tick labels.

INPUT:

- c - an rgb 3-tuple of numbers between 0 and 1

If called with no input, return the current tick_label_color setting.

EXAMPLES:

```
sage: p = plot(cos, (-3,3))
sage: p.tick_label_color()
(0, 0, 0)
sage: p.tick_label_color((1,0,0))
sage: p.tick_label_color()
(1.0, 0.0, 0.0)
sage: p
```

xmax(*xmax=None*)

EXAMPLES:

```
sage: g = line([(-1,1), (3,2)])
sage: g.xmax()
3.0
sage: g.xmax(10)
sage: g.xmax()
10.0
```

xmin(*xmin=None*)

EXAMPLES:

```
sage: g = line([(-1,1), (3,2)])
sage: g.xmin()
-1.0
sage: g.xmin(-3)
sage: g.xmin()
-3.0
```

ymax(*ymax=None*)

EXAMPLES:

```
sage: g = line([(-1,1), (3,2)])
sage: g.ymax()
2.0
sage: g.ymax(10)
sage: g.ymax()
10.0
```

ymin (*ymin=None*)

EXAMPLES:

```
sage: g = line([(-1,1), (3,2)])
sage: g.ymin()
1.0
sage: g.ymin(-3)
sage: g.ymin()
-3.0
```

class GraphicsArray (*array*)

GraphicsArray takes a (m x n) list of lists of graphics objects and plots them all on one canvas.

append (*g*)

ncols ()

nrows ()

save (*filename=None, dpi=100, figsize=(6, 3.7082039324993699), axes=None, **args*)

save the `graphics_array` to (for now) a png called 'filename'.

show (*filename=None, dpi=100, figsize=(6, 3.7082039324993699), axes=None, **args*)

Show this graphics array using the default viewer.

OPTIONAL INPUT:

- `filename` - (default: None) string
- `dpi` - dots per inch
- `figsize` - [width, height] (same for square aspect)
- `axes` - (default: True)
- `fontsize` - positive integer
- `frame` - (default: False) draw a frame around the image

EXAMPLES: This draws a graphics array with four trig plots and no axes in any of the plots.

```
sage: G = graphics_array([[plot(sin), plot(cos)], [plot(tan), plot(sec)]])
sage: G.show(axes=False)
```

adaptive_refinement (*f, p1, p2, adaptive_tolerance=0.01, adaptive_recursion=5, level=0*)

The adaptive refinement algorithm for plotting a function f. See the docstring for plot for a description of the algorithm.

INPUT:

- `f` - a function of one variable
- `p1, p2` - two points to refine between
- `adaptive_recursion` - (default: 5) how many levels of recursion to go before giving up when doing adaptive refinement. Setting this to 0 disables adaptive refinement.
- `adaptive_tolerance` - (default: 0.01) how large a relative difference should be before the adaptive refinement code considers it significant; see documentation for generate_plot_points for more information. See the documentation for plot() for more information on how the adaptive refinement algorithm works.

OUTPUT:

- `list` - a list of points to insert between p1 and p2 to get a better linear approximation between them

TESTS:

```
sage: from sage.plot.plot import adaptive_refinement
sage: adaptive_refinement(sin, (0,0), (pi,0), adaptive_tolerance=0.01, adaptive_recursion=0)
[]
sage: adaptive_refinement(sin, (0,0), (pi,0), adaptive_tolerance=0.01)
[(0.125000000000000*pi, 0.38268343236508978), (0.187500000000000*pi, 0.55557023301960218), (0.25
```

This shows that lowering adaptive_tolerance and raising adaptive_recursion both increase the number of subdivision points, though which one creates more points is heavily dependent upon the function being plotted.

```
sage: x = var('x')
sage: f(x) = sin(1/x)
sage: n1 = len(adaptive_refinement(f, (0,0), (pi,0), adaptive_tolerance=0.01)); n1
15
sage: n2 = len(adaptive_refinement(f, (0,0), (pi,0), adaptive_recursion=10, adaptive_tolerance=0
79
sage: n3 = len(adaptive_refinement(f, (0,0), (pi,0), adaptive_tolerance=0.001)); n3
26
```

adjust_figsize_for_aspect_ratio(*figsize, aspect_ratio, xmin, xmax, ymin, ymax*)

Adjust the figsize in case the user also specifies an aspect ratio.

INPUTS: figsize - a sequence of two positive real numbers aspect_ratio - a positive real number xmin, xmax, ymin, ymax - real numbers

EXAMPLES: This function is used mainly internally by plotting code so we explicitly import it:

```
sage: from sage.plot.plot import adjust_figsize_for_aspect_ratio
```

This returns (5,5), since the requested aspect ratio is 1 and the x and y ranges are the same, so that's the right size rendered image to produce a 1:1 ratio internally. 5 is used instead of 3 since the image size is always adjusted to the larger of the figsize dimensions.

```
sage: adjust_figsize_for_aspect_ratio([3,5], 1, 0, 2, 0, 2)
(5, 5)
```

Here we give a scalar figsize, which is automatically converted to the figsize `(figsize, figsize/golden_ratio)`.

```
sage: adjust_figsize_for_aspect_ratio(3, 1, 0, 2, 0, 2)
(3, 3)
```

Here we omit the aspect ratio so the figsize is just returned.

```
sage: adjust_figsize_for_aspect_ratio([5,6], None, 0, 2, 0, 2)
[5, 6]
```

Here we have an aspect ratio of 2, and since the x and y ranges are the same the returned figsize is twice as wide as tall:

```
sage: adjust_figsize_for_aspect_ratio([3,5], 2, 0, 2, 0, 2)
(5, 5/2)
```

Here the x range is rather large, so to get an aspect ratio where circles look twice as wide as they are tall, we have to shrink the y size of the image.

```
sage: adjust_figsize_for_aspect_ratio([3,5], 2, 0, 10, 0, 2)
(5, 1/2)
```

float_to_html(*r, g, b*)

This is a function to present tuples of RGB floats as HTML-happy hex for matplotlib. This may not seem necessary, but there are some odd cases where matplotlib is just plain schizophrenic – for an example, do

EXAMPLES:

```
sage: vertex_colors = {(1.0, 0.8571428571428571, 0.0): [4, 5, 6], (0.28571428571428559, 0.0, 1.0
sage: graphs.DodecahedralGraph().show(vertex_colors=vertex_colors)
```

Notice how the colors don't respect the partition at all.....

generate_plot_points(*f, xrange, plot_points=5, adaptive_tolerance=0.01, adaptive_recursion=5, randomize=True*)

Calculate plot points for a function f in the interval xrange. The adaptive refinement algorithm is also automatically invoked with a *relative* adaptive tolerance of adaptive_tolerance; see below.

INPUT:

- `f` - a function of one variable
- `p1, p2` - two points to refine between
- `plot_points` - (default: 5) the minimal number of plot points. (Note however that in any actual plot a number is passed to this, with default value 200.)
- `adaptive_recursion` - (default: 5) how many levels of recursion to go before giving up when doing adaptive refinement. Setting this to 0 disables adaptive refinement.
- `adaptive_tolerance` - (default: 0.01) how large the relative difference should be before the adaptive refinement code considers it significant. If the actual difference is greater than adaptive_tolerance*delta, where delta is the initial subinterval size for the given xrange and plot_points, then the algorithm will consider it significant.

OUTPUT:

- a list of points (x, f(x)) in the interval xrange, which aproximate the function f.

TESTS:

```
sage: from sage.plot.plot import generate_plot_points
sage: generate_plot_points(sin, (0, pi), plot_points=2, adaptive_recursion=0)
[(0.0, 0.0), (3.1415926535897931, 1.2246...e-16)]

sage: generate_plot_points(sin(x).function(x), (-pi, pi), randomize=False)
[(-3.1415926535897931, -1.2246...e-16), (-2.748893571891069,
-0.3826834323650898...), (-2.3561944901923448, -0.707106781186547...),
(-2.1598449493429825, -0.831469612302545...), (-1.9634954084936207,
-0.92387953251128674), (-1.7671458676442586, -0.98078528040323043),
(-1.5707963267948966, -1.0), (-1.3744467859455345,
-0.98078528040323043), (-1.1780972450961724, -0.92387953251128674),
(-0.98174770424681035, -0.831469612302545...), (-0.78539816339744828,
-0.707106781186547...), (-0.39269908169872414, -0.38268343236508978),
(0.0, 0.0), (0.39269908169872414, 0.38268343236508978),
(0.78539816339744828, 0.707106781186547...), (0.98174770424681035,
0.831469612302545...), (1.1780972450961724, 0.92387953251128674),
(1.3744467859455345, 0.98078528040323043), (1.5707963267948966, 1.0),
(1.7671458676442586, 0.98078528040323043), (1.9634954084936207,
0.92387953251128674), (2.1598449493429825, 0.831469612302545...),
(2.3561944901923448, 0.707106781186547...), (2.748893571891069,
0.3826834323650898...), (3.1415926535897931, 1.2246...e-16)]
```

This shows that lowering adaptive_tolerance and raising adaptive_recursion both increase the number of subdivision points. (Note that which creates more points is heavily dependent on the particular function plotted.)

```
sage: x = var('x')
sage: f(x) = sin(1/x)
sage: [len(generate_plot_points(f, (-pi, pi), plot_points=16, adaptive_tolerance=i, randomize=Fa
```

```
[97, 161, 275]

sage: [len(generate_plot_points(f, (-pi, pi), plot_points=16, adaptive_recursion=i, randomize=Fa
[97, 499, 2681]
```

graphics_array (*array, n=None, m=None*)

graphics_array take a list of lists (or tuples) of graphics objects and plots them all on one canvas (single plot).

INPUT:

- array - a list of lists or tuples
- n, m - (optional) integers - if n and m are given then the input array is flattened and turned into an n x m array, with blank graphics objects padded at the end, if necessary.

EXAMPLE: Make some plots of sin functions:

```
sage: f(x) = sin(x)
sage: g(x) = sin(2*x)
sage: h(x) = sin(4*x)
sage: p1 = plot(f,-2*pi,2*pi,rgbcolor=hue(0.5))
sage: p2 = plot(g,-2*pi,2*pi,rgbcolor=hue(0.9))
sage: p3 = parametric_plot((f,g),0,2*pi,rgbcolor=hue(0.6))
sage: p4 = parametric_plot((f,h),0,2*pi,rgbcolor=hue(1.0))
```

Now make a graphics array out of the plots; then you can type either: ga.show() or ga.save().

```
sage: graphics_array(((p1,p2),(p3,p4)))
```

Here we give only one row:

```
sage: p1 = plot(sin,-4,4)
sage: p2 = plot(cos,-4,4)
sage: g = graphics_array([p1, p2]); print g
Graphics Array of size 1 x 2
sage: g.show()
```

hue (*h, s=1, v=1*)

hue(h,s=1,v=1) where 'h' stands for hue, 's' stands for saturation, 'v' stands for value. hue returns a tuple of rgb intensities (r, g, b) All values are in the range 0 to 1.

INPUT:

- h, s, v - real numbers between 0 and 1. Note that if any are not in this range they are automatically normalized to be in this range by reducing them modulo 1.

OUTPUT: A valid RGB tuple.

EXAMPLES:

```
sage: hue(0.6)
(0.0, 0.40000000000000036, 1.0)
```

hue is an easy way of getting a broader range of colors for graphics

```
sage: plot(sin, -2, 2, rgbcolor=hue(0.6))
```

is_Graphics(*x*)

Return True if x is a Graphics object.

EXAMPLES:

```
sage: from sage.plot.plot import is_Graphics
sage: is_Graphics(1)
False
sage: is_Graphics(disk((0.0, 0.0), 1, (0, pi/2)))
True
```

list_plot(*data, plotjoined=False, **kwargs*)

`list_plot` takes a single list of data, in which case it forms a list of tuples (i, di) where i goes from 0 to $\text{len}(data) - 1$ and di is the i^{th} data value, and puts points at those tuple values.

`list_plot` also takes a list of tuples (dxi, dyi) where dxi is the i^{th} data representing the x-value, and dyi is the i^{th} y-value. If `plotjoined=True` , then a line spanning all the data is drawn instead.

EXAMPLES:

```
sage: list_plot([i^2 for i in range(5)])
```

Here are a bunch of random red points:

```
sage: r = [(random(),random()) for _ in range(20)]
sage: list_plot(r,rgbcolor=(1,0,0))
```

This gives all the random points joined in a purple line:

```
sage: list_plot(r, plotjoined=True, rgbcolor=(1,0,1))
```

If you have separate lists of x values and y values which you want to plot against each other, use the `zip` command to make a single list whose entries are pairs of (x, y) values, and feed the result into `list_plot`:

```
sage: x_coords = [cos(t)^3 for t in srange(0, 2*pi, 0.02)]
sage: y_coords = [sin(t)^3 for t in srange(0, 2*pi, 0.02)]
sage: list_plot(zip(x_coords, y_coords))
```

TESTS: We check to see that the x/y min/max data are set correctly.

```
sage: d = list_plot([(100,100), (120, 120)]).get_minmax_data()
sage: d['xmin']
100.0
sage: d['ymin']
100.0
```

minmax_data(*xdata, ydata, dict=False*)

Returns the minimums and maximums of xdata and ydata.

If dict is False, then minmax_data returns the tuple (xmin, xmax, ymin, ymax); otherwise, it returns a dictionary whose keys are 'xmin', 'xmax', 'ymin', and 'ymax' and whose values are the corresponding values.

EXAMPLES:

```
sage: from sage.plot.plot import minmax_data
sage: minmax_data([], [])
(-1, 1, -1, 1)
sage: minmax_data([-1, 2], [4, -3])
(-1, 2, -3, 4)
sage: d = minmax_data([-1, 2], [4, -3], dict=True)
```

```
sage: list(sorted(d.items()))
[('xmax', 2), ('xmin', -1), ('ymax', 4), ('ymin', -3)]
```

parametric_plot (*funcs, *args, **kwargs*)

parametric_plot takes two or three functions as a list or a tuple and makes a plot with the first function giving the x coordinates, the second function giving the y coordinates, and the third function (if present) giving the z coordinates.

In the 2d case, parametric_plot is equivalent to the plot command with the option parametric=True. In the 3d case, parametric_plot is equivalent to parametric_plot3d. See each of these functions for more help and examples.

INPUT:

- funcs - 2 or 3-tuple of functions
- other options - passed to plot or parametric_plot3d

EXAMPLES: We draw some 2d parametric plots:

```
sage: t = var('t')
sage: parametric_plot( (sin(t), sin(2*t)), (t, 0, 2*pi), rgbcolor=hue(0.6) )
sage: parametric_plot((1, t), (t, 0, 4))
```

Note that in parametric_plot, there is only fill or no fill.

```
sage: parametric_plot((t, t^2), (t, -4, 4), fill = True)
```

A filled Hypotrochoid:

```
sage: parametric_plot([cos(x) + 2 * cos(x/4), sin(x) - 2 * sin(x/4)], 0, 8*pi, fill = True)

sage: parametric_plot( (5*cos(x), 5*sin(x), x), (x,-12, 12), plot_points=150, color="red")

sage: y=var('y')
sage: parametric_plot( (5*cos(x), x*y, cos(x*y)), (x, -4,4), (y,-4,4))
```

TESTS:

```
sage: parametric_plot((x, t^2), (x, -4, 4))
...
ValueError: the number of functions and the number of free variables is not a possible combinati

sage: parametric_plot((1, x+t), (x, -4, 4))
...
ValueError: the number of functions and the number of free variables is not a possible combinati

sage: parametric_plot((-t, x+t), (x, -4, 4))
...
ValueError: the number of functions and the number of free variables is not a possible combinati

sage: parametric_plot((1, x+t, y), (x, -4, 4), (t, -4, 4))
...
ValueError: the number of functions and the number of free variables is not a possible combinati
```

plot (**args, **kwds*)

Use plot by writing

```
plot(X, ...)
```

where X is a Sage object (or list of Sage objects) that either is callable and returns numbers that can be coerced to floats, or has a plot method that returns a `GraphicPrimitive` object.

Type `plot.options` for a dictionary of the default options for plots. You can change this to change the defaults for all future plots. Use `plot.reset()` to reset to the default options.

PLOT OPTIONS:

- `plot_points` - (default: 200) the minimal number of plot points.
- `adaptive_recursion` - (default: 5) how many levels of recursion to go before giving up when doing adaptive refinement. Setting this to 0 disables adaptive refinement.
- `adaptive_tolerance` - (default: 0.01) how large a difference should be before the adaptive refinement code considers it significant. See the documentation further below for more information, starting at "the algorithm used to insert".
- `xmin` - starting x value
- `xmax` - ending x value
- `color` - an rgb-tuple (r,g,b) with each of r,g,b between 0 and 1, or a color name as a string (e.g., 'purple'), or an HTML color such as '#aaff0b'.
- `detect_poles` - (Default: False) If set to True poles are detected. If set to "show" vertical asymptotes are drawn.

APPEARANCE OPTIONS:

The following options affect the appearance of the line through the points on the graph of X (these are the same as for the line function):

INPUT:

- `alpha` - How transparent the line is
- `thickness` - How thick the line is
- `rgbcolor` - The color as an rgb tuple
- `hue` - The color given as a hue

Any MATPLOTLIB line option may also be passed in. E.g.,

- `linestyle` - The style of the line, which is one of '–' (dashed), '-.' (dash dot), '-' (solid), 'steps', ':' (dotted)
- `marker` - "'0' (tickleft), '1' (tickright), '2' (tickup), '3' (tickdown), '' (nothing), ' ' (nothing), '+' (plus), ',' (pixel), '.' (point), '1' (tri_down), '3' (tri_left), '2' (tri_up), '4' (tri_right), '<' (triangle_left), '>' (triangle_right), 'None' (nothing), 'D' (diamond), 'H' (hexagon2), '_' (hline), '^' (triangle_up), 'd' (thin_diamond), 'h' (hexagon1), 'o' (circle), 'p' (pentagon), 's' (square), 'v' (triangle_down), 'x' (x), 'l' (vline)"
- `markersize` - the size of the marker in points
- `markeredgecolor` - the markerfacecolor can be any color arg
- `markeredgewidth` - the size of the marker edge in points

FILLING OPTIONS: INPUT:

- `fill` - (Default: None) One of:
  - "axis" or True: Fill the area between the function and the x-axis.
  - "min": Fill the area between the function and its minimal value.
  - "max": Fill the area between the function and its maximal value.
  - a number c: Fill the area between the function and the horizontal line y = c.
  - a function g: Fill the area between the function that is plotted and g.

– a dictonary d (only if a list of functions are plotted): The keys of the dictionary should be integers. The value of d[i] specifies the fill options for the i-th function in the list. If d[i] == [j]: Fill the area between the i-th and the j-th function in the list. (But if d[i] == j: Fill the area between the i-th function in the list and the horizontal line y = j.)

- `fillcolor` - (default: 'automatic') The color of the fill. Either 'automatic' or a color.
- `fillalpha` - (default: 0.5) How transparent the fill is. A number between 0 and 1.

Note that this function does NOT simply sample equally spaced points between xmin and xmax. Instead it computes equally spaced points and add small perturbations to them. This reduces the possibility of, e.g., sampling sin only at multiples of 2π, which would yield a very misleading graph.

EXAMPLES: We plot the sin function:

```
sage: P = plot(sin, (0,10)); print P
Graphics object consisting of 1 graphics primitive
sage: len(P)      # number of graphics primitives
1
sage: len(P[0])   # how many points were computed (random)
225
sage: P           # render
```

```
sage: P = plot(sin, (0,10), plot_points=10); print P
Graphics object consisting of 1 graphics primitive
sage: len(P[0])   # random output
32
sage: P           # render
```

We plot with randomize=False, which makes the initial sample points evenly spaced (hence always the same). Adaptive plotting might insert other points, however, unless adaptive_recursion=0.

```
sage: p=plot(1, (x,0,3), plot_points=4, randomize=False, adaptive_recursion=0)
sage: list(p[0])
[(0.0, 1.0), (1.0, 1.0), (2.0, 1.0), (3.0, 1.0)]
```

Some colored functions:

```
sage: plot(sin, 0, 10, rgbcolor='#ff00ff')
sage: plot(sin, 0, 10, rgbcolor='purple')
```

We plot several functions together by passing a list of functions as input:

```
sage: plot([sin(n*x) for n in [1..4]], (0, pi))
```

The function $\sin(1/x)$ wiggles wildly near 0. Sage adapts to this and plots extra points near the origin.

```
sage: plot(sin(1/x), (x, -1, 1))
```

Note that the independent variable may be omitted if there is no ambiguity:

```
sage: plot(sin(1/x), (-1, 1))
```

The algorithm used to insert extra points is actually pretty simple. On the picture drawn by the lines below:

```
sage: p = plot(x^2, (-0.5, 1.4)) + line([(0,0), (1,1)], rgbcolor='green')
sage: p += line([(0.5, 0.5), (0.5, 0.5^2)], rgbcolor='purple')
sage: p += point(((0, 0), (0.5, 0.5), (0.5, 0.5^2), (1, 1)), rgbcolor='red', pointsize=20)
sage: p += text('A', (-0.05, 0.1), rgbcolor='red')
sage: p += text('B', (1.01, 1.1), rgbcolor='red')
sage: p += text('C', (0.48, 0.57), rgbcolor='red')
sage: p += text('D', (0.53, 0.18), rgbcolor='red')
sage: p.show(axes=False, xmin=-0.5, xmax=1.4, ymin=0, ymax=2)
```

You have the function (in blue) and its approximation (in green) passing through the points A and B. The algorithm finds the midpoint C of AB and computes the distance between C and D. If that distance exceeds the adaptive_tolerance threshold (*relative* to the size of the initial plot subintervals), the point D is added to the curve. If D is added to the curve, then the algorithm is applied recursively to the points A and D, and D and B. It is repeated adaptive_recursion times (5, by default).

The actual sample points are slightly randomized, so the above plots may look slightly different each time you draw them.

We draw the graph of an elliptic curve as the union of graphs of 2 functions.

```
sage: def h1(x): return abs(sqrt(x^3  - 1))
sage: def h2(x): return -abs(sqrt(x^3  - 1))
sage: P = plot([h1, h2], 1,4)
sage: P          # show the result
```

We can also directly plot the elliptic curve:

```
sage: E = EllipticCurve([0,-1])
sage: plot(E, (1, 4), rgbcolor=hue(0.6))
```

We can change the line style to one of '–' (dashed), '-.' (dash dot), '-' (solid), 'steps', ':' (dotted):

```
sage: plot(sin(x), 0, 10, linestyle='-.')
```

Sage currently ignores points that cannot be evaluated

```
sage: set_verbose(-1)
sage: plot(-x*log(x), (x,0,1))  # this works fine since the failed endpoint is just skipped.
sage: set_verbose(0)
```

This prints out a warning and plots where it can (we turn off the warning by setting the verbose mode temporarily to -1.)

```
sage: set_verbose(-1)
sage: plot(x^(1/3), (x,-1,1))
sage: set_verbose(0)
```

To plot the negative real cube root, use something like the following:

```
sage: plot(lambda x : RR(x).nth_root(3), (x,-1, 1))
```

We can detect the poles of a function:: sage: plot(gamma, (-3, 4), detect_poles = True).show(ymin = -5, ymax = 5)

We draw the Gamma-Function with its poles highlighted:: sage: plot(gamma, (-3, 4), detect_poles = 'show').show(ymin = -5, ymax = 5)

The basic options for filling a plot:

```
sage: p1 = plot(sin(x), -pi, pi, fill = 'axis')
sage: p2 = plot(sin(x), -pi, pi, fill = 'min')
sage: p3 = plot(sin(x), -pi, pi, fill = 'max')
sage: p4 = plot(sin(x), -pi, pi, fill = 0.5)
sage: graphics_array([[p1, p2], [p3, p4]]).show(frame=True, axes=False)

sage: plot([sin(x), cos(2*x)*sin(4*x)], -pi, pi, fill = {0: 1}, fillcolor = 'red', fillalpha = 1
```

A example about the growth of prime numbers:

```
sage: plot(1.13*log(x), 1, 100, fill = lambda x: nth_prime(x)/floor(x), fillcolor = 'red')
```

Fill the area between a function and its asymptote:

```
sage: f = (2*x^3+2*x-1)/((x-2)*(x+1))
sage: plot([f, 2*x+2], -7,7, fill = {0: [1]}, fillcolor='#ccc').show(ymin=-20, ymax=20)
```

Fill the area between a list of functions and the x-axis:

```
sage: def b(n): return lambda x: bessel_J(n, x)
sage: plot([b(n) for n in [1..5]], 0, 20, fill = 'axis')
```

Note that to fill between the ith and jth functions, you must use dictionary key-value pairs i:[j]; key-value pairs like i:j will fill between the ith function and the line y=j:

```
sage: def b(n): return lambda x: bessel_J(n, x) + 0.5*(n-1)
sage: plot([b(c) for c in [1..5]], 0, 40, fill = dict([(i, [i+1]) for i in [0..3]]))
sage: plot([b(c) for c in [1..5]], 0, 40, fill = dict([(i, i+1) for i in [0..3]]))
```

TESTS:

We do not randomize the endpoints:

```
sage: p = plot(x, (x,-1,1))
sage: p[0].xdata[0] == -1
True
sage: p[0].xdata[-1] == 1
True
```

We check to make sure that the x/y min/max data get set correctly when there are multiple functions.

```
sage: d = plot([sin(x), cos(x)], 100, 120).get_minmax_data()
sage: d['xmin']
100.0
sage: d['xmax']
120.0
```

We check various combinations of tuples and functions, ending with tests that lambda functions work properly with explicit variable declaration, without a tuple.

```
sage: p = plot(lambda x: x,(x,-1,1))
sage: p = plot(lambda x: x,-1,1)
sage: p = plot(x,x,-1,1)
sage: p = plot(x,-1,1)
sage: p = plot(x^2,x,-1,1)
sage: p = plot(x^2,xmin=-1,xmax=2)
sage: p = plot(lambda x: x,x,-1,1)
sage: p = plot(lambda x: x^2,x,-1,1)
```

```
sage: p = plot(lambda x: 1/x,x,-1,1)
sage: f(x) = sin(x+3)-.1*x^3
sage: p = plot(lambda x: f(x),x,-1,1)
```

We check to handle cases where the function gets evaluated at a point which causes an 'inf' or '-inf' result to be produced.

```
sage: p = plot(1/x, 0, 1)
sage: p = plot(-1/x, 0, 1)
```

Bad options now give better errors:

```
sage: P = plot(sin(1/x), (x,-1,3), foo=10)
...
RuntimeError: Error in line(): option 'foo' not valid.
```

polar_plot (*funcs, *args, **kwds*)

`polar_plot` takes a single function or a list or tuple of functions and plots them with polar coordinates in the given domain.

This function is equivalent to the plot command with the option polar=True. For more help on options, see the documentation for plot.

INPUT:

- `funcs` - a function
- other options are passed to plot

EXAMPLES:

Here is a blue 8-leaved petal:

```
sage: polar_plot(sin(5*x)^2, (x, 0, 2*pi), color='blue')
```

A red figure-8:

```
sage: polar_plot(abs(sqrt(1 - sin(x)^2)), (x, 0, 2*pi), color='red')
```

A green limacon of Pascal:

```
sage: polar_plot(2 + 2*cos(x), (x, 0, 2*pi), rgbcolor=hue(0.3))
```

Several polar plots:

```
sage: polar_plot([2*sin(x), 2*cos(x)], (x, 0, 2*pi))
```

A filled spiral:

```
sage: polar_plot(sqrt, 0, 2 * pi, fill = True)
```

Fill the area between two functions:

```
sage: polar_plot(cos(4*x) + 1.5, 0, 2*pi, fill=0.5 * cos(4*x) + 2.5, fillcolor='orange').show(as
```

Fill the area between several spirals:

```
sage: polar_plot([(1.2+k*0.2)*log(x) for k in range(6)], 1, 3 * pi, fill = {0: [1], 2: [3], 4: [
```

rainbow(*n, format='hex'*)

Given an integer n, returns a list of colors, represented in HTML hex, that changes smoothly in hue from one end of the spectrum to the other. Written in order to easily represent vertex partitions on graphs.

AUTHORS:

- Robert L. Miller

EXAMPLE:

```
sage: from sage.plot.plot import rainbow
sage: rainbow(7)
['#ff0000', '#ffda00', '#48ff00', '#00ff91', '#0091ff', '#4800ff', '#ff00da']
sage: rainbow(7, 'rgbtuple')
[(1.0, 0.0, 0.0), (1.0, 0.8571428571428571, 0.0), (0.28571428571428581, 1.0, 0.0), (0.0, 1.0, 0.
```

reshape(*v, n, m*)

setup_for_eval_on_grid(*v, xrange, yrange, plot_points*)

INPUT:

- `v` - a list of functions
- `xrange` - 2 or 3 tuple (if 3, first is a variable)
- `yrange` - 2 or 3 tuple
- `plot_points` - a positive integer

OUTPUT:

- `g` - tuple of fast callable functions
- `xstep` - step size in xdirection
- `ystep` - step size in ydirection
- `xrange` - tuple of 2 floats
- `yrange` - tuple of 2 floats

EXAMPLES:

```
sage: x,y = var('x,y')
sage: sage.plot.plot.setup_for_eval_on_grid([x^2 + y^2], (x,0,5), (y,0,pi), 11)
([<sage.ext... object at ...>],
 0.5,
 0.31415926535897931,
 (0.0, 5.0),
 (0.0, 3.1415926535897931))
```

We always plot at least two points; one at the beginning and one at the end of the ranges.

```
sage: sage.plot.plot.setup_for_eval_on_grid([x^2+y^2], (x,0,1), (y,-1,1), 1)
([<sage.ext... object at ...>],
1.0,
2.0,
(0.0, 1.0),
(-1.0, 1.0))
```

show_default(*default=None*)

Set the default for showing plots using any plot commands. If called with no arguments, returns the current default.

If this is `True` (the default) then any plot object when displayed will be displayed as an actual plot instead of text, i.e., the show command is not needed.

EXAMPLES: The default starts out as `True`:

```
sage: show_default()
True
```

We set it to `False`.

```
sage: show_default(False)
```

We see that it is `False`.

```
sage: show_default()
False
```

Now plot commands will not display their plots by default.

Turn back on default display.

```
sage: show_default(True)
```

to_float_list(*v*)

Given a list or tuple or iterable v, coerce each element of v to a float and make a list out of the result.

EXAMPLES:

```
sage: from sage.plot.plot import to_float_list
sage: to_float_list([1,1/2,3])
[1.0, 0.5, 3.0]
```

var_and_list_of_values(*v, plot_points*)

INPUT:

- `v` - (v0, v1) or (var, v0, v1); if the former return the range of values between v0 and v1 taking plot_points steps; if var is given, also return var.
- `plot_points` - integer = 2 (the endpoints)

OUTPUT:

- `var` - a variable or None
- `list` - a list of floats

EXAMPLES:

```
sage: from sage.plot.plot import var_and_list_of_values
sage: var_and_list_of_values((var('theta'), 2, 5),  5)
(theta, [2.0, 2.75, 3.5, 4.25, 5.0])
sage: var_and_list_of_values((2, 5),  5)
(None, [2.0, 2.75, 3.5, 4.25, 5.0])
sage: var_and_list_of_values((var('theta'), 2, 5),  2)
(theta, [2.0, 5.0])
sage: var_and_list_of_values((2, 5),  2)
(None, [2.0, 5.0])
```

xydata_from_point_list (*points*)

Returns two lists (xdata, ydata), each coerced to a list of floats, which correspond to the x-coordinates and the y-coordinates of the points.

The points parameter can be a list of 2-tuples or some object that yields a list of one or two numbers.

This function can potentially be very slow for large point sets.

4.2 Animated plots

EXAMPLES: We plot a circle shooting up to the right:

```
sage: a = animate([circle((i,i), 1-1/(i+1), hue=i/10) for i in srange(0,2,0.2)],
...                xmin=0,ymin=0,xmax=2,ymax=2,figsize=[2,2])
sage: a.show() # optional -- requires convert command
```

class Animation (*v, **kwds*)

Return an animation of a sequence of plots of objects.

INPUT:

- `v` - list of Sage objects. These should preferably be graphics objects, but if they aren't then plot is called on them.
- `xmin, xmax, ymin, ymax` - the ranges of the x and y axes.
- `**kwds` - all additional inputs are passed onto the rendering command. E.g., use figsize to adjust the resolution and aspect ratio.

EXAMPLES:

```
sage: a = animate([sin(x + float(k)) for k in srange(0,2*pi,0.3)],
...                xmin=0, xmax=2*pi, figsize=[2,1])
sage: a
Animation with 21 frames
sage: a[:5]
Animation with 5 frames
sage: a.show()          # optional -- requires convert command
sage: a[:5].show()      # optional
```

The `show` function takes arguments to specify the delay between frames (measured in hundredths of a second, default value 20) and the number of iterations (default value 0, which means to iterate forever). To iterate 4 times with half a second between each frame:

```
sage: a.show(delay=50, iterations=4) # optional
```

An animation of drawing a parabola:

```
sage: step = 0.1
sage: L = Graphics()
sage: v = []
sage: for i in srange(0,1,step):
...       L += line([(i,i^2),(i+step,(i+step)^2)], rgbcolor=(1,0,0), thickness=2)
...       v.append(L)
sage: a = animate(v, xmin=0, ymin=0)
sage: a.show() # optional -- requires convert command
sage: show(L)
```

TESTS: This illustrates that ticket #2066 is fixed (setting axes ranges when an endpoint is 0):

```
sage: animate([plot(sin, -1,1)], xmin=0, ymin=0)._Animation__kwds['xmin']
0
```

gif(*delay=20, savefile=None, iterations=0, show_path=False*)

Returns an animated gif composed from rendering the graphics objects in self.

This function will only work if the ImageMagick command line tools package is installed, i.e., you have the "convert" command.

INPUT:

- delay - (default: 20) delay in hundredths of a second between frames
- savefile - file that the animated gif gets saved to
- iterations - integer (default: 0); number of iterations of animation. If 0, loop forever.
- show_path - boolean (default: False); if True, print the path to the saved file

If savefile is not specified: in notebook mode, display the animation; otherwise, save it to a default file name.

EXAMPLES:

```
sage: a = animate([sin(x + float(k)) for k in srange(0,2*pi,0.7)],
...                xmin=0, xmax=2*pi, figsize=[2,1])
sage: a.gif()               # optional -- requires convert command
sage: a.gif(delay=35, iterations=3)       # optional
sage: a.gif(savefile='my_animation.gif')  # optional
sage: a.gif(savefile='my_animation.gif', show_path=True) # optional
Animation saved to .../my_animation.gif.
```

Note: If ImageMagick is not installed, you will get an error message like this:

```
/usr/local/share/sage/local/bin/sage-native-execute: 8: convert:
not found

Error: ImageMagick does not appear to be installed. Saving an
animation to a GIF file or displaying an animation requires
ImageMagick, so please install it and try again.
```

See www.imagemagick.org, for example.

AUTHORS:

- William Stein

graphics_array(*ncols=3*)

Return a graphics array with the given number of columns with plots of the frames of this animation.

EXAMPLES:

```
sage: E = EllipticCurve('37a')
sage: v = [E.change_ring(GF(p)).plot(pointsize=30) for p in [97, 101, 103, 107]]
sage: a = animate(v, xmin=0, ymin=0)
sage: a
Animation with 4 frames
sage: a.show()        # optional -- requires convert command

sage: g = a.graphics_array()
sage: print g
Graphics Array of size 1 x 3
sage: g.show(figsize=[4,1]) # optional

sage: g = a.graphics_array(ncols=2)
sage: print g
Graphics Array of size 2 x 2
sage: g.show('sage.png')         # optional
```

png (*dir=None*)

Return the absolute path to a temp directory that contains the rendered png's of all the images in this animation.

EXAMPLES:

```
sage: a = animate([plot(x^2 + n) for n in range(4)])
sage: d = a.png()
sage: v = os.listdir(d); v.sort(); v
['00000000.png', '00000001.png', '00000002.png', '00000003.png']
```

save (*filename=None, show_path=False*)

Save this animation into a gif or sobj file.

INPUT:

- `filename` - (default: None) name of save file
- `show_path` - boolean (default: False); if True, print the path to the saved file

If filename is None, then in notebook mode, display the animation; othewise, save the animation to a gif file. If filename ends in '.gif', save to a gif file. If filename ends in '.sobj', save to an sobj file.

In all other cases, print an error.

EXAMPLES:

```
sage: a = animate([sin(x + float(k)) for k in srange(0,2*pi,0.7)],
...                xmin=0, xmax=2*pi, figsize=[2,1])
sage: a.save()          # optional -- requires convert command
sage: a.save('wave.gif')    # optional
sage: a.save('wave.gif', show_path=True)    # optional
Animation saved to file .../wave.gif.
sage: a.save('wave0.sobj')  # optional
sage: a.save('wave1.sobj', show_path=True)  # optional
Animation saved to file wave1.sobj.
```

show (*delay=20, iterations=0*)

Show this animation.

INPUT:

- `delay` - (default: 20) delay in hundredths of a second between frames
- `iterations` - integer (default: 0); number of iterations of animation. If 0, loop forever.

Note: Currently this is done using an animated gif, though this could change in the future. This requires that the ImageMagick command line tools package be installed, i.e., that you have the `convert` command.

EXAMPLES:

```
sage: a = animate([sin(x + float(k)) for k in srange(0,2*pi,0.7)],
...                xmin=0, xmax=2*pi, figsize=[2,1])
sage: a.show()        # optional -- requires convert command
```

The preceding will loop the animation forever. If you want to show only three iterations instead:

```
sage: a.show(iterations=3)     # optional
```

To put a half-second delay between frames:

```
sage: a.show(delay=50)         # optional
```

Note: If ImageMagick is not installed, you will get an error message like this:

```
/usr/local/share/sage/local/bin/sage-native-execute: 8: convert:
not found
```

```
  Error: ImageMagick does not appear to be installed. Saving an
  animation to a GIF file or displaying an animation requires
  ImageMagick, so please install it and try again.

See www.imagemagick.org, for example.
```

CHAPTER

FIVE

3D GRAPHICS

5.1 Introduction.

EXAMPLES:

```
sage: x, y = var('x y')
sage: W = plot3d(sin(pi*((x)^2+(y)^2))/2,(x,-1,1),(y,-1,1), frame=False, color='purple', opacity=0.8)
sage: S = sphere((0,0,0),size=0.3, color='red', aspect_ratio=[1,1,1])
sage: show(W + S, figsize=8)
```

5.2 Parametric Plots

adapt_if_symbolic(*f*)

If f is symbolic find the variables u, v to substitute into f. Otherwise raise a TypeError.

This function is used internally by the plot commands for efficiency reasons only.

adapt_to_callable(*f, nargs=None*)

Tries to make every function in f into a (fast) callable function, returning a new list of functions and the expected arguments.

INPUT:

- **f – a list of functions; these can be symbolic expressions,** polynomials, etc
- nargs – number of input args to have in the output functions

OUTPUT: functions, expected arguments

parametric_plot3d(*f, urange, vrange=None, plot_points='automatic', boundary_style=None, **kwds*)

Return a parametric three-dimensional space curve or surface.

There are four ways to call this function:

- parametric_plot3d([f_x, f_y, f_z], (u_min, u_max)): f_x, f_y, f_z are three functions and $u_{\min}$ and $u_{\max}$ are real numbers
- parametric_plot3d([f_x, f_y, f_z], (u, u_min, u_max)): f_x, f_y, f_z can be viewed as functions of u
- parametric_plot3d([f_x, f_y, f_z], (u_min, u_max), (v_min, v_max)): f_x, f_y, f_z are each functions of two variables
- parametric_plot3d([f_x, f_y, f_z], (u, u_min, u_max), (v, v_min, v_max)): f_x, f_y, f_z can be viewed as functions of u and v

INPUT:

- `f` - a 3-tuple of functions or expressions
- `urange` - a 2-tuple (u_min, u_max) or a 3-tuple (u, u_min, u_max)
- `vrange` - (optional - only used for surfaces) a 2-tuple (v_min, v_max) or a 3-tuple (v, v_min, v_max)
- `plot_points` - (default: "automatic", which is 75 for curves and [40,40] for surfaces) initial number of sample points in each parameter; an integer for a curve, and a pair of integers for a surface.
- `boundary_style` - (default: None, no boundary) a dict that describes how to draw the boundaries of regions by giving options that are passed to the line3d command.
- `mesh` - bool (default: False) whether to display mesh grid lines
- `dots` - bool (default: False) whether to display dots at mesh grid points

Note:

1. By default for a curve any points where f_x, f_y, or f_z do not evaluate to a real number are skipped.
2. Currently for a surface f_x, f_y, and f_z have to be defined everywhere. This will change.
3. mesh and dots are not supported when using the Tachyon raytracer renderer.

EXAMPLES: We demonstrate each of the four ways to call this function.

1. A space curve defined by three functions of 1 variable:

```
sage: parametric_plot3d( (sin, cos, lambda u: u/10), (0, 20))
```

   Note above the lambda function, which creates a callable Python function that sends u to $u/10$.

2. Next we draw the same plot as above, but using symbolic functions:

```
sage: u = var('u')
sage: parametric_plot3d( (sin(u), cos(u), u/10), (u, 0, 20))
```

3. We draw a parametric surface using 3 Python functions (defined using lambda):

```
sage: f = (lambda u,v: cos(u), lambda u,v: sin(u)+cos(v), lambda u,v: sin(v))
sage: parametric_plot3d(f, (0, 2*pi), (-pi, pi))
```

4. The surface, but with a mesh:

```
sage: u, v = var('u,v')
sage: parametric_plot3d((cos(u), sin(u) + cos(v), sin(v)), (u, 0, 2*pi), (v, -pi, pi), mesh=
```

5. The same surface, but where the defining functions are symbolic:

```
sage: u, v = var('u,v')
sage: parametric_plot3d((cos(u), sin(u) + cos(v), sin(v)), (u, 0, 2*pi), (v, -pi, pi))
```

   We increase the number of plot points, and make the surface green and transparent:

```
sage: parametric_plot3d((cos(u), sin(u) + cos(v), sin(v)), (u, 0, 2*pi), (v, -pi, pi), color
```

We call the space curve function but with polynomials instead of symbolic variables.

```
sage: R.<t> = RDF[]
sage: parametric_plot3d( (t, t^2, t^3), (t, 0, 3) )
```

Next we plot the same curve, but because we use (0, 3) instead of (t, 0, 3), each polynomial is viewed as a callable function of one variable:

```
sage: parametric_plot3d( (t, t^2, t^3), (0, 3) )
```

We do a plot but mix a symbolic input, and an integer:

```
sage: t = var('t')
sage: parametric_plot3d( (1, sin(t), cos(t)), (t, 0, 3) )
```

We specify a boundary style to show us the values of the function at its extrema:

```
sage: u, v = var('u,v')
sage: parametric_plot3d((cos(u), sin(u) + cos(v), sin(v)), (u, 0, pi), (v, 0, pi), \
...                     boundary_style={"color": "black", "thickness": 2})
```

Any options you would normally use to specify the appearance of a curve are valid as entries in the boundary_style dict.

MANY MORE EXAMPLES:

We plot two interlinked tori:

```
sage: u, v = var('u,v')
sage: f1 = (4+(3+cos(v))*sin(u), 4+(3+cos(v))*cos(u), 4+sin(v))
sage: f2 = (8+(3+cos(v))*cos(u), 3+sin(v), 4+(3+cos(v))*sin(u))
sage: p1 = parametric_plot3d(f1, (u,0,2*pi), (v,0,2*pi), texture="red")
sage: p2 = parametric_plot3d(f2, (u,0,2*pi), (v,0,2*pi), texture="blue")
sage: p1 + p2
```

A cylindrical Star of David:

```
sage: u,v = var('u v')
sage: f_x = cos(u)*cos(v)*(abs(cos(3*v/4))^500 + abs(sin(3*v/4))^500)^(-1/260)*(abs(cos(4*u/4))^
sage: f_y = cos(u)*sin(v)*(abs(cos(3*v/4))^500 + abs(sin(3*v/4))^500)^(-1/260)*(abs(cos(4*u/4))^
sage: f_z = sin(u)*(abs(cos(4*u/4))^200 + abs(sin(4*u/4))^200)^(-1/200)
sage: parametric_plot3d([f_x, f_y, f_z], (u, -pi, pi), (v, 0, 2*pi))
```

Double heart:

```
sage: u, v = var('u,v')
sage: f_x = ( abs(v) - abs(u) - abs(tanh((1/sqrt(2))*u)/(1/sqrt(2))) + abs(tanh((1/sqrt(2))*v)/(
sage: f_y = ( abs(v) - abs(u) - abs(tanh((1/sqrt(2))*u)/(1/sqrt(2))) - abs(tanh((1/sqrt(2))*v)/(
sage: f_z = sin(u)*(abs(cos(4*u/4))^1 + abs(sin(4*u/4))^1)^(-1/1)
sage: parametric_plot3d([f_x, f_y, f_z], (u, 0, pi), (v, -pi, pi))
```

Heart:

```
sage: u, v = var('u,v')
sage: f_x = cos(u)*(4*sqrt(1-v^2)*sin(abs(u))^abs(u))
sage: f_y = sin(u) *(4*sqrt(1-v^2)*sin(abs(u))^abs(u))
sage: f_z = v
sage: parametric_plot3d([f_x, f_y, f_z], (u, -pi, pi), (v, -1, 1), frame=False, color="red")
```

Green bowtie:

```
sage: u, v = var('u,v')
sage: f_x = sin(u) / (sqrt(2) + sin(v))
sage: f_y = sin(u) / (sqrt(2) + cos(v))
sage: f_z = cos(u) / (1 + sqrt(2))
sage: parametric_plot3d([f_x, f_y, f_z], (u, -pi, pi), (v, -pi, pi), frame=False, color="green")
```

Boy's surface http://en.wikipedia.org/wiki/Boy's_surface

```
sage: u, v = var('u,v')
sage: fx = 2/3* (cos(u)* cos(2*v) + sqrt(2)* sin(u)* cos(v))* cos(u) / (sqrt(2) - sin(2*u)* sin(
sage: fy = 2/3* (cos(u)* sin(2*v) - sqrt(2)* sin(u)* sin(v))* cos(u) / (sqrt(2) - sin(2*u)* sin(
sage: fz = sqrt(2)* cos(u)* cos(u) / (sqrt(2) - sin(2*u)* sin(3*v))
sage: parametric_plot3d([fx, fy, fz], (u, -2*pi, 2*pi), (v, 0, pi), plot_points = [90,90], frame
```

Maeder's_Owl (pretty but can't find an internet reference):

```
sage: u, v = var('u,v')
sage: fx = v *cos(u) - 0.5* v^2 * cos(2* u)
sage: fy = -v *sin(u) - 0.5* v^2 * sin(2* u)
sage: fz = 4 *v^1.5 * cos(3 *u / 2) / 3
sage: parametric_plot3d([fx, fy, fz], (u, -2*pi, 2*pi), (v, 0, 1),plot_points = [90,90], frame=F
```

Bracelet:

```
sage: u, v = var('u,v')
sage: fx = (2 + 0.2*sin(2*pi*u))*sin(pi*v)
sage: fy = 0.2*cos(2*pi*u) *3*cos(2*pi*v)
sage: fz = (2 + 0.2*sin(2*pi*u))*cos(pi*v)
sage: parametric_plot3d([fx, fy, fz], (u, 0, pi/2), (v, 0, 3*pi/4), frame=False, color="gray")
```

Green goblet

```
sage: u, v = var('u,v')
sage: fx = cos(u)*cos(2*v)
sage: fy = sin(u)*cos(2*v)
sage: fz = sin(v)
sage: parametric_plot3d([fx, fy, fz], (u, 0, 2*pi), (v, 0, pi), frame=False, color="green")
```

Funny folded surface - with square projection:

```
sage: u, v = var('u,v')
sage: fx = cos(u)*sin(2*v)
sage: fy = sin(u)*cos(2*v)
sage: fz = sin(v)
sage: parametric_plot3d([fx, fy, fz], (u, 0, 2*pi), (v, 0, 2*pi), frame=False, color="green")
```

Surface of revolution of figure 8:

```
sage: u, v = var('u,v')
sage: fx = cos(u)*sin(2*v)
sage: fy = sin(u)*sin(2*v)
sage: fz = sin(v)
sage: parametric_plot3d([fx, fy, fz], (u, 0, 2*pi), (v, 0, 2*pi), frame=False, color="green")
```

Yellow Whitney's umbrella http://en.wikipedia.org/wiki/Whitney_umbrella:

```
sage: u, v = var('u,v')
sage: fx = u*v
sage: fy = u
sage: fz = v^2
sage: parametric_plot3d([fx, fy, fz], (u, -1, 1), (v, -1, 1), frame=False, color="yellow")
```

Cross cap http://en.wikipedia.org/wiki/Cross-cap:

```
sage: u, v = var('u,v')
sage: fx = (1+cos(v))*cos(u)
sage: fy = (1+cos(v))*sin(u)
sage: fz = -tanh((2/3)*(u-pi))*sin(v)
sage: parametric_plot3d([fx, fy, fz], (u, 0, 2*pi), (v, 0, 2*pi), frame=False, color="red")
```

Twisted torus:

```
sage: u, v = var('u,v')
sage: fx = (3+sin(v)+cos(u))*cos(2*v)
sage: fy = (3+sin(v)+cos(u))*sin(2*v)
sage: fz = sin(u)+2*cos(v)
sage: parametric_plot3d([fx, fy, fz], (u, 0, 2*pi), (v, 0, 2*pi), frame=False, color="red")
```

Four intersecting discs:

```
sage: u, v = var('u,v')
sage: fx = v *cos(u) -0.5*v^2*cos(2*u)
sage: fy = -v*sin(u) -0.5*v^2*sin(2*u)
sage: fz = 4* v^1.5 *cos(3* u / 2) / 3
sage: parametric_plot3d([fx, fy, fz], (u, 0, 4*pi), (v, 0,2*pi), frame=False, color="red", opaci
```

Steiner surface/Roman's surface (see http://en.wikipedia.org/wiki/Roman_surface and http://en.wikipedia.org/wiki/Steiner_surface):

```
sage: u, v = var('u,v')
sage: fx = (sin(2 * u) * cos(v) * cos(v))
sage: fy = (sin(u) * sin(2 * v))
sage: fz = (cos(u) * sin(2 * v))
sage: parametric_plot3d([fx, fy, fz], (u, -pi/2, pi/2), (v, -pi/2,pi/2), frame=False, color="red
```

Klein bottle? (see http://en.wikipedia.org/wiki/Klein_bottle):

```
sage: u, v = var('u,v')
sage: fx = (3*(1+sin(v)) + 2*(1-cos(v)/2)*cos(u))*cos(v)
sage: fy = (4+2*(1-cos(v)/2)*cos(u))*sin(v)
sage: fz = -2*(1-cos(v)/2) * sin(u)
sage: parametric_plot3d([fx, fy, fz], (u, 0, 2*pi), (v, 0, 2*pi), frame=False, color="green")
```

A Figure 8 embedding of the Klein bottle (see http://en.wikipedia.org/wiki/Klein_bottle):

```
sage: u, v = var('u,v')
sage: fx = (2 + cos(v/2)* sin(u) - sin(v/2)* sin(2 *u))* cos(v)
sage: fy = (2 + cos(v/2)* sin(u) - sin(v/2)* sin(2 *u))* sin(v)
sage: fz = sin(v/2)* sin(u) + cos(v/2) *sin(2* u)
sage: parametric_plot3d([fx, fy, fz], (u, 0, 2*pi), (v, 0, 2*pi), frame=False, color="red")
```

Enneper's surface (see http://en.wikipedia.org/wiki/Enneper_surface):

```
sage: u, v = var('u,v')
sage: fx = u -u^3/3  + u*v^2
sage: fy = v -v^3/3  + v*u^2
sage: fz = u^2 - v^2
sage: parametric_plot3d([fx, fy, fz], (u, -2, 2), (v, -2, 2), frame=False, color="red")
```

Henneberg's surface (see http://xahlee.org/surface/gallery_m.html)

```
sage: u, v = var('u,v')
sage: fx = 2*sinh(u)*cos(v) -(2/3)*sinh(3*u)*cos(3*v)
sage: fy = 2*sinh(u)*sin(v) +(2/3)*sinh(3*u)*sin(3*v)
sage: fz = 2*cosh(2*u)*cos(2*v)
sage: parametric_plot3d([fx, fy, fz], (u, -1, 1), (v, -pi/2, pi/2), frame=False, color="red")
```

Dini's spiral

```
sage: u, v = var('u,v')
sage: fx = cos(u)*sin(v)
sage: fy = sin(u)*sin(v)
sage: fz = (cos(v)+log(tan(v/2))) + 0.2*u
sage: parametric_plot3d([fx, fy, fz], (u, 0, 12.4), (v, 0.1, 2),frame=False, color="red")
```

Catalan's surface (see http://xahlee.org/surface/catalan/catalan.html):

```
sage: u, v = var('u,v')
sage: fx = u-sin(u)*cosh(v)
sage: fy = 1-cos(u)*cosh(v)
sage: fz = 4*sin(1/2*u)*sinh(v/2)
sage: parametric_plot3d([fx, fy, fz], (u, -pi, 3*pi), (v, -2, 2), frame=False, color="red")
```

A Conchoid:

```
sage: u, v = var('u,v')
sage: k = 1.2; k_2 = 1.2; a = 1.5
sage: f = (k^u*(1+cos(v))*cos(u), k^u*(1+cos(v))*sin(u), k^u*sin(v)-a*k_2^u)
sage: parametric_plot3d(f, (u,0,6*pi), (v,0,2*pi), plot_points=[40,40], texture=(0,0.5,0))
```

A Mobius strip:

```
sage: u,v = var("u,v")
sage: parametric_plot3d([cos(u)*(1+v*cos(u/2)), sin(u)*(1+v*cos(u/2)), 0.2*v*sin(u/2)], (u,0, 4*
```

A Twisted Ribon

```
sage: u, v = var('u,v')
sage: parametric_plot3d([3*sin(u)*cos(v), 3*sin(u)*sin(v), cos(v)], (u,0, 2*pi), (v, 0, pi),plot
```

An Ellipsoid:

```
sage: u, v = var('u,v')
sage: parametric_plot3d([3*sin(u)*cos(v), 2*sin(u)*sin(v), cos(u)], (u,0, 2*pi), (v, 0, 2*pi),pl
```

A Cone:

```
sage: u, v = var('u,v')
sage: parametric_plot3d([u*cos(v), u*sin(v), u], (u, -1, 1), (v, 0, 2*pi+0.5), plot_points=[50,5
```

A Paraboloid:

```
sage: u, v = var('u,v')
sage: parametric_plot3d([u*cos(v), u*sin(v), u^2], (u, 0, 1), (v, 0, 2*pi+0.4), plot_points=[50,
```

A Hyperboloid:

```
sage: u, v = var('u,v')
sage: plot3d(u^2-v^2, (u, -1, 1), (v, -1, 1), plot_points=[50,50])
```

A weird looking surface - like a Mobius band but also an O:

```
sage: u, v = var('u,v')
sage: parametric_plot3d([sin(u)*cos(u)*log(u^2)*sin(v), (u^2)^(1/6)*(cos(u)^2)^(1/4)*cos(v), sin
```

A heart, but not a cardioid (for my wife):

```
sage: u, v = var('u,v')
sage: p1 = parametric_plot3d([sin(u)*cos(u)*log(u^2)*v*(1-v)/2, ((u^6)^(1/20)*(cos(u)^2)^(1/4)-1
sage: p2 = parametric_plot3d([-sin(u)*cos(u)*log(u^2)*v*(1-v)/2, ((u^6)^(1/20)*(cos(u)^2)^(1/4)-
sage: show(p1+p2, frame=False)
```

A Hyperhelicoidal:

```
sage: u = var("u")
sage: v = var("v")
sage: fx = (sinh(v)*cos(3*u))/(1+cosh(u)*cosh(v))
sage: fy = (sinh(v)*sin(3*u))/(1+cosh(u)*cosh(v))
sage: fz = (cosh(v)*sinh(u))/(1+cosh(u)*cosh(v))
sage: parametric_plot3d([fx, fy, fz], (u, -pi, pi), (v, -pi, pi), plot_points = [50,50], frame=F
```

A Helicoid (lines through a helix, http://en.wikipedia.org/wiki/Helix):

```
sage: u, v = var('u,v')
sage: fx = sinh(v)*sin(u)
sage: fy = -sinh(v)*cos(u)
sage: fz = 3*u
sage: parametric_plot3d([fx, fy, fz], (u, -pi, pi), (v, -pi, pi), plot_points = [50,50], frame=F
```

Kuen's surface (http://www.math.umd.edu/research/bianchi/Gifccsurfs/ccsurfs.html):

```
sage: fx = (2*(cos(u) + u*sin(u))*sin(v))/(1+ u^2*sin(v)^2)
sage: fy = (2*(sin(u) - u*cos(u))*sin(v))/(1+ u^2*sin(v)^2)
sage: fz = log(tan(1/2 *v)) + (2*cos(v))/(1+ u^2*sin(v)^2)
sage: parametric_plot3d([fx, fy, fz], (u, 0, 2*pi), (v, 0.01, pi-0.01), plot_points = [50,50], f
```

A 5-pointed star:

```
sage: fx = cos(u)*cos(v)*(abs(cos(1*u/4))^0.5 + abs(sin(1*u/4))^0.5)^(-1/0.3)*(abs(cos(5*v/4))^1
sage: fy = cos(u)*sin(v)*(abs(cos(1*u/4))^0.5 + abs(sin(1*u/4))^0.5)^(-1/0.3)*(abs(cos(5*v/4))^1
sage: fz = sin(u)*(abs(cos(1*u/4))^0.5 + abs(sin(1*u/4))^0.5)^(-1/0.3)
sage: parametric_plot3d([fx, fy, fz], (u, -pi/2, pi/2), (v, 0, 2*pi), plot_points = [50,50], fra
```

A cool self-intersecting surface (Eppener surface?):

```
sage: fx = u - u^3/3 + u*v^2
sage: fy = v - v^3/3 + v*u^2
sage: fz = u^2 - v^2
sage: parametric_plot3d([fx, fy, fz], (u, -25, 25), (v, -25, 25), plot_points = [50,50], frame=F
```

The breather surface (http://en.wikipedia.org/wiki/Breather_surface):

```
sage: fx = (2*sqrt(0.84)*cosh(0.4*u)*(-(sqrt(0.84)*cos(v)*cos(sqrt(0.84)*v)) - sin(v)*sin(sqrt(0
sage: fy = (2*sqrt(0.84)*cosh(0.4*u)*(-(sqrt(0.84)*sin(v)*cos(sqrt(0.84)*v)) + cos(v)*sin(sqrt(0
sage: fz = -u + (2*0.84*cosh(0.4*u)*sinh(0.4*u))/(0.4*((sqrt(0.84)*cosh(0.4*u))^2 + (0.4*sin(sqr
sage: parametric_plot3d([fx, fy, fz], (u, -13.2, 13.2), (v, -37.4, 37.4), plot_points = [90,90],
```

TESTS:

```
sage: u, v = var('u,v')
sage: plot3d(u^2-v^2, (u, -1, 1), (u, -1, 1))
...
ValueError: plot variables should be distinct, but both are u.
```

From Trac #2858:

```
sage: parametric_plot3d((u,-u,v), (u,-10,10),(v,-10,10))
sage: f(u)=u; g(v)=v^2; parametric_plot3d((g,f,f), (-10,10),(-10,10))
```

From Trac #5368:

```
sage: x, y = var('x,y')
sage: plot3d(x*y^2 - sin(x), (x,-1,1), (y,-1,1))
```

parametric_plot3d_curve (*f, urange, plot_points, **kwds*)
This function is used internally by the `parametric_plot3d` command.

parametric_plot3d_surface (*f, urange, vrange, plot_points, boundary_style, **kwds*)
This function is used internally by the `parametric_plot3d` command.

5.3 Implicit Plots

implicit_plot3d (*f, xrange, yrange, zrange, **kwds*)
Plots an isosurface of a function.

INPUT:

- `f` - function
- `xrange` - a 2-tuple (x_min, x_max) or a 3-tuple (x, x_min, x_max)
- `yrange` - a 2-tuple (y_min, y_may) or a 3-tuple (y, y_min, y_may)
- `zrange` - a 2-tuple (z_min, z_maz) or a 3-tuple (z, z_min, z_maz)
- `plot_points` - (default: "automatic", which is 50) the number of function evaluations in each direction. (The number of cubes in the marching cubes algorithm will be one less than this). Can be a triple of integers, to specify a different resolution in each of x,y,z.
- `contour` - (default: 0) plot the isosurface f(x,y,z)==contour. Can be a list, in which case multiple contours are plotted.
- `region` - (default: None) If region is given, it must be a Python callable. Only segments of the surface where region(x,y,z) returns a number >0 will be included in the plot. (Note that returning a Python boolean is acceptable, since True == 1 and False == 0).

EXAMPLES:

```
sage: var('x,y,z')
(x, y, z)
```

A simple sphere:

```
sage: implicit_plot3d(x^2+y^2+z^2==4, (x, -3, 3), (y, -3,3), (z, -3,3))
```

A nested set of spheres with a hole cut out:

```
sage: implicit_plot3d((x^2 + y^2 + z^2), (x, -2, 2), (y, -2, 2), (z, -2, 2), plot_points=60, con
...                   region=lambda x,y,z: x<=0.2 or y>=0.2 or z<=0.2).show(viewer='tachyon')
```

A very pretty example from http://iat.ubalt.edu/summers/math/platsol.htm:

```
sage: T = RDF(golden_ratio)
sage: p = 2 - (cos(x + T*y) + cos(x - T*y) + cos(y + T*z) + cos(y - T*z) + cos(z - T*x) + cos(z
sage: r = 4.77
sage: implicit_plot3d(p, (x, -r, r), (y, -r, r), (z, -r, r), plot_points=40).show(viewer='tachyc
```

As I write this (but probably not as you read it), it's almost Valentine's day, so let's try a heart (from http://mathworld.wolfram.com/HeartSurface.html)

```
sage: p = (x^2+9/4*y^2+z^2-1)^3-x^2*z^3-9/(80)*y^2*z^3
sage: r = 1.5
sage: implicit_plot3d(p, (x, -r,r), (y, -r,r), (z, -r,r), plot_points=80, color='red', smooth=Fa
```

The same examples also work with the default Jmol viewer; for example:

```
sage: T = RDF(golden_ratio)
sage: p = 2 - (cos(x + T*y) + cos(x - T*y) + cos(y + T*z) + cos(y - T*z) + cos(z - T*x) + cos(z
sage: r = 4.77
sage: implicit_plot3d(p, (x, -r, r), (y, -r, r), (z, -r, r), plot_points=40).show()
```

Here we use smooth=True with a Tachyon graph:

```
sage: implicit_plot3d(x^2 + y^2 + z^2, (x, -2, 2), (y, -2, 2), (z, -2, 2), contour=4, smooth=Tru
```

We explicitly specify a gradient function (in conjunction with smooth=True) and invert the normals:

```
sage: gx = lambda x, y, z: -(2*x + y^2 + z^2)
sage: gy = lambda x, y, z: -(x^2 + 2*y + z^2)
sage: gz = lambda x, y, z: -(x^2 + y^2 + 2*z)
sage: implicit_plot3d(x^2+y^2+z^2, (x, -2, 2), (y, -2, 2), (z, -2, 2), contour=4, \
...       plot_points=40, smooth=True, gradient=(gx, gy, gz)).show(viewer='tachyon')
```

A graph of two metaballs interacting with each other:

```
sage: def metaball(x0, y0, z0): return 1 / ((x-x0)^2 + (y-y0)^2 + (z-z0)^2)
sage: implicit_plot3d(metaball(-0.6, 0, 0) + metaball(0.6, 0, 0), (x, -2, 2), (y, -2, 2), (z, -2
```

MANY MORE EXAMPLES:

A kind of saddle:

```
sage: implicit_plot3d(x^3 + y^2 - z^2, (x, -2, 2), (y, -2, 2), (z, -2, 2), plot_points=60, contc
```

A smooth surface with six radial openings:

```
sage: implicit_plot3d(-(cos(x) + cos(y) + cos(z)), (x, -4, 4), (y, -4, 4), (z, -4, 4))
```

A cube composed of eight conjoined blobs:

```
sage: implicit_plot3d(x^2 + y ^2 + z^2 +cos(4*x)+cos(4*y)+cos(4*z)-0.2, (x, -2, 2), (y, -2, 2),
```

A variation of the blob cube featuring heterogeneously sized blobs:

```
sage: implicit_plot3d(x^2 + y ^2 + z^2 +sin(4*x) + sin(4*y) + sin(4*z) -1, (x, -2, 2), (y, -2, 2
```

A klein bottle:

```
sage: implicit_plot3d((x^2+y^2+z^2+2*y-1)*((x^2+y^2+z^2-2*y-1)^2-8*z^2)+16*x*z*(x^2+y^2+z^2-2*y-
```

A leminescate:

```
sage: implicit_plot3d(4*x^2*(x^2+y^2+z^2+z)+y^2*(y^2+z^2-1), (x, -0.5, 0.5), (y, -1, 1), (z, -1,
```

Drope:

```
sage: implicit_plot3d(z - 4*x*exp(-x^2-y^2), (x, -2, 2), (y, -2, 2), (z, -1.7, 1.7))
```

A cube with a circular aperture on each face:

```
sage: implicit_plot3d(((1/2.3)^2 *(x^2 + y^2 + z^2))^-6 + ( (1/2)^8 * (x^8 + y^8 + z^8) )^6 -1,
```

A simple hyperbolic surface:

```
sage: implicit_plot3d(x*x + y - z*z, (x, -1, 1), (y, -1, 1), (z, -1, 1))
```

A hyperboloid:

```
sage: implicit_plot3d(x^2 + y^2 - z^2 -0.3, (x, -2, 2), (y, -2, 2), (z, -1.8, 1.8))
```

Duplin cycloid:

```
sage: implicit_plot3d((2^2 - 0^2 - (2 + 2.1)^2) * (2^2 - 0^2 - (2 - 2.1)^2)*(x^4+y^4+z^4)+ 2*((2
```

Sinus:

```
sage: implicit_plot3d(sin(pi*((x)^2+(y)^2))/2 +z, (x, -1, 1), (y, -1, 1), (z, -1, 1))
```

A torus:

```
sage: implicit_plot3d((sqrt(x*x+y*y)-3)^2 + z*z - 1, (x, -4, 4), (y, -4, 4), (z, -1, 1))
```

An octahedron:

```
sage: implicit_plot3d(abs(x)+abs(y)+abs(z) - 1, (x, -1, 1), (y, -1, 1), (z, -1, 1))
```

A cube:

```
sage: implicit_plot3d(x^100 + y^100 + z^100 -1, (x, -2, 2), (y, -2, 2), (z, -2, 2))
```

Toupie:

```
sage: implicit_plot3d((sqrt(x*x+y*y)-3)^3 + z*z - 1, (x, -4, 4), (y, -4, 4), (z, -6, 6))
```

A cube with rounded edges:

```
sage: implicit_plot3d(x^4 + y^4 + z^4 - (x^2 + y^2 + z^2), (x, -2, 2), (y, -2, 2), (z, -2, 2))
```

Chmutov:

```
sage: implicit_plot3d(x^4 + y^4 + z^4 - (x^2 + y^2 + z^2-0.3), (x, -1.5, 1.5), (y, -1.5, 1.5), (
```

Further Chutmov:

```
sage: implicit_plot3d(2*(x^2*(3-4*x^2)^2+y^2*(3-4*y^2)^2+z^2*(3-4*z^2)^2) -3, (x, -1.3, 1.3), (y
```

Clebsch:

```
sage: implicit_plot3d(81*(x^3+y^3+z^3)-189*(x^2*y+x^2*z+y^2*x+y^2*z+z^2*x+z^2*y) +54*x*y*z+126*(
```

Looks like a water droplet:

```
sage: implicit_plot3d(x^2 +y^2 -(1-z)*z^2, (x, -1.5, 1.5), (y, -1.5, 1.5), (z, -1, 1))
```

Sphere in a cage:

```
sage: implicit_plot3d((x^8 + z^30 + y^8 - (x^4 + z^50 + y^4 -0.3))*(x^2 + y^2 + z^2 -0.5), (x, -
```

Ortho circle:

```
sage: implicit_plot3d(((x^2 + y^2 - 1)^2 + z^2)* ((y^2 + z^2 - 1)^2 + x^2)* ((z^2 + x^2 - 1)^2 +
```

Cube sphere:

```
sage: implicit_plot3d(12 - ((1/2.3)^2 *(x^2 + y^2 + z^2))^-6 - ( (1/2)^8 * (x^8 + y^8 + z^8) )^6
```

Two cylinders intersect to make a cross:

```
sage: implicit_plot3d((x^2 + y^2 - 1) * ( x^2 + z^2 - 1) - 1, (x, -3, 3), (y, -3, 3), (z, -3, 3)
```

Three cylinders intersect in a similar fashion:

```
sage: implicit_plot3d((x^2 + y^2 - 1) * ( x^2 + z^2 - 1)* ( y^2 + z^2 - 1) - 1, (x, -3, 3), (y,
```

A sphere-ish object with twelve holes, four on each XYZ plane:

```
sage: implicit_plot3d(3*(cos(x) + cos(y) + cos(z)) + 4* cos(x) * cos(y) * cos(z), (x, -3, 3), (y
```

A gyroid:

```
sage: implicit_plot3d(cos(x) * sin(y) + cos(y) * sin(z) + cos(z) * sin(x), (x, -4, 4), (y, -4, 4
```

Tetrahedra:

```
sage: implicit_plot3d((x^2 + y^2 + z^2)^2 + 8*x*y*z - 10*(x^2 + y^2 + z^2) + 25, (x, -4, 4), (y,
```

TESTS:

Test a separate resolution in the X direction; this should look like a regular sphere:

```
sage: implicit_plot3d(x^2 + y^2 + z^2, (x, -2, 2), (y, -2, 2), (z, -2, 2), plot_points=(10, 40,
```

Test using different plot ranges in the different directions; this should generate half of a sphere:

```
sage: implicit_plot3d(x^2 + y^2 + z^2, (x, 0, 2), (y, -2, 2), (z, -2, 2), contour=4)
```

Extra keyword arguments will be passed to show():

```
sage: implicit_plot3d(x^2 + y^2 + z^2, (x, -2, 2), (y, -2, 2), (z, -2, 2), contour=4, viewer='ta
```

5.4 List Plots

list_plot3d(*v, interpolation_type='default', texture='automatic', point_list=None, **kwds*)

A 3-dimensional plot of a surface defined by the list v of points in 3-dimensional space.
INPUT:

- `v` - something that defines a set of points in 3 space, for example:
  - a matrix
  - a list of 3-tuples
  - a list of lists (all of the same length) - this is treated the same as a matrix.
- `texture` - (default: "automatic"), solid light blue

OPTIONAL KEYWORDS:

- `interpolation_type` - 'linear', 'nn' (nearest neighbor), 'spline'
  'linear' will perform linear interpolation
  The option 'nn' will interpolate by averaging the value of the nearest neighbors, this produces an interpolating function that is smoother than a linear interpolation, it has one derivative everywhere except at the sample points.
  The option 'spline' interpolates using a bivariate B-spline.
  When v is a matrix the default is to use linear interpolation, when v is a list of points the default is nearest neighbor.
- `degree` - an integer between 1 and 5, controls the degree of spline used for spline interpolation. For data that is highly oscillatory use higher values
- `point_list` - If point_list=True is passed, then if the array is a list of lists of length three, it will be treated as an array of points rather than a 3xn array.
- `num_points` - Number of points to sample interpolating function in each direction. By default for an nxn array this is n.
- `**kwds` - all other arguments are passed to the surface function

OUTPUT: a 3d plot
EXAMPLES:
We plot a matrix that illustrates summation modulo n.

```
sage: n = 5; list_plot3d(matrix(RDF,n,[(i+j)%n for i in [1..n] for j in [1..n]]))
```

We plot a matrix of values of sin.

```
sage: pi = float(pi)
sage: m = matrix(RDF, 6, [sin(i^2 + j^2) for i in [0,pi/5,..,pi] for j in [0,pi/5,..,pi]])
sage: list_plot3d(m, texture='yellow', frame_aspect_ratio=[1,1,1/3])
```

Though it doesn't change the shape of the graph, increasing num_points can increase the clarity of the graph.

```
sage: list_plot3d(m, texture='yellow', frame_aspect_ratio=[1,1,1/3],num_points=40)
```

We can change the interpolation type.

```
sage: list_plot3d(m, texture='yellow', interpolation_type='nn',frame_aspect_ratio=[1,1,1/3])
```

We can make this look better by increasing the number of samples.

```
sage: list_plot3d(m, texture='yellow', interpolation_type='nn',frame_aspect_ratio=[1,1,1/3],
```

Let's try a spline.

```
sage: list_plot3d(m, texture='yellow', interpolation_type='spline',frame_aspect_ratio=[1,1,1
```

That spline doesn't capture the oscillation very well; let's try a higher degree spline.

```
sage: list_plot3d(m, texture='yellow', interpolation_type='spline', degree=5, frame_aspect_r
```

We plot a list of lists:

```
sage: show(list_plot3d([[1, 1, 1, 1], [1, 2, 1, 2], [1, 1, 3, 1], [1, 2, 1, 4]]))
```

We plot a list of points. As a first example we can extract the (x,y,z) coordinates from the above example and make a list plot out of it. By default we do linear interpolation.

```
sage: l=[]
sage: for i in range(6):
...       for j in range(6):
...          l.append((float(i*pi/5),float(j*pi/5),m[i,j]))
sage: list_plot3d(l,texture='yellow')
```

Note that the points do not have to be regularly sampled. For example:

```
sage: l=[]
sage: for i in range(-5,5):
...       for j in range(-5,5):
...          l.append((normalvariate(0,1),normalvariate(0,1),normalvariate(0,1)))
sage: list_plot3d(l,interpolation_type='nn',texture='yellow',num_points=100)
```

TESTS: We plot 0, 1, and 2 points:

```
sage: list_plot3d([])
sage: list_plot3d([(2,3,4)])
sage: list_plot3d([(0,0,1), (2,3,4)])
```

However, if two points are given with the same x,y coordinates but different z coordinates, an exception will be raised:

```
sage: pts =[(-4/5, -2/5, -2/5), (-4/5, -2/5, 2/5), (-4/5, 2/5, -2/5), (-4/5, 2/5, 2/5), (-2/
sage: show(list_plot3d(pts, interpolation_type='nn'))
...
ValueError: Two points with same x,y coordinates and different z coordinates were given. Int
```

Additionally we need at least 3 points to do the interpolation:

```
sage: mat = matrix(RDF, 1, 2, [3.2, 1.550])
sage: show(list_plot3d(mat,interpolation_type='nn'))
...
ValueError: We need at least 3 points to perform the interpolation
```

list_plot3d_array_of_arrays(*v, interpolation_type, texture, **kwds*)

list_plot3d_matrix(*m, texture, **kwds*)

list_plot3d_tuples(*v, interpolation_type, texture, **kwds*)

5.5 Plotting Functions.

EXAMPLES:

```
sage: def f(x,y):
...       return math.sin(y*y+x*x)/math.sqrt(x*x+y*y+.0001)
...
sage: P = plot3d(f,(-3,3),(-3,3), adaptive=True, color=rainbow(60, 'rgbtuple'), max_bend=.1, max_dept
sage: P.show()
```

```
sage: def f(x,y):
...       return math.exp(x/5)*math.sin(y)
...
sage: P = plot3d(f,(-5,5),(-5,5), adaptive=True, color=['red','yellow'])
sage: from sage.plot.plot3d.plot3d import axes
sage: S = P + axes(6, color='black')
sage: S.show()
```

We plot "cape man":

```
sage: S = sphere(size=.5, color='yellow')

sage: from sage.plot.plot3d.shapes import Cone
sage: S += Cone(.5, .5, color='red').translate(0,0,.3)

sage: S += sphere((.45,-.1,.15), size=.1, color='white') + sphere((.51,-.1,.17), size=.05, color='bla
sage: S += sphere((.45, .1,.15),size=.1, color='white') + sphere((.51, .1,.17), size=.05, color='blac
sage: S += sphere((.5,0,-.2),size=.1, color='yellow')
sage: def f(x,y): return math.exp(x/5)*math.cos(y)
sage: P = plot3d(f,(-5,5),(-5,5), adaptive=True, color=['red','yellow'], max_depth=10)
sage: cape_man = P.scale(.2) + S.translate(1,0,0)
sage: cape_man.show(aspect_ratio=[1,1,1])
```

AUTHORS:

- Tom Boothby: adaptive refinement triangles
- Josh Kantor: adaptive refinement triangles
- Robert Bradshaw (2007-08): initial version of this file
- William Stein (2007-12, 2008-01): improving 3d plotting

class **TrivialTriangleFactory**()

smooth_triangle(*a, b, c, da, db, dc, color=None*)

triangle(*a, b, c, color=None*)

axes(*scale=1, radius=None, **kwds*)

plot3d(*f, urange, vrange, adaptive=False, **kwds*)

INPUT:

- `f` - a symbolic expression or function of 2 variables
- `urange` - a 2-tuple (u_min, u_max) or a 3-tuple (u, u_min, u_max)
- `vrange` - a 2-tuple (v_min, v_max) or a 3-tuple (v, v_min, v_max)
- `adaptive` - (default: False) whether to use adaptive refinement to draw the plot (slower, but may look better)
- `mesh` - bool (default: False) whether to display mesh grid lines
- `dots` - bool (default: False) whether to display dots at mesh grid points

Note: `mesh` and `dots` are not supported when using the Tachyon raytracer renderer.

EXAMPLES: We plot a 3d function defined as a Python function:

```
sage: plot3d(lambda x, y: x^2 + y^2, (-2,2), (-2,2))
```

We plot the same 3d function but using adaptive refinement:

```
sage: plot3d(lambda x, y: x^2 + y^2, (-2,2), (-2,2), adaptive=True)
```

Adaptive refinement but with more points:

```
sage: plot3d(lambda x, y: x^2 + y^2, (-2,2), (-2,2), adaptive=True, initial_depth=5)
```

We plot some 3d symbolic functions:

```
sage: x, y = var('x,y')
sage: plot3d(x^2 + y^2, (x,-2,2), (y,-2,2))
sage: plot3d(sin(x*y), (x, -pi, pi), (y, -pi, pi))
```

A 3d plot with a mesh:

```
sage: var('x,y')
(x, y)
sage: plot3d(sin(x-y)*y*cos(x),(x,-3,3),(y,-3,3), mesh=True)
```

Two wobby translucent planes:

```
sage: x,y = var('x,y')
sage: P = plot3d(x+y+sin(x*y), (x,-10,10),(y,-10,10), opacity=0.87, color='blue')
sage: Q = plot3d(x-2*y-cos(x*y),(x,-10,10),(y,-10,10),opacity=0.3,color='red')
sage: P + Q
```

We draw two parametric surfaces and a transparent plane:

```
sage: L = plot3d(lambda x,y: 0, (-5,5), (-5,5), color="lightblue", opacity=0.8)
sage: P = plot3d(lambda x,y: 4 - x^3 - y^2, (-2,2), (-2,2), color='green')
sage: Q = plot3d(lambda x,y: x^3 + y^2 - 4, (-2,2), (-2,2), color='orange')
sage: L + P + Q
```

We draw the "Sinus" function (water ripple-like surface):

```
sage: x, y = var('x y')
sage: plot3d(sin(pi*(x^2+y^2))/2,(x,-1,1),(y,-1,1))
```

Hill and valley (flat surface with a bump and a dent):

```
sage: x, y = var('x y')
sage: plot3d( 4*x*exp(-x^2-y^2), (x,-2,2), (y,-2,2))
```

TESTS: Listing the same plot variable twice gives an error.

```
sage: x, y = var('x y')
sage: plot3d( 4*x*exp(-x^2-y^2), (x,-2,2), (x,-2,2))
...
ValueError: plot variables should be distinct, but both are x.
```

plot3d_adaptive(*f, x_range, y_range, color='automatic', grad_f=None, max_bend=0.5, max_depth=5, initial_depth=4, num_colors=128, **kwds*)

Adaptive 3d plotting of a function of two variables.

This is used internally by the plot3d command when the option `adaptive=True` is given.

INPUT:

- f - a symbolic function or a Python function of 3 variables.
- x_range - x range of values: 2-tuple (xmin, xmax) or 3-tuple (x,xmin,xmax)
- y_range - y range of values: 2-tuple (ymin, ymax) or 3-tuple (y,ymin,ymax)
- grad_f - gradient of f as a Python function
- color - "automatic" - a rainbow of num_colors colors
- num_colors - (default: 128) number of colors to use with default color
- max_bend - (default: 0.5)
- max_depth - (default: 5)
- initial_depth - (default: 4)
- **kwds - standard graphics parameters

EXAMPLES: We plot $\sin(xy)$:

```
sage: from sage.plot.plot3d.plot3d import plot3d_adaptive
sage: x,y=var('x,y'); plot3d_adaptive(sin(x*y), (x,-pi,pi), (y,-pi,pi), initial_depth=5)
```

5.6 Platonic Solids.

EXAMPLES: The five platonic solids in a row;

```
sage: G = tetrahedron((0,-3.5,0), color='blue') + cube((0,-2,0),color=(.25,0,.5)) +\
      octahedron(color='red') + dodecahedron((0,2,0), color='orange') +\
      icosahedron(center=(0,4,0), color='yellow')
sage: G.show(aspect_ratio=[1,1,1])
```

All the platonic solids in the same place:

```
sage: G = tetrahedron(color='blue',opacity=0.7) + \
      cube(color=(.25,0,.5), opacity=0.7) +\
      octahedron(color='red', opacity=0.7) + \
      dodecahedron(color='orange', opacity=0.7) + icosahedron(opacity=0.7)
sage: G.show(aspect_ratio=[1,1,1])
```

Display nice faces only:

```
sage: icosahedron().stickers(['red','blue'], .075, .1)
```

AUTHORS:

- Robert Bradshaw (2007, 2008): initial version
- William Stein

cube (*center=(0, 0, 0), size=1, color=None, frame_thickness=0, frame_color=None, **kwds*)
A 3D cube centered at the origin with default side lengths 1.

INPUT:

- center - (default: (0,0,0))
- size - (default: 1) the side lengths of the cube

- color - a string that describes a color; this can also be a list of 3-tuples or strings length 6 or 3, in which case the faces (and oppositive faces) are colored.
- frame_thickness - (default: 0) if positive, then thickness of the frame
- frame_color - (default: None) if given, gives the color of the frame
- opacity - (default: 1) if less than 1 then it's transparent

EXAMPLES:

A simple cube:

```
sage: cube()
```

A red cube:

```
sage: cube(color="red")
```

A transparent grey cube that contains a red cube:

```
sage: cube(opacity=0.8, color='grey') + cube(size=3/4)
```

A transparent colored cube:

```
sage: cube(color=['red', 'green', 'blue'], opacity=0.5)
```

A bunch of random cubes:

```
sage: v = [(random(), random(), random()) for _ in [1..30]]
sage: sum([cube((10*a,10*b,10*c), size=random()/3, color=(a,b,c)) for a,b,c in v])
```

Non-square cubes (boxes):

```
sage: cube(aspect_ratio=[1,1,1]).scale([1,2,3])
sage: cube(color=['red', 'blue', 'green'],aspect_ratio=[1,1,1]).scale([1,2,3])
```

And one that is colored:

```
sage: cube(color=['red', 'blue', 'green', 'black', 'white', 'orange'],                    aspect_
```

A nice translucent color cube with a frame:

```
sage: c = cube(color=['red', 'blue', 'green'], frame=False, frame_thickness=2,
sage: c
```

A raytraced color cube with frame and transparency:

```
sage: c.show(viewer='tachyon')
```

AUTHORS:

- William Stein

dodecahedron (*center=(0, 0, 0), size=1, **kwds*)

A dodecahedron.

INPUT:

- center - (default: (0,0,0))
- size - (default: 1)

- `color` - a string that describes a color; this can also be a list of 3-tuples or strings length 6 or 3, in which case the faces (and oppositive faces) are colored.
- `opacity` - (default: 1) if less than 1 then is transparent

EXAMPLES: A plain Dodecahedron:

```
sage: dodecahedron()
```

A translucent dodecahedron that contains a black sphere:

```
sage: dodecahedron(color='orange', opacity=0.8) + \
      sphere(size=0.5, color='black')
```

CONSTRUCTION: This is how we construct a dodecahedron. We let one point be $Q = (0, 1, 0)$.

Now there are three points spaced equally on a circle around the north pole. The other requirement is that the angle between them be the angle of a pentagon, namely $3\pi/5$. This is enough to determine them. Placing one on the xz-plane we have.

$P_1 = \left(t, 0, \sqrt{1-t^2}\right)$

$P_2 = \left(-\frac{1}{2}t, \frac{\sqrt{3}}{2}t, \sqrt{1-t^2}\right)$

$P_3 = \left(-\frac{1}{2}t, \frac{\sqrt{3}}{2}t, \sqrt{1-t^2}\right)$

Solving $\frac{(P_1-Q)\cdot(P_2-Q)}{|P_1-Q||P_2-Q|} = \cos(3\pi/5)$ we get $t = 2/3$.

Now we have 6 points $R_1, ..., R_6$ to close the three top pentagons. These can be found by mirroring P_2 and P_3 by the yz-plane and rotating around the y-axis by the angle θ from Q to P_1. Note that $\cos(\theta) = t = 2/3$ and so $\sin(\theta) = \sqrt{5}/3$. Rotation gives us the other four.

Now we reflect through the origin for the bottom half.

AUTHORS:

- Robert Bradshaw, William Stein

icosahedron (*center=(0, 0, 0), size=1, **kwds*)

An icosahedron.

INPUT:

- `center` - (default: (0,0,0))
- `size` - (default: 1)
- `color` - a string that describes a color; this can also be a list of 3-tuples or strings length 6 or 3, in which case the faces (and oppositive faces) are colored.
- `opacity` - (default: 1) if less than 1 then is transparent

EXAMPLES:

```
sage: icosahedron()
```

Two icosahedrons at different positions of different sizes.

```
sage: icosahedron((-1/2,0,1), color='orange') + \
      icosahedron((2,0,1), size=1/2, aspect_ratio=[1,1,1])
```

index_face_set (*face_list, point_list, enclosed, **kwds*)

octahedron(*center=(0, 0, 0), size=1, **kwds*)

Return an octahedron.

INPUT:

- `center` - (default: (0,0,0))
- `size` - (default: 1)
- `color` - a string that describes a color; this can also be a list of 3-tuples or strings length 6 or 3, in which case the faces (and oppositive faces) are colored.
- `opacity` - (default: 1) if less than 1 then is transparent

EXAMPLES:

```
sage: octahedron((1,4,3), color='orange') + \
            octahedron((0,2,1), size=2, opacity=0.6)
```

prep(*G, center, size, kwds*)

tetrahedron(*center=(0, 0, 0), size=1, **kwds*)

A 3d tetrahedron.

INPUT:

- `center` - (default: (0,0,0))
- `size` - (default: 1)
- `color` - a word that describes a color
- `rgbcolor` - (r,g,b) with r, g, b between 0 and 1 that describes a color
- `opacity` - (default: 1) if less than 1 then is transparent

EXAMPLES: A default colored tetrahedron at the origin:

```
sage: tetrahedron()
```

A transparent green tetrahedron in front of a solid red one:

```
sage: tetrahedron(opacity=0.8, color='green') + tetrahedron((-2,1,0),color='red')
```

A translucent tetrahedron sharing space with a sphere:

```
sage: tetrahedron(color='yellow',opacity=0.7) + sphere(r=.5, color='red')
```

A big tetrahedron:

```
sage: tetrahedron(size=10)
```

A wide tetrahedron:

```
sage: tetrahedron(aspect_ratio=[1,1,1]).scale((4,4,1))
```

A red and blue tetrahedron touching noses:

```
sage: tetrahedron(color='red') + tetrahedron((0,0,-2)).scale([1,1,-1])
```

A Dodecahedral complex of 5 tetrahedrons (a more elaborate examples from Peter Jipsen):

```
sage: v=(sqrt(5.)/2-5/6, 5/6*sqrt(3.)-sqrt(15.)/2, sqrt(5.)/3)
sage: t=acos(sqrt(5.)/3)/2
sage: t1=tetrahedron(aspect_ratio=(1,1,1), opacity=0.5).rotateZ(t)
sage: t2=tetrahedron(color='red', opacity=0.5).rotateZ(t).rotate(v,2*pi/5)
sage: t3=tetrahedron(color='green', opacity=0.5).rotateZ(t).rotate(v,4*pi/5)
sage: t4=tetrahedron(color='yellow', opacity=0.5).rotateZ(t).rotate(v,6*pi/5)
sage: t5=tetrahedron(color='orange', opacity=0.5).rotateZ(t).rotate(v,8*pi/5)
sage: show(t1+t2+t3+t4+t5, frame=False, zoom=1.3)
```

AUTHORS:

- Robert Bradshaw and William Stein

5.7 Lines, Frames, Spheres, Points, Dots, and Text

class Line (*points, thickness=5, corner_cutoff=0.5, arrow_head=False, **kwds*)

Draw a 3d line joining a sequence of points.

This line has a fixed diameter unaffected by transformations and zooming. It may be smoothed if `corner_cutoff < 1`.

INPUT:

- `points` - list of points to pass through
- `thickness` - diameter of the line
- `corner_cutoff` - threshold for smoothing (see the corners() method) this is the minimum cosine between adjacent segments to smooth
- `arrow_head` - if True make this curve into an arrow

EXAMPLES:

```
sage: from sage.plot.plot3d.shapes2 import Line
sage: Line([(i*math.sin(i), i*math.cos(i), i/3) for i in range(30)], arrow_head=True)
```

Smooth angles less than 90 degrees:

```
sage: Line([(0,0,0),(1,0,0),(2,1,0),(0,1,0)], corner_cutoff=0)
```

bounding_box()

corners (*corner_cutoff=None, max_len=None*)

Figures out where the curve turns too sharply to pretend it's smooth.

INPUT: Maximum cosine of angle between adjacent line segments before adding a corner

OUTPUT: List of points at which to start a new line. This always includes the first point, and never the last.

EXAMPLES:

Every point:

```
sage: from sage.plot.plot3d.shapes2 import Line
sage: Line([(0,0,0),(1,0,0),(2,1,0),(0,1,0)], corner_cutoff=1).corners()
[(0, 0, 0), (1, 0, 0), (2, 1, 0)]
```

Greater than 90 degrees:

```
sage: Line([(0,0,0),(1,0,0),(2,1,0),(0,1,0)], corner_cutoff=0).corners()
[(0, 0, 0), (2, 1, 0)]
```

No corners:

```
sage: Line([(0,0,0),(1,0,0),(2,1,0),(0,1,0)], corner_cutoff=-1).corners()
(0, 0, 0)
```

An intermediate value:

```
sage: Line([(0,0,0),(1,0,0),(2,1,0),(0,1,0)], corner_cutoff=.5).corners()
[(0, 0, 0), (2, 1, 0)]
```

jmol_repr(*render_params*)

obj_repr(*render_params*)

tachyon_repr(*render_params*)

class Point(*center, size=1, **kwds*)

Create a position in 3-space, represented by a sphere of fixed size.

INPUT:

- `center` - point (3-tuple)
- `size` - (default: 1)

bounding_box()

jmol_repr(*render_params*)

obj_repr(*render_params*)

tachyon_repr(*render_params*)

avg(*a, b*)

dot(*(x0, y0, z0), (x1, y1, z1)*)

frame3d(*lower_left, upper_right, **kwds*)

Draw a frame in 3d.

frame_labels(*lower_left, upper_right, label_lower_left, label_upper_right, eps=1, **kwds*)

line3d(*points, thickness=1, radius=None, arrow_head=False, **kwds*)

Draw a 3d line joining a sequence of points.

One may specify either a thickness or radius. If a thickness is specified, this line will have a constant diameter regardless of scaling and zooming. If a radius is specified, it will behave as a series of cylinders.

INPUT:

- `points` - a list of at least 2 points
- `thickness` - (default: 1)
- `radius` - (default: None)
- `arrow_head` - (default: False)
- `color` - a word that describes a color
- `rgbcolor` - (r,g,b) with r, g, b between 0 and 1 that describes a color
- `opacity` - (default: 1) if less than 1 then is transparent

EXAMPLES:

A line in 3-space:

```
sage: line3d([(1,2,3), (1,0,-2), (3,1,4), (2,1,-2)])
```

The same line but red:

```
sage: line3d([(1,2,3), (1,0,-2), (3,1,4), (2,1,-2)], color='red')
```

A transparent thick green line and a little blue line:

```
sage: line3d([(0,0,0), (1,1,1), (1,0,2)], opacity=0.5, radius=0.1, \
             color='green') + line3d([(0,1,0), (1,0,2)])
```

A Dodecahedral complex of 5 tetrahedrons (a more elaborate examples from Peter Jipsen):

```
sage: def tetra(col):
...       return line3d([(0,0,1), (2*sqrt(2.)/3,0,-1./3), (-sqrt(2.)/3, sqrt(6.)/3,-1./3),\
...              (-sqrt(2.)/3,-sqrt(6.)/3,-1./3), (0,0,1), (-sqrt(2.)/3, sqrt(6.)/3,-1./3),\
...              (-sqrt(2.)/3,-sqrt(6.)/3,-1./3), (2*sqrt(2.)/3,0,-1./3)],\
...              color=col, thickness=10, aspect_ratio=[1,1,1])
...
sage: v  = (sqrt(5.)/2-5/6, 5/6*sqrt(3.)-sqrt(15.)/2, sqrt(5.)/3)
sage: t  = acos(sqrt(5.)/3)/2
sage: t1 = tetra('blue').rotateZ(t)
sage: t2 = tetra('red').rotateZ(t).rotate(v,2*pi/5)
sage: t3 = tetra('green').rotateZ(t).rotate(v,4*pi/5)
sage: t4 = tetra('yellow').rotateZ(t).rotate(v,6*pi/5)
sage: t5 = tetra('orange').rotateZ(t).rotate(v,8*pi/5)
sage: show(t1+t2+t3+t4+t5, frame=False)
```

point3d(*v, size=5, **kwds*)

Plot a point or list of points in 3d space.

INPUT:

- `v` - a point or list of points
- `size` - (default: 5) size of the point (or points)
- `color` - a word that describes a color
- `rgbcolor` - (r,g,b) with r, g, b between 0 and 1 that describes a color
- `opacity` - (default: 1) if less than 1 then is transparent

EXAMPLES:

```
sage: sum([point3d((i,i^2,i^3), size=5) for i in range(10)])
```

We check to make sure this works with vectors.

sage: pl = point3d([vector(ZZ,(1, 0, 0)), vector(ZZ,(0, 1, 0)), (-1, -1, 0)])

polygon3d(**args, **kwds*)

Draw a polygon in 3d.

INPUT:

- `points` - the vertices of the polygon

Type `polygon3d.options` for a dictionary of the default options for polygons. You can change this to change the defaults for all future polygons. Use `polygon3d.reset()` to reset to the default options.

EXAMPLES:

A simple trangle:

```
sage: polygon3d([[0,0,0], [1,2,3], [3,0,0]])
```

Some modern art – a random polygon:

```
sage: v = [(randrange(-5,5), randrange(-5,5), randrange(-5, 5)) for _ in range(10)]
sage: polygon3d(v)
```

A bent transparent green triangle:

```
sage: polygon3d([[1, 2, 3], [0,1,0], [1,0,1], [3,0,0]], color=(0,1,0), alpha=0.7)
```

ruler (*start, end, ticks=4, sub_ticks=4, absolute=False, snap=False, **kwds*)

ruler_frame (*lower_left, upper_right, ticks=4, sub_ticks=4, **kwds*)

sphere (*center=(0, 0, 0), size=1, **kwds*)

Return a plot of a sphere of radius size centered at (x, y, z).

INPUT:

- `(x,y,z)` - center (default: (0,0,0)
- `size` - the radius (default: 1)

EXAMPLES: A simple sphere:

```
sage: sphere()
```

Two spheres touching:

```
sage: sphere(center=(-1,0,0)) + sphere(center=(1,0,0), aspect_ratio=[1,1,1])
```

Spheres of radii 1 and 2 one stuck into the other:

```
sage: sphere(color='orange') + sphere(color=(0,0,0.3), \
            center=(0,0,-2),size=2,opacity=0.9)
```

We draw a transparent sphere on a saddle.

```
sage: u,v = var('u v')
sage: saddle = plot3d(u^2 - v^2, (u,-2,2), (v,-2,2))
sage: sphere((0,0,1), color='red', opacity=0.5, aspect_ratio=[1,1,1]) + saddle
```

TESTS:

```
sage: T = sage.plot.plot3d.texture.Texture('red')
sage: S = sphere(texture=T)
sage: T in S.texture_set()
True
```

text3d (*txt, (x, y, z), **kwds*)

Display 3d text.

INPUT:

- `txt` - some text
- `(x,y,z)` - position
- `**kwds` - standard 3d graphics options

Note: There is no way to change the font size or opacity yet.

EXAMPLES: We write the word Sage in red at position (1,2,3):

```
sage: text3d("Sage", (1,2,3), color=(0.5,0,0))
```

We draw a multicolor spiral of numbers:

```
sage: sum([text3d('%.1f'%n, (cos(n),sin(n),n), color=(n/2,1-n/2,0)) \
           for n in [0,0.2,..,8]])
```

Another example

```
sage: text3d("Sage is really neat!!",(2,12,1))
```

And in 3d in two places:

```
sage: text3d("Sage is...",(2,12,1), rgbcolor=(1,0,0)) + text3d("quite powerful!!",(4,10,0), rgbc
```

validate_frame_size(*size*)

5.8 Base classes for 3D Graphics objects and plotting.

AUTHORS:

- Robert Bradshaw (2007-02): inital version
- Robert Bradshaw (2007-08): Cythonization, much optimization
- William Stein (2008)

TODO: - finish integrating tachyon - good default lights, camera

class BoundingSphere()

A bounding sphere is like a bounding box, but is simpler to deal with and behaves better under rotations.

transform()

Returns the bounding sphere of this sphere acted on by T. This always returns a new sphere, even if the resulting object is an ellipsoid.

EXAMPLES:

```
sage: from sage.plot.plot3d.transform import Transformation
sage: from sage.plot.plot3d.base import BoundingSphere
sage: BoundingSphere((0,0,0), 10).transform(Transformation(trans=(1,2,3)))
Center (1.0, 2.0, 3.0) radius 10.0
sage: BoundingSphere((0,0,0), 10).transform(Transformation(scale=(1/2, 1, 2)))
Center (0.0, 0.0, 0.0) radius 20.0
sage: BoundingSphere((0,0,3), 10).transform(Transformation(scale=(2, 2, 2)))
Center (0.0, 0.0, 6.0) radius 20.0
```

class Graphics3d()

This is the baseclass for all 3d graphics objects.

aspect_ratio()

Sets or gets the preferred aspect ratio of self.

EXAMPLES:

```
sage: D = dodecahedron()
sage: D.aspect_ratio()
[1.0, 1.0, 1.0]
sage: D.aspect_ratio([1,2,3])
sage: D.aspect_ratio()
[1.0, 2.0, 3.0]
sage: D.aspect_ratio(1)
sage: D.aspect_ratio()
[1.0, 1.0, 1.0]
```

bounding_box()

Returns the lower and upper corners of a 3d bounding box for self. This is used for rendering and self should fit entirely within this box.

Specifically, the first point returned should have x, y, and z coordinates should be the respective infimum over all points in self, and the second point is the supremum.

The default return value is simply the box containing the origin.

EXAMPLES:

```
sage: sphere((1,1,1), 2).bounding_box()
((-1.0, -1.0, -1.0), (3.0, 3.0, 3.0))
sage: G = line3d([(1, 2, 3), (-1,-2,-3)])
sage: G.bounding_box()
((-1.0, -2.0, -3.0), (1.0, 2.0, 3.0))
```

default_render_params()

Returns an instance of RenderParams suitable for plotting this object.

EXAMPLES:

```
sage: type(dodecahedron().default_render_params())
<class 'sage.plot.plot3d.base.RenderParams'>
```

export_jmol()

A jmol scene consists of a script which refers to external files. Fortunately, we are able to put all of them in a single zip archive, which is the output of this call.

EXAMPLES:

```
sage: out_file = sage.misc.misc.tmp_filename() + ".jmol"
sage: G = sphere((1, 2, 3), 5) + cube() + sage.plot.plot3d.shapes.Text("hi")
sage: G.export_jmol(out_file)
sage: import zipfile
sage: z = zipfile.ZipFile(out_file)
sage: z.namelist()
['obj_...pmesh', 'SCRIPT']

sage: print z.read('SCRIPT')
data "model list"
2
empty
Xx 0 0 0
Xx 5.5 5.5 5.5
end "model list"; show data
select *
wireframe off; spacefill off
set labelOffset 0 0
background [255,255,255]
spin OFF
moveto 0 -764 -346 -545 76.39
centerAt absolute {0 0 0}
```

```
zoom 100
frank OFF
set perspectivedepth ON
isosurface sphere_1  center {1.0 2.0 3.0} sphere 5.0
color isosurface  [102,102,255]
pmesh obj_... "obj_...pmesh"
color pmesh  [102,102,255]
select atomno = 1
color atom  [102,102,255]
label "hi"

sage: print z.read(z.namelist()[0])
24
0.5 0.5 0.5
-0.5 0.5 0.5
...
-0.5 -0.5 -0.5
6
5
0
1
...
```

flatten()

Try to reduce the depth of the scene tree by consolidating groups and transformations.

The generic Graphics3d object can't be made flatter.

EXAMPLES:

```
sage: G = sage.plot.plot3d.base.Graphics3d()
sage: G.flatten() is G
True
```

frame_aspect_ratio()

Sets or gets the preferred frame aspect ratio of self.

EXAMPLES:

```
sage: D = dodecahedron()
sage: D.frame_aspect_ratio()
[1.0, 1.0, 1.0]
sage: D.frame_aspect_ratio([2,2,1])
sage: D.frame_aspect_ratio()
[2.0, 2.0, 1.0]
sage: D.frame_aspect_ratio(1)
sage: D.frame_aspect_ratio()
[1.0, 1.0, 1.0]
```

jmol_repr()

A (possibly nested) list of strings which will be concatenated and used by jmol to render self. (Nested lists of strings are used because otherwise all the intermediate concatenations can kill performance). This may refer to several remove files, which are stored in render_parames.output_archive.

EXAMPLES:

```
sage: G = sage.plot.plot3d.base.Graphics3d()
sage: G.jmol_repr(G.default_render_params())
[]
sage: G = sphere((1, 2, 3))
sage: G.jmol_repr(G.default_render_params())
[['isosurface sphere_1  center {1.0 2.0 3.0} sphere 1.0\ncolor isosurface  [102,102,255]']]
```

mtl_str()

Returns the contents of a .mtl file, to be used to provide coloring information for an .obj file.

EXAMPLES:: sage: G = tetrahedron(color='red') + tetrahedron(color='yellow', opacity=0.5) sage: print G.mtl_str() newmtl ... Ka 0.5 0.0 0.0 Kd 1.0 0.0 0.0 Ks 0.0 0.0 0.0 illum 1 Ns 1 d 1 newmtl ... Ka 0.5 0.5 0.0 Kd 1.0 1.0 0.0 Ks 0.0 0.0 0.0 illum 1 Ns 1 d 0.500000000000000

obj()

An .obj scene file (as a string) containing the this object. A .mtl file of the same name must also be produced for coloring.

EXAMPLES:

```
sage: from sage.plot.plot3d.shapes import ColorCube
sage: print ColorCube(1, ['red', 'yellow', 'blue']).obj()
g obj_1
usemtl ...
v 1 1 1
v -1 1 1
v -1 -1 1
v 1 -1 1
f 1 2 3 4
...
g obj_6
usemtl ...
v -1 -1 1
v -1 1 1
v -1 1 -1
v -1 -1 -1
f 21 22 23 24
```

obj_repr()

A (possibly nested) list of strings which will be concatenated and used to construct an .obj file of self. (Nested lists of strings are used because otherwise all the intermediate concatenations can kill performance). This may include a reference to color information which is stored elsewhere.

EXAMPLES:

```
sage: G = sage.plot.plot3d.base.Graphics3d()
sage: G.obj_repr(G.default_render_params())
[]
sage: G = cube()
sage: G.obj_repr(G.default_render_params())
['g obj_1',
 'usemtl ...',
 ['v 0.5 0.5 0.5',
  'v -0.5 0.5 0.5',
  'v -0.5 -0.5 0.5',
  'v 0.5 -0.5 0.5',
  'v 0.5 0.5 -0.5',
  'v -0.5 0.5 -0.5',
  'v 0.5 -0.5 -0.5',
  'v -0.5 -0.5 -0.5'],
 ['f 1 2 3 4',
  'f 1 5 6 2',
  'f 1 4 7 5',
  'f 6 5 7 8',
  'f 7 4 3 8',
  'f 3 2 6 8'],
 []]
```

rotate()

Returns self rotated about the vector v by $theta$ radians.

EXAMPLES:

```
sage: from sage.plot.plot3d.shapes import Cone
sage: v = (1,2,3)
sage: G = arrow3d((0, 0, 0), v)
sage: G += Cone(1/5, 1).translate((0, 0, 2))
sage: C = Cone(1/5, 1, opacity=.25).translate((0, 0, 2))
sage: G += sum(C.rotate(v, pi*t/4) for t in [1..7])
sage: G.show(aspect_ratio=1)

sage: from sage.plot.plot3d.shapes import Box
sage: Box(1/3, 1/5, 1/7).rotate((1, 1, 1), pi/3).show(aspect_ratio=1)
```

rotateX()

Returns self rotated about the x-axis by the given angle.

EXAMPLES:

```
sage: from sage.plot.plot3d.shapes import Cone
sage: G = Cone(1/5, 1) + Cone(1/5, 1, opacity=.25).rotateX(pi/2)
sage: G.show(aspect_ratio=1)
```

rotateY()

Returns self rotated about the y-axis by the given angle.

EXAMPLES:

```
sage: from sage.plot.plot3d.shapes import Cone
sage: G = Cone(1/5, 1) + Cone(1/5, 1, opacity=.25).rotateY(pi/3)
sage: G.show(aspect_ratio=1)
```

rotateZ()

Returns self rotated about the z-axis by the given angle.

EXAMPLES:

```
sage: from sage.plot.plot3d.shapes import Box
sage: G = Box(1/2, 1/3, 1/5) + Box(1/2, 1/3, 1/5, opacity=.25).rotateZ(pi/5)
sage: G.show(aspect_ratio=1)
```

scale()

Returns self scaled in the x, y, and z directions.

EXAMPLES:

```
sage: G = dodecahedron() + dodecahedron(opacity=.5).scale(2)
sage: G.show(aspect_ratio=1)
sage: G = icosahedron() + icosahedron(opacity=.5).scale([1, 1/2, 2])
sage: G.show(aspect_ratio=1)
```

TESTS:

```
sage: G = sphere((0, 0, 0), 1)
sage: G.scale(2)
sage: G.scale(1, 2, 1/2).show(aspect_ratio=1)
sage: G.scale(2).bounding_box()
((-2.0, -2.0, -2.0), (2.0, 2.0, 2.0))
```

show()

INPUT:

- `viewer` - string (default: 'jmol'), how to view the plot 'jmol': interactive 3d (java) 'tachyon': a static png image (ray traced) 'java3d': interactive opengl based 3d
- `filename` - string (default: a temp file); file to save the image to

- verbosity - display information about rendering the figure
- figsize - (default: 5); x or pair [x,y] for numbers, e.g., [5,5]; controls the size of the output figure. E.g., with Tachyon the number of pixels in each direction is 100 times figsize[0]. This is ignored for the jmol embedded renderer.
- aspect_ratio - (default: "automatic") - aspect ratio of the coordinate system itself. Give [1,1,1] to make spheres look round.
- frame_aspect_ratio - (default: "automatic") aspect ratio of frame that contains the 3d scene.
- zoom - (default: 1) how zoomed in
- frame - (default: True) if True, draw a bounding frame with labels
- axes - (deault: False) if True, draw coordinate axes
- **kwds - other options, which make sense for particular rendering engines

CHANGING DEFAULTS: Defaults can be uniformly changed by importing a dictionary and changing it. For example, here we change the default so images display without a frame instead of with one:

```
sage: from sage.plot.plot3d.base import SHOW_DEFAULTS
sage: SHOW_DEFAULTS['frame'] = False
```

This sphere will not have a frame around it:

```
sage: sphere((0,0,0))
```

We change the default back:

```
sage: SHOW_DEFAULTS['frame'] = True
```

Now this sphere is enclosed in a frame:

```
sage: sphere((0,0,0))
```

EXAMPLES: We illustrate use of the aspect_ratio option:

```
sage: x, y = var('x,y')
sage: p = plot3d(2*sin(x*y), (x, -pi, pi), (y, -pi, pi))
sage: p.show(aspect_ratio=[1,1,1])
```

This looks flattened, but filled with the plot:

```
sage: p.show(frame_aspect_ratio=[1,1,1/16])
```

This looks flattened, but the plot is square and smaller:

```
sage: p.show(aspect_ratio=[1,1,1], frame_aspect_ratio=[1,1,1/8])
```

tachyon()

An tachyon input file (as a string) containing the this object.

EXAMPLES:

```
sage: print sphere((1, 2, 3), 5, color='yellow').tachyon()
begin_scene
resolution 400 400
         camera
        ...
      plane
        center -2000 -1000 -500
        normal 2.3 2.4 2.0
        TEXTURE
            AMBIENT 1.0 DIFFUSE 1.0 SPECULAR 1.0 OPACITY 1.0
            COLOR 1.0 1.0 1.0
            TEXFUNC 0
    Texdef texture...
```

```
  Ambient 0.333333333333 Diffuse 0.666666666667 Specular 0.0 Opacity 1
   Color 1.0 1.0 0.0

Sphere center 1.0 -2.0 3.0 Rad 0.5 texture...
end_scene
```

tachyon_repr()

A (possibly nested) list of strings which will be concatenated and used by tachyon to render self. (Nested lists of strings are used because otherwise all the intermediate concatenations can kill performance). This may include a reference to color information which is stored elsewhere.

EXAMPLES:: sage: G = sage.plot.plot3d.base.Graphics3d() sage: G.tachyon_repr(G.default_render_params()) [] sage: G = sphere((1, 2, 3)) sage: G.tachyon_repr(G.default_render_params()) ['Sphere center 1.0 2.0 3.0 Rad 1.0 texture...']

testing_render_params()

Returns an instance of RenderParams suitable for testing this object. In particular, it opens up '/dev/null' as an auxiliary zip file for jmol.

EXAMPLES:

```
sage: type(dodecahedron().testing_render_params())
<class 'sage.plot.plot3d.base.RenderParams'>
```

texture

texture_set()

Often the textures of a 3d file format are kept separate from the objects themselves. This function returns the set of textures used, so they can be defined in a preamble or separate file.

EXAMPLES:

```
sage: sage.plot.plot3d.base.Graphics3d().texture_set()
set([])

sage: G = tetrahedron(color='red') + tetrahedron(color='yellow') + tetrahedron(color='red',
sage: G.texture_set()
set([Texture(texture..., red, ff0000), Texture(texture..., yellow, ffff00), Texture(texture.
```

transform()

Apply a transformation to self, where the inputs are passed onto a TransformGroup object. Mostly for internal use; see the translate, scale, and rotate methods for more details.

EXAMPLES:

```
sage: sphere((0,0,0), 1).transform(trans=(1, 0, 0), scale=(2,3,4)).bounding_box()
((-1.0, -3.0, -4.0), (3.0, 3.0, 4.0))
```

translate()

Return self translated by the given vector (which can be given either as a 3-iterable or via positional

arguments).

EXAMPLES:

```
sage: icosahedron() + sum(icosahedron(opacity=0.25).translate(2*n, 0, 0) for n in [1..4])
sage: icosahedron() + sum(icosahedron(opacity=0.25).translate([-2*n, n, n^2]) for n in [1..4
```

TESTS:

```
sage: G = sphere((0, 0, 0), 1)
sage: G.bounding_box()
((-1.0, -1.0, -1.0), (1.0, 1.0, 1.0))
sage: G.translate(0, 0, 1).bounding_box()
((-1.0, -1.0, 0.0), (1.0, 1.0, 2.0))
sage: G.translate(-1, 5, 0).bounding_box()
((-2.0, 4.0, -1.0), (0.0, 6.0, 1.0))
```

viewpoint()

Returns the viewpoint of this plot. Currently only a stub for x3d.

EXAMPLES:

```
sage: type(dodecahedron().viewpoint())
<class 'sage.plot.plot3d.base.Viewpoint'>
```

x3d()

An x3d scene file (as a string) containing the this object.

EXAMPLES:

```
sage: print sphere((1, 2, 3), 5).x3d()
<X3D version='3.0' profile='Immersive' xmlns:xsd='http://www.w3.org/2001/XMLSchema-instance'
<head>
<meta name='title' content='sage3d'/>
</head>
<Scene>
<Viewpoint position='0 0 6'/>
<Transform translation='1 2 3'>
<Shape><Sphere radius='5.0'/><Appearance><Material diffuseColor='0.4 0.4 1.0' shininess='1'
</Transform>
</Scene>
</X3D>

sage: G = icosahedron() + sphere((0,0,0), 0.5, color='red')
sage: print G.x3d()
<X3D version='3.0' profile='Immersive' xmlns:xsd='http://www.w3.org/2001/XMLSchema-instance'
<head>
<meta name='title' content='sage3d'/>
</head>
<Scene>
<Viewpoint position='0 0 6'/>
<Shape>
<IndexedFaceSet coordIndex='...'>
  <Coordinate point='...'/>
</IndexedFaceSet>
<Appearance><Material diffuseColor='0.4 0.4 1.0' shininess='1' specularColor='0.0 0.0 0.0'/>
<Transform translation='0 0 0'>
<Shape><Sphere radius='0.5'/><Appearance><Material diffuseColor='1.0 0.0 0.0' shininess='1'
</Transform>
</Scene>
</X3D>
```

class **Graphics3dGroup**()

This class represents a collection of 3d objects. Usually they are formed implicitly by summing.

bounding_box()

Box that contains the bounding boxes of all the objects that make up self.

EXAMPLES:

```
sage: A = sphere((0,0,0), 5)
sage: B = sphere((1, 5, 10), 1)
sage: A.bounding_box()
((-5.0, -5.0, -5.0), (5.0, 5.0, 5.0))
sage: B.bounding_box()
((0.0, 4.0, 9.0), (2.0, 6.0, 11.0))
sage: (A+B).bounding_box()
((-5.0, -5.0, -5.0), (5.0, 6.0, 11.0))
sage: (A+B).show(aspect_ratio=1, frame=True)

sage: sage.plot.plot3d.base.Graphics3dGroup([]).bounding_box()
((0.0, 0.0, 0.0), (0.0, 0.0, 0.0))
```

flatten()

Try to reduce the depth of the scene tree by consolidating groups and transformations.

EXAMPLES:

```
sage: G = sum([circle((0, 0), t) for t in [1..10]], sphere()); G
sage: G.flatten()
sage: len(G.all)
2
sage: len(G.flatten().all)
11
```

jmol_repr()

The jmol representation of a group is simply the concatenation of the representation of its objects.

EXAMPLES:

```
sage: G = sphere() + sphere((1,2,3))
sage: G.jmol_repr(G.default_render_params())
[[['isosurface sphere_1  center {0.0 0.0 0.0} sphere 1.0\ncolor isosurface  [102,102,255]']]
 [['isosurface sphere_2  center {1.0 2.0 3.0} sphere 1.0\ncolor isosurface  [102,102,255]']]
```

obj_repr()

The obj representation of a group is simply the concatenation of the representation of its objects.

EXAMPLES:

```
sage: G = tetrahedron() + tetrahedron().translate(10, 10, 10)
sage: G.obj_repr(G.default_render_params())
[['g obj_1',
  'usemtl ...',
  ['v 0 0 1',
   'v 0.942809 0 -0.333333',
   'v -0.471405 0.816497 -0.333333',
   'v -0.471405 -0.816497 -0.333333'],
  ['f 1 2 3', 'f 2 4 3', 'f 1 3 4', 'f 1 4 2'],
  []],
 [['g obj_2',
   'usemtl ...',
   ['v 10 10 11',
    'v 10.9428 10 9.66667',
    'v 9.5286 10.8165 9.66667',
    'v 9.5286 9.1835 9.66667'],
```

```
        ['f 5 6 7', 'f 6 8 7', 'f 5 7 8', 'f 5 8 6'],
        []]]]
```

set_texture()

EXAMPLES:

```
sage: G = dodecahedron(color='red', opacity=.5) + icosahedron((3, 0, 0), color='blue')
sage: G
sage: G.set_texture(color='yellow')
sage: G
```

tachyon_repr()

The tachyon representation of a group is simply the concatenation of the representations of its objects.

EXAMPLES:

```
sage: G = sphere() + sphere((1,2,3))
sage: G.tachyon_repr(G.default_render_params())
[['Sphere center 0.0 0.0 0.0 Rad 1.0 texture...'],
 ['Sphere center 1.0 2.0 3.0 Rad 1.0 texture...']]
```

texture_set()

The texture set of a group is simply the union of the textures of all its objects.

EXAMPLES:

```
sage: G = sphere(color='red') + sphere(color='yellow')
sage: G.texture_set()
set([Texture(texture..., yellow, ffff00), Texture(texture... red, ff0000)])

sage: T = sage.plot.plot3d.texture.Texture('blue'); T
Texture(texture..., blue, 0000ff)
sage: G = sphere(texture=T) + sphere((1, 1, 1), texture=T)
sage: len(G.texture_set())
1
```

transform()

Transforming this entire group simply makes a transform group with the same contents.

EXAMPLES:

```
sage: G = dodecahedron(color='red', opacity=.5) + icosahedron(color='blue')
sage: G
sage: G.transform(scale=(2,1/2,1))
sage: G.transform(trans=(1,1,3))
```

x3d_str()

The x3d representation of a group is simply the concatenation of the representation of its objects.

EXAMPLES:

```
sage: G = sphere() + sphere((1,2,3))
sage: print G.x3d_str()
<Transform translation='0 0 0'>
<Shape><Sphere radius='1.0'/><Appearance><Material diffuseColor='0.4 0.4 1.0' shininess='1'
</Transform>
<Transform translation='1 2 3'>
<Shape><Sphere radius='1.0'/><Appearance><Material diffuseColor='0.4 0.4 1.0' shininess='1'
</Transform>
```

class **PrimitiveObject**()

This is the base class for the non-container 3d objects.

get_texture()
EXAMPLES:

```
sage: G = dodecahedron(color='red')
sage: G.get_texture()
Texture(texture..., red, ff0000)
```

jmol_repr()
Default behavior is to render the triangulation. The actual polygon data is stored in a separate file.
EXAMPLES:

```
sage: from sage.plot.plot3d.shapes import Torus
sage: G = Torus(1, .5)
sage: G.jmol_repr(G.testing_render_params())
['pmesh obj_1 "obj_1.pmesh"\ncolor pmesh  [102,102,255]']
```

obj_repr()
Default behavior is to render the triangulation.
EXAMPLES:

```
sage: from sage.plot.plot3d.shapes import Torus
sage: G = Torus(1, .5)
sage: G.obj_repr(G.default_render_params())
['g obj_1',
 'usemtl ...',
 ['v 0 1 0.5',
 ...
  'f ...'],
 []]
```

set_texture()
EXAMPLES:

```
sage: G = dodecahedron(color='red'); G
sage: G.set_texture(color='yellow'); G
```

tachyon_repr()
Default behavior is to render the triangulation.
EXAMPLES:

```
sage: from sage.plot.plot3d.shapes import Torus
sage: G = Torus(1, .5)
sage: G.tachyon_repr(G.default_render_params())
['TRI V0 0 1 0.5
...
'texture...']
```

texture_set()
EXAMPLES:

```
sage: G = dodecahedron(color='red')
sage: G.texture_set()
set([Texture(texture..., red, ff0000)])
```

x3d_str()
EXAMPLES:

```
sage: sphere().flatten().x3d_str()
"<Transform>\n<Shape><Sphere radius='1.0'/><Appearance><Material diffuseColor='0.4 0.4 1.0'
```

class RenderParams()

This class is a container for all parameters that may be needed to render triangulate/render an object to a certain format. It can contain both cumulative and global parameters.

Of particular note is the transformation object, which holds the cumulative transformation from the root of the scene graph to this node in the tree.

pop_transform()

Remove the last transformation off the stack, resetting self.transform to the previous value.

EXAMPLES:

```
sage: from sage.plot.plot3d.transform import Transformation
sage: params = sage.plot.plot3d.base.RenderParams()
sage: T = Transformation(trans=(100, 500, 0))
sage: params.push_transform(T)
sage: params.transform.get_matrix()
[  1.0   0.0   0.0 100.0]
[  0.0   1.0   0.0 500.0]
[  0.0   0.0   1.0   0.0]
[  0.0   0.0   0.0   1.0]
sage: params.push_transform(Transformation(trans=(-100, 500, 200)))
sage: params.transform.get_matrix()
[   1.0    0.0    0.0    0.0]
[   0.0    1.0    0.0 1000.0]
[   0.0    0.0    1.0  200.0]
[   0.0    0.0    0.0    1.0]
sage: params.pop_transform()
sage: params.transform.get_matrix()
[  1.0   0.0   0.0 100.0]
[  0.0   1.0   0.0 500.0]
[  0.0   0.0   1.0   0.0]
[  0.0   0.0   0.0   1.0]
```

push_transform()

Push a transformation onto the stack, updating self.transform.

EXAMPLES:

```
sage: from sage.plot.plot3d.transform import Transformation
sage: params = sage.plot.plot3d.base.RenderParams()
sage: params.transform is None
True
sage: T = Transformation(scale=(10,20,30))
sage: params.push_transform(T)
sage: params.transform.get_matrix()
[10.0  0.0  0.0  0.0]
[ 0.0 20.0  0.0  0.0]
[ 0.0  0.0 30.0  0.0]
[ 0.0  0.0  0.0  1.0]
sage: params.push_transform(T)  # scale again
sage: params.transform.get_matrix()
[100.0   0.0   0.0   0.0]
[  0.0 400.0   0.0   0.0]
[  0.0   0.0 900.0   0.0]
[  0.0   0.0   0.0   1.0]
```

unique_name()

Returns a unique identifier starting with desc.

EXAMPLES:

```
sage: params = sage.plot.plot3d.base.RenderParams()
sage: params.unique_name()
'name_1'
sage: params.unique_name()
'name_2'
sage: params.unique_name('texture')
'texture_3'
```

class TransformGroup()

This class is a container for a group of objects with a common transformation.

bounding_box()

Returns the bounding box of self, i.e. the box containing the contents of self after applying the transformation.

EXAMPLES:

```
sage: G = cube()
sage: G.bounding_box()
((-0.5, -0.5, -0.5), (0.5, 0.5, 0.5))
sage: G.scale(4).bounding_box()
((-2.0, -2.0, -2.0), (2.0, 2.0, 2.0))
sage: G.rotateZ(pi/4).bounding_box()
((-0.70710678118654746, -0.70710678118654746, -0.5),
 (0.70710678118654746, 0.70710678118654746, 0.5))
```

flatten()

Try to reduce the depth of the scene tree by consolidating groups and transformations.

EXAMPLES:

```
sage: G = sphere((1,2,3)).scale(100)
sage: T = G.get_transformation()
sage: T.get_matrix()
[100.0   0.0   0.0   0.0]
[  0.0 100.0   0.0   0.0]
[  0.0   0.0 100.0   0.0]
[  0.0   0.0   0.0   1.0]

sage: G.flatten().get_transformation().get_matrix()
[100.0   0.0   0.0 100.0]
[  0.0 100.0   0.0 200.0]
[  0.0   0.0 100.0 300.0]
[  0.0   0.0   0.0   1.0]
```

get_transformation()

Returns the actual transformation object associated with self.

EXAMPLES:

```
sage: G = sphere().scale(100)
sage: T = G.get_transformation()
sage: T.get_matrix()
[100.0   0.0   0.0   0.0]
[  0.0 100.0   0.0   0.0]
[  0.0   0.0 100.0   0.0]
[  0.0   0.0   0.0   1.0]
```

jmol_repr()

Transformations for jmol are applied at the leaf nodes.

EXAMPLES:

```
sage: G = sphere((1,2,3)).scale(2)
sage: G.jmol_repr(G.default_render_params())
[[['isosurface sphere_1  center {2.0 4.0 6.0} sphere 2.0\ncolor isosurface  [102,102,255]']]
```

obj_repr()

Transformations for .obj files are applied at the leaf nodes.

EXAMPLES:

```
sage: G = cube().scale(4).translate(1, 2, 3)
sage: G.obj_repr(G.default_render_params())
[['g obj_1',
  'usemtl ...',
  ['v 3 4 5',
   'v -1 4 5',
   'v -1 0 5',
   'v 3 0 5',
   'v 3 4 1',
   'v -1 4 1',
   'v 3 0 1',
   'v -1 0 1'],
  ['f 1 2 3 4',
   'f 1 5 6 2',
   'f 1 4 7 5',
   'f 6 5 7 8',
   'f 7 4 3 8',
   'f 3 2 6 8'],
  []]]
```

tachyon_repr()

Transformations for Tachyon are applied at the leaf nodes.

EXAMPLES:

```
sage: G = sphere((1,2,3)).scale(2)
sage: G.tachyon_repr(G.default_render_params())
[['Sphere center 2.0 4.0 6.0 Rad 2.0 texture...']]
```

transform()

Transforming this entire group can be done by composing transformations.

EXAMPLES:

```
sage: G = dodecahedron(color='red', opacity=.5) + icosahedron(color='blue')
sage: G
sage: G.transform(scale=(2,1/2,1))
sage: G.transform(trans=(1,1,3))
```

x3d_str()

To apply a transformation to a set of objects in x3d, simply make them all children of an x3d Transform node.

EXAMPLES:

```
sage: sphere((1,2,3)).x3d_str()
"<Transform translation='1 2 3'>\n<Shape><Sphere radius='1.0'/><Appearance><Material diffuse
```

class **Viewpoint**()

This class represents a viewpoint, necessary for x3d.

In the future, there could be multiple viewpoints, and they could have more properties. (Currently they only hold a position).

x3d_str()
EXAMPLES:

```
sage: sphere((0,0,0), 100).viewpoint().x3d_str()
"<Viewpoint position='0 0 6'/>"
```

flatten_list()
This is an optimized routine to turn a list of lists (of lists ...) into a single list. We generate data in a non-flat format to avoid multiple data copying, and then concatenate it all at the end.

This is NOT recursive, otherwise there would be a lot of redundant copying (which we are trying to avoid in the first place, though at least it would be just the pointers).

EXAMPLES:

```
sage: from sage.plot.plot3d.base import flatten_list
sage: flatten_list([])
[]
sage: flatten_list([[[[]]]])
[]
sage: flatten_list([['a', 'b'], 'c'])
['a', 'b', 'c']
sage: flatten_list([['a'], [['b'], 'c'], ['d'], [['e', 'f', 'g']]])
['a', 'b', 'c', 'd', 'e', 'f', 'g']
```

max3()
Return the componentwise maximum of a list of 3-tuples.

EXAMPLES:

```
sage: from sage.plot.plot3d.base import min3, max3
sage: max3([(-1,2,5), (-3, 4, 2)])
(-1, 4, 5)
```

min3()
Return the componentwise minimum of a list of 3-tuples.

EXAMPLES:

```
sage: from sage.plot.plot3d.base import min3, max3
sage: min3([(-1,2,5), (-3, 4, 2)])
(-3, 2, 2)
```

optimal_aspect_ratios()

optimal_extra_kwds()
Given a list v of dictionaries, this function merges them such that later dictionaries have precedence.

point_list_bounding_box()
EXAMPLES:

```
sage: from sage.plot.plot3d.base import point_list_bounding_box
sage: point_list_bounding_box([(1,2,3),(4,5,6),(-10,0,10)])
((-10.0, 0.0, 3.0), (4.0, 5.0, 10.0))
```

5.9 The Tachyon 3D Ray Tracer

Given any 3D graphics object one can compute a raytraced representation by typing `show(viewer='tachyon')`. For example, we draw two translucent spheres that contain a red tube, and render the result using Tachyon.

```
sage: S = sphere(opacity=0.8, aspect_ratio=[1,1,1])
sage: L = line3d([(0,0,0),(2,0,0)], thickness=10, color='red')
sage: M = S + S.translate((2,0,0)) + L
sage: M.show(viewer='tachyon')
```

One can also directly control Tachyon, which gives a huge amount of flexibility. For example, here we directly use Tachyon to draw 3 spheres on the coordinate axes. Notice that the result is gorgeous:

```
sage: t = Tachyon(xres=500,yres=500, camera_center=(2,0,0))
sage: t.light((4,3,2), 0.2, (1,1,1))
sage: t.texture('t2', ambient=0.1, diffuse=0.9, specular=0.5, opacity=1.0, color=(1,0,0))
sage: t.texture('t3', ambient=0.1, diffuse=0.9, specular=0.5, opacity=1.0, color=(0,1,0))
sage: t.texture('t4', ambient=0.1, diffuse=0.9, specular=0.5, opacity=1.0, color=(0,0,1))
sage: t.sphere((0,0.5,0), 0.2, 't2')
sage: t.sphere((0.5,0,0), 0.2, 't3')
sage: t.sphere((0,0,0.5), 0.2, 't4')
sage: t.show()
```

class **Cylinder**(*center, axis, radius, texture*)

str()

class **FCylinder**(*base, apex, radius, texture*)

str()

class **Light**(*center, radius, color*)

str()

class **ParametricPlot**(*f, t_0, t_f, tex, r=0.10000000000000001, cylinders=True, min_depth=4, max_depth=8, e_rel=0.01, e_abs=0.01*)

str()

tol(*est, val*)

class **Plane**(*center, normal, texture*)

str()

class PlotBlock(*left, left_c, top, top_c, right, right_c, bottom, bottom_c*)

class Sphere(*center, radius, texture*)

str()

class Tachyon(*xres=350, yres=350, zoom=1.0, antialiasing=False, aspectratio=1.0, raydepth=8, camera_center=(-3, 0, 0), updir=(0, 0, 1), look_at=(0, 0, 0), viewdir=None, projection='PERSPECTIVE'*)

Create a scene the can be rendered using the Tachyon ray tracer.

INPUT:

- `xres` - (default 350)
- `yres` - (default 350)
- `zoom` - (default 1.0)
- `antialiasing` - (default False)
- `aspectratio` - (default 1.0)
- `raydepth` - (default 5)
- `camera_center` - (default (-3, 0, 0))
- `updir` - (default (0, 0, 1))
- `look_at` - (default (0,0,0))
- `viewdir` - (default None)
- `projection` - (default 'PERSPECTIVE')

OUTPUT: A Tachyon 3d scene.

Note that the coordinates are by default such that z is up, positive y is to the {left} and x is toward you. This is not oriented according to the right hand rule.

EXAMPLES: Spheres along the twisted cubic.

```
sage: t = Tachyon(xres=512,yres=512, camera_center=(3,0.3,0))
sage: t.light((4,3,2), 0.2, (1,1,1))
sage: t.texture('t0', ambient=0.1, diffuse=0.9, specular=0.5, opacity=1.0, color=(1.0,0,0))
sage: t.texture('t1', ambient=0.1, diffuse=0.9, specular=0.3, opacity=1.0, color=(0,1.0,0))
sage: t.texture('t2', ambient=0.2,diffuse=0.7, specular=0.5, opacity=0.7, color=(0,0,1.0))
sage: k=0
sage: for i in srange(-1,1,0.05):
...     k += 1
...     t.sphere((i,i^2-0.5,i^3), 0.1, 't%s'%(k%3))
...
sage: t.show()
```

Another twisted cubic, but with a white background, got by putting infinite planes around the scene.

```
sage: t = Tachyon(xres=512,yres=512, camera_center=(3,0.3,0), raydepth=8)
sage: t.light((4,3,2), 0.2, (1,1,1))
sage: t.texture('t0', ambient=0.1, diffuse=0.9, specular=0.5, opacity=1.0, color=(1.0,0,0))
sage: t.texture('t1', ambient=0.1, diffuse=0.9, specular=0.3, opacity=1.0, color=(0,1.0,0))
sage: t.texture('t2', ambient=0.2,diffuse=0.7, specular=0.5, opacity=0.7, color=(0,0,1.0))
sage: t.texture('white', color=(1,1,1))
sage: t.plane((0,0,-1), (0,0,1), 'white')
sage: t.plane((0,-20,0), (0,1,0), 'white')
sage: t.plane((-20,0,0), (1,0,0), 'white')
```

```
sage: k=0
sage: for i in srange(-1,1,0.05):
...     k += 1
...     t.sphere((i,i^2 - 0.5,i^3), 0.1, 't%s'%(k%3))
...     t.cylinder((0,0,0), (0,0,1), 0.05,'t1')
...
sage: t.show()
```

Many random spheres:

```
sage: t = Tachyon(xres=512,yres=512, camera_center=(2,0.5,0.5), look_at=(0.5,0.5,0.5), raydepth=
sage: t.light((4,3,2), 0.2, (1,1,1))
sage: t.texture('t0', ambient=0.1, diffuse=0.9, specular=0.5, opacity=1.0, color=(1.0,0,0))
sage: t.texture('t1', ambient=0.1, diffuse=0.9, specular=0.3, opacity=1.0, color=(0,1.0,0))
sage: t.texture('t2', ambient=0.2, diffuse=0.7, specular=0.5, opacity=0.7, color=(0,0,1.0))
sage: k=0
sage: for i in range(100):
...     k += 1
...     t.sphere((random(),random(), random()), random()/10, 't%s'%(k%3))
...
sage: t.show()
```

Points on an elliptic curve, their height indicated by their height above the axis:

```
sage: t = Tachyon(camera_center=(5,2,2), look_at=(0,1,0))
sage: t.light((10,3,2), 0.2, (1,1,1))
sage: t.texture('t0', ambient=0.1, diffuse=0.9, specular=0.5, opacity=1.0, color=(1,0,0))
sage: t.texture('t1', ambient=0.1, diffuse=0.9, specular=0.5, opacity=1.0, color=(0,1,0))
sage: t.texture('t2', ambient=0.1, diffuse=0.9, specular=0.5, opacity=1.0, color=(0,0,1))
sage: E = EllipticCurve('37a')
sage: P = E([0,0])
sage: Q = P
sage: n = 100
sage: for i in range(n):   # increase 20 for a better plot
...     Q = Q + P
...     t.sphere((Q[1], Q[0], ZZ(i)/n), 0.1, 't%s'%(i%3))
...
sage: t.show()
```

A beautiful picture of rational points on a rank 1 elliptic curve.

```
sage: t = Tachyon(xres=1000, yres=800, camera_center=(2,7,4), look_at=(2,0,0), raydepth=4)
sage: t.light((10,3,2), 1, (1,1,1))
sage: t.light((10,-3,2), 1, (1,1,1))
sage: t.texture('black', color=(0,0,0))
sage: t.texture('red', color=(1,0,0))
sage: t.texture('grey', color=(.9,.9,.9))
sage: t.plane((0,0,0),(0,0,1),'grey')
sage: t.cylinder((0,0,0),(1,0,0),.01,'black')
sage: t.cylinder((0,0,0),(0,1,0),.01,'black')
sage: E = EllipticCurve('37a')
sage: P = E([0,0])
sage: Q = P
sage: n = 100
sage: for i in range(n):
...     Q = Q + P
...     c = i/n + .1
...     t.texture('r%s'%i,color=(float(i/n),0,0))
```

```
...     t.sphere((Q[0], -Q[1], .01), .04, 'r%s'%i)
...
...
sage: t.show()     # long time, e.g., 10-20 seconds
```

A beautiful spiral.

```
sage: t = Tachyon(xres=800,yres=800, camera_center=(2,5,2), look_at=(2.5,0,0))
sage: t.light((0,0,100), 1, (1,1,1))
sage: t.texture('r', ambient=0.1, diffuse=0.9, specular=0.5, opacity=1.0, color=(1,0,0))
sage: for i in srange(0,50,0.1):
...     t.sphere((i/10,sin(i),cos(i)), 0.05, 'r')
...
sage: t.texture('white', color=(1,1,1), opacity=1, specular=1, diffuse=1)
sage: t.plane((0,0,-100), (0,0,-100), 'white')
sage: t.show()
```

collect (*objects*)
Add a set of objects to the scene from a collection

cylinder (*center, axis, radius, texture*)

fcylinder (*base, apex, radius, texture*)

light (*center, radius, color*)

parametric_plot (*f, t_0, t_f, tex, r=0.10000000000000001, cylinders=True, min_depth=4, max_depth=8, e_rel=0.01, e_abs=0.01*)
Plots a space curve as a series of speheres and finite cylinders. Example (twisted cubic)

```
sage: f = lambda t: (t,t^2,t^3)
sage: t = Tachyon(camera_center=(5,0,4))
sage: t.texture('t')
sage: t.light((-20,-20,40), 0.2, (1,1,1))
sage: t.parametric_plot(f,-5,5,'t',min_depth=6)
```

plane (*center, normal, texture*)

plot (*f, (xmin, xmax), (ymin, ymax), texture, grad_f=None, max_bend=0.69999999999999996, max_depth=5, initial_depth=3, num_colors=None*)
INPUT:

- `f` - Function of two variables, which returns a float (or coercable to a float) (xmin,xmax)
- `(ymin,ymax)` - defines the rectangle to plot over texture: Name of texture to be used Optional arguments:
- `grad_f` - gradient function. If specified, smooth triangles will be used.
- `max_bend` - Cosine of the threshold angle between triangles used to determine whether or not to recurse after the minimum depth
- `max_depth` - maximum recursion depth. Maximum triangles plotted = 2^{2*max_depth}
- `initial_depth` - minimum recursion depth. No error-tolerance checking is performed below this depth. Minimum triangles plotted: 2^{2*min_depth}
- `num_colors` - Number of rainbow bands to color the plot with. Texture supplied will be cloned (with different colors) using the texture_recolor method of the Tachyon object.

Plots a function by constructing a mesh with nonstandard sampling density without gaps. At very high resolutions (depths 10) it becomes very slow. Cython may help. Complexity is approx. $O(2^{2*maxdepth})$. This algorithm has been optimized for speed, not memory - values from f(x,y) are recycled rather than calling the function multiple times. At high recursion depth, this may cause problems for some machines.

Flat Triangles:

```
sage: t = Tachyon(xres=512,yres=512, camera_center=(4,-4,3),viewdir=(-4,4,-3), raydepth=4)
sage: t.light((4.4,-4.4,4.4), 0.2, (1,1,1))
sage: def f(x,y): return float(sin(x*y))
sage: t.texture('t0', ambient=0.1, diffuse=0.9, specular=0.1,  opacity=1.0, color=(1.0,0,0))
sage: t.plot(f,(-4,4),(-4,4),"t0",max_depth=5,initial_depth=3, num_colors=60)  # increase mi
sage: t.show()
```

Plotting with Smooth Triangles (requires explicit gradient function):

```
sage: t = Tachyon(xres=512,yres=512, camera_center=(4,-4,3),viewdir=(-4,4,-3), raydepth=4)
sage: t.light((4.4,-4.4,4.4), 0.2, (1,1,1))
sage: def f(x,y): return float(sin(x*y))
sage: def g(x,y): return ( float(y*cos(x*y)), float(x*cos(x*y)), 1 )
sage: t.texture('t0', ambient=0.1, diffuse=0.9, specular=0.1,  opacity=1.0, color=(1.0,0,0))
sage: t.plot(f,(-4,4),(-4,4),"t0",max_depth=5,initial_depth=3, grad_f = g)  # increase min_d
sage: t.show()
```

Preconditions: f is a scalar function of two variables, grad_f is None or a triple-valued function of two variables, min_x != max_x, min_y != max_y

```
sage: f = lambda x,y: x*y
sage: t = Tachyon()
sage: t.plot(f,(2.,2.),(-2.,2.),'')
...
ValueError: Plot rectangle is really a line.  Make sure min_x != max_x and min_y != max_y.
```

save (*filename='sage.png', verbose=0, block=True, extra_opts=''*)

INPUT:

- `filename` - (default: 'sage.png') output filename; the extension of the filename determines the type. Supported types include:
- `tga` - 24-bit (uncompressed)
- `bmp` - 24-bit Windows BMP (uncompressed)
- `ppm` - 24-bit PPM (uncompressed)
- `rgb` - 24-bit SGI RGB (uncompressed)
- `png` - 24-bit PNG (compressed, lossless)
- `verbose` - integer; (default: 0)
- `0` - silent
- `1` - some output
- `2` - very verbose output
- `block` - bool (default: True); if False, run the rendering command in the background.
- `extra_opts` - passed directly to tachyon command line. Use tachyon_rt.usage() to see some of the possibilities.

show (*verbose=0, extra_opts=''*)

smooth_triangle (*vertex_1, vertex_2, vertex_3, normal_1, normal_2, normal_3, texture*)

sphere (*center, radius, texture*)

str ()

texfunc (*type=0, center=(0, 0, 0), rotate=(0, 0, 0), scale=(1, 1, 1)*)

INPUT:

- `type` - (default: 0)
  1. No special texture, plain shading
  2. 3D checkerboard function, like a rubik's cube
  3. Grit Texture, randomized surface color

4.3D marble texture, uses object's base color
5.3D wood texture, light and dark brown, not very good yet
6.3D gradient noise function (can't remember what it looks like)
7.Don't remember
8.Cylindrical Image Map, requires ppm filename (don't know how to specify name in sage?!)
9.Spherical Image Map, requires ppm filename (don't know how to specify name in sage?!)
10.Planar Image Map, requires ppm filename (don't know how to specify name in sage?!)

- `center` - (default: (0,0,0))
- `rotate` - (default: (0,0,0))
- `scale` - (default: (1,1,1))

EXAMPLES: We draw an infinite checkboard:

```
sage: t = Tachyon(camera_center=(2,7,4), look_at=(2,0,0))
sage: t.texture('black', color=(0,0,0), texfunc=1)
sage: t.plane((0,0,0),(0,0,1),'black')
sage: t.show()
```

texture(*name, ambient=0.20000000000000001, diffuse=0.80000000000000004, specular=0.0, opacity=1.0, color=(1.0, 0.0, 0.5), texfunc=0, phong=0, phongsize=0.5, phongtype='PLASTIC'*)

INPUT:

- `name` - string; the name of the texture (to be used later)
- `ambient` - (default: 0.2)
- `diffuse` - (default: 0.8)
- `specular` - (default: 0.0)
- `opacity` - (default: 1.0)
- `color` - (default: (1.0,0.0,0.5))
- `texfunc` - (default: 0); a texture function; this is either the output of self.texfunc, or a number between 0 and 9, inclusive. See the docs for self.texfunc.
- `phong` - (default: 0)
- `phongsize` - (default: 0.5)
- `phongtype` - (default: "PLASTIC")

EXAMPLES: We draw a scene with 4 sphere that illustrates various uses of the texture command:

```
sage: t = Tachyon(camera_center=(2,5,4), look_at=(2,0,0), raydepth=6)
sage: t.light((10,3,4), 1, (1,1,1))
sage: t.texture('mirror', ambient=0.05, diffuse=0.05, specular=.9, opacity=0.9, color=(.8,.8
sage: t.texture('grey', color=(.8,.8,.8), texfunc=3)
sage: t.plane((0,0,0),(0,0,1),'grey')
sage: t.sphere((4,-1,1), 1, 'mirror')
sage: t.sphere((0,-1,1), 1, 'mirror')
sage: t.sphere((2,-1,1), 0.5, 'mirror')
sage: t.sphere((2,1,1), 0.5, 'mirror')
sage: show(t)
```

texture_recolor(*name, colors*)

triangle(*vertex_1, vertex_2, vertex_3, texture*)

class **TachyonPlot**(*tachyon, f, (min_x, max_x), (min_y, max_y), tex, g=None, min_depth=4, max_depth=8, e_rel=0.01, e_abs=0.01, num_colors=None*)

extrema(*list*)

interface(*n, p, p_c, q, q_c*)

plot_block(*min_x, mid_x, max_x, min_y, mid_y, max_y, sw_z, nw_z, se_z, ne_z, mid_z, depth*)

str()

tol(*(est, val)*)

tol_list(*l*)

triangulate(*p, c*)

class TachyonSmoothTriangle(*a, b, c, da, db, dc, color=0*)

str()

class TachyonTriangle(*a, b, c, color=0*)

str()

class TachyonTriangleFactory(*tach, tex*)

get_colors(*list*)

smooth_triangle(*a, b, c, da, db, dc, color=None*)

triangle(*a, b, c, color=None*)

class Texfunc(*type=0, center=(0, 0, 0), rotate=(0, 0, 0), scale=(1, 1, 1)*)

str()

class Texture(*name, ambient=0.20000000000000001, diffuse=0.80000000000000004, specular=0.0, opacity=1.0, color=(1.0, 0.0, 0.5), texfunc=0, phong=0, phongsize=0, phongtype='PLASTIC'*)

recolor(*name, color*)

str()

hue(*h, s=1, v=1*)

hue(h,s=1,v=1) where 'h' stands for hue, 's' stands for saturation, 'v' stands for value. hue returns a list of rgb intensities (r, g, b) All values are in the range 0 to 1.

INPUT:

- `h, s, v` - real numbers between 0 and 1. Note that if any are not in this range they are automatically normalized to be in this range by reducing them modulo 1.

OUTPUT: A valid RGB tuple.

EXAMPLES:

```
sage: hue(0.6)
(0.0, 0.40000000000000036, 1.0)
```

hue is an easy way of getting a broader range of colors for graphics

```
sage: p = plot(sin, -2, 2, rgbcolor=hue(0.6))
```

tostr(*s*)

CHAPTER

SIX

GAMES

Sage includes a simple Sudoku solver. It also has a Rubik's cube solver (see *Rubik's Cube Group*).

6.1 Sudoku Solver

Given a 9x9 Sudoku puzzle as an integer matrix, this routine finds a single solution.

grid_has_k (*A, i, j, k*)

Checks for the presence of k in the 3x3 subgrid containing the location in row i and column j.

INPUT:

- A - a 9x9 matrix with entries from 0, 1..9
- i - integer specifying row i
- j - integer specifying column j
- k - an integer from 1..9

OUTPUT:

boolean - True exactly when k is present in the 3x3 sub-grid that also has the entry in row i and column j.

EXAMPLES:

```
sage: from sage.games.sudoku import grid_has_k
sage: B = matrix(ZZ, 9, 9, [ [0,0,0,0,1,0,9,0,0], [8,0,0,4,0,0,0,0,0], [2,0,0,0,0,0,0,0,0], [0,7
sage: B
[0 0 0 0 1 0 9 0 0]
[8 0 0 4 0 0 0 0 0]
[2 0 0 0 0 0 0 0 0]
[0 7 0 0 3 0 0 0 0]
[0 0 0 0 0 0 2 0 4]
[0 0 0 0 0 0 0 5 8]
[0 6 0 0 0 0 1 3 0]
[7 0 0 2 0 0 0 0 0]
[0 0 0 8 0 0 0 0 0]
sage: grid_has_k(B, 3, 2, 7)
True
sage: grid_has_k(B, 3, 2, 1)
False
```

solve_recursive (*A, i, j*)

Completes a Sudoku puzzle starting at (an empty) square in row i and column j

INPUT:

- A - a 9x9 matrix with integer entries from 0, 1..9
- i - integer specifying row i
- j - integer specifying column j

OUTPUT:

matrix - a 9x9 matrix over ZZ

If square (i, j) is non-zero (not empty) then A is returned immediately
If there is no way to complete the puzzle then None is returned
Otherwise a recursive call is made, which will eventually return a (partial) solution or None

NOTES:

As a practical matter this should be called with (i, j) being the first empty square (in row-major order), though nothing prohibits starting at another square (empty or not), and possibly getting a partially complete square back as output.

EXAMPLES:

This puzzle has only 17 non-empty squares (hints) and has a unique solution. At this writing (2009/04/11) there are no known 16-hint Sudoku puzzles with a unique solution. It is number 3000 in Gordon Royle's database of 17-hint uniquely-solvable puzzles [1].

Here we just test finding a possible completion if we started midway through the bottom row.

```
sage: from sage.games.sudoku import solve_recursive
sage: B = matrix(ZZ, 9, 9, [ [0,0,0,0,1,0,9,0,0], [8,0,0,4,0,0,0,0,0], [2,0,0,0,0,0,0,0,0], [0,7
sage: B
[0 0 0 0 1 0 9 0 0]
[8 0 0 4 0 0 0 0 0]
[2 0 0 0 0 0 0 0 0]
[0 7 0 0 3 0 0 0 0]
[0 0 0 0 0 0 2 0 4]
[0 0 0 0 0 0 0 5 8]
[0 6 0 0 0 0 1 3 0]
[7 0 0 2 0 0 0 0 0]
[0 0 0 8 0 0 0 0 0]
sage: solve_recursive(B, 8, 5)
[0 0 0 0 1 0 9 0 0]
[8 0 0 4 0 0 0 0 0]
[2 0 0 0 0 0 0 0 0]
[0 7 0 0 3 0 0 0 0]
[0 0 0 0 0 0 2 0 4]
[0 0 0 0 0 0 0 5 8]
[0 6 0 0 0 0 1 3 0]
[7 0 0 2 0 0 0 0 0]
[0 0 0 8 0 1 4 2 5]
```

Now we perturb B to make the (8,7) square impossible to complete. And we start at an empty square a little further back up the matrix.

```
sage: B[0,7], B[1,7], B[2,7] = 2, 6, 7
sage: B[8,0], B[8, 1] = 4, 9
sage: B
[0 0 0 0 1 0 9 2 0]
[8 0 0 4 0 0 0 6 0]
[2 0 0 0 0 0 0 7 0]
[0 7 0 0 3 0 0 0 0]
[0 0 0 0 0 0 2 0 4]
```

```
[0 0 0 0 0 0 0 5 8]
[0 6 0 0 0 0 1 3 0]
[7 0 0 2 0 0 0 0 0]
[4 9 0 8 0 0 0 0 0]
sage: print solve_recursive(B, 7, 1)
None
```

REFERENCES:

- [1] Gordon Royle, Minimum Sudoku, http://people.csse.uwa.edu.au/gordon/sudokumin.php, (2009/04/11)

sudoku(A)

Solve the 9x9 Sudoku puzzle contained in the matrix A.

INPUT:

- A - a 9x9 matrix with integer entries from 0, 1..9. A 0 indicates an empty square

OUTPUT:

matrix - a 9x9 matrix over ZZ containing the first solution found

ALGORITHM:

A solution is found by examining blank cells in turn, determining which symbols are in use in the corresponding row, column and 3x3 sub-grid, and then making recursive calls exhausting all possibilities at that blank cell. Basically this is a depth-first search to the first solution, with pruning accomplished according to only the basic requirements of a legitimate completed Sudoku.

EXAMPLES:

```
sage: A = matrix(ZZ,9,[5,0,0, 0,8,0, 0,4,9, 0,0,0, 5,0,0, 0,3,0, 0,6,7, 3,0,0, 0,0,1,  1,5,0, 0,
sage: A
[5 0 0 0 8 0 0 4 9]
[0 0 0 5 0 0 0 3 0]
[0 6 7 3 0 0 0 0 1]
[1 5 0 0 0 0 0 0 0]
[0 0 0 2 0 8 0 0 0]
[0 0 0 0 0 0 0 1 8]
[7 0 0 0 0 4 1 5 0]
[0 3 0 0 0 2 0 0 0]
[4 9 0 0 5 0 0 0 3]
sage: sudoku(A)
[5 1 3 6 8 7 2 4 9]
[8 4 9 5 2 1 6 3 7]
[2 6 7 3 4 9 5 8 1]
[1 5 8 4 6 3 9 7 2]
[9 7 4 2 1 8 3 6 5]
[3 2 6 7 9 5 4 1 8]
[7 8 2 9 3 4 1 5 6]
[6 3 5 1 7 2 8 9 4]
[4 9 1 8 5 6 7 2 3]
```

Now we perturb A slightly to make the $(3, 5)$ entry impossible to complete.

```
sage: A[1,4], A[2,4] = 7, 9
sage: A[3,6], A[3,7], A[3,8] = 3, 4, 6
sage: A
[5 0 0 0 8 0 0 4 9]
[0 0 0 5 7 0 0 3 0]
[0 6 7 3 9 0 0 0 1]
```

```
[1 5 0 0 0 0 3 4 6]
[0 0 0 2 0 8 0 0 0]
[0 0 0 0 0 0 0 1 8]
[7 0 0 0 0 4 1 5 0]
[0 3 0 0 0 2 0 0 0]
[4 9 0 0 5 0 0 0 3]
sage: print sudoku(A)
None
```

7.1.1 Graph Format

The Sage Graph Class: NetworkX plus

Sage graphs are actually NetworkX graphs, wrapped in a Sage class. In fact, any graph can produce its underlying NetworkX graph. For example,

```
sage: import networkx
sage: G = graphs.PetersenGraph()
sage: N = G.networkx_graph()
sage: isinstance(N, networkx.graph.Graph)
True
```

The NetworkX graph is essentially a dictionary of dictionaries:

```
sage: N.adj
{0: {1: None, 4: None, 5: None}, 1: {0: None, 2: None, 6: None}, 2: {1: None, 3: None, 7: None}, 3:
```

Each dictionary key is a vertex label, and each key in the following dictionary is a neighbor of that vertex. In undirected graphs, there is redundancy: for example, the dictionary containing the entry `1: {2: None}` implies it must contain `{2: {1: None}`. The innermost entry of `None` is related to edge labeling (see section *Labels*).

Supported formats

Sage Graphs can be created from a wide range of inputs. A few examples are covered here.

- NetworkX dictionary format:

```
sage: d = {0: [1,4,5], 1: [2,6], 2: [3,7], 3: [4,8], 4: [9], \
      5: [7, 8], 6: [8,9], 7: [9]}
sage: G = Graph(d); G
Graph on 10 vertices
sage: G.plot().show()    # or G.show()
```

- A NetworkX graph:

```
sage: K = networkx.complete_bipartite_graph(12,7)
sage: G = Graph(K)
sage: G.degree()
[7, 7, 7, 7, 7, 7, 7, 7, 7, 7, 7, 7, 12, 12, 12, 12, 12, 12, 12]
```

- graph6 or sparse6 format:

```
sage: s = ':I`AKGsaOs`cI]Gb~'
sage: G = Graph(s, sparse=True); G
Looped multi-graph on 10 vertices
sage: G.plot().show()    # or G.show()
```

Note that the `\` character is an escape character in Python, and also a character used by graph6 strings:

```
sage: G = Graph('Ihe\n@GUA')
...
RuntimeError: The string (Ihe) seems corrupt: for n = 10, the string is too short.
```

In Python, the escaped character `\` is represented by `\\`:

```
sage: G = Graph('Ihe\\n@GUA')
sage: G.plot().show()     # or G.show()
```

- adjacency matrix: In an adjacency matrix, each column and each row represent a vertex. If a 1 shows up in row i, column j, there is an edge (i, j).

```
sage: M = Matrix([(0,1,0,0,1,1,0,0,0,0),(1,0,1,0,0,0,1,0,0,0), \
(0,1,0,1,0,0,0,1,0,0), (0,0,1,0,1,0,0,0,1,0),(1,0,0,1,0,0,0,0,0,1), \
(1,0,0,0,0,0,0,1,1,0), (0,1,0,0,0,0,0,0,1,1),(0,0,1,0,0,1,0,0,0,1), \
(0,0,0,1,0,1,1,0,0,0), (0,0,0,0,1,0,1,1,0,0)])
sage: M
[0 1 0 0 1 1 0 0 0 0]
[1 0 1 0 0 0 1 0 0 0]
[0 1 0 1 0 0 0 1 0 0]
[0 0 1 0 1 0 0 0 1 0]
[1 0 0 1 0 0 0 0 0 1]
[1 0 0 0 0 0 0 1 1 0]
[0 1 0 0 0 0 0 0 1 1]
[0 0 1 0 0 1 0 0 0 1]
[0 0 0 1 0 1 1 0 0 0]
[0 0 0 0 1 0 1 1 0 0]
sage: G = Graph(M); G
Graph on 10 vertices
sage: G.plot().show()     # or G.show()
```

- incidence matrix: In an incidence matrix, each row represents a vertex and each column reprensents an edge.

```
sage: M = Matrix([(-1,0,0,0,1,0,0,0,0,0,-1,0,0,0,0), \
(1,-1,0,0,0,0,0,0,0,0,0,-1,0,0,0), (0,1,-1,0,0,0,0,0,0,0,0,0,-1,0,0), \
(0,0,1,-1,0,0,0,0,0,0,0,0,0,-1,0), (0,0,0,1,-1,0,0,0,0,0,0,0,0,0,-1), \
(0,0,0,0,0,-1,0,0,0,1,1,0,0,0,0), (0,0,0,0,0,0,0,1,-1,0,0,1,0,0,0), \
(0,0,0,0,0,1,-1,0,0,0,0,0,1,0,0), (0,0,0,0,0,0,0,0,1,-1,0,0,0,1,0), \
(0,0,0,0,0,0,1,-1,0,0,0,0,0,0,1)])
sage: M
[-1  0  0  0  1  0  0  0  0  0 -1  0  0  0  0]
[ 1 -1  0  0  0  0  0  0  0  0  0 -1  0  0  0]
[ 0  1 -1  0  0  0  0  0  0  0  0  0 -1  0  0]
[ 0  0  1 -1  0  0  0  0  0  0  0  0  0 -1  0]
[ 0  0  0  1 -1  0  0  0  0  0  0  0  0  0 -1]
[ 0  0  0  0  0 -1  0  0  0  1  1  0  0  0  0]
[ 0  0  0  0  0  0  0  1 -1  0  0  1  0  0  0]
[ 0  0  0  0  0  1 -1  0  0  0  0  0  1  0  0]
[ 0  0  0  0  0  0  0  0  1 -1  0  0  0  1  0]
[ 0  0  0  0  0  0  1 -1  0  0  0  0  0  0  1]
sage: G = Graph(M); G
Graph on 10 vertices
sage: G.plot().show()     # or G.show()
```

7.1.2 Generators

If you wish to iterate through all the isomorphism types of graphs, type, for example:

```
sage: for g in graphs(4):
...       print g.spectrum()
[0.0, 0.0, 0.0, 0.0]
```

```
...
[-1.0, -1.0, -1.0, 3.0]
```

For some commonly used graphs to play with, type

```
sage: graphs.[tab]          # not tested
```

and hit {tab}. Most of these graphs come with their own custom plot, so you can see how people usually visualize these graphs.

```
sage: G = graphs.PetersenGraph()
sage: G.plot().show()     # or G.show()
sage: G.degree_histogram()
[0, 0, 0, 10]
sage: G.adjacency_matrix()
[0 1 0 0 1 1 0 0 0 0]
[1 0 1 0 0 0 1 0 0 0]
[0 1 0 1 0 0 0 1 0 0]
[0 0 1 0 1 0 0 0 1 0]
[1 0 0 1 0 0 0 0 0 1]
[1 0 0 0 0 0 0 1 1 0]
[0 1 0 0 0 0 0 0 1 1]
[0 0 1 0 0 1 0 0 0 1]
[0 0 0 1 0 1 1 0 0 0]
[0 0 0 0 1 0 1 1 0 0]
```

```
sage: S = G.subgraph([0,1,2,3])
sage: S.plot().show()     # or S.show()
sage: S.density()
1/2
```

```
sage: G = GraphQuery(display_cols=['graph6'], num_vertices=7, diameter=5)
sage: L = G.get_graphs_list()
sage: graphs_list.show_graphs(L)
```

7.1.3 Labels

Each vertex can have any hashable object as a label. These are things like strings, numbers, and tuples. Each edge is given a default label of `None`, but if specified, edges can have any label at all. Edges between vertices u and v are represented typically as `(u, v, l)`, where `l` is the label for the edge.

Note that vertex labels themselves cannot be mutable items:

```
sage: M = Matrix( [[0,0],[0,0]] )
sage: G = Graph({ 0 : { M : None } })
...
TypeError: mutable matrices are unhashable
```

However, if one wants to define a dictionary, with the same keys and arbitrary objects for entries, one can make that association:

```
sage: d = {0 : graphs.DodecahedralGraph(), 1 : graphs.FlowerSnark(), \
      2 : graphs.MoebiusKantorGraph(), 3 : graphs.PetersenGraph() }
sage: d[2]
Moebius-Kantor Graph: Graph on 16 vertices
sage: T = graphs.TetrahedralGraph()
sage: T.vertices()
[0, 1, 2, 3]
sage: T.set_vertices(d)
sage: T.get_vertex(1)
Flower Snark: Graph on 20 vertices
```

7.1.4 Database

There is a database available for searching for graphs that satisfy a certain set of parameters, including number of vertices and edges, density, maximum and minimum degree, diameter, radius, and connectivity. To see a list of all search parameter keywords broken down by their designated table names, type

```
sage: graph_db_info()
{...}
```

For more details on datatypes or keyword input, enter

```
sage:  GraphQuery?    # not tested
```

The results of a query can be viewed with the show method, or can be viewed individually by iterating through the results:

```
sage: Q = GraphQuery(display_cols=['graph6'],num_vertices=7, diameter=5)
sage: Q.show()
Graph6
--------------------
F@?]O
F@OKg
F?`po
F?gqg
FIAHo
F@R@o
FA_pW
FGC{o
FEOhW
```

Show each graph as you iterate through the results:

```
sage: for g in Q:
...       show(g)
```

7.1.5 Visualization

To see a graph G you are working with, right now there are two main options. You can view the graph in two dimensions via matplotlib with `show()`.

```
sage: G = graphs.RandomGNP(15,.3)
sage: G.show()
```

Or you can view it in three dimensions via jmol with `show3d()`.

```
sage: G.show3d()
```

7.1.6 Graph classes and methods

class **DiGraph**(*data=None, pos=None, loops=None, format=None, boundary=, [], weighted=None, implementation='networkx', sparse=True, vertex_labels=True, **kwds*)

Directed graph.

INPUT:

- `data` - can be any of the following:
  1. A NetworkX digraph
  2. A dictionary of dictionaries
  3. A dictionary of lists
  4. A numpy matrix or ndarray
  5. A Sage adjacency matrix or incidence matrix
  6. A pygraphviz agraph
  7. A SciPy sparse matrix
- `pos` - a positioning dictionary: for example, the spring layout from NetworkX for the 5-cycle is:

```
{0: [-0.91679746, 0.88169588],
 1: [ 0.47294849, 1.125     ],
 2: [ 1.125     ,-0.12867615],
 3: [ 0.12743933,-1.125     ],
 4: [-1.125     ,-0.50118505]}
```

- `name` - (must be an explicitly named parameter, i.e., name="complete") gives the graph a name
- `loops` - boolean, whether to allow loops (ignored if data is an instance of the DiGraph class)
- `multiedges` - boolean, whether to allow multiple edges (ignored if data is an instance of the DiGraph class)
- `weighted` - whether digraph thinks of itself as weighted or not. See self.weighted()
- `format` - if None, DiGraph tries to guess- can be several values, including:
  - `'adjacency_matrix'` - a square Sage matrix M, with M[i,j] equal to the number of edges {i,j}
  - `'incidence_matrix'` - a Sage matrix, with one column C for each edge, where if C represents {i, j}, C[i] is -1 and C[j] is 1
  - `'weighted_adjacency_matrix'` - a square Sage matrix M, with M[i,j] equal to the weight of the single edge {i,j}. Given this format, weighted is ignored (assumed True).
- `boundary` - a list of boundary vertices, if none, digraph is considered as a 'digraph without boundary'
- `implementation` - what to use as a backend for the graph. Currently, the options are either 'networkx' or 'c_graph'
- `sparse` - only for implementation == 'c_graph'. Whether to use sparse or dense graphs as backend. Note that currently dense graphs do not have edge labels, nor can they be multigraphs
- `vertex_labels` - only for implementation == 'c_graph'. Whether to allow any object as a vertex (slower), or only the integers 0, ..., n-1, where n is the number of vertices.

EXAMPLES:

1.A NetworkX XDiGraph:

```
sage: import networkx
sage: g = networkx.XDiGraph({0:[1,2,3], 2:[4]})
sage: DiGraph(g)
Digraph on 5 vertices
```

2.A NetworkX digraph:

```
sage: import networkx
sage: g = networkx.DiGraph({0:[1,2,3], 2:[4]})
sage: DiGraph(g)
Digraph on 5 vertices
```

Note that in all cases, we copy the networkX structure.

```
sage: import networkx
sage: g = networkx.DiGraph({0:[1,2,3], 2:[4]})
sage: G = DiGraph(g, implementation='networkx')
sage: H = DiGraph(g, implementation='networkx')
sage: G._backend._nxg is H._backend._nxg
False
```

3.A dictionary of dictionaries:

```
sage: g = DiGraph({0:{1:'x',2:'z',3:'a'}, 2:{5:'out'}}, implementation='networkx'); g
Digraph on 5 vertices
```

The labels ('x', 'z', 'a', 'out') are labels for edges. For example, 'out' is the label for the edge from 2 to 5. Labels can be used as weights, if all the labels share some common parent.

4.A dictionary of lists:

```
sage: g = DiGraph({0:[1,2,3], 2:[4]}); g
Digraph on 5 vertices
```

5.A list of vertices and a function describing adjacencies. Note that the list of vertices and the function must be enclosed in a list (i.e., [list of vertices, function]).

We construct a graph on the integers 1 through 12 such that there is a directed edge from i to j if and only if i divides j.

```
sage: g=DiGraph([[1..12],lambda i,j: i!=j and i.divides(j)], implementation='networkx')
sage: g.vertices()
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12]
sage: g.adjacency_matrix()
[0 1 1 1 1 1 1 1 1 1 1 1]
[0 0 0 1 0 1 0 1 0 1 0 1]
[0 0 0 0 0 1 0 0 1 0 0 1]
[0 0 0 0 0 0 0 1 0 0 0 1]
[0 0 0 0 0 0 0 0 0 1 0 0]
[0 0 0 0 0 0 0 0 0 0 0 1]
[0 0 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0]
```

6.A numpy matrix or ndarray:

```
sage: import numpy
sage: A = numpy.array([[0,1,0],[1,0,0],[1,1,0]])
sage: DiGraph(A, implementation='networkx')
Digraph on 3 vertices
```

7. A Sage matrix: Note: If format is not specified, then Sage assumes a square matrix is an adjacency matrix, and a nonsquare matrix is an incidence matrix.

   •an adjacency matrix:

```
sage: M = Matrix([[0, 1, 1, 1, 0],[0, 0, 0, 0, 0],[0, 0, 0, 0, 1],[0, 0, 0, 0, 0],[0, 0,
[0 1 1 1 0]
[0 0 0 0 0]
[0 0 0 0 1]
[0 0 0 0 0]
[0 0 0 0 0]
sage: DiGraph(M)
Digraph on 5 vertices
```

   •an incidence matrix:

```
sage: M = Matrix(6, [-1,0,0,0,1, 1,-1,0,0,0, 0,1,-1,0,0, 0,0,1,-1,0, 0,0,0,1,-1, 0,0,0,0
[-1  0  0  0  1]
[ 1 -1  0  0  0]
[ 0  1 -1  0  0]
[ 0  0  1 -1  0]
[ 0  0  0  1 -1]
[ 0  0  0  0  0]
sage: DiGraph(M)
Digraph on 6 vertices
```

8. A c_graph implemented DiGraph can be constructed from a networkx implemented DiGraph if its vertex set is equal to range(n):

```
sage: D = DiGraph({0:[1],1:[2],2:[0]}, implementation="networkx")
sage: E = DiGraph(D,implementation="c_graph")
sage: D == E
True
```

9. A dig6 string: Sage automatically recognizes whether a string is in dig6 format, which is a directed version of graph6:

```
sage: D = DiGraph('IRAaDCIIOWEOKcPWAo')
sage: D
Digraph on 10 vertices

sage: D = DiGraph('IRAaDCIIOEOKcPWAo')
...
RuntimeError: The string (IRAaDCIIOEOKcPWAo) seems corrupt: for n = 10, the string is too sh

sage: D = DiGraph("IRAaDCI'OWEOKcPWAo")
...
RuntimeError: The string seems corrupt: valid characters are
?@ABCDEFGHIJKLMNOPQRSTUVWXYZ[\]^_`abcdefghijklmnopqrstuvwxyz{|}~
```

dig6_string()

Returns the dig6 representation of the digraph as an ASCII string. Valid for single (no multiple edges) digraphs on 0 to 262143 vertices.

EXAMPLE:

```
sage: D = DiGraph()
sage: D.dig6_string()
'?'
sage: D.add_edge(0,1)
sage: D.dig6_string()
'AO'
```

graphviz_string()

Returns a representation in the DOT language, ready to render in graphviz.

REFERENCES:

- http://www.graphviz.org/doc/info/lang.html

EXAMPLE:

```
sage: G = DiGraph({0:{1:None,2:None}, 1:{2:None}, 2:{3:'foo'}, 3:{}}, implementation='networ
sage: s = G.graphviz_string(); s
'digraph {\n"0";"1";"2";"3";\n"0"->"1";"0"->"2";"1"->"2";"2"->"3"[label="foo"];\n}'
```

in_degree(*vertices=None, labels=False*)

Same as degree, but for in degree.

EXAMPLES:

```
sage: D = DiGraph( { 0: [1,2,3], 1: [0,2], 2: [3], 3: [4], 4: [0,5], 5: [1] } )
sage: D.in_degree(vertices = [0,1,2], labels=True)
{0: 2, 1: 2, 2: 2}
sage: D.in_degree()
[2, 2, 2, 2, 1, 1]
sage: G = graphs.PetersenGraph().to_directed()
sage: G.in_degree(0)
3
```

in_degree_iterator(*vertices=None, labels=False*)

Same as degree_iterator, but for in degree.

EXAMPLES:

```
sage: D = graphs.Grid2dGraph(2,4).to_directed()
sage: for i in D.in_degree_iterator():
...     print i
3
3
2
3
2
2
2
3
sage: for i in D.in_degree_iterator(labels=True):
...     print i
((0, 1), 3)
((1, 2), 3)
((0, 0), 2)
((0, 2), 3)
((1, 3), 2)
((1, 0), 2)
((0, 3), 2)
((1, 1), 3)
```

incoming_edge_iterator(*vertices=None, labels=True*)

Return an iterator over all arriving edges from vertices, or over all edges if vertices is None.

EXAMPLE:

```
sage: D = DiGraph( { 0: [1,2,3], 1: [0,2], 2: [3], 3: [4], 4: [0,5], 5: [1] } )
sage: for a in D.incoming_edge_iterator([0]):
...     print a
(1, 0, None)
(4, 0, None)
```

incoming_edges(*vertices=None, labels=True*)

Returns a list of edges arriving at vertices.

INPUT:

- `labels` - if False, each edge is a tuple (u,v) of vertices.

EXAMPLE:

```
sage: D = DiGraph( { 0: [1,2,3], 1: [0,2], 2: [3], 3: [4], 4: [0,5], 5: [1] } )
sage: D.incoming_edges([0])
[(1, 0, None), (4, 0, None)]
```

is_directed()

Since digraph is directed, returns True.

EXAMPLE:

```
sage: DiGraph().is_directed()
True
```

is_directed_acyclic()

Returns whether the digraph is acyclic or not.

A directed graph is acyclic if for any vertex v, there is no directed path that starts and ends at v. Every directed acyclic graph (dag) corresponds to a partial ordering of its vertices, however multiple dags may lead to the same partial ordering.

EXAMPLES:

```
sage: D = DiGraph({ 0:[1,2,3], 4:[2,5], 1:[8], 2:[7], 3:[7], 5:[6,7], 7:[8], 6:[9], 8:[10],
sage: D.plot(layout='circular').show()
sage: D.is_directed_acyclic()
True

sage: D.add_edge(9,7)
sage: D.is_directed_acyclic()
True

sage: D.add_edge(7,4)
sage: D.is_directed_acyclic()
False
```

out_degree(*vertices=None, labels=False*)

Same as degree, but for out degree.

EXAMPLES:

```
sage: D = DiGraph( { 0: [1,2,3], 1: [0,2], 2: [3], 3: [4], 4: [0,5], 5: [1] } )
sage: D.out_degree(vertices = [0,1,2], labels=True)
{0: 3, 1: 2, 2: 1}
sage: D.out_degree()
[3, 2, 1, 1, 2, 1]
```

out_degree_iterator(*vertices=None, labels=False*)

Same as degree_iterator, but for out degree.

EXAMPLES:

```
sage: D = graphs.Grid2dGraph(2,4).to_directed()
sage: for i in D.out_degree_iterator():
...    print i
3
3
2
3
2
2
2
3
sage: for i in D.out_degree_iterator(labels=True):
...    print i
((0, 1), 3)
((1, 2), 3)
((0, 0), 2)
((0, 2), 3)
((1, 3), 2)
((1, 0), 2)
((0, 3), 2)
((1, 1), 3)
```

outgoing_edge_iterator(*vertices=None, labels=True*)

Return an iterator over all departing edges from vertices, or over all edges if vertices is None.

EXAMPLE:

```
sage: D = DiGraph( { 0: [1,2,3], 1: [0,2], 2: [3], 3: [4], 4: [0,5], 5: [1] } )
sage: for a in D.outgoing_edge_iterator([0]):
...    print a
(0, 1, None)
(0, 2, None)
(0, 3, None)
```

outgoing_edges(*vertices=None, labels=True*)

Returns a list of edges departing from vertices.

INPUT:

- `labels` - if False, each edge is a tuple (u,v) of vertices.

EXAMPLE:

```
sage: D = DiGraph( { 0: [1,2,3], 1: [0,2], 2: [3], 3: [4], 4: [0,5], 5: [1] } )
sage: D.outgoing_edges([0])
[(0, 1, None), (0, 2, None), (0, 3, None)]
```

predecessor_iterator(*vertex*)

Returns an iterator over predecessor vertices of vertex.

EXAMPLE:

```
sage: D = DiGraph( { 0: [1,2,3], 1: [0,2], 2: [3], 3: [4], 4: [0,5], 5: [1] } )
sage: for a in D.predecessor_iterator(0):
...    print a
1
4
```

predecessors(*vertex*)

Returns a list of predecessor vertices of vertex.

EXAMPLE:

```
sage: D = DiGraph( { 0: [1,2,3], 1: [0,2], 2: [3], 3: [4], 4: [0,5], 5: [1] } )
sage: D.predecessors(0)
[1, 4]
```

reverse()

Returns a copy of digraph with edges reversed in direction.

EXAMPLES:

```
sage: D = DiGraph({ 0: [1,2,3], 1: [0,2], 2: [3], 3: [4], 4: [0,5], 5: [1] })
sage: D.reverse()
Reverse of (): Digraph on 6 vertices
```

strongly_connected_components()

Returns a list of lists of vertices, each list representing a strongly connected component.

EXAMPLES:

```
sage: D = DiGraph( { 0 : [1, 3], 1 : [2], 2 : [3], 4 : [5, 6], 5 : [6] } )
sage: D.connected_components()
[[0, 1, 2, 3], [4, 5, 6]]
sage: D = DiGraph( { 0 : [1, 3], 1 : [2], 2 : [3], 4 : [5, 6], 5 : [6] } )
sage: D.strongly_connected_components()
[[3], [2], [1], [0], [6], [5], [4]]
sage: D.add_edge([2,0])
sage: D.strongly_connected_components()
[[0, 1, 2], [3], [6], [5], [4]]
```

successor_iterator(*vertex*)

Returns an iterator over successor vertices of vertex.

EXAMPLE:

```
sage: D = DiGraph( { 0: [1,2,3], 1: [0,2], 2: [3], 3: [4], 4: [0,5], 5: [1] } )
sage: for a in D.successor_iterator(0):
...    print a
1
2
3
```

successors(*vertex*)

Returns a list of successor vertices of vertex.

EXAMPLE:

```
sage: D = DiGraph( { 0: [1,2,3], 1: [0,2], 2: [3], 3: [4], 4: [0,5], 5: [1] } )
sage: D.successors(0)
[1, 2, 3]
```

to_directed()

Since the graph is already directed, simply returns a copy of itself.

EXAMPLE:

```
sage: DiGraph({0:[1,2,3],4:[5,1]}).to_directed()
Digraph on 6 vertices
```

to_undirected(*implementation='networkx'*)

Returns an undirected version of the graph. Every directed edge becomes an edge.

EXAMPLE:

```
sage: D = DiGraph({0:[1,2],1:[0]})
sage: G = D.to_undirected()
sage: D.edges(labels=False)
```

```
[(0, 1), (0, 2), (1, 0)]
sage: G.edges(labels=False)
[(0, 1), (0, 2)]
```

topological_sort()

Returns a topological sort of the digraph if it is acyclic, and raises a TypeError if the digraph contains a directed cycle.

A topological sort is an ordering of the vertices of the digraph such that each vertex comes before all of its successors. That is, if u comes before v in the sort, then there may be a directed path from u to v, but there will be no directed path from v to u.

EXAMPLES:

```
sage: D = DiGraph({ 0:[1,2,3], 4:[2,5], 1:[8], 2:[7], 3:[7], 5:[6,7], 7:[8], 6:[9], 8:[10],
sage: D.plot(layout='circular').show()
sage: D.topological_sort()
[4, 5, 6, 9, 0, 1, 2, 3, 7, 8, 10]

sage: D.add_edge(9,7)
sage: D.topological_sort()
[4, 5, 6, 9, 0, 1, 2, 3, 7, 8, 10]

sage: D.add_edge(7,4)
sage: D.topological_sort()
...
TypeError: Digraph is not acyclic-- there is no topological sort.
```

Note: There is a recursive version of this in NetworkX, but it has problems:

```
sage: import networkx
sage: D = DiGraph({ 0:[1,2,3], 4:[2,5], 1:[8], 2:[7], 3:[7], 5:[6,7], 7:[8], 6:[9], 8:[10],
sage: N = D.networkx_graph()
sage: networkx.topological_sort(N)
[4, 5, 6, 9, 0, 1, 2, 3, 7, 8, 10]
sage: networkx.topological_sort_recursive(N) is None
True
```

topological_sort_generator()

Returns a list of all topological sorts of the digraph if it is acyclic, and raises a TypeError if the digraph contains a directed cycle.

A topological sort is an ordering of the vertices of the digraph such that each vertex comes before all of its successors. That is, if u comes before v in the sort, then there may be a directed path from u to v, but there will be no directed path from v to u. See also Graph.topological_sort().

AUTHORS:

- Mike Hansen - original implementation
- Robert L. Miller: wrapping, documentation

EXAMPLES:

```
sage: D = DiGraph({ 0:[1,2], 1:[3], 2:[3,4] })
sage: D.plot(layout='circular').show()
sage: D.topological_sort_generator()
[[0, 1, 2, 3, 4], [0, 1, 2, 4, 3], [0, 2, 1, 3, 4], [0, 2, 1, 4, 3], [0, 2, 4, 1, 3]]
```

```
sage: for sort in D.topological_sort_generator():
...       for edge in D.edge_iterator():
...           u,v,l = edge
...           if sort.index(u) > sort.index(v):
...               print "This should never happen."
```

class GenericGraph()

Base class for graphs and digraphs.

add_cycle(*vertices*)

Adds a cycle to the graph with the given vertices. If the vertices are already present, only the edges are added.

For digraphs, adds the directed cycle, whose orientation is determined by the list. Adds edges (vertices[u], vertices[u+1]) and (vertices[-1], vertices[0]).

INPUT:

- `vertices` - a list of indices for the vertices of the cycle to be added.

EXAMPLES:

```
sage: G = Graph(implementation='networkx')
sage: G.add_vertices(range(10)); G
Graph on 10 vertices
sage: show(G)
sage: G.add_cycle(range(20)[10:20])
sage: show(G)
sage: G.add_cycle(range(10))
sage: show(G)

sage: D = DiGraph(implementation='networkx')
sage: D.add_cycle(range(4))
sage: D.edges()
[(0, 1, None), (1, 2, None), (2, 3, None), (3, 0, None)]
```

add_edge(*u, v=None, label=None*)

Adds an edge from u and v.

INPUT: The following forms are all accepted:

- G.add_edge(1, 2)
- G.add_edge((1, 2))
- G.add_edges([(1, 2)])
- G.add_edge(1, 2, 'label')
- G.add_edge((1, 2, 'label'))
- G.add_edges([(1, 2, 'label')])

WARNING: The following intuitive input results in nonintuitive output:

```
sage: G = Graph(implementation='networkx')
sage: G.add_edge((1,2), 'label')
sage: G.networkx_graph().adj           # random output order
{'label': {(1, 2): None}, (1, 2): {'label': None}}
```

Use one of these instead:

```
sage: G = Graph(implementation='networkx')
sage: G.add_edge((1,2), label="label")
sage: G.networkx_graph().adj           # random output order
{1: {2: 'label'}, 2: {1: 'label'}}
```

```
sage: G = Graph(implementation='networkx')
sage: G.add_edge(1,2,'label')
sage: G.networkx_graph().adj            # random output order
{1: {2: 'label'}, 2: {1: 'label'}}
```

add_edges(*edges*)

Add edges from an iterable container.

EXAMPLE:

```
sage: G = graphs.DodecahedralGraph()
sage: H = Graph(implementation='networkx')
sage: H.add_edges( G.edge_iterator() ); H
Graph on 20 vertices
sage: G = graphs.DodecahedralGraph().to_directed()
sage: H = DiGraph(implementation='networkx')
sage: H.add_edges( G.edge_iterator() ); H
Digraph on 20 vertices
```

add_path(*vertices*)

Adds a cycle to the graph with the given vertices. If the vertices are already present, only the edges are added.

For digraphs, adds the directed path vertices[0], ..., vertices[-1].

INPUT:

- `vertices` - a list of indices for the vertices of the cycle to be added.

EXAMPLES:

```
sage: G = Graph(implementation='networkx')
sage: G.add_vertices(range(10)); G
Graph on 10 vertices
sage: show(G)
sage: G.add_path(range(20)[10:20])
sage: show(G)
sage: G.add_path(range(10))
sage: show(G)

sage: D = DiGraph(sparse=True)
sage: D.add_path(range(4))
sage: D.edges()
[(0, 1, None), (1, 2, None), (2, 3, None)]
```

add_vertex(*name=None*)

Creates an isolated vertex. If the vertex already exists, then nothing is done.

INPUT:

- `n` - Name of the new vertex. If no name is specified, then the vertex will be represented by the least integer not already representing a vertex. Name must be an immutable object.

As it is implemented now, if a graph G has a large number of vertices with numeric labels, then G.add_vertex() could potentially be slow.

EXAMPLES:

```
sage: G = Graph(sparse=True); G.add_vertex(); G
Graph on 1 vertex

sage: D = DiGraph(sparse=True); D.add_vertex(); D
Digraph on 1 vertex
```

add_vertices(*vertices*)

Add vertices to the (di)graph from an iterable container of vertices. Vertices that already exist in the graph will not be added again.

EXAMPLES:

```
sage: d = {0: [1,4,5], 1: [2,6], 2: [3,7], 3: [4,8], 4: [9], 5: [7,8], 6: [8,9], 7: [9]}
sage: G = Graph(d, sparse=True)
sage: G.add_vertices([10,11,12])
sage: G.vertices()
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12]
sage: G.add_vertices(graphs.CycleGraph(25).vertices())
sage: G.vertices()
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24]
```

adjacency_matrix(*sparse=None, boundary_first=False*)

Returns the adjacency matrix of the (di)graph. Each vertex is represented by its position in the list returned by the vertices() function.

The matrix returned is over the integers. If a different ring is desired, use either the change_ring function or the matrix function.

INPUT:

- `sparse` - whether to represent with a sparse matrix
- `boundary_first` - whether to represent the boundary vertices in the upper left block

EXAMPLES:

```
sage: G = graphs.CubeGraph(4)
sage: G.adjacency_matrix()
[0 1 1 0 1 0 0 0 1 0 0 0 0 0 0 0]
[1 0 0 1 0 1 0 0 0 1 0 0 0 0 0 0]
[1 0 0 1 0 0 1 0 0 0 1 0 0 0 0 0]
[0 1 1 0 0 0 0 1 0 0 0 1 0 0 0 0]
[1 0 0 0 0 1 1 0 0 0 0 0 1 0 0 0]
[0 1 0 0 1 0 0 1 0 0 0 0 0 1 0 0]
[0 0 1 0 1 0 0 1 0 0 0 0 0 0 1 0]
[0 0 0 1 0 1 1 0 0 0 0 0 0 0 0 1]
[1 0 0 0 0 0 0 0 0 1 1 0 1 0 0 0]
[0 1 0 0 0 0 0 0 1 0 0 1 0 1 0 0]
[0 0 1 0 0 0 0 0 1 0 0 1 0 0 1 0]
[0 0 0 1 0 0 0 0 0 1 1 0 0 0 0 1]
[0 0 0 0 1 0 0 0 1 0 0 0 0 1 1 0]
[0 0 0 0 0 1 0 0 0 1 0 0 1 0 0 1]
[0 0 0 0 0 0 1 0 0 0 1 0 1 0 0 1]
[0 0 0 0 0 0 0 1 0 0 0 1 0 1 1 0]

sage: matrix(GF(2),G) # matrix over GF(2)
[0 1 1 0 1 0 0 0 1 0 0 0 0 0 0 0]
[1 0 0 1 0 1 0 0 0 1 0 0 0 0 0 0]
[1 0 0 1 0 0 1 0 0 0 1 0 0 0 0 0]
[0 1 1 0 0 0 0 1 0 0 0 1 0 0 0 0]
[1 0 0 0 0 1 1 0 0 0 0 0 1 0 0 0]
[0 1 0 0 1 0 0 1 0 0 0 0 0 1 0 0]
[0 0 1 0 1 0 0 1 0 0 0 0 0 0 1 0]
[0 0 0 1 0 1 1 0 0 0 0 0 0 0 0 1]
[1 0 0 0 0 0 0 0 0 1 1 0 1 0 0 0]
[0 1 0 0 0 0 0 0 1 0 0 1 0 1 0 0]
[0 0 1 0 0 0 0 0 1 0 0 1 0 0 1 0]
[0 0 0 1 0 0 0 0 0 1 1 0 0 0 0 1]
[0 0 0 0 1 0 0 0 1 0 0 0 0 1 1 0]
```

```
[0 0 0 0 0 1 0 0 0 1 0 0 1 0 0 1]
[0 0 0 0 0 0 1 0 0 0 1 0 1 0 0 1]
[0 0 0 0 0 0 0 1 0 0 0 1 0 1 1 0]

sage: D = DiGraph( { 0: [1,2,3], 1: [0,2], 2: [3], 3: [4], 4: [0,5], 5: [1] } )
sage: D.adjacency_matrix()
[0 1 1 1 0 0]
[1 0 1 0 0 0]
[0 0 0 1 0 0]
[0 0 0 0 1 0]
[1 0 0 0 0 1]
[0 1 0 0 0 0]
```

TESTS:

```
sage: graphs.CubeGraph(8).adjacency_matrix().parent()
Full MatrixSpace of 256 by 256 dense matrices over Integer Ring
sage: graphs.CubeGraph(9).adjacency_matrix().parent()
Full MatrixSpace of 512 by 512 sparse matrices over Integer Ring
```

all_paths (*start, end*)

Returns a list of all paths (also lists) between a pair of vertices (start, end) in the (di)graph.

EXAMPLES:

```
sage: eg1 = Graph({0:[1,2], 1:[4], 2:[3,4], 4:[5], 5:[6]})
sage: eg1.all_paths(0,6)
[[0, 1, 4, 5, 6], [0, 2, 4, 5, 6]]
sage: eg2 = graphs.PetersenGraph()
sage: sorted(eg2.all_paths(1,4))
[[1, 0, 4],
 [1, 0, 5, 7, 2, 3, 4],
 [1, 0, 5, 7, 2, 3, 8, 6, 9, 4],
 [1, 0, 5, 7, 9, 4],
 [1, 0, 5, 7, 9, 6, 8, 3, 4],
 [1, 0, 5, 8, 3, 2, 7, 9, 4],
 [1, 0, 5, 8, 3, 4],
 [1, 0, 5, 8, 6, 9, 4],
 [1, 0, 5, 8, 6, 9, 7, 2, 3, 4],
 [1, 2, 3, 4],
 [1, 2, 3, 8, 5, 0, 4],
 [1, 2, 3, 8, 5, 7, 9, 4],
 [1, 2, 3, 8, 6, 9, 4],
 [1, 2, 3, 8, 6, 9, 7, 5, 0, 4],
 [1, 2, 7, 5, 0, 4],
 [1, 2, 7, 5, 8, 3, 4],
 [1, 2, 7, 5, 8, 6, 9, 4],
 [1, 2, 7, 9, 4],
 [1, 2, 7, 9, 6, 8, 3, 4],
 [1, 2, 7, 9, 6, 8, 5, 0, 4],
 [1, 6, 8, 3, 2, 7, 5, 0, 4],
 [1, 6, 8, 3, 2, 7, 9, 4],
 [1, 6, 8, 3, 4],
 [1, 6, 8, 5, 0, 4],
 [1, 6, 8, 5, 7, 2, 3, 4],
 [1, 6, 8, 5, 7, 9, 4],
 [1, 6, 9, 4],
 [1, 6, 9, 7, 2, 3, 4],
 [1, 6, 9, 7, 2, 3, 8, 5, 0, 4],
 [1, 6, 9, 7, 5, 0, 4],
```

```
 [1, 6, 9, 7, 5, 8, 3, 4]]
sage: dg = DiGraph({0:[1,3], 1:[3], 2:[0,3]})
sage: sorted(dg.all_paths(0,3))
[[0, 1, 3], [0, 3]]
sage: ug = dg.to_undirected()
sage: sorted(ug.all_paths(0,3))
[[0, 1, 3], [0, 2, 3], [0, 3]]
```

allow_loops (*new*)

Changes whether loops are permitted in the (di)graph.

INPUT:

- `new` - boolean.

EXAMPLES:

```
sage: G = Graph(loops=True); G
Looped graph on 0 vertices
sage: G.has_loops()
False
sage: G.allows_loops()
True
sage: G.add_edge((0,0))
sage: G.has_loops()
True
sage: G.loops()
[(0, 0, None)]
sage: G.allow_loops(False); G
Graph on 1 vertex
sage: G.has_loops()
False
sage: G.edges()
[]

sage: D = DiGraph(loops=True); D
Looped digraph on 0 vertices
sage: D.has_loops()
False
sage: D.allows_loops()
True
sage: D.add_edge((0,0))
sage: D.has_loops()
True
sage: D.loops()
[(0, 0, None)]
sage: D.allow_loops(False); D
Digraph on 1 vertex
sage: D.has_loops()
False
sage: D.edges()
[]
```

allow_multiple_edges (*new*)

Changes whether multiple edges are permitted in the (di)graph.

INPUT:

- `new` - boolean.

EXAMPLES:

```
sage: G = Graph(multiedges=True); G
Multi-graph on 0 vertices
sage: G.has_multiple_edges()
False
sage: G.allows_multiple_edges()
True
sage: G.add_edges([(0,1)]*3)
sage: G.has_multiple_edges()
True
sage: G.multiple_edges()
[(0, 1, None), (0, 1, None), (0, 1, None)]
sage: G.allow_multiple_edges(False); G
Graph on 2 vertices
sage: G.has_multiple_edges()
False
sage: G.edges()
[(0, 1, None)]

sage: D = DiGraph(multiedges=True); D
Multi-digraph on 0 vertices
sage: D.has_multiple_edges()
False
sage: D.allows_multiple_edges()
True
sage: D.add_edges([(0,1)]*3)
sage: D.has_multiple_edges()
True
sage: D.multiple_edges()
[(0, 1, None), (0, 1, None), (0, 1, None)]
sage: D.allow_multiple_edges(False); D
Digraph on 2 vertices
sage: D.has_multiple_edges()
False
sage: D.edges()
[(0, 1, None)]
```

allows_loops()

Returns whether loops are permitted in the (di)graph.

EXAMPLES:

```
sage: G = Graph(loops=True); G
Looped graph on 0 vertices
sage: G.has_loops()
False
sage: G.allows_loops()
True
sage: G.add_edge((0,0))
sage: G.has_loops()
True
sage: G.loops()
[(0, 0, None)]
sage: G.allow_loops(False); G
Graph on 1 vertex
sage: G.has_loops()
False
sage: G.edges()
[]
```

```
sage: D = DiGraph(loops=True); D
Looped digraph on 0 vertices
sage: D.has_loops()
False
sage: D.allows_loops()
True
sage: D.add_edge((0,0))
sage: D.has_loops()
True
sage: D.loops()
[(0, 0, None)]
sage: D.allow_loops(False); D
Digraph on 1 vertex
sage: D.has_loops()
False
sage: D.edges()
[]
```

allows_multiple_edges()

Returns whether multiple edges are permitted in the (di)graph.

EXAMPLES:

```
sage: G = Graph(multiedges=True); G
Multi-graph on 0 vertices
sage: G.has_multiple_edges()
False
sage: G.allows_multiple_edges()
True
sage: G.add_edges([(0,1)]*3)
sage: G.has_multiple_edges()
True
sage: G.multiple_edges()
[(0, 1, None), (0, 1, None), (0, 1, None)]
sage: G.allow_multiple_edges(False); G
Graph on 2 vertices
sage: G.has_multiple_edges()
False
sage: G.edges()
[(0, 1, None)]

sage: D = DiGraph(multiedges=True); D
Multi-digraph on 0 vertices
sage: D.has_multiple_edges()
False
sage: D.allows_multiple_edges()
True
sage: D.add_edges([(0,1)]*3)
sage: D.has_multiple_edges()
True
sage: D.multiple_edges()
[(0, 1, None), (0, 1, None), (0, 1, None)]
sage: D.allow_multiple_edges(False); D
Digraph on 2 vertices
sage: D.has_multiple_edges()
False
sage: D.edges()
[(0, 1, None)]
```

am(*sparse=None, boundary_first=False*)

Returns the adjacency matrix of the (di)graph. Each vertex is represented by its position in the list returned by the vertices() function.

The matrix returned is over the integers. If a different ring is desired, use either the change_ring function or the matrix function.

INPUT:

- `sparse` - whether to represent with a sparse matrix
- `boundary_first` - whether to represent the boundary vertices in the upper left block

EXAMPLES:

```
sage: G = graphs.CubeGraph(4)
sage: G.adjacency_matrix()
[0 1 1 0 1 0 0 0 1 0 0 0 0 0 0 0]
[1 0 0 1 0 1 0 0 0 1 0 0 0 0 0 0]
[1 0 0 1 0 0 1 0 0 0 1 0 0 0 0 0]
[0 1 1 0 0 0 0 1 0 0 0 1 0 0 0 0]
[1 0 0 0 0 1 1 0 0 0 0 0 1 0 0 0]
[0 1 0 0 1 0 0 1 0 0 0 0 0 1 0 0]
[0 0 1 0 1 0 0 1 0 0 0 0 0 0 1 0]
[0 0 0 1 0 1 1 0 0 0 0 0 0 0 0 1]
[1 0 0 0 0 0 0 0 0 1 1 0 1 0 0 0]
[0 1 0 0 0 0 0 0 1 0 0 1 0 1 0 0]

sage: D = DiGraph( { 0: [1,2,3], 1: [0,2], 2: [3], 3: [4], 4: [0,5], 5: [1] } )
sage: D.adjacency_matrix()
[0 1 1 1 0 0]
[1 0 1 0 0 0]
[0 0 0 1 0 0]
[0 0 0 0 1 0]
[1 0 0 0 0 1]
[0 1 0 0 0 0]
```

TESTS:

```
sage: graphs.CubeGraph(8).adjacency_matrix().parent()
Full MatrixSpace of 256 by 256 dense matrices over Integer Ring
sage: graphs.CubeGraph(9).adjacency_matrix().parent()
Full MatrixSpace of 512 by 512 sparse matrices over Integer Ring
```

antisymmetric()

Returns True if the relation given by the graph is antisymmetric and False otherwise.

A graph represents an antisymmetric relation if there being a path from a vertex x to a vertex y implies that there is not a path from y to x unless x=y.

A directed acyclic graph is antisymmetric. An undirected graph is never antisymmetric unless it is just a union of isolated vertices.

```
sage: graphs.RandomGNP(20,0.5).antisymmetric()
False
sage: digraphs.RandomDirectedGNR(20,0.5).antisymmetric()
True
```

automorphism_group(*partition=None, translation=False, verbosity=0, edge_labels=False, order=False, return_group=True, orbits=False*)

Returns the largest subgroup of the automorphism group of the (di)graph whose orbit partition is finer than the partition given. If no partition is given, the unit partition is used and the entire automorphism group is given.

INPUT:

- `translation` - if True, then output includes a a dictionary translating from keys == vertices to entries == elements of 1,2,...,n (since permutation groups can currently only act on positive integers).
- `partition` - default is the unit partition, otherwise computes the subgroup of the full automorphism group respecting the partition.
- `edge_labels` - default False, otherwise allows only permutations respecting edge labels.
- `order` - (default False) if True, compute the order of the automorphism group
- `return_group` - default True
- `orbits` - returns the orbits of the group acting on the vertices of the graph

OUTPUT: The order of the output is group, translation, order, orbits. However, there are options to turn each of these on or off.

EXAMPLES: Graphs:

```
sage: graphs_query = GraphQuery(display_cols=['graph6'],num_vertices=4)
sage: L = graphs_query.get_graphs_list()
sage: graphs_list.show_graphs(L)
sage: for g in L:
...     G = g.automorphism_group()
...     G.order(), G.gens()
(24, [(2,3), (1,2), (1,4)])
(4, [(2,3), (1,4)])
(2, [(1,2)])
(8, [(1,2), (1,4)(2,3)])
(6, [(1,2), (1,4)])
(6, [(2,3), (1,2)])
(2, [(1,4)(2,3)])
(2, [(1,2)])
(8, [(2,3), (1,3)(2,4), (1,4)])
(4, [(2,3), (1,4)])
(24, [(2,3), (1,2), (1,4)])
sage: C = graphs.CubeGraph(4)
sage: G = C.automorphism_group()
sage: M = G.character_table()
```

```
sage: M.determinant()
-712483534798848
sage: G.order()
384

sage: D = graphs.DodecahedralGraph()
sage: G = D.automorphism_group()
sage: A5 = AlternatingGroup(5)
sage: Z2 = CyclicPermutationGroup(2)
sage: H = A5.direct_product(Z2)[0] #see documentation for direct_product to explain the [0]
sage: G.is_isomorphic(H)
True
```

Multigraphs:

```
sage: G = Graph(multiedges=True, implementation='networkx')
sage: G.add_edge(('a', 'b'))
sage: G.add_edge(('a', 'b'))
sage: G.add_edge(('a', 'b'))
sage: G.automorphism_group()
Permutation Group with generators [(1,2)]
```

Digraphs:

```
sage: D = DiGraph( { 0:[1], 1:[2], 2:[3], 3:[4], 4:[0] } )
sage: D.automorphism_group()
Permutation Group with generators [(1,2,3,4,5)]
```

Edge labeled graphs:

```
sage: G = Graph(implementation='networkx')
sage: G.add_edges( [(0,1,'a'),(1,2,'b'),(2,3,'c'),(3,4,'b'),(4,0,'a')] )
sage: G.automorphism_group(edge_labels=True)
Permutation Group with generators [(1,4)(2,3)]

sage: G = Graph({0 : {1 : 7}})
sage: G.automorphism_group(translation=True, edge_labels=True)
(Permutation Group with generators [(1,2)], {0: 2, 1: 1})

sage: foo = Graph()
sage: bar = Graph(implementation='c_graph')
sage: foo.add_edges([(0,1,1),(1,2,2), (2,3,3)])
sage: bar.add_edges([(0,1,1),(1,2,2), (2,3,3)])
sage: foo.automorphism_group(translation=True, edge_labels=True)
(Permutation Group with generators [()], {0: 4, 1: 1, 2: 2, 3: 3})
sage: foo.automorphism_group(translation=True)
(Permutation Group with generators [(1,2)(3,4)], {0: 4, 1: 1, 2: 2, 3: 3})
sage: bar.automorphism_group(translation=True, edge_labels=True)
(Permutation Group with generators [()], {0: 4, 1: 1, 2: 2, 3: 3})
sage: bar.automorphism_group(translation=True)
(Permutation Group with generators [(1,2)(3,4)], {0: 4, 1: 1, 2: 2, 3: 3})
```

You can also ask for just the order of the group:

```
sage: G = graphs.PetersenGraph()
sage: G.automorphism_group(return_group=False, order=True)
120
```

Or, just the orbits (recall the Petersen graph is transitive!)

```
sage: G = graphs.PetersenGraph()
sage: G.automorphism_group(return_group=False, orbits=True)
[[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]]
```

blocks_and_cut_vertices()

Computes the blocks and cut vertices of the graph. In the case of a digraph, this computation is done on the underlying graph.

A cut vertex is one whose deletion increases the number of connected components. A block is a maximal induced subgraph which itself has no cut vertices. Two distinct blocks cannot overlap in more than a single cut vertex.

OUTPUT: (B, C), where B is a list of blocks- each is a list of vertices and the blocks are the corresponding induced subgraphs- and C is a list of cut vertices.

EXAMPLES:

```
sage: graphs.PetersenGraph().blocks_and_cut_vertices()
([[0, 1, 2, 3, 8, 5, 7, 9, 4, 6]], [])
sage: graphs.PathGraph(6).blocks_and_cut_vertices()
([[5, 4], [4, 3], [3, 2], [2, 1], [0, 1]], [4, 3, 2, 1])
sage: graphs.CycleGraph(7).blocks_and_cut_vertices()
([[0, 1, 2, 3, 4, 5, 6]], [])
sage: graphs.KrackhardtKiteGraph().blocks_and_cut_vertices()
([[9, 8], [8, 7], [0, 1, 3, 2, 5, 6, 4, 7]], [8, 7])
```

ALGORITHM: 8.3.8 in [1]. Notice the typo - the stack must also be considered as one of the blocks at termination.

REFERENCE:

- [1] D. Jungnickel, Graphs, Networks and Algorithms, Springer, 2005.

breadth_first_search(*u, ignore_direction=False*)

Returns an iterator over vertices in a breadth-first ordering.

INPUT:

- `u` - vertex at which to start search
- `ignore_direction` - (default False) only applies to directed graphs. If True, searches across edges in either direction.

EXAMPLES:

```
sage: G = Graph( { 0: {1: 1}, 1: {2: 1}, 2: {3: 1}, 3: {4: 2}, 4: {0: 2} } )
sage: list(G.breadth_first_search(0))
[0, 1, 4, 2, 3]
sage: list(G.depth_first_search(0))
[0, 4, 3, 2, 1]

sage: D = DiGraph( { 0: {1: 1}, 1: {2: 1}, 2: {3: 1}, 3: {4: 2}, 4: {0: 2} } )
sage: list(D.breadth_first_search(0))
[0, 1, 2, 3, 4]
sage: list(D.depth_first_search(0))
[0, 1, 2, 3, 4]

sage: D = DiGraph({1:[0], 2:[0]})
sage: list(D.breadth_first_search(0))
[0]
sage: list(D.breadth_first_search(0, ignore_direction=True))
[0, 1, 2]
```

canonical_label(*partition=None, certify=False, verbosity=0, edge_labels=False*)

Returns the canonical label with respect to the partition. If no partition is given, uses the unit partition.

INPUT:

- `partition` - if given, the canonical label with respect to this partition will be computed. The default is the unit partition.
- `certify` - if True, a dictionary mapping from the (di)graph to its canonical label will be given.
- `verbosity` - gets passed to nice: prints helpful output.
- `edge_labels` - default False, otherwise allows only permutations respecting edge labels.

EXAMPLE:

```
sage: D = graphs.DodecahedralGraph()
sage: E = D.canonical_label(); E
Dodecahedron: Graph on 20 vertices
sage: D.canonical_label(certify=True)
(Dodecahedron: Graph on 20 vertices, {0: 0, 1: 19, 2: 16, 3: 15, 4: 9, 5: 1, 6: 10, 7: 8, 8:
sage: D.is_isomorphic(E)
True
```

Multigraphs:

```
sage: G = Graph(multiedges=True)
sage: G.add_edge((0,1))
sage: G.add_edge((0,1))
sage: G.add_edge((0,1))
sage: G.canonical_label()
Multi-graph on 2 vertices
```

Digraphs:

```
sage: P = graphs.PetersenGraph()
sage: DP = P.to_directed()
sage: DP.canonical_label().adjacency_matrix()
[0 0 0 0 0 0 0 1 1 1]
[0 0 0 0 1 0 1 0 0 1]
[0 0 0 1 0 0 1 0 1 0]
[0 0 1 0 0 1 0 0 0 1]
[0 1 0 0 0 1 0 0 1 0]
[0 0 0 1 1 0 0 1 0 0]
[0 1 1 0 0 0 0 1 0 0]
[1 0 0 0 0 1 1 0 0 0]
[1 0 1 0 1 0 0 0 0 0]
[1 1 0 1 0 0 0 0 0 0]
```

Edge labeled graphs:

```
sage: G = Graph(implementation='networkx')
sage: G.add_edges( [(0,1,'a'),(1,2,'b'),(2,3,'c'),(3,4,'b'),(4,0,'a')] )
sage: G.canonical_label(edge_labels=True)
Graph on 5 vertices
```

cartesian_product(*other*)

Returns the Cartesian product of self and other.

The Cartesian product of G and H is the graph L with vertex set V(L) equal to the Cartesian product of the vertices V(G) and V(H), and ((u,v), (w,x)) is an edge iff either - (u, w) is an edge of self and v = x, or - (v, x) is an edge of other and u = w.

EXAMPLES:

```
sage: Z = graphs.CompleteGraph(2)
sage: C = graphs.CycleGraph(5)
sage: P = C.cartesian_product(Z); P
Graph on 10 vertices
sage: P.plot().show()
```

```
sage: D = graphs.DodecahedralGraph()
sage: P = graphs.PetersenGraph()
sage: C = D.cartesian_product(P); C
Graph on 200 vertices
sage: C.plot().show()
```

categorical_product(*other*)

Returns the tensor product, also called the categorical product, of self and other.

The tensor product of G and H is the graph L with vertex set V(L) equal to the Cartesian product of the vertices V(G) and V(H), and ((u,v), (w,x)) is an edge iff - (u, w) is an edge of self, and - (v, x) is an edge of other.

EXAMPLES:

```
sage: Z = graphs.CompleteGraph(2)
sage: C = graphs.CycleGraph(5)
sage: T = C.tensor_product(Z); T
Graph on 10 vertices
sage: T.plot().show()

sage: D = graphs.DodecahedralGraph()
sage: P = graphs.PetersenGraph()
sage: T = D.tensor_product(P); T
Graph on 200 vertices
sage: T.plot().show()
```

center()

Returns the set of vertices in the center, i.e. whose eccentricity is equal to the radius of the (di)graph.

In other words, the center is the set of vertices achieving the minimum eccentricity.

EXAMPLES:

```
sage: G = graphs.DiamondGraph()
sage: G.center()
[1, 2]
sage: P = graphs.PetersenGraph()
sage: P.subgraph(P.center()) == P
True
sage: S = graphs.StarGraph(19)
sage: S.center()
[0]
sage: G = Graph(sparse=True)
sage: G.center()
[]
sage: G.add_vertex()
sage: G.center()
[0]
```

characteristic_polynomial(*var='x', laplacian=False*)

Returns the characteristic polynomial of the adjacency matrix of the (di)graph.

INPUT:

- `laplacian` - if True, use the Laplacian matrix instead (see self.kirchhoff_matrix())

EXAMPLE:

```
sage: P = graphs.PetersenGraph()
sage: P.characteristic_polynomial()
x^10 - 15*x^8 + 75*x^6 - 24*x^5 - 165*x^4 + 120*x^3 + 120*x^2 - 160*x + 48
sage: P.characteristic_polynomial(laplacian=True)
x^10 - 30*x^9 + 390*x^8 - 2880*x^7 + 13305*x^6 - 39882*x^5 + 77640*x^4 - 94800*x^3 + 66000*x
```

check_embedding_validity(*embedding=None*)

Checks whether an _embedding attribute is defined on self and if so, checks for accuracy. Returns True if everything is okay, False otherwise.

If embedding=None will test the attribute _embedding.

EXAMPLES:

```
sage: d = {0: [1, 5, 4], 1: [0, 2, 6], 2: [1, 3, 7], 3: [8, 2, 4], 4: [0, 9, 3], 5: [0, 8, 7
sage: G = graphs.PetersenGraph()
sage: G.check_embedding_validity(d)
True
```

clear()

Empties the graph of vertices and edges and removes name, boundary, associated objects, and position information.

EXAMPLE:

```
sage: G=graphs.CycleGraph(4); G.set_vertices({0:'vertex0'})
sage: G.order(); G.size()
4
4
sage: len(G._pos)
4
sage: G.name()
'Cycle graph'
sage: G.get_vertex(0)
'vertex0'
sage: H = G.copy(implementation='c_graph', sparse=True)
sage: H.clear()
sage: H.order(); H.size()
0
0
sage: len(H._pos)
0
sage: H.name()
''
sage: H.get_vertex(0)
sage: H = G.copy(implementation='networkx')
sage: H.clear()
sage: H.order(); H.size()
0
0
sage: len(H._pos)
0
sage: H.name()
''
sage: H.get_vertex(0)
```

cluster_transitivity()

Returns the transitivity (fraction of transitive triangles) of the graph.

The clustering coefficient of a graph is the fraction of possible triangles that are triangles, c_i = triangles_i / (k_i*(k_i-1)/2) where k_i is the degree of vertex i, [1]. A coefficient for the whole graph is the average of the c_i. Transitivity is the fraction of all possible triangles which are triangles, T = 3*triangles/triads, [1].

REFERENCE:

- [1] Aric Hagberg, Dan Schult and Pieter Swart. NetworkX documentation. [Online] Available: https://networkx.lanl.gov/reference/networkx/

EXAMPLES:

```
sage: (graphs.FruchtGraph()).cluster_transitivity()
0.25
```

cluster_triangles(*nbunch=None, with_labels=False*)

Returns the number of triangles for nbunch of vertices as an ordered list.

The clustering coefficient of a graph is the fraction of possible triangles that are triangles, c_i = triangles_i / (k_i*(k_i-1)/2) where k_i is the degree of vertex i, [1]. A coefficient for the whole graph is the average of the c_i. Transitivity is the fraction of all possible triangles which are triangles, T = 3*triangles/triads, [1].

INPUT:

- `nbunch` - The vertices to inspect. If nbunch=None, returns data for all vertices in the graph
- `with_labels` - (boolean) default False returns list as above True returns dict keyed by vertex labels.

REFERENCE:

- [1] Aric Hagberg, Dan Schult and Pieter Swart. NetworkX documentation. [Online] Available: https://networkx.lanl.gov/reference/networkx/

EXAMPLES:

```
sage: (graphs.FruchtGraph()).cluster_triangles()
[1, 1, 0, 1, 1, 1, 1, 1, 0, 1, 1, 0]
sage: (graphs.FruchtGraph()).cluster_triangles(with_labels=True)
{0: 1, 1: 1, 2: 0, 3: 1, 4: 1, 5: 1, 6: 1, 7: 1, 8: 0, 9: 1, 10: 1, 11: 0}
sage: (graphs.FruchtGraph()).cluster_triangles(nbunch=[0,1,2])
[1, 1, 0]
```

clustering_average()

Returns the average clustering coefficient.

The clustering coefficient of a graph is the fraction of possible triangles that are triangles, c_i = triangles_i / (k_i*(k_i-1)/2) where k_i is the degree of vertex i, [1]. A coefficient for the whole graph is the average of the c_i. Transitivity is the fraction of all possible triangles which are triangles, T = 3*triangles/triads, [1].

REFERENCE:

- [1] Aric Hagberg, Dan Schult and Pieter Swart. NetworkX documentation. [Online] Available: https://networkx.lanl.gov/reference/networkx/

EXAMPLES:

```
sage: (graphs.FruchtGraph()).clustering_average()
0.25
```

clustering_coeff(*nbunch=None, with_labels=False, weights=False*)

Returns the clustering coefficient for each vertex in nbunch as an ordered list.

The clustering coefficient of a graph is the fraction of possible triangles that are triangles, c_i = triangles_i / (k_i*(k_i-1)/2) where k_i is the degree of vertex i, [1]. A coefficient for the whole graph is the average of the c_i. Transitivity is the fraction of all possible triangles which are triangles, T = 3*triangles/triads, [1].

INPUT:

- `nbunch` - the vertices to inspect (default None returns data on all vertices in graph)
- `with_labels` - (boolean) default False returns list as above True returns dict keyed by vertex labels.
- `weights` - default is False. If both with_labels and weights are True, then returns a clustering coefficient dict and a dict of weights based on degree. Weights are the fraction of connected triples in the graph that include the keyed vertex.

REFERENCE:

- [1] Aric Hagberg, Dan Schult and Pieter Swart. NetworkX documentation. [Online] Available: https://networkx.lanl.gov/reference/networkx/

EXAMPLES:

```
sage: (graphs.FruchtGraph()).clustering_coeff()
[0.3333333333333331, 0.3333333333333331, 0.0, 0.3333333333333331, 0.3333333333333331, 0.
sage: (graphs.FruchtGraph()).clustering_coeff(with_labels=True)
{0: 0.3333333333333331, 1: 0.3333333333333331, 2: 0.0, 3: 0.3333333333333331, 4: 0.333333
sage: (graphs.FruchtGraph()).clustering_coeff(with_labels=True,weights=True)
({0: 0.3333333333333331, 1: 0.3333333333333331, 2: 0.0, 3: 0.3333333333333331, 4: 0.33333
sage: (graphs.FruchtGraph()).clustering_coeff(nbunch=[0,1,2])
[0.3333333333333331, 0.3333333333333331, 0.0]
sage: (graphs.FruchtGraph()).clustering_coeff(nbunch=[0,1,2],with_labels=True,weights=True)
({0: 0.3333333333333331, 1: 0.3333333333333331, 2: 0.0}, {0: 0.083333333333333329, 1: 0.08
```

coarsest_equitable_refinement(*partition, sparse=False*)

Returns the coarsest partition which is finer than the input partition, and equitable with respect to self.

A partition is equitable with respect to a graph if for every pair of cells C1, C2 of the partition, the number of edges from a vertex of C1 to C2 is the same, over all vertices in C1.

A partition P1 is finer than P2 (P2 is coarser than P1) if every cell of P1 is a subset of a cell of P2.

INPUT:

- `partition` - a list of lists
- `sparse` - (default False) whether to use sparse or dense representation- for small graphs, use dense for speed

EXAMPLES:

```
sage: G = graphs.PetersenGraph()
sage: G.coarsest_equitable_refinement([[0],range(1,10)])
[[0], [2, 3, 6, 7, 8, 9], [1, 4, 5]]
sage: G = graphs.CubeGraph(3)
sage: verts = G.vertices()
sage: Pi = [verts[:1], verts[1:]]
sage: Pi
[['000'], ['001', '010', '011', '100', '101', '110', '111']]
sage: G.coarsest_equitable_refinement(Pi)
[['000'], ['011', '101', '110'], ['111'], ['001', '010', '100']]
```

Note that given an equitable partition, this function returns that partition:

```
sage: P = graphs.PetersenGraph()
sage: prt = [[0], [1, 4, 5], [2, 3, 6, 7, 8, 9]]
sage: P.coarsest_equitable_refinement(prt)
[[0], [1, 4, 5], [2, 3, 6, 7, 8, 9]]

sage: ss = (graphs.WheelGraph(6)).line_graph(labels=False)
sage: prt = [[(0, 1)], [(0, 2), (0, 3), (0, 4), (1, 2), (1, 4)], [(2, 3), (3, 4)]]
sage: ss.coarsest_equitable_refinement(prt)
...
TypeError: Partition ([[(0, 1)], [(0, 2), (0, 3), (0, 4), (1, 2), (1, 4)], [(2, 3), (3, 4)]]

sage: ss = (graphs.WheelGraph(5)).line_graph(labels=False)
sage: ss.coarsest_equitable_refinement(prt)
[[(0, 1)], [(1, 2), (1, 4)], [(0, 3)], [(0, 2), (0, 4)], [(2, 3), (3, 4)]]
```

ALGORITHM: Brendan D. McKay's Master's Thesis, University of Melbourne, 1976.

complement()

Returns the complement of the (di)graph.

The complement of a graph has the same vertices, but exactly those edges that are not in the original graph. This is not well defined for graphs with multiple edges.

EXAMPLE:

```
sage: P = graphs.PetersenGraph()
sage: P.plot().show()
sage: PC = P.complement()
sage: PC.plot().show()

sage: graphs.TetrahedralGraph().complement().size()
0
sage: graphs.CycleGraph(4).complement().edges()
[(0, 2, None), (1, 3, None)]
sage: graphs.CycleGraph(4).complement()
complement(Cycle graph): Graph on 4 vertices
sage: G = Graph(multiedges=True)
sage: G.add_edges([(0,1)]*3)
sage: G.complement()
...
TypeError: Complement not well defined for (di)graphs with multiple edges.
```

connected_component_containing_vertex(*vertex*)

Returns a list of the vertices connected to vertex.

EXAMPLE:

```
sage: G = Graph( { 0 : [1, 3], 1 : [2], 2 : [3], 4 : [5, 6], 5 : [6] } )
sage: G.connected_component_containing_vertex(0)
[0, 1, 2, 3]
sage: D = DiGraph( { 0 : [1, 3], 1 : [2], 2 : [3], 4 : [5, 6], 5 : [6] } )
sage: D.connected_component_containing_vertex(0)
[0, 1, 2, 3]
```

connected_components()

Returns a list of lists of vertices, each list representing a connected component. The list is ordered from largest to smallest component.

EXAMPLE:

```
sage: G = Graph( { 0 : [1, 3], 1 : [2], 2 : [3], 4 : [5, 6], 5 : [6] } )
sage: G.connected_components()
[[0, 1, 2, 3], [4, 5, 6]]
sage: D = DiGraph( { 0 : [1, 3], 1 : [2], 2 : [3], 4 : [5, 6], 5 : [6] } )
sage: D.connected_components()
[[0, 1, 2, 3], [4, 5, 6]]
```

connected_components_number()

Returns the number of connected components.

EXAMPLE:

```
sage: G = Graph( { 0 : [1, 3], 1 : [2], 2 : [3], 4 : [5, 6], 5 : [6] } )
sage: G.connected_components_number()
2
sage: D = DiGraph( { 0 : [1, 3], 1 : [2], 2 : [3], 4 : [5, 6], 5 : [6] } )
sage: D.connected_components_number()
2
```

connected_components_subgraphs()

Returns a list of connected components as graph objects.

EXAMPLE:

```
sage: G = Graph( { 0 : [1, 3], 1 : [2], 2 : [3], 4 : [5, 6], 5 : [6] } )
sage: L = G.connected_components_subgraphs()
sage: graphs_list.show_graphs(L)
sage: D = DiGraph( { 0 : [1, 3], 1 : [2], 2 : [3], 4 : [5, 6], 5 : [6] } )
```

```
sage: L = D.connected_components_subgraphs()
sage: graphs_list.show_graphs(L)
```

copy(*implementation='networkx', sparse=True*)

Creates a copy of the graph.

EXAMPLES:

```
sage: g=Graph({0:[0,1,1,2]},loops=True,multiedges=True,implementation='networkx')
sage: g==g.copy()
True
sage: g=DiGraph({0:[0,1,1,2],1:[0,1]},loops=True,multiedges=True,implementation='networkx')
sage: g==g.copy()
True
```

Note that vertex associations are also kept:

```
sage: d = {0 : graphs.DodecahedralGraph(), 1 : graphs.FlowerSnark(), 2 : graphs.MoebiusKanto
sage: T = graphs.TetrahedralGraph()
sage: T.set_vertices(d)
sage: T2 = T.copy()
sage: T2.get_vertex(0)
Dodecahedron: Graph on 20 vertices
```

Notice that the copy is at least as deep as the objects:

```
sage: T2.get_vertex(0) is T.get_vertex(0)
False
```

TESTS: We make copies of the _pos and _boundary attributes.

```
sage: g = graphs.PathGraph(3)
sage: h = g.copy()
sage: h._pos is g._pos
False
sage: h._boundary is g._boundary
False
```

cores(*with_labels=False*)

Returns the core number for each vertex in an ordered list.

'K-cores in graph theory were introduced by Seidman in 1983 and by Bollobas in 1984 as a method of (destructively) simplifying graph topology to aid in analysis and visualization. They have been more recently defined as the following by Batagelj et al: given a graph G with vertices set V and edges set E, the k-core is computed by pruning all the vertices (with their respective edges) with degree less than k. That means that if a vertex u has degree d_u, and it has n neighbors with degree less than k, then the degree of u becomes d_u - n, and it will be also pruned if k d_u - n. This operation can be useful to filter or to study some properties of the graphs. For instance, when you compute the 2-core of graph G, you are cutting all the vertices which are in a tree part of graph. (A tree is a graph with no loops),' [1].

INPUT:

- `with_labels` - default False returns list as described above. True returns dict keyed by vertex labels.

REFERENCE:

- [1] K-core. Wikipedia. (2007). [Online] Available: http://en.wikipedia.org/wiki/K-core
- [2] Boris Pittel, Joel Spencer and Nicholas Wormald. Sudden Emergence of a Giant k-Core in a Random Graph. (1996). J. Combinatorial Theory. Ser B 67. pages 111-151. [Online] Available: http://cs.nyu.edu/cs/faculty/spencer/papers/k-core.pdf

EXAMPLES:

```
sage: (graphs.FruchtGraph()).cores()
[3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3]
sage: (graphs.FruchtGraph()).cores(with_labels=True)
{0: 3, 1: 3, 2: 3, 3: 3, 4: 3, 5: 3, 6: 3, 7: 3, 8: 3, 9: 3, 10: 3, 11: 3}
```

degree(*vertices=None, labels=False*)

Gives the degree (in + out for digraphs) of a vertex or of vertices.

INPUT:

- `vertices` - If vertices is a single vertex, returns the number of neighbors of vertex. If vertices is an iterable container of vertices, returns a list of degrees. If vertices is None, same as listing all vertices.
- `labels` - see OUTPUT

OUTPUT: Single vertex- an integer. Multiple vertices- a list of integers. If labels is True, then returns a dictionary mapping each vertex to its degree.

EXAMPLES:

```
sage: P = graphs.PetersenGraph()
sage: P.degree(5)
3

sage: K = graphs.CompleteGraph(9)
sage: K.degree()
[8, 8, 8, 8, 8, 8, 8, 8, 8]

sage: D = DiGraph( { 0: [1,2,3], 1: [0,2], 2: [3], 3: [4], 4: [0,5], 5: [1] } )
sage: D.degree(vertices = [0,1,2], labels=True)
{0: 5, 1: 4, 2: 3}
sage: D.degree()
[5, 4, 3, 3, 3, 2]
```

degree_histogram()

Returns a list, whose ith entry is the frequency of degree i.

EXAMPLE:

```
sage: G = graphs.Grid2dGraph(9,12)
sage: G.degree_histogram()
[0, 0, 4, 34, 70]

sage: G = graphs.Grid2dGraph(9,12).to_directed()
sage: G.degree_histogram()
[0, 0, 0, 0, 4, 0, 34, 0, 70]
```

degree_iterator(*vertices=None, labels=False*)

Returns an iterator over the degrees of the (di)graph. In the case of a digraph, the degree is defined as the sum of the in-degree and the out-degree, i.e. the total number of edges incident to a given vertex.

INPUT: labels=False: returns an iterator over degrees. labels=True: returns an iterator over tuples (vertex, degree).

- `vertices` - if specified, restrict to this subset.

EXAMPLES:

```
sage: G = graphs.Grid2dGraph(3,4)
sage: for i in G.degree_iterator():
...     print i
3
4
2
...
```

```
2
3
sage: for i in G.degree_iterator(labels=True):
...     print i
((0, 1), 3)
((1, 2), 4)
((0, 0), 2)
...
((0, 3), 2)
((0, 2), 3)

sage: D = graphs.Grid2dGraph(2,4).to_directed()
sage: for i in D.degree_iterator():
...     print i
6
6
...
4
6
sage: for i in D.degree_iterator(labels=True):
...     print i
((0, 1), 6)
((1, 2), 6)
...
((0, 3), 4)
((1, 1), 6)
```

degree_to_cell(*vertex, cell*)

Returns the number of edges from vertex to an edge in cell. In the case of a digraph, returns a tuple (in_degree, out_degree).

EXAMPLES:

```
sage: G = graphs.CubeGraph(3)
sage: cell = G.vertices()[:3]
sage: G.degree_to_cell('011', cell)
2
sage: G.degree_to_cell('111', cell)
0

sage: D = DiGraph({ 0:[1,2,3], 1:[3,4], 3:[4,5]})
sage: cell = [0,1,2]
sage: D.degree_to_cell(5, cell)
(0, 0)
sage: D.degree_to_cell(3, cell)
(2, 0)
sage: D.degree_to_cell(0, cell)
(0, 2)
```

delete_edge(*u, v=None, label=None*)

Delete the edge from u to v, returning silently if vertices or edge does not exist.

INPUT: The following forms are all accepted:

- G.delete_edge(1, 2)
- G.delete_edge((1, 2))
- G.delete_edges([(1, 2)])
- G.delete_edge(1, 2, 'label')
- G.delete_edge((1, 2, 'label'))
- G.delete_edges([(1, 2, 'label')])

EXAMPLES:

```
sage: G = graphs.CompleteGraph(19)
sage: G.size()
171
sage: G.delete_edge( 1, 2 )
sage: G.delete_edge( (3, 4) )
sage: G.delete_edges( [ (5, 6), (7, 8) ] )
sage: G.delete_edge( 9, 10, 'label' )
sage: G.delete_edge( (11, 12, 'label') )
sage: G.delete_edges( [ (13, 14, 'label') ] )
sage: G.size()
164
sage: G.has_edge( (11, 12) )
False
```

Note that even though the edge (11, 12) has no label, it still gets deleted: NetworkX does not pay attention to labels here.

```
sage: D = graphs.CompleteGraph(19).to_directed()
sage: D.size()
342
sage: D.delete_edge( 1, 2 )
sage: D.delete_edge( (3, 4) )
sage: D.delete_edges( [ (5, 6), (7, 8) ] )
sage: D.delete_edge( 9, 10, 'label' )
sage: D.delete_edge( (11, 12, 'label') )
sage: D.delete_edges( [ (13, 14, 'label') ] )
sage: D.size()
335
sage: D.has_edge( (11, 12) )
False
```

delete_edges(*edges*)

Delete edges from an iterable container.

EXAMPLE:

```
sage: K12 = graphs.CompleteGraph(12)
sage: K4 = graphs.CompleteGraph(4)
sage: K12.size()
66
sage: K12.delete_edges(K4.edge_iterator())
sage: K12.size()
60

sage: K12 = graphs.CompleteGraph(12).to_directed()
sage: K4 = graphs.CompleteGraph(4).to_directed()
sage: K12.size()
132
sage: K12.delete_edges(K4.edge_iterator())
sage: K12.size()
120
```

delete_multiedge(*u*, *v*)

Deletes all edges from u and v.

EXAMPLE:

```
sage: G = Graph(multiedges=True, implementation='networkx')
sage: G.add_edges([(0,1), (0,1), (0,1), (1,2), (2,3)])
sage: G.edges()
```

```
[(0, 1, None), (0, 1, None), (0, 1, None), (1, 2, None), (2, 3, None)]
sage: G.delete_multiedge( 0, 1 )
sage: G.edges()
[(1, 2, None), (2, 3, None)]

sage: D = DiGraph(multiedges=True)
sage: D.add_edges([(0,1,1), (0,1,2), (0,1,3), (1,0), (1,2), (2,3)])
sage: D.edges()
[(0, 1, 1), (0, 1, 2), (0, 1, 3), (1, 0, None), (1, 2, None), (2, 3, None)]
sage: D.delete_multiedge( 0, 1 )
sage: D.edges()
[(1, 0, None), (1, 2, None), (2, 3, None)]
```

delete_vertex(*vertex, in_order=False*)

Deletes vertex, removing all incident edges. Deleting a non-existant vertex will raise an exception.

INPUT:

- `in_order` - (default False) If True, this deletes the ith vertex in the sorted list of vertices, i.e. G.vertices()[i]

EXAMPLES:

```
sage: G = Graph(graphs.WheelGraph(9), sparse=True)
sage: G.delete_vertex(0); G.show()

sage: D = DiGraph({0:[1,2,3,4,5],1:[2],2:[3],3:[4],4:[5],5:[1]}, implementation='networkx')
sage: D.delete_vertex(0); D
Digraph on 5 vertices
sage: D.vertices()
[1, 2, 3, 4, 5]
sage: D.delete_vertex(0)
...
NetworkXError: node 0 not in graph

sage: G = graphs.CompleteGraph(4).line_graph(labels=False)
sage: G.vertices()
[(0, 1), (0, 2), (0, 3), (1, 2), (1, 3), (2, 3)]
sage: G.delete_vertex(0, in_order=True)
sage: G.vertices()
[(0, 2), (0, 3), (1, 2), (1, 3), (2, 3)]
sage: G = graphs.PathGraph(5)
sage: G.set_vertices({0: 'no delete', 1: 'delete'})
sage: G.set_boundary([1,2])
sage: G.delete_vertex(1)
sage: G.get_vertices()
{0: 'no delete', 2: None, 3: None, 4: None}
sage: G.get_boundary()
[2]
sage: G.get_pos()
{0: [0, 0], 2: [2, 0], 3: [3, 0], 4: [4, 0]}
```

delete_vertices(*vertices*)

Remove vertices from the (di)graph taken from an iterable container of vertices. Deleting a non-existant vertex will raise an exception.

EXAMPLE:

```
sage: D = DiGraph({0:[1,2,3,4,5],1:[2],2:[3],3:[4],4:[5],5:[1]}, implementation='networkx')
sage: D.delete_vertices([1,2,3,4,5]); D
Digraph on 1 vertex
```

```
sage: D.vertices()
[0]
sage: D.delete_vertices([1])
...
NetworkXError: node 1 not in graph
```

density()

Returns the density (number of edges divided by number of possible edges).

In the case of a multigraph, raises an error, since there is an infinite number of possible edges.

EXAMPLE:

```
sage: d = {0: [1,4,5], 1: [2,6], 2: [3,7], 3: [4,8], 4: [9], 5: [7, 8], 6: [8,9], 7: [9]}
sage: G = Graph(d); G.density()
1/3
sage: G = Graph({0:[1,2], 1:[0] }); G.density()
2/3
sage: G = DiGraph({0:[1,2], 1:[0] }); G.density()
1/2
```

Note that there are more possible edges on a looped graph:

```
sage: G.allow_loops(True)
sage: G.density()
1/3
```

depth_first_search(*u, ignore_direction=False*)

Returns an iterator over vertices in a depth-first ordering.

INPUT:

- u - vertex at which to start search
- ignore_direction - (default False) only applies to directed graphs. If True, searches across edges in either direction.

EXAMPLES:

```
sage: G = Graph( { 0: {1: 1}, 1: {2: 1}, 2: {3: 1}, 3: {4: 2}, 4: {0: 2} } )
sage: list(G.breadth_first_search(0))
[0, 1, 4, 2, 3]
sage: list(G.depth_first_search(0))
[0, 4, 3, 2, 1]

sage: D = DiGraph( { 0: {1: 1}, 1: {2: 1}, 2: {3: 1}, 3: {4: 2}, 4: {0: 2} } )
sage: list(D.breadth_first_search(0))
[0, 1, 2, 3, 4]
sage: list(D.depth_first_search(0))
[0, 1, 2, 3, 4]

sage: D = DiGraph({1:[0], 2:[0]})
sage: list(D.depth_first_search(0))
[0]
sage: list(D.depth_first_search(0, ignore_direction=True))
[0, 2, 1]
```

diameter()

Returns the largest distance between any two vertices. Returns Infinity if the (di)graph is not connected.

EXAMPLES:

```
sage: G = graphs.PetersenGraph()
sage: G.diameter()
2
```

```
sage: G = Graph( { 0 : [], 1 : [], 2 : [1] } )
sage: G.diameter()
+Infinity
```

Although max( ) is usually defined as -Infinity, since the diameter will never be negative, we define it to be zero:

```
sage: G = graphs.EmptyGraph()
sage: G.diameter()
0
```

disjoint_union(*other, verbose_relabel=True*)

Returns the disjoint union of self and other.

If the graphs have common vertices, the vertices will be renamed to form disjoint sets.

INPUT:

- `verbose_relabel` - (defaults to True) If True and the graphs have common vertices, then each vertex v in the first graph will be changed to '0,v' and each vertex u in the second graph will be changed to '1,u'. If False, the vertices of the first graph and the second graph will be relabeled with consecutive integers.

EXAMPLE:

```
sage: G = graphs.CycleGraph(3)
sage: H = graphs.CycleGraph(4)
sage: J = G.disjoint_union(H); J
Cycle graph disjoint_union Cycle graph: Graph on 7 vertices
sage: J.vertices()
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (1, 3)]
sage: J = G.disjoint_union(H, verbose_relabel=False); J
Cycle graph disjoint_union Cycle graph: Graph on 7 vertices
sage: J.vertices()
[0, 1, 2, 3, 4, 5, 6]
```

If the vertices are already disjoint and verbose_relabel is True, then the vertices are not relabeled.

```
sage: G=Graph({'a': ['b']}, implementation='networkx')
sage: G.name("Custom path")
sage: G.name()
'Custom path'
sage: H=graphs.CycleGraph(3)
sage: J=G.disjoint_union(H); J
Custom path disjoint_union Cycle graph: Graph on 5 vertices
sage: J.vertices()
[0, 1, 2, 'a', 'b']
```

disjunctive_product(*other*)

Returns the disjunctive product of self and other.

The disjunctive product of G and H is the graph L with vertex set V(L) equal to the Cartesian product of the vertices V(G) and V(H), and ((u,v), (w,x)) is an edge iff either - (u, w) is an edge of self, or - (v, x) is an edge of other.

EXAMPLES:

```
sage: Z = graphs.CompleteGraph(2)
sage: D = Z.disjunctive_product(Z); D
Graph on 4 vertices
sage: D.plot().show()

sage: C = graphs.CycleGraph(5)
sage: D = C.disjunctive_product(Z); D
```

```
Graph on 10 vertices
sage: D.plot().show()
```

distance(*u, v*)

Returns the (directed) distance from u to v in the (di)graph, i.e. the length of the shortest path from u to v.

EXAMPLES:

```
sage: G = graphs.CycleGraph(9)
sage: G.distance(0,1)
1
sage: G.distance(0,4)
4
sage: G.distance(0,5)
4
sage: G = Graph( {0:[], 1:[]} )
sage: G.distance(0,1)
+Infinity
```

eccentricity(*v=None, dist_dict=None, with_labels=False*)

Return the eccentricity of vertex (or vertices) v.

The eccentricity of a vertex is the maximum distance to any other vertex.

INPUT:

- `v` - either a single vertex or a list of vertices. If it is not specified, then it is taken to be all vertices.
- `dist_dict` - optional, a dict of dicts of distance.
- `with_labels` - Whether to return a list or a dict.

EXAMPLES:

```
sage: G = graphs.KrackhardtKiteGraph()
sage: G.eccentricity()
[4, 4, 4, 4, 4, 3, 3, 2, 3, 4]
sage: G.vertices()
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
sage: G.eccentricity(7)
2
sage: G.eccentricity([7,8,9])
[3, 4, 2]
sage: G.eccentricity([7,8,9], with_labels=True) == {8: 3, 9: 4, 7: 2}
True
sage: G = Graph( { 0 : [], 1 : [], 2 : [1] } )
sage: G.eccentricity()
[+Infinity, +Infinity, +Infinity]
sage: G = Graph({0:[]})
sage: G.eccentricity(with_labels=True)
{0: 0}
sage: G = Graph({0:[], 1:[]})
sage: G.eccentricity(with_labels=True)
{0: +Infinity, 1: +Infinity}
```

edge_boundary(*vertices1, vertices2=None, labels=True*)

Returns a list of edges (u,v,l) with u in vertices1 and v in vertices2. If vertices2 is None, then it is set to the complement of vertices1.

In a digraph, the external boundary of a vertex v are those vertices u with an arc (v, u).

INPUT:

- `labels` - if False, each edge is a tuple (u,v) of vertices.

EXAMPLE:

```
sage: K = graphs.CompleteBipartiteGraph(9,3)
sage: len(K.edge_boundary( [0,1,2,3,4,5,6,7,8], [9,10,11] ))
27
sage: K.size()
27
```

Note that the edge boundary preserves direction:

```
sage: K = graphs.CompleteBipartiteGraph(9,3).to_directed()
sage: len(K.edge_boundary( [0,1,2,3,4,5,6,7,8], [9,10,11] ))
27
sage: K.size()
54
```

```
sage: D = DiGraph({0:[1,2], 3:[0]})
sage: D.edge_boundary([0])
[(0, 1, None), (0, 2, None)]
sage: D.edge_boundary([0], labels=False)
[(0, 1), (0, 2)]
```

edge_iterator(*vertices=None, labels=True, ignore_direction=False*)

Returns an iterator over the edges incident with any vertex given. If the graph is directed, iterates over edges going out only. If vertices is None, then returns an iterator over all edges. If self is directed, returns outgoing edges only.

INPUT:

- `labels` - if False, each edge is a tuple (u,v) of vertices.
- `ignore_direction` - (default False) only applies to directed graphs. If True, searches across edges in either direction.

EXAMPLE:

```
sage: for i in graphs.PetersenGraph().edge_iterator([0]):
...     print i
(0, 1, None)
(0, 4, None)
(0, 5, None)
sage: D = DiGraph( { 0 : [1,2], 1: [0] } )
sage: for i in D.edge_iterator([0]):
...     print i
(0, 1, None)
(0, 2, None)
```

```
sage: G = graphs.TetrahedralGraph()
sage: list(G.edge_iterator(labels=False))
[(0, 1), (0, 2), (0, 3), (1, 2), (1, 3), (2, 3)]
```

```
sage: D = DiGraph({1:[0], 2:[0]})
sage: list(D.edge_iterator(0))
[]
sage: list(D.edge_iterator(0, ignore_direction=True))
[(1, 0, None), (2, 0, None)]
```

edge_label(*u, v=None*)

Returns the label of an edge. Note that if the graph allows multiple edges, then a list of labels on the edge is returned.

EXAMPLE:

```
sage: G = Graph({0 : {1 : 'edgelabel'}}, implementation='networkx')
sage: G.edges(labels=False)
[(0, 1)]
sage: G.edge_label( 0, 1 )
'edgelabel'
sage: D = DiGraph({0 : {1 : 'edgelabel'}}, implementation='networkx')
sage: D.edges(labels=False)
[(0, 1)]
sage: D.edge_label( 0, 1 )
'edgelabel'

sage: G = Graph(multiedges=True)
sage: [G.add_edge(0,1,i) for i in range(1,6)]
[None, None, None, None, None]
sage: sorted(G.edge_label(0,1))
[1, 2, 3, 4, 5]
```

edge_labels()

Returns a list of edge labels.

EXAMPLE:

```
sage: G = Graph({0:{1:'x',2:'z',3:'a'}, 2:{5:'out'}}, implementation='networkx')
sage: G.edge_labels()
['x', 'z', 'a', 'out']
sage: G = DiGraph({0:{1:'x',2:'z',3:'a'}, 2:{5:'out'}}, implementation='networkx')
sage: G.edge_labels()
['x', 'z', 'a', 'out']
```

edges(*labels=True, sort=True*)

Return a list of edges. Each edge is a triple (u,v,l) where u and v are vertices and l is a label.

INPUT:

- `labels` - (bool; default: True) if False, each edge is a tuple (u,v) of vertices.
- `sort` - (bool; default: True) if True, ensure that the list of edges is sorted.

OUTPUT: A list of tuples. It is safe to change the returned list.

EXAMPLES:

```
sage: graphs.DodecahedralGraph().edges()
[(0, 1, None), (0, 10, None), (0, 19, None), (1, 2, None), (1, 8, None), (2, 3, None), (2, 6

sage: graphs.DodecahedralGraph().edges(labels=False)
[(0, 1), (0, 10), (0, 19), (1, 2), (1, 8), (2, 3), (2, 6), (3, 4), (3, 19), (4, 5), (4, 17),

sage: D = graphs.DodecahedralGraph().to_directed()
sage: D.edges()
[(0, 1, None), (0, 10, None), (0, 19, None), (1, 0, None), (1, 2, None), (1, 8, None), (2, 1
sage: D.edges(labels = False)
[(0, 1), (0, 10), (0, 19), (1, 0), (1, 2), (1, 8), (2, 1), (2, 3), (2, 6), (3, 2), (3, 4), (
```

edges_incident(*vertices=None, labels=True*)

Returns a list of edges incident with any vertex given. If vertices is None, returns a list of all edges in graph. For digraphs, only lists outward edges.

INPUT:

- `label` - if False, each edge is a tuple (u,v) of vertices.

EXAMPLE:

```
sage: graphs.PetersenGraph().edges_incident([0,9], labels=False)
[(0, 1), (0, 4), (0, 5), (9, 4), (9, 6), (9, 7)]
sage: D = DiGraph({0:[1]})
sage: D.edges_incident([0])
[(0, 1, None)]
sage: D.edges_incident([1])
[]
```

eigenspaces(*laplacian=False*)

Returns the eigenspaces of the adjacency matrix of the graph.

INPUT:

- `laplacian` - if True, use the Laplacian matrix instead (see self.kirchhoff_matrix())

EXAMPLE:

```
sage: C = graphs.CycleGraph(5)
sage: E = C.eigenspaces()
sage: E[0][0]
-1.618...
sage: E[1][0]  # eigenspace computation is somewhat random
Vector space of degree 5 and dimension 1 over Real Double Field
User basis matrix:
[ 0.632... -0.632... -0.447... -0.013... 0.073...]

sage: D = C.to_directed()
sage: F = D.eigenspaces()
sage: abs(E[0][0] - F[0][0]) < 0.00001
True
```

genus(*set_embedding=True, on_embedding=None, minimal=True, maximal=False, circular=False, ordered=True*)

Returns the minimal genus of the graph. The genus of a compact surface is the number of handles it has. The genus of a graph is the minimal genus of the surface it can be embedded into.

Note - This function uses Euler's formula and thus it is necessary to consider only connected graphs.

INPUT:

- `set_embedding (boolean)` - whether or not to store an embedding attribute of the computed (minimal) genus of the graph. (Default is True).
- `on_embedding (dict)` - a combinatorial embedding to compute the genus of the graph on. Note that this must be a valid embedding for the graph. The dictionary structure is given by: vertex1: [neighbor1, neighbor2, neighbor3], vertex2: [neighbor] where there is a key for each vertex in the graph and a (clockwise) ordered list of each vertex's neighbors as values. on_embedding takes precedence over a stored _embedding attribute if minimal is set to False. Note that as a shortcut, the user can enter on_embedding=True to compute the genus on the current _embedding attribute. (see eg's.)
- `minimal (boolean)` - whether or not to compute the minimal genus of the graph (i.e., testing all embeddings). If minimal is False, then either maximal must be True or on_embedding must not be None. If on_embedding is not None, it will take priority over minimal. Similarly, if maximal is True, it will take priority over minimal.
- `maximal (boolean)` - whether or not to compute the maximal genus of the graph (i.e., testin all embeddings). If maximal is False, then either minimal must be True or on_embedding must not be None. If on_embedding is not None, it will take priority over maximal. However, maximal takes priority over the default minimal.
- `circular (boolean)` - whether or not to compute the genus preserving a planar embedding of the boundary. (Default is False). If circular is True, on_embedding is not a valid option.
- `ordered (boolean)` - if circular is True, then whether or not the boundary order may be permuted. (Default is True, which means the boundary order is preserved.)

EXAMPLES:

```
sage: g = graphs.PetersenGraph()
sage: g.genus() # tests for minimal genus by default
1
sage: g.genus(on_embedding=True, maximal=True) # on_embedding overrides minimal and maximal
1
sage: g.genus(maximal=True) # setting maximal to True overrides default minimal=True
3
sage: g.genus(on_embedding=g.get_embedding()) # can also send a valid combinatorial embeddir
3
sage: (graphs.CubeGraph(3)).genus()
0
sage: K23 = graphs.CompleteBipartiteGraph(2,3)
sage: K23.genus()
0
sage: K33 = graphs.CompleteBipartiteGraph(3,3)
sage: K33.genus()
1
```

Using the circular argument, we can compute the minimal genus preserving a planar, ordered boundary:

```
sage: cube = graphs.CubeGraph(3)
sage: cube.set_boundary(['001','110'])
sage: cube.genus()
0
sage: cube.is_circular_planar()
False
sage: cube.genus(circular=True) #long time
1
sage: cube.genus(circular=True, maximal=True) #long time
3
sage: cube.genus(circular=True, on_embedding=True) #long time
3
```

get_boundary()

Returns the boundary of the (di)graph.

EXAMPLE:

```
sage: G = graphs.PetersenGraph()
sage: G.set_boundary([0,1,2,3,4])
sage: G.get_boundary()
[0, 1, 2, 3, 4]
```

get_embedding()

Returns the attribute _embedding if it exists. _embedding is a dictionary organized with vertex labels as keys and a list of each vertex's neighbors in clockwise order.

Error-checked to insure valid embedding is returned.

EXAMPLES:

```
sage: G = graphs.PetersenGraph()
sage: G.genus()
1
sage: G.get_embedding()
{0: [1, 5, 4],
 1: [0, 2, 6],
 2: [1, 3, 7],
 3: [8, 2, 4],
 4: [0, 9, 3],
 5: [0, 8, 7],
```

```
 6: [8, 1, 9],
 7: [9, 2, 5],
 8: [3, 5, 6],
 9: [4, 6, 7]}
```

get_pos()

Returns the position dictionary, a dictionary specifying the coordinates of each vertex.

EXAMPLES: By default, the position of a graph is None:

```
sage: G = Graph()
sage: G.get_pos()
sage: G.get_pos() is None
True
sage: P = G.plot(save_pos=True)
sage: G.get_pos()
{}
```

Some of the named graphs come with a pre-specified positioning:

```
sage: G = graphs.PetersenGraph()
sage: G.get_pos()
{0: [..., ...],
 ...
 9: [..., ...]}
```

get_vertex(*vertex*)

Retrieve the object associated with a given vertex.

INPUT:

- `vertex` - the given vertex

EXAMPLES:

```
sage: d = {0 : graphs.DodecahedralGraph(), 1 : graphs.FlowerSnark(), 2 : graphs.MoebiusKanto
sage: d[2]
Moebius-Kantor Graph: Graph on 16 vertices
sage: T = graphs.TetrahedralGraph()
sage: T.vertices()
[0, 1, 2, 3]
sage: T.set_vertices(d)
sage: T.get_vertex(1)
Flower Snark: Graph on 20 vertices
```

get_vertices(*verts=None*)

Return a dictionary of the objects associated to each vertex.

INPUT:

- `verts` - iterable container of vertices

EXAMPLES:

```
sage: d = {0 : graphs.DodecahedralGraph(), 1 : graphs.FlowerSnark(), 2 : graphs.MoebiusKanto
sage: T = graphs.TetrahedralGraph()
sage: T.set_vertices(d)
sage: T.get_vertices([1,2])
{1: Flower Snark: Graph on 20 vertices,
 2: Moebius-Kantor Graph: Graph on 16 vertices}
```

girth()

Computes the girth of the graph. For directed graphs, computes the girth of the undirected graph.

The girth is the length of the shortest cycle in the graph. Graphs without cycles have infinite girth.

EXAMPLES:

```
sage: graphs.TetrahedralGraph().girth()
3
sage: graphs.CubeGraph(3).girth()
4
sage: graphs.PetersenGraph().girth()
5
sage: graphs.HeawoodGraph().girth()
6
sage: graphs.trees(9).next().girth()
+Infinity
```

graphplot(**args, **kwds*)

Returns a GraphPlot object.

EXAMPLES:

Creating a graphplot object uses the same options as graph.plot():

```
sage: g = Graph({}, loops=True, multiedges=True)
sage: g.add_edges([(0,0,'a'),(0,0,'b'),(0,1,'c'),(0,1,'d'),
...       (0,1,'e'),(0,1,'f'),(0,1,'f'),(2,1,'g'),(2,2,'h')])
sage: g.set_boundary([0,1])
sage: GP = g.graphplot(edge_labels=True, color_by_label=True, edge_style='dashed')
sage: GP.plot()
```

We can modify the graphplot object. Notice that the changes are cumulative:

```
sage: GP.set_edges(edge_style='solid')
sage: GP.plot()
sage: GP.set_vertices(talk=True)
sage: GP.plot()
```

graphviz_string()

Returns a representation in the DOT language, ready to render in graphviz.

EXAMPLES:

```
sage: G = Graph({0:{1:None,2:None}, 1:{0:None,2:None}, 2:{0:None,1:None,3:'foo'}, 3:{2:'foo'
sage: s = G.graphviz_string()
sage: s
'graph {\n"0";"1";"2";"3";\n"0"--"1";"0"--"2";"1"--"2";"2"--"3"[label="foo"];\n}'
```

graphviz_to_file_named(*filename*)

Write a representation in the DOT language to the named file, ready to render in graphviz.

EXAMPLES:

```
sage: G = Graph({0:{1:None,2:None}, 1:{0:None,2:None}, 2:{0:None,1:None,3:'foo'}, 3:{2:'foo'
sage: G.graphviz_to_file_named(os.environ['SAGE_TESTDIR']+'/temp_graphviz')
sage: open(os.environ['SAGE_TESTDIR']+'/temp_graphviz').read()
'graph {\n"0";"1";"2";"3";\n"0"--"1";"0"--"2";"1"--"2";"2"--"3"[label="foo"];\n}'
```

has_edge(*u, v=None, label=None*)

Returns True if (u, v) is an edge, False otherwise.

INPUT: The following forms are accepted by NetworkX:

- G.has_edge(1, 2)
- G.has_edge((1, 2))
- G.has_edge(1, 2, 'label')

EXAMPLE:

```
sage: graphs.EmptyGraph().has_edge(9,2)
False
sage: DiGraph().has_edge(9,2)
False
sage: G = Graph(implementation='networkx')
sage: G.add_edge(0,1,"label")
sage: G.has_edge(0,1,"different label")
False
sage: G.has_edge(0,1,"label")
True
```

has_loops()

Returns whether there are loops in the (di)graph.

EXAMPLES:

```
sage: G = Graph(loops=True); G
Looped graph on 0 vertices
sage: G.has_loops()
False
sage: G.allows_loops()
True
sage: G.add_edge((0,0))
sage: G.has_loops()
True
sage: G.loops()
[(0, 0, None)]
sage: G.allow_loops(False); G
Graph on 1 vertex
sage: G.has_loops()
False
sage: G.edges()
[]

sage: D = DiGraph(loops=True); D
Looped digraph on 0 vertices
sage: D.has_loops()
False
sage: D.allows_loops()
True
sage: D.add_edge((0,0))
sage: D.has_loops()
True
sage: D.loops()
[(0, 0, None)]
sage: D.allow_loops(False); D
Digraph on 1 vertex
sage: D.has_loops()
False
sage: D.edges()
[]
```

has_multiple_edges(*to_undirected=False*)

Returns whether there are multiple edges in the (di)graph.

INPUT: to_undirected – (default: False) If True, runs the test on the undirected version of a DiGraph. Otherwise, treats DiGraph edges (u,v) and (v,u) as unique individual edges.

EXAMPLES:

```
sage: G = Graph(multiedges=True); G
Multi-graph on 0 vertices
sage: G.has_multiple_edges()
False
sage: G.allows_multiple_edges()
True
sage: G.add_edges([(0,1)]*3)
sage: G.has_multiple_edges()
True
sage: G.multiple_edges()
[(0, 1, None), (0, 1, None), (0, 1, None)]
sage: G.allow_multiple_edges(False); G
Graph on 2 vertices
sage: G.has_multiple_edges()
False
sage: G.edges()
[(0, 1, None)]

sage: D = DiGraph(multiedges=True); D
Multi-digraph on 0 vertices
sage: D.has_multiple_edges()
False
sage: D.allows_multiple_edges()
True
sage: D.add_edges([(0,1)]*3)
sage: D.has_multiple_edges()
True
sage: D.multiple_edges()
[(0, 1, None), (0, 1, None), (0, 1, None)]
sage: D.allow_multiple_edges(False); D
Digraph on 2 vertices
sage: D.has_multiple_edges()
False
sage: D.edges()
[(0, 1, None)]

sage: G = DiGraph({1:{2: 'h'}, 2:{1:'g'}})
sage: G.has_multiple_edges()
False
sage: G.has_multiple_edges(to_undirected=True)
True
sage: G.multiple_edges()
[]
sage: G.multiple_edges(to_undirected=True)
[(1, 2, 'h'), (2, 1, 'g')]
```

has_vertex(*vertex*)

Return True if vertex is one of the vertices of this graph.

INPUT:

- `vertex` - an integer

OUTPUT:

- `bool` - True or False

EXAMPLES:

```
sage: g = Graph({0:[1,2,3], 2:[4]}); g
Graph on 5 vertices
sage: 2 in g
```

```
True
sage: 10 in g
False
sage: graphs.PetersenGraph().has_vertex(99)
False
```

incidence_matrix(*sparse=True*)

Returns an incidence matrix of the (di)graph. Each row is a vertex, and each column is an edge. Note that in the case of graphs, there is a choice of orientation for each edge.

EXAMPLE:

```
sage: G = graphs.CubeGraph(3)
sage: G.incidence_matrix()
[-1 -1 -1  0  0  0  0  0  0  0  0  0]
[ 0  0  1 -1 -1  0  0  0  0  0  0  0]
[ 0  1  0  0  0 -1 -1  0  0  0  0  0]
[ 0  0  0  0  1  0  1 -1  0  0  0  0]
[ 1  0  0  0  0  0  0  0 -1 -1  0  0]
[ 0  0  0  1  0  0  0  0  0  1 -1  0]
[ 0  0  0  0  0  1  0  0  1  0  0 -1]
[ 0  0  0  0  0  0  0  1  0  0  1  1]

sage: D = DiGraph( { 0: [1,2,3], 1: [0,2], 2: [3], 3: [4], 4: [0,5], 5: [1] } )
sage: D.incidence_matrix()
[-1 -1 -1  0  0  0  0  0  1  1]
[ 0  0  1 -1  0  0  0  1 -1  0]
[ 0  1  0  1 -1  0  0  0  0  0]
[ 1  0  0  0  1 -1  0  0  0  0]
[ 0  0  0  0  0  1 -1  0  0 -1]
[ 0  0  0  0  0  0  1 -1  0  0]
```

interior_paths(*start, end*)

Returns an exhaustive list of paths (also lists) through only interior vertices from vertex start to vertex end in the (di)graph.

Note - start and end do not necessarily have to be boundary vertices.

INPUT:

- `start` - the vertex of the graph to search for paths from
- `end` - the vertex of the graph to search for paths to

EXAMPLES:

```
sage: eg1 = Graph({0:[1,2], 1:[4], 2:[3,4], 4:[5], 5:[6]})
sage: sorted(eg1.all_paths(0,6))
[[0, 1, 4, 5, 6], [0, 2, 4, 5, 6]]
sage: eg2 = eg1.copy()
sage: eg2.set_boundary([0,1,3])
sage: sorted(eg2.interior_paths(0,6))
[[0, 2, 4, 5, 6]]
sage: sorted(eg2.all_paths(0,6))
[[0, 1, 4, 5, 6], [0, 2, 4, 5, 6]]
sage: eg3 = graphs.PetersenGraph()
sage: eg3.set_boundary([0,1,2,3,4])
sage: sorted(eg3.all_paths(1,4))
[[1, 0, 4],
 [1, 0, 5, 7, 2, 3, 4],
 [1, 0, 5, 7, 2, 3, 8, 6, 9, 4],
 [1, 0, 5, 7, 9, 4],
 [1, 0, 5, 7, 9, 6, 8, 3, 4],
```

```
 [1, 0, 5, 8, 3, 2, 7, 9, 4],
 [1, 0, 5, 8, 3, 4],
 [1, 0, 5, 8, 6, 9, 4],
 [1, 0, 5, 8, 6, 9, 7, 2, 3, 4],
 [1, 2, 3, 4],
 [1, 2, 3, 8, 5, 0, 4],
 [1, 2, 3, 8, 5, 7, 9, 4],
 [1, 2, 3, 8, 6, 9, 4],
 [1, 2, 3, 8, 6, 9, 7, 5, 0, 4],
 [1, 2, 7, 5, 0, 4],
 [1, 2, 7, 5, 8, 3, 4],
 [1, 2, 7, 5, 8, 6, 9, 4],
 [1, 2, 7, 9, 4],
 [1, 2, 7, 9, 6, 8, 3, 4],
 [1, 2, 7, 9, 6, 8, 5, 0, 4],
 [1, 6, 8, 3, 2, 7, 5, 0, 4],
 [1, 6, 8, 3, 2, 7, 9, 4],
 [1, 6, 8, 3, 4],
 [1, 6, 8, 5, 0, 4],
 [1, 6, 8, 5, 7, 2, 3, 4],
 [1, 6, 8, 5, 7, 9, 4],
 [1, 6, 9, 4],
 [1, 6, 9, 7, 2, 3, 4],
 [1, 6, 9, 7, 2, 3, 8, 5, 0, 4],
 [1, 6, 9, 7, 5, 0, 4],
 [1, 6, 9, 7, 5, 8, 3, 4]]
sage: sorted(eg3.interior_paths(1,4))
[[1, 6, 8, 5, 7, 9, 4], [1, 6, 9, 4]]
sage: dg = DiGraph({0:[1,3,4], 1:[3], 2:[0,3,4],4:[3]}, boundary=[4])
sage: sorted(dg.all_paths(0,3))
[[0, 1, 3], [0, 3], [0, 4, 3]]
sage: sorted(dg.interior_paths(0,3))
[[0, 1, 3], [0, 3]]
sage: ug = dg.to_undirected()
sage: sorted(ug.all_paths(0,3))
[[0, 1, 3], [0, 2, 3], [0, 2, 4, 3], [0, 3], [0, 4, 2, 3], [0, 4, 3]]
sage: sorted(ug.interior_paths(0,3))
[[0, 1, 3], [0, 2, 3], [0, 3]]
```

is_circular_planar(*ordered=True, on_embedding=None, kuratowski=False, set_embedding=False, set_pos=False*)

A graph (with nonempty boundary) is circular planar if it has a planar embedding in which all boundary vertices can be drawn in order on a disc boundary, with all the interior vertices drawn inside the disc.

Returns True if the graph is circular planar, and False if it is not. If kuratowski is set to True, then this function will return a tuple, with boolean first entry and second entry the Kuratowski subgraph or minor isolated by the Boyer-Myrvold algorithm. Note that this graph might contain a vertex or edges that were not in the initial graph. These would be elements referred to below as parts of the wheel and the star, which were added to the graph to require that the boundary can be drawn on the boundary of a disc, with all other vertices drawn inside (and no edge crossings). For more information, refer to reference [2].

This is a linear time algorithm to test for circular planarity. It relies on the edge-addition planarity algorithm due to Boyer-Myrvold. We accomplish linear time for circular planarity by modifying the graph before running the general planarity algorithm.

REFERENCE:

- [1] John M. Boyer and Wendy J. Myrvold, On the Cutting Edge: Simplified O(n) Planarity by Edge Addition. Journal of Graph Algorithms and Applications, Vol. 8, No. 3, pp. 241-273, 2004.
- [2] Kirkman, Emily A. O(n) Circular Planarity Testing. [Online] Available: soon!

INPUT:

- `ordered` - whether or not to consider the order of the boundary (set ordered=False to see if there is any possible boundary order that will satisfy circular planarity)
- `kuratowski` - if set to True, returns a tuple with boolean first entry and the Kuratowski subgraph or minor as the second entry. See notes above.
- `on_embedding` - the embedding dictionary to test planarity on. (i.e.: will return True or False only for the given embedding.)
- `set_embedding` - whether or not to set the instance field variable that contains a combinatorial embedding (clockwise ordering of neighbors at each vertex). This value will only be set if a circular planar embedding is found. It is stored as a Python dict: v1: [n1,n2,n3] where v1 is a vertex and n1,n2,n3 are its neighbors.
- `set_pos` - whether or not to set the position dictionary (for plotting) to reflect the combinatorial embedding. Note that this value will default to False if set_emb is set to False. Also, the position dictionary will only be updated if a circular planar embedding is found.

EXAMPLES:

```
sage: g439 = Graph({1:[5,7], 2:[5,6], 3:[6,7], 4:[5,6,7]}, implementation='networkx')
sage: g439.set_boundary([1,2,3,4])
sage: g439.show(figsize=[2,2], vertex_labels=True, vertex_size=175)
sage: g439.is_circular_planar()
False
sage: g439.is_circular_planar(kuratowski=True)
(False, Graph on 7 vertices)
sage: g439.set_boundary([1,2,3])
sage: g439.is_circular_planar(set_embedding=True, set_pos=False)
True
sage: g439.is_circular_planar(kuratowski=True)
(True, None)
sage: g439.get_embedding()
{1: [7, 5],
 2: [5, 6],
 3: [6, 7],
 4: [7, 6, 5],
 5: [4, 2, 1],
 6: [4, 3, 2],
 7: [3, 4, 1]}
```

Order matters:

```
sage: K23 = graphs.CompleteBipartiteGraph(2,3)
sage: K23.set_boundary([0,1,2,3])
sage: K23.is_circular_planar()
False
sage: K23.is_circular_planar(ordered=False)
True
sage: K23.set_boundary([0,2,1,3]) # Diff Order!
sage: K23.is_circular_planar(set_embedding=True)
True
```

For graphs without a boundary, circular planar is the same as planar:

```
sage: g = graphs.KrackhardtKiteGraph()
sage: g.is_circular_planar()
True
```

is_clique(*vertices=None, directed_clique=False*)

Returns True if the set `vertices` is a clique, False if not. A clique is a set of vertices such that there is an edge between any two vertices.

INPUT:

- `vertices` - Vertices can be a single vertex or an iterable container of vertices, e.g. a list, set, graph, file or numeric array. If not passed, defaults to the entire graph.
- `directed_clique` - (default False) If set to False, only consider the underlying undirected graph. If set to True and the graph is directed, only return True if all possible edges in _both_ directions exist.

EXAMPLE:

```
sage: g = graphs.CompleteGraph(4)
sage: g.is_clique([1,2,3])
True
sage: g.is_clique()
True
sage: h = graphs.CycleGraph(4)
sage: h.is_clique([1,2])
True
sage: h.is_clique([1,2,3])
False
sage: h.is_clique()
False
sage: i = graphs.CompleteGraph(4).to_directed()
sage: i.delete_edge([0,1])
sage: i.is_clique()
True
sage: i.is_clique(directed_clique=True)
False
```

is_connected()

Indicates whether the (di)graph is connected. Note that in a graph, path connected is equivalent to connected.

EXAMPLE:

```
sage: G = Graph( { 0 : [1, 2], 1 : [2], 3 : [4, 5], 4 : [5] } )
sage: G.is_connected()
False
sage: G.add_edge(0,3)
sage: G.is_connected()
True
sage: D = DiGraph( { 0 : [1, 2], 1 : [2], 3 : [4, 5], 4 : [5] } )
sage: D.is_connected()
False
sage: D.add_edge(0,3)
sage: D.is_connected()
True
sage: D = DiGraph({1:[0], 2:[0]})
sage: D.is_connected()
True
```

is_drawn_free_of_edge_crossings()

Returns True is the position dictionary for this graph is set and that position dictionary gives a planar embedding.

This simply checks all pairs of edges that don't share a vertex to make sure that they don't intersect.

Note: This function require that _pos attribute is set. (Returns False otherwise.)

EXAMPLES:

```
sage: D = graphs.DodecahedralGraph()
sage: D.set_planar_positions()
sage: D.is_drawn_free_of_edge_crossings()
True
```

is_equitable(*partition, quotient_matrix=False*)

Checks whether the given partition is equitable with respect to self.

A partition is equitable with respect to a graph if for every pair of cells C1, C2 of the partition, the number of edges from a vertex of C1 to C2 is the same, over all vertices in C1.

INPUT:

- `partition` - a list of lists
- `quotient_matrix` - (default False) if True, and the partition is equitable, returns a matrix over the integers whose rows and columns represent cells of the partition, and whose i,j entry is the number of vertices in cell j adjacent to each vertex in cell i (since the partition is equitable, this is well defined)

EXAMPLE:

```
sage: G = graphs.PetersenGraph()
sage: G.is_equitable([[0,4],[1,3,5,9],[2,6,8],[7]])
False
sage: G.is_equitable([[0,4],[1,3,5,9],[2,6,8,7]])
True
sage: G.is_equitable([[0,4],[1,3,5,9],[2,6,8,7]], quotient_matrix=True)
[1 2 0]
[1 0 2]
[0 2 1]

sage: ss = (graphs.WheelGraph(6)).line_graph(labels=False)
sage: prt = [[(0, 1)], [(0, 2), (0, 3), (0, 4), (1, 2), (1, 4)], [(2, 3), (3, 4)]]

sage: ss.is_equitable(prt)
...
TypeError: Partition [[(0, 1)], [(0, 2), (0, 3), (0, 4), (1, 2), (1, 4)], [(2, 3), (3, 4)]]

sage: ss = (graphs.WheelGraph(5)).line_graph(labels=False)
sage: ss.is_equitable(prt)
False
```

is_eulerian()

Return true if the graph has an tour that visits each edge exactly once.

EXAMPLES:

```
sage: graphs.CompleteGraph(4).is_eulerian()
False
sage: graphs.CycleGraph(4).is_eulerian()
True
sage: g = DiGraph({0:[1,2], 1:[2]}); g.is_eulerian()
False
sage: g = DiGraph({0:[2], 1:[3], 2:[0,1], 3:[2]}); g.is_eulerian()
True
```

is_forest()

Return True if the graph is a forest, i.e. a disjoint union of trees.

EXAMPLE:

```
sage: seven_acre_wood = sum(graphs.trees(7), Graph())
sage: seven_acre_wood.is_forest()
True
```

is_independent_set(*vertices=None*)

Returns True if the set `vertices` is an independent set, False if not. An independent set is a set of vertices such that there is no edge between any two vertices.

INPUT:

- `vertices` - Vertices can be a single vertex or an iterable container of vertices, e.g. a list, set, graph, file or numeric array. If not passed, defaults to the entire graph.

EXAMPLE:

```
sage: graphs.CycleGraph(4).is_independent_set([1,3])
True
sage: graphs.CycleGraph(4).is_independent_set([1,2,3])
False
```

is_isomorphic(*other, certify=False, verbosity=0, edge_labels=False*)

Tests for isomorphism between self and other.

INPUT:

- `certify` - if True, then output is (a,b), where a is a boolean and b is either a map or None.
- `edge_labels` - default False, otherwise allows only permutations respecting edge labels.

EXAMPLES: Graphs:

```
sage: from sage.groups.perm_gps.permgroup_named import SymmetricGroup
sage: D = graphs.DodecahedralGraph()
sage: E = D.copy()
sage: gamma = SymmetricGroup(20).random_element()
sage: E.relabel(gamma)
sage: D.is_isomorphic(E)
True

sage: D = graphs.DodecahedralGraph()
sage: S = SymmetricGroup(20)
sage: gamma = S.random_element()
sage: E = D.copy()
sage: E.relabel(gamma)
sage: a,b = D.is_isomorphic(E, certify=True); a
True
sage: from sage.plot.plot import GraphicsArray
sage: from sage.graphs.graph_fast import spring_layout_fast
sage: position_D = spring_layout_fast(D)
sage: position_E = {}
sage: for vert in position_D:
...     position_E[b[vert]] = position_D[vert]
sage: GraphicsArray([D.plot(pos=position_D), E.plot(pos=position_E)]).show()

sage: g=graphs.HeawoodGraph()
sage: g.is_isomorphic(g)
True
```

Multigraphs:

```
sage: G = Graph(multiedges=True)
sage: G.add_edge((0,1,1))
sage: G.add_edge((0,1,2))
sage: G.add_edge((0,1,3))
sage: G.add_edge((0,1,4))
sage: H = Graph(multiedges=True, implementation='networkx')
sage: H.add_edge((3,4))
sage: H.add_edge((3,4))
sage: H.add_edge((3,4))
sage: H.add_edge((3,4))
sage: G.is_isomorphic(H)
True
```

Digraphs:

```
sage: A = DiGraph( { 0 : [1,2] } )
sage: B = DiGraph( { 1 : [0,2] } )
sage: A.is_isomorphic(B, certify=True)
(True, {0: 1, 1: 0, 2: 2})
```

Edge labeled graphs:

```
sage: G = Graph(implementation='networkx')
sage: G.add_edges( [(0,1,'a'),(1,2,'b'),(2,3,'c'),(3,4,'b'),(4,0,'a')] )
sage: H = G.relabel([1,2,3,4,0], inplace=False)
sage: G.is_isomorphic(H, edge_labels=True)
True
```

is_planar(*on_embedding=None, kuratowski=False, set_embedding=False, set_pos=False*)

Returns True if the graph is planar, and False otherwise. This wraps the reference implementation provided by John Boyer of the linear time planarity algorithm by edge addition due to Boyer Myrvold. (See reference code in graphs.planarity).

Note - the argument on_embedding takes precedence over set_embedding. This means that only the on_embedding combinatorial embedding will be tested for planarity and no _embedding attribute will be set as a result of this function call, unless on_embedding is None.

REFERENCE:

- [1] John M. Boyer and Wendy J. Myrvold, On the Cutting Edge: Simplified O(n) Planarity by Edge Addition. Journal of Graph Algorithms and Applications, Vol. 8, No. 3, pp. 241-273, 2004.

INPUT:

- `kuratowski` - returns a tuple with boolean as first entry. If the graph is nonplanar, will return the Kuratowski subgraph or minor as the second tuple entry. If the graph is planar, returns None as the second entry.
- `on_embedding` - the embedding dictionary to test planarity on. (i.e.: will return True or False only for the given embedding.)
- `set_embedding` - whether or not to set the instance field variable that contains a combinatorial embedding (clockwise ordering of neighbors at each vertex). This value will only be set if a planar embedding is found. It is stored as a Python dict: v1: [n1,n2,n3] where v1 is a vertex and n1,n2,n3 are its neighbors.
- `set_pos` - whether or not to set the position dictionary (for plotting) to reflect the combinatorial embedding. Note that this value will default to False if set_emb is set to False. Also, the position dictionary will only be updated if a planar embedding is found.

EXAMPLES:

```
sage: g = graphs.CubeGraph(4)
sage: g.is_planar()
False

sage: g = graphs.CircularLadderGraph(4)
sage: g.is_planar(set_embedding=True)
True
sage: g.get_embedding()
{0: [1, 4, 3],
 1: [2, 5, 0],
 2: [3, 6, 1],
 3: [0, 7, 2],
 4: [0, 5, 7],
 5: [1, 6, 4],
 6: [2, 7, 5],
 7: [4, 6, 3]}
```

```
sage: g = graphs.PetersenGraph()
sage: (g.is_planar(kuratowski=True))[1].adjacency_matrix()
[0 1 0 0 0 1 0 0 0 0]
[1 0 1 0 0 0 1 0 0 0]
[0 1 0 1 0 0 0 0 0 0]
[0 0 1 0 1 0 0 0 1 0]
[0 0 0 1 0 0 0 0 0 1]
[1 0 0 0 0 0 0 1 1 0]
[0 1 0 0 0 0 0 0 1 1]
[0 0 0 0 0 1 0 0 0 1]
[0 0 0 1 0 1 1 0 0 0]
[0 0 0 0 1 0 1 1 0 0]

sage: k43 = graphs.CompleteBipartiteGraph(4,3)
sage: result = k43.is_planar(kuratowski=True); result
(False, Graph on 6 vertices)
sage: result[1].is_isomorphic(graphs.CompleteBipartiteGraph(3,3))
True
```

is_subgraph(*other*)

Tests whether self is a subgraph of other.

EXAMPLE:

```
sage: P = graphs.PetersenGraph()
sage: G = P.subgraph(range(6))
sage: G.is_subgraph(P)
True
```

is_transitively_reduced()

Returns True if the digraph is transitively reduced and False otherwise.

A digraph is transitively reduced if it is equal to its transitive reduction.

EXAMPLES:

```
sage: d = DiGraph({0:[1],1:[2],2:[3]})
sage: d.is_transitively_reduced()
True

sage: d = DiGraph({0:[1,2],1:[2]})
sage: d.is_transitively_reduced()
False

sage: d = DiGraph({0:[1,2],1:[2],2:[]})
sage: d.is_transitively_reduced()
False
```

is_tree()

Return True if the graph is a tree.

EXAMPLES:

```
sage: for g in graphs.trees(6):
...       g.is_tree()
True
True
True
True
True
True
```

is_vertex_transitive(*partition=None, verbosity=0, edge_labels=False, order=False, return_group=True, orbits=False*)

Returns whether the automorphism group of self is transitive within the partition provided, by default the unit partition of the vertices of self (thus by default tests for vertex transitivity in the usual sense).

EXAMPLE:

```
sage: G = Graph({0:[1],1:[2]})
sage: G.is_vertex_transitive()
False
sage: P = graphs.PetersenGraph()
sage: P.is_vertex_transitive()
True
sage: D = graphs.DodecahedralGraph()
sage: D.is_vertex_transitive()
True
sage: R = graphs.RandomGNP(2000, .01)
sage: R.is_vertex_transitive()
False
```

kirchhoff_matrix(*weighted=None, **kwds*)

Returns the Kirchhoff matrix (a.k.a. the Laplacian) of the graph.

The Kirchhoff matrix is defined to be D - M, where D is the diagonal degree matrix (each diagonal entry is the degree of the corresponding vertex), and M is the adjacency matrix.

If weighted == True, the weighted adjacency matrix is used for M, and the diagonal entries are the row-sums of M.

Note that any additional keywords will be pased on to either the adjacency_matrix or weighted_adjacency_matrix method.

AUTHORS:

- Tom Boothby

EXAMPLES:

```
sage: G = Graph(sparse=True)
sage: G.add_edges([(0,1,1),(1,2,2),(0,2,3),(0,3,4)])
sage: M = G.kirchhoff_matrix(weighted=True); M
[ 8 -1 -3 -4]
[-1  3 -2  0]
[-3 -2  5  0]
[-4  0  0  4]
sage: M = G.kirchhoff_matrix(); M
[ 3 -1 -1 -1]
[-1  2 -1  0]
[-1 -1  2  0]
[-1  0  0  1]
sage: G.set_boundary([2,3])
sage: M = G.kirchhoff_matrix(weighted=True, boundary_first=True); M
[ 5  0 -3 -2]
[ 0  4 -4  0]
[-3 -4  8 -1]
[-2  0 -1  3]
sage: M = G.kirchhoff_matrix(boundary_first=True); M
[ 2  0 -1 -1]
[ 0  1 -1  0]
[-1 -1  3 -1]
[-1  0 -1  2]
sage: M = G.laplacian_matrix(boundary_first=True); M
[ 2  0 -1 -1]
[ 0  1 -1  0]
[-1 -1  3 -1]
[-1  0 -1  2]
```

```
sage: M = G.laplacian_matrix(boundary_first=True, sparse=False); M
[ 2  0 -1 -1]
[ 0  1 -1  0]
[-1 -1  3 -1]
[-1  0 -1  2]
```

A weighted directed graph with loops:

```
sage: G = DiGraph({1:{1:2,2:3}, 2:{1:4}}, weighted=True)
sage: G.laplacian_matrix()
[ 3 -3]
[-4  4]
```

laplacian_matrix(*weighted=None, **kwds*)

Returns the Kirchhoff matrix (a.k.a. the Laplacian) of the graph.

The Kirchhoff matrix is defined to be D - M, where D is the diagonal degree matrix (each diagonal entry is the degree of the corresponding vertex), and M is the adjacency matrix.

If weighted == True, the weighted adjacency matrix is used for M, and the diagonal entries are the row-sums of M.

Note that any additional keywords will be pased on to either the adjacency_matrix or weighted_adjacency_matrix method.

AUTHORS:

- Tom Boothby

EXAMPLES:

```
sage: G = Graph(sparse=True)
sage: G.add_edges([(0,1,1),(1,2,2),(0,2,3),(0,3,4)])
sage: M = G.kirchhoff_matrix(weighted=True); M
[ 8 -1 -3 -4]
[-1  3 -2  0]
[-3 -2  5  0]
[-4  0  0  4]
sage: M = G.kirchhoff_matrix(); M
[ 3 -1 -1 -1]
[-1  2 -1  0]
[-1 -1  2  0]
[-1  0  0  1]
sage: G.set_boundary([2,3])
sage: M = G.kirchhoff_matrix(weighted=True, boundary_first=True); M
[ 5  0 -3 -2]
[ 0  4 -4  0]
[-3 -4  8 -1]
[-2  0 -1  3]
sage: M = G.kirchhoff_matrix(boundary_first=True); M
[ 2  0 -1 -1]
[ 0  1 -1  0]
[-1 -1  3 -1]
[-1  0 -1  2]
sage: M = G.laplacian_matrix(boundary_first=True); M
[ 2  0 -1 -1]
[ 0  1 -1  0]
[-1 -1  3 -1]
[-1  0 -1  2]
sage: M = G.laplacian_matrix(boundary_first=True, sparse=False); M
[ 2  0 -1 -1]
[ 0  1 -1  0]
[-1 -1  3 -1]
```

```
[-1  0 -1  2]
```

A weighted directed graph with loops:

```
sage: G = DiGraph({1:{1:2,2:3}, 2:{1:4}}, weighted=True)
sage: G.laplacian_matrix()
[ 3 -3]
[-4  4]
```

lexicographic_product (*other*)

Returns the lexicographic product of self and other.

The lexicographic product of G and H is the graph L with vertex set V(L) equal to the Cartesian product of the vertices V(G) and V(H), and ((u,v), (w,x)) is an edge iff - (u, w) is an edge of self, or - u = w and (v, x) is an edge of other.

EXAMPLES:

```
sage: Z = graphs.CompleteGraph(2)
sage: C = graphs.CycleGraph(5)
sage: L = C.lexicographic_product(Z); L
Graph on 10 vertices
sage: L.plot().show()

sage: D = graphs.DodecahedralGraph()
sage: P = graphs.PetersenGraph()
sage: L = D.lexicographic_product(P); L
Graph on 200 vertices
sage: L.plot().show()
```

line_graph (*labels=True*)

Returns the line graph of the (di)graph.

The line graph of an undirected graph G is an undirected graph H such that the vertices of H are the edges of G and two vertices e and f of H are adjacent if e and f share a common vertex in G. In other words, an edge in H represents a path of length 2 in G.

The line graph of a directed graph G is a directed graph H such that the vertices of H are the edges of G and two vertices e and f of H are adjacent if e and f share a common vertex in G and the terminal vertex of e is the initial vertex of f. In other words, an edge in H represents a (directed) path of length 2 in G.

EXAMPLE:

```
sage: g=graphs.CompleteGraph(4)
sage: h=g.line_graph()
sage: h.vertices()
[(0, 1, None),
(0, 2, None),
(0, 3, None),
(1, 2, None),
(1, 3, None),
(2, 3, None)]
sage: h.am()
[0 1 1 1 1 0]
[1 0 1 1 0 1]
[1 1 0 0 1 1]
[1 1 0 0 1 1]
[1 0 1 1 0 1]
[0 1 1 1 1 0]
sage: h2=g.line_graph(labels=False)
sage: h2.vertices()
[(0, 1), (0, 2), (0, 3), (1, 2), (1, 3), (2, 3)]
sage: h2.am()==h.am()
```

```
True
sage: g = DiGraph([[1..4],lambda i,j: i<j], implementation='networkx')
sage: h = g.line_graph()
sage: h.vertices()
[(1, 2, None),
(1, 3, None),
(1, 4, None),
(2, 3, None),
(2, 4, None),
(3, 4, None)]
sage: h.edges()
[((1, 2, None), (2, 3, None), None),
 ((1, 2, None), (2, 4, None), None),
 ((1, 3, None), (3, 4, None), None),
 ((2, 3, None), (3, 4, None), None)]
```

loop_edges()

Returns a list of all loops in the graph.

EXAMPLE:

```
sage: G = Graph(4, loops=True)
sage: G.add_edges( [ (0,0), (1,1), (2,2), (3,3), (2,3) ] )
sage: G.loop_edges()
[(0, 0, None), (1, 1, None), (2, 2, None), (3, 3, None)]

sage: D = DiGraph(4, loops=True)
sage: D.add_edges( [ (0,0), (1,1), (2,2), (3,3), (2,3) ] )
sage: D.loop_edges()
[(0, 0, None), (1, 1, None), (2, 2, None), (3, 3, None)]

sage: G = Graph(4, loops=True, multiedges=True)
sage: G.add_edges([(i,i) for i in range(4)])
sage: G.loop_edges()
[(0, 0, None), (1, 1, None), (2, 2, None), (3, 3, None)]
```

loop_vertices()

Returns a list of vertices with loops.

EXAMPLE:

```
sage: G = Graph({0 : [0], 1: [1,2,3], 2: [3]}, loops=True)
sage: G.loop_vertices()
[0, 1]
```

loops(*new=None, labels=True*)

Returns any loops in the (di)graph.

INPUT: new – deprecated labels – whether returned edges have labels ((u,v,l)) or not ((u,v)).

EXAMPLES: sage: G = Graph(loops=True); G Looped graph on 0 vertices sage: G.has_loops() False sage: G.allows_loops() True sage: G.add_edge((0,0)) sage: G.has_loops() True sage: G.loops() [(0, 0, None)] sage: G.allow_loops(False); G Graph on 1 vertex sage: G.has_loops() False sage: G.edges() []

sage: D = DiGraph(loops=True); D Looped digraph on 0 vertices sage: D.has_loops() False sage: D.allows_loops() True sage: D.add_edge((0,0)) sage: D.has_loops() True sage: D.loops() [(0, 0, None)] sage: D.allow_loops(False); D Digraph on 1 vertex sage: D.has_loops() False sage: D.edges() []

multiple_edges(*new=None, to_undirected=False, labels=True*)

Returns any multiple edges in the (di)graph.

EXAMPLES:

```
sage: G = Graph(multiedges=True); G
Multi-graph on 0 vertices
sage: G.has_multiple_edges()
False
sage: G.allows_multiple_edges()
True
sage: G.add_edges([(0,1)]*3)
sage: G.has_multiple_edges()
True
sage: G.multiple_edges()
[(0, 1, None), (0, 1, None), (0, 1, None)]
sage: G.allow_multiple_edges(False); G
Graph on 2 vertices
sage: G.has_multiple_edges()
False
sage: G.edges()
[(0, 1, None)]

sage: D = DiGraph(multiedges=True); D
Multi-digraph on 0 vertices
sage: D.has_multiple_edges()
False
sage: D.allows_multiple_edges()
True
sage: D.add_edges([(0,1)]*3)
sage: D.has_multiple_edges()
True
sage: D.multiple_edges()
[(0, 1, None), (0, 1, None), (0, 1, None)]
sage: D.allow_multiple_edges(False); D
Digraph on 2 vertices
sage: D.has_multiple_edges()
False
sage: D.edges()
[(0, 1, None)]

sage: G = DiGraph({1:{2: 'h'}, 2:{1:'g'}})
sage: G.has_multiple_edges()
False
sage: G.has_multiple_edges(to_undirected=True)
True
sage: G.multiple_edges()
[]
sage: G.multiple_edges(to_undirected=True)
[(1, 2, 'h'), (2, 1, 'g')]
```

name (*new=None*)

INPUT:

- `new` - if not None, then this becomes the new name of the (di)graph. (if new == '', removes any name)

EXAMPLE:

```
sage: d = {0: [1,4,5], 1: [2,6], 2: [3,7], 3: [4,8], 4: [9], 5: [7, 8], 6: [8,9], 7: [9]}
sage: G = Graph(d); G
Graph on 10 vertices
sage: G.name("Petersen Graph"); G
Petersen Graph: Graph on 10 vertices
sage: G.name(new=""); G
Graph on 10 vertices
```

```
sage: G.name()
''
```

neighbor_iterator(*vertex*)

Return an iterator over neighbors of vertex.

EXAMPLE:

```
sage: G = graphs.CubeGraph(3)
sage: for i in G.neighbor_iterator('010'):
...    print i
011
000
110
sage: D = G.to_directed()
sage: for i in D.neighbor_iterator('010'):
...    print i
011
000
110

sage: D = DiGraph({0:[1,2], 3:[0]})
sage: list(D.neighbor_iterator(0))
[1, 2, 3]
```

neighbors(*vertex*)

Return a list of neighbors (in and out if directed) of vertex.

G[vertex] also works.

EXAMPLE:

```
sage: P = graphs.PetersenGraph()
sage: sorted(P.neighbors(3))
[2, 4, 8]
sage: sorted(P[4])
[0, 3, 9]
```

networkx_graph(*copy=True*)

Creates a new NetworkX graph from the Sage graph.

INPUT:

- `copy` - if False, and the underlying implementation is a NetworkX graph, then the actual object itself is returned.

EXAMPLES:

```
sage: G = graphs.TetrahedralGraph()
sage: N = G.networkx_graph()
sage: type(N)
<class 'networkx.xgraph.XGraph'>

sage: G = graphs.TetrahedralGraph()
sage: G = Graph(G, implementation='networkx')
sage: N = G.networkx_graph()
sage: G._backend._nxg is N
False

sage: G = Graph(graphs.TetrahedralGraph(), implementation='networkx')
sage: N = G.networkx_graph(copy=False)
sage: G._backend._nxg is N
True
```

num_edges()
Returns the number of edges.
EXAMPLE:

```
sage: G = graphs.PetersenGraph()
sage: G.size()
15
```

num_verts()
Returns the number of vertices. Note that len(G) returns the number of vertices in G also.
EXAMPLE:

```
sage: G = graphs.PetersenGraph()
sage: G.order()
10

sage: G = graphs.TetrahedralGraph()
sage: len(G)
4
```

number_of_loops()
Returns the number of edges that are loops.
EXAMPLE:

```
sage: G = Graph(4, loops=True)
sage: G.add_edges( [ (0,0), (1,1), (2,2), (3,3), (2,3) ] )
sage: G.edges(labels=False)
[(0, 0), (1, 1), (2, 2), (2, 3), (3, 3)]
sage: G.number_of_loops()
4

sage: D = DiGraph(4, loops=True)
sage: D.add_edges( [ (0,0), (1,1), (2,2), (3,3), (2,3) ] )
sage: D.edges(labels=False)
[(0, 0), (1, 1), (2, 2), (2, 3), (3, 3)]
sage: D.number_of_loops()
4
```

order()
Returns the number of vertices. Note that len(G) returns the number of vertices in G also.
EXAMPLE:

```
sage: G = graphs.PetersenGraph()
sage: G.order()
10

sage: G = graphs.TetrahedralGraph()
sage: len(G)
4
```

periphery()
Returns the set of vertices in the periphery, i.e. whose eccentricity is equal to the diameter of the (di)graph.
In other words, the periphery is the set of vertices achieving the maximum eccentricity.
EXAMPLES:

```
sage: G = graphs.DiamondGraph()
sage: G.periphery()
[0, 3]
sage: P = graphs.PetersenGraph()
```

```
sage: P.subgraph(P.periphery()) == P
True
sage: S = graphs.StarGraph(19)
sage: S.periphery()
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19]
sage: G = Graph(sparse=True)
sage: G.periphery()
[]
sage: G.add_vertex()
sage: G.periphery()
[0]
```

plot(**args, **kwds*)

Returns a graphics object representing the (di)graph.

INPUT:

- `pos` - an optional positioning dictionary
- `layout` - what kind of layout to use, takes precedence over pos
  - 'circular' – plots the graph with vertices evenly distributed on a circle
  - 'spring' - uses the traditional spring layout, using the graph's current positions as initial positions
  - 'tree' - the (di)graph must be a tree. One can specify the root of the tree using the keyword tree_root, otherwise a root will be selected at random. Then the tree will be plotted in levels, depending on minimum distance for the root.
- `vertex_labels` - whether to print vertex labels
- `edge_labels` - whether to print edge labels. By default, False, but if True, the result of str(l) is printed on the edge for each label l. Labels equal to None are not printed (to set edge labels, see set_edge_label).
- `vertex_size` - size of vertices displayed
- `vertex_shape` - the shape to draw the vertices (Not available for multiedge digraphs.
- `graph_border` - whether to include a box around the graph
- `vertex_colors` - optional dictionary to specify vertex colors: each key is a color recognizable by matplotlib, and each corresponding entry is a list of vertices. If a vertex is not listed, it looks invisible on the resulting plot (it doesn't get drawn).
- `edge_colors` - a dictionary specifying edge colors: each key is a color recognized by matplotlib, and each entry is a list of edges.
- `partition` - a partition of the vertex set. if specified, plot will show each cell in a different color. vertex_colors takes precedence.
- `scaling_term` – default is 0.05. if vertices are getting chopped off, increase; if graph is too small, decrease. should be positive, but values much bigger than 1/8 won't be useful unless the vertices are huge
- `talk` - if true, prints large vertices with white backgrounds so that labels are legible on slides
- `iterations` - how many iterations of the spring layout algorithm to go through, if applicable
- `color_by_label` - if True, color edges by their labels
- `heights` - if specified, this is a dictionary from a set of floating point heights to a set of vertices
- `edge_style` - keyword arguments passed into the edge-drawing routine. This currently only works for directed graphs, since we pass off the undirected graph to networkx
- `tree_root` - a vertex of the tree to be used as the root for the layout="tree" option. If no root is specified, then one is chosen at random. Ignored unless layout='tree'.
- `tree_orientation` - "up" or "down" (default is "down"). If "up" (resp., "down"), then the root of the tree will appear on the bottom (resp., top) and the tree will grow upwards (resp. downwards). Ignored unless layout='tree'.
- `save_pos` - save position computed during plotting

EXAMPLES:

```
sage: from sage.graphs.graph_plot import graphplot_options
sage: list(sorted(graphplot_options.iteritems()))
[...]

sage: from math import sin, cos, pi
sage: P = graphs.PetersenGraph()
sage: d = {'#FF0000':[0,5], '#FF9900':[1,6], '#FFFF00':[2,7], '#00FF00':[3,8], '#0000FF':[4,
sage: pos_dict = {}
sage: for i in range(5):
...     x = float(cos(pi/2 + ((2*pi)/5)*i))
...     y = float(sin(pi/2 + ((2*pi)/5)*i))
...     pos_dict[i] = [x,y]
...
sage: for i in range(10)[5:]:
...     x = float(0.5*cos(pi/2 + ((2*pi)/5)*i))
...     y = float(0.5*sin(pi/2 + ((2*pi)/5)*i))
...     pos_dict[i] = [x,y]
...
sage: pl = P.plot(pos=pos_dict, vertex_colors=d)
sage: pl.show()

sage: C = graphs.CubeGraph(8)
sage: P = C.plot(vertex_labels=False, vertex_size=0, graph_border=True)
sage: P.show()

sage: G = graphs.HeawoodGraph()
sage: for u,v,l in G.edges():
...     G.set_edge_label(u,v,'(' + str(u) + ',' + str(v) + ')')
sage: G.plot(edge_labels=True).show()

sage: D = DiGraph( { 0: [1, 10, 19], 1: [8, 2], 2: [3, 6], 3: [19, 4], 4: [17, 5], 5: [6, 15
sage: for u,v,l in D.edges():
...     D.set_edge_label(u,v,'(' + str(u) + ',' + str(v) + ')')
sage: D.plot(edge_labels=True, layout='circular').show()

sage: from sage.plot.plot import rainbow
sage: C = graphs.CubeGraph(5)
sage: R = rainbow(5)
sage: edge_colors = {}
sage: for i in range(5):
...     edge_colors[R[i]] = []

 8: [0.29..., -0.40...],
 9: [0.47..., 0.15...]}
sage: P = G.plot(save_pos=True, layout='spring')

The following illustrates the format of a position dictionary,
but due to numerical noise we do not check the values themselves.

sage: G.get_pos()
{0: [..., ...],
 1: [..., ...],
 2: [..., ...],
 3: [..., ...],
 4: [..., ...],
 5: [..., ...],
 6: [..., ...],
 7: [..., ...],
 8: [..., ...],
 9: [..., ...]}

sage: T = list(graphs.trees(7))
sage: t = T[3]
sage: t.plot(heights={0:[0], 1:[4,5,1], 2:[2], 3:[3,6]})

sage: T = list(graphs.trees(7))
sage: t = T[3]
sage: t.plot(heights={0:[0], 1:[4,5,1], 2:[2], 3:[3,6]})
sage: t.set_edge_label(0,1,-7)
sage: t.set_edge_label(0,5,3)
sage: t.set_edge_label(0,5,99)
sage: t.set_edge_label(1,2,1000)
sage: t.set_edge_label(3,2,'spam')
```

```
sage: t.set_edge_label(2,6,3/2)
sage: t.set_edge_label(0,4,66)
sage: t.plot(heights={0:[0], 1:[4,5,1], 2:[2], 3:[3,6]}, edge_labels=True)

sage: T = list(graphs.trees(7))
sage: t = T[3]
sage: t.plot(layout='tree')

sage: t = DiGraph('JCC???@A??GO??CO??GO??')
sage: t.plot(layout='tree', tree_root=0, tree_orientation="up")
sage: D = DiGraph({0:[1,2,3], 2:[1,4], 3:[0]})
sage: D.plot()

sage: D = DiGraph(multiedges=True)
sage: for i in range(5):
...       D.add_edge((i,i+1,'a'))
...       D.add_edge((i,i-1,'b'))
sage: D.plot(edge_labels=True,edge_colors=D._color_by_label())

sage: g = Graph({}, loops=True, multiedges=True)
sage: g.add_edges([(0,0,'a'),(0,0,'b'),(0,1,'c'),(0,1,'d'),
...       (0,1,'e'),(0,1,'f'),(0,1,'f'),(2,1,'g'),(2,2,'h')])
sage: g.plot(edge_labels=True, color_by_label=True, edge_style='dashed')

sage: S = SupersingularModule(389)
sage: H = S.hecke_matrix(2)
sage: D = DiGraph(H)
sage: P = D.plot()

sage: G=Graph({'a':['a','b','b','b','e'],'b':['c','d','e'],'c':['c','d','d','d'],'d':['e']})
sage: G.show(pos={'a':[0,1],'b':[1,1],'c':[2,0],'d':[1,0],'e':[0,0]})
```

plot3d(*bgcolor=(1, 1, 1), vertex_colors=None, vertex_size=0.059999999999999998, edge_colors=None, edge_size=0.02, edge_size2=0.032500000000000001, pos3d=None, iterations=50, color_by_label=False, engine='jmol', **kwds*)

Plot a graph in three dimensions.

INPUT:

- `bgcolor` - rgb tuple (default: (1,1,1))
- `vertex_size` - float (default: 0.06)
- `vertex_colors` - optional dictionary to specify vertex colors: each key is a color recognizable by tachyon (rgb tuple (default: (1,0,0))), and each corresponding entry is a list of vertices. If a vertex is not listed, it looks invisible on the resulting plot (it doesn't get drawn).
- `edge_colors` - a dictionary specifying edge colors: each key is a color recognized by tachyon (default: (0,0,0)), and each entry is a list of edges.
- `edge_size` - float (default: 0.02)
- `edge_size2` - float (default: 0.0325), used for Tachyon sleeves
- `pos3d` - a position dictionary for the vertices
- `iterations` - how many iterations of the spring layout algorithm to go through, if applicable
- `engine` - which renderer to use. Options:
  - `'jmol'` - default
  - `'tachyon'`
- `xres` - resolution
- `yres` - resolution
- `**kwds` - passed on to the rendering engine

EXAMPLES:

```
sage: G = graphs.CubeGraph(5)
sage: G.plot3d(iterations=500, edge_size=None, vertex_size=0.04)
```

We plot a fairly complicated Cayley graph:

```
sage: A5 = AlternatingGroup(5); A5
Alternating group of order 5!/2 as a permutation group
sage: G = A5.cayley_graph()
sage: G.plot3d(vertex_size=0.03, edge_size=0.01, vertex_colors={(1,1,1):G.vertices()}, bgcol
```

Some Tachyon examples:

```
sage: D = graphs.DodecahedralGraph()
sage: P3D = D.plot3d(engine='tachyon')
sage: P3D.show() # long time

sage: G = graphs.PetersenGraph()
sage: G.plot3d(engine='tachyon', vertex_colors={(0,0,1):G.vertices()}).show() # long time

sage: C = graphs.CubeGraph(4)
sage: C.plot3d(engine='tachyon', edge_colors={(0,1,0):C.edges()}, vertex_colors={(1,1,1):C.v

sage: K = graphs.CompleteGraph(3)
sage: K.plot3d(engine='tachyon', edge_colors={(1,0,0):[(0,1,None)], (0,1,0):[(0,2,None)], (0
```

A directed version of the dodecahedron

```
sage: D = DiGraph( { 0: [1, 10, 19], 1: [8, 2], 2: [3, 6], 3: [19, 4], 4: [17, 5], 5: [6, 15
sage: D.plot3d().show() # long time

sage: P = graphs.PetersenGraph().to_directed()
sage: from sage.plot.all import rainbow
sage: edges = P.edges()
sage: R = rainbow(len(edges), 'rgbtuple')
sage: edge_colors = {}
sage: for i in range(len(edges)):
...       edge_colors[R[i]] = [edges[i]]
sage: P.plot3d(engine='tachyon', edge_colors=edge_colors).show() # long time

sage: G=Graph({'a':['a','b','b','b','e'],'b':['c','d','e'],'c':['c','d','d','d'],'d':['e']})
sage: G.show3d()
...
NotImplementedError: 3D plotting of multiple edges or loops not implemented.
```

radius()

Returns the radius of the (di)graph.

The radius is defined to be the minimum eccentricity of any vertex, where the eccentricity is the maximum distance to any other vertex.

EXAMPLES: The more symmetric a graph is, the smaller (diameter - radius) is.

```
sage: G = graphs.BarbellGraph(9, 3)
sage: G.radius()
3
sage: G.diameter()
6

sage: G = graphs.OctahedralGraph()
sage: G.radius()
```

```
2
sage: G.diameter()
2
```

random_subgraph (*p, inplace=False*)

Return a random subgraph that contains each vertex with prob. p.

EXAMPLE:

```
sage: P = graphs.PetersenGraph()
sage: P.random_subgraph(.25)
Subgraph of (Petersen graph): Graph on 4 vertices
```

relabel (*perm=None, inplace=True, return_map=False*)

Uses a dictionary, list, or permutation to relabel the (di)graph. If perm is a dictionary d, each old vertex v is a key in the dictionary, and its new label is d[v].

If perm is a list, we think of it as a map $i \mapsto perm[i]$ with the assumption that the vertices are $\{0, 1, ..., n-1\}$.

If perm is a permutation, the permutation is simply applied to the graph, under the assumption that the vertices are $\{0, 1, ..., n-1\}$. The permutation acts on the set $\{1, 2, ..., n\}$, where we think of $n = 0$.

If no arguments are provided, the graph is relabeled to be on the vertices $\{0, 1, ..., n-1\}$.

INPUT:

- `inplace` - default is True. If True, modifies the graph and returns nothing. If False, returns a relabeled copy of the graph.
- `return_map` - default is False. If True, returns the dictionary representing the map.

EXAMPLES:

```
sage: G = graphs.PathGraph(3)
sage: G.am()
[0 1 0]
[1 0 1]
[0 1 0]
```

Relabeling using a dictionary:

```
sage: G.relabel({1:2,2:1}, inplace=False).am()
[0 0 1]
[0 0 1]
[1 1 0]
```

Relabeling using a list:

```
sage: G.relabel([0,2,1], inplace=False).am()
[0 0 1]
[0 0 1]
[1 1 0]
```

Relabeling using a Sage permutation:

```
sage: from sage.groups.perm_gps.permgroup_named import SymmetricGroup
sage: S = SymmetricGroup(3)
sage: gamma = S('(1,2)')
sage: G.relabel(gamma, inplace=False).am()
[0 0 1]
[0 0 1]
[1 1 0]
```

Relabeling to simpler labels:

```
sage: G = graphs.CubeGraph(3)
sage: G.vertices()
['000', '001', '010', '011', '100', '101', '110', '111']
sage: G.relabel()
sage: G.vertices()
[0, 1, 2, 3, 4, 5, 6, 7]

sage: G = graphs.CubeGraph(3)
sage: expecting = {'000': 0, '001': 1, '010': 2, '011': 3, '100': 4, '101': 5, '110': 6, '11
sage: G.relabel(return_map=True) == expecting
True
```

TESTS:

```
sage: P = Graph(graphs.PetersenGraph(), sparse=True)
sage: P.delete_edge([0,1])
sage: P.add_edge((4,5))
sage: P.add_edge((2,6))
sage: P.delete_vertices([0,1])
sage: P.relabel()
```

The attributes are properly updated too

```
sage: G = graphs.PathGraph(5)
sage: G.set_vertices({0: 'before', 1: 'delete', 2: 'after'})
sage: G.set_boundary([1,2,3])
sage: G.delete_vertex(1)
sage: G.relabel()
sage: G.get_vertices()
{0: 'before', 1: 'after', 2: None, 3: None}
sage: G.get_boundary()
[1, 2]
sage: G.get_pos()
{0: [0, 0], 1: [2, 0], 2: [3, 0], 3: [4, 0]}
```

remove_loops(*vertices=None*)

Removes loops on vertices in vertices. If vertices is None, removes all loops.

EXAMPLE

```
sage: G = Graph(4, loops=True)
sage: G.add_edges( [ (0,0), (1,1), (2,2), (3,3), (2,3) ] )
sage: G.edges(labels=False)
[(0, 0), (1, 1), (2, 2), (2, 3), (3, 3)]
sage: G.remove_loops()
sage: G.edges(labels=False)
[(2, 3)]
sage: G.allows_loops()
True
sage: G.has_loops()
False

sage: D = DiGraph(4, loops=True)
sage: D.add_edges( [ (0,0), (1,1), (2,2), (3,3), (2,3) ] )
sage: D.edges(labels=False)
[(0, 0), (1, 1), (2, 2), (2, 3), (3, 3)]
sage: D.remove_loops()
sage: D.edges(labels=False)
[(2, 3)]
sage: D.allows_loops()
True
```

```
sage: D.has_loops()
False
```

remove_multiple_edges()

Removes all multiple edges, retaining one edge for each.

EXAMPLE:

```
sage: G = Graph(multiedges=True, implementation='networkx')
sage: G.add_edges( [ (0,1), (0,1), (0,1), (0,1), (1,2) ] )
sage: G.edges(labels=False)
[(0, 1), (0, 1), (0, 1), (0, 1), (1, 2)]

sage: G.remove_multiple_edges()
sage: G.edges(labels=False)
[(0, 1), (1, 2)]

sage: D = DiGraph(multiedges=True)
sage: D.add_edges( [ (0,1,1), (0,1,2), (0,1,3), (0,1,4), (1,2) ] )
sage: D.edges(labels=False)
[(0, 1), (0, 1), (0, 1), (0, 1), (1, 2)]
sage: D.remove_multiple_edges()
sage: D.edges(labels=False)
[(0, 1), (1, 2)]
```

set_boundary(*boundary*)

Sets the boundary of the (di)graph.

EXAMPLE:

```
sage: G = graphs.PetersenGraph()
sage: G.set_boundary([0,1,2,3,4])
sage: G.get_boundary()
[0, 1, 2, 3, 4]
sage: G.set_boundary((1..4))
sage: G.get_boundary()
[1, 2, 3, 4]
```

set_edge_label(*u, v, l*)

Set the edge label of a given edge.

Note: There can be only one edge from u to v for this to make sense. Otherwise, an error is raised.

INPUT:

- `u, v` - the vertices (and direction if digraph) of the edge
- `l` - the new label

EXAMPLES:

```
sage: SD = DiGraph( { 1:[18,2], 2:[5,3], 3:[4,6], 4:[7,2], 5:[4], 6:[13,12], 7:[18,8,10], 8:
sage: SD.set_edge_label(1, 18, 'discrete')
sage: SD.set_edge_label(4, 7, 'discrete')
sage: SD.set_edge_label(2, 5, 'h = 0')
sage: SD.set_edge_label(7, 18, 'h = 0')
sage: SD.set_edge_label(7, 10, 'aut')
sage: SD.set_edge_label(8, 10, 'aut')
sage: SD.set_edge_label(8, 9, 'label')
sage: SD.set_edge_label(8, 6, 'no label')
sage: SD.set_edge_label(13, 17, 'k > h')
sage: SD.set_edge_label(13, 14, 'k = h')
sage: SD.set_edge_label(17, 15, 'v_k finite')
sage: SD.set_edge_label(14, 15, 'v_k m.c.r.')
```

```
sage: posn = {1:[ 3,-3],  2:[0,2],  3:[0, 13],  4:[3,9],  5:[3,3],  6:[16, 13], 7:[6,1],  8:
sage: SD.plot(pos=posn, vertex_size=400, vertex_colors={'#FFFFFF':range(1,19)}, edge_labels=

sage: G = graphs.HeawoodGraph()
sage: for u,v,l in G.edges():
...     G.set_edge_label(u,v,'(' + str(u) + ',' + str(v) + ')')
sage: G.edges()
    [(0, 1, '(0,1)'),
     (0, 5, '(0,5)'),
     (0, 13, '(0,13)'),
     ...
     (11, 12, '(11,12)'),
     (12, 13, '(12,13)')]

sage: g = Graph({0: [0,1,1,2]}, loops=True, multiedges=True, implementation='networkx')
sage: g.set_edge_label(0,0,'test')
sage: g.edges()
[(0, 0, 'test'), (0, 1, None), (0, 1, None), (0, 2, None)]
sage: g.add_edge(0,0,'test2')
sage: g.set_edge_label(0,0,'test3')
...
RuntimeError: Cannot set edge label, since there are multiple edges from 0 to 0.

sage: dg = DiGraph({0 : [1], 1 : [0]}, sparse=True)
sage: dg.set_edge_label(0,1,5)
sage: dg.set_edge_label(1,0,9)
sage: dg.outgoing_edges(1)
[(1, 0, 9)]
sage: dg.incoming_edges(1)
[(0, 1, 5)]
sage: dg.outgoing_edges(0)
[(0, 1, 5)]
sage: dg.incoming_edges(0)
[(1, 0, 9)]

sage: G = Graph({0:{1:1}}, implementation='c_graph')
sage: G.num_edges()
1
sage: G.set_edge_label(0,1,1)
sage: G.num_edges()
1
```

set_embedding(*embedding*)

Sets a combinatorial embedding dictionary to _embedding attribute. Dictionary is organized with vertex labels as keys and a list of each vertex's neighbors in clockwise order.

Dictionary is error-checked for validity.

INPUT:

- `embedding` - a dictionary

EXAMPLES:

```
sage: G = graphs.PetersenGraph()
sage: G.set_embedding({0: [1, 5, 4], 1: [0, 2, 6], 2: [1, 3, 7], 3: [8, 2, 4], 4: [0, 9, 3],
sage: G.set_embedding({'s': [1, 5, 4], 1: [0, 2, 6], 2: [1, 3, 7], 3: [8, 2, 4], 4: [0, 9, 3
...
Exception: embedding is not valid for Petersen graph
```

set_planar_positions(*set_embedding=False, on_embedding=None, external_face=None, test=False, circular=False*)

Uses Schnyder's algorithm to determine positions for a planar embedding of self, raising an error if self is not planar.

INPUT:

- `set_embedding` - if True, sets the combinatorial embedding used (see self.get_embedding())
- `on_embedding` - dict: provide a combinatorial embedding
- `external_face` - ignored
- `test` - if True, perform sanity tests along the way
- `circular` - ignored

EXAMPLES:

```
sage: g = graphs.PathGraph(10)
sage: g.set_planar_positions(test=True)
True
sage: g = graphs.BalancedTree(3,4)
sage: g.set_planar_positions(test=True)
True
sage: g = graphs.CycleGraph(7)
sage: g.set_planar_positions(test=True)
True
sage: g = graphs.CompleteGraph(5)
sage: g.set_planar_positions(test=True,set_embedding=True)
...
Exception: Complete graph is not a planar graph.
```

set_pos (*pos*)

Sets the position dictionary, a dictionary specifying the coordinates of each vertex.

EXAMPLE: Note that set_pos will allow you to do ridiculous things, which will not blow up until plotting:

```
sage: G = graphs.PetersenGraph()
sage: G.get_pos()
{0: [..., ...],
 ...
 9: [..., ...]}

sage: G.set_pos('spam')
sage: P = G.plot()
...
TypeError: string indices must be integers
```

set_vertex (*vertex, object*)

Associate an arbitrary object with a vertex.

INPUT:

- `vertex` - which vertex
- `object` - object to associate to vertex

EXAMPLE:

```
sage: T = graphs.TetrahedralGraph()
sage: T.vertices()
[0, 1, 2, 3]
sage: T.set_vertex(1, graphs.FlowerSnark())
sage: T.get_vertex(1)
Flower Snark: Graph on 20 vertices
```

set_vertices (*vertex_dict*)

Associate arbitrary objects with each vertex, via an association dictionary.

INPUT:

- `vertex_dict` - the association dictionary

EXAMPLES:

```
sage: d = {0 : graphs.DodecahedralGraph(), 1 : graphs.FlowerSnark(), 2 : graphs.MoebiusKanto
sage: d[2]
Moebius-Kantor Graph: Graph on 16 vertices
sage: T = graphs.TetrahedralGraph()
sage: T.vertices()
[0, 1, 2, 3]
sage: T.set_vertices(d)
sage: T.get_vertex(1)
Flower Snark: Graph on 20 vertices
```

shortest_path(*u, v, by_weight=False, bidirectional=True*)

Returns a list of vertices representing some shortest path from u to v: if there is no path from u to v, the list is empty.

INPUT:

- `by_weight` - if False, uses a breadth first search. If True, takes edge weightings into account, using Dijkstra's algorithm.
- `bidirectional` - if True, the algorithm will expand vertices from u and v at the same time, making two spheres of half the usual radius. This generally doubles the speed (consider the total volume in each case).

EXAMPLE:

```
sage: D = graphs.DodecahedralGraph()
sage: D.shortest_path(4, 9)
[4, 17, 16, 12, 13, 9]
sage: D.shortest_path(5, 5)
[5]
sage: D.delete_edges(D.edges_incident(13))
sage: D.shortest_path(13, 4)
[]
sage: G = Graph( { 0: {1: 1}, 1: {2: 1}, 2: {3: 1}, 3: {4: 2}, 4: {0: 2} }, sparse=True )
sage: G.plot(edge_labels=True).show()
sage: G.shortest_path(0, 3)
[0, 4, 3]
sage: G.shortest_path(0, 3, by_weight=True)
[0, 1, 2, 3]
```

shortest_path_all_pairs(*by_weight=True, default_weight=1*)

Uses the Floyd-Warshall algorithm to find a shortest weighted path for each pair of vertices.

The weights (labels) on the vertices can be anything that can be compared and can be summed.

INPUT:

- `by_weight` - If False, figure distances by the numbers of edges.
- `default_weight` - (defaults to 1) The default weight to assign edges that don't have a weight (i.e., a label).

OUTPUT: A tuple (dist, pred). They are both dicts of dicts. The first indicates the length dist[u][v] of the shortest weighted path from u to v. The second is more complicated- it indicates the predecessor pred[u][v] of v in the shortest path from u to v.

EXAMPLE:

```
sage: G = Graph( { 0: {1: 1}, 1: {2: 1}, 2: {3: 1}, 3: {4: 2}, 4: {0: 2} }, sparse=True )
sage: G.plot(edge_labels=True).show()
sage: dist, pred = G.shortest_path_all_pairs()
sage: dist
```

```
{0: {0: 0, 1: 1, 2: 2, 3: 3, 4: 2}, 1: {0: 1, 1: 0, 2: 1, 3: 2, 4: 3}, 2: {0: 2, 1: 1, 2: 0,
sage: pred
{0: {0: None, 1: 0, 2: 1, 3: 2, 4: 0}, 1: {0: 1, 1: None, 2: 1, 3: 2, 4: 0}, 2: {0: 1, 1: 2,
sage: pred[0]
{0: None, 1: 0, 2: 1, 3: 2, 4: 0}
```

So for example the shortest weighted path from 0 to 3 is obtained as follows. The predecessor of 3 is pred[0][3] == 2, the predecessor of 2 is pred[0][2] == 1, and the predecessor of 1 is pred[0][1] == 0.

```
sage: G = Graph( { 0: {1:None}, 1: {2:None}, 2: {3: 1}, 3: {4: 2}, 4: {0: 2} }, sparse=True
sage: G.shortest_path_all_pairs(by_weight=False)
({0: {0: 0, 1: 1, 2: 2, 3: 2, 4: 1},
1: {0: 1, 1: 0, 2: 1, 3: 2, 4: 2},
2: {0: 2, 1: 1, 2: 0, 3: 1, 4: 2},
3: {0: 2, 1: 2, 2: 1, 3: 0, 4: 1},
4: {0: 1, 1: 2, 2: 2, 3: 1, 4: 0}},
{0: {0: None, 1: 0, 2: 1, 3: 4, 4: 0},
1: {0: 1, 1: None, 2: 1, 3: 2, 4: 0},
2: {0: 1, 1: 2, 2: None, 3: 2, 4: 3},
3: {0: 4, 1: 2, 2: 3, 3: None, 4: 3},
4: {0: 4, 1: 0, 2: 3, 3: 4, 4: None}})
sage: G.shortest_path_all_pairs()
({0: {0: 0, 1: 1, 2: 2, 3: 3, 4: 2},
1: {0: 1, 1: 0, 2: 1, 3: 2, 4: 3},
2: {0: 2, 1: 1, 2: 0, 3: 1, 4: 3},
3: {0: 3, 1: 2, 2: 1, 3: 0, 4: 2},
4: {0: 2, 1: 3, 2: 3, 3: 2, 4: 0}},
{0: {0: None, 1: 0, 2: 1, 3: 2, 4: 0},
1: {0: 1, 1: None, 2: 1, 3: 2, 4: 0},
2: {0: 1, 1: 2, 2: None, 3: 2, 4: 3},
3: {0: 1, 1: 2, 2: 3, 3: None, 4: 3},
4: {0: 4, 1: 0, 2: 3, 3: 4, 4: None}})
sage: G.shortest_path_all_pairs(default_weight=200)
({0: {0: 0, 1: 200, 2: 5, 3: 4, 4: 2},
1: {0: 200, 1: 0, 2: 200, 3: 201, 4: 202},
2: {0: 5, 1: 200, 2: 0, 3: 1, 4: 3},
3: {0: 4, 1: 201, 2: 1, 3: 0, 4: 2},
4: {0: 2, 1: 202, 2: 3, 3: 2, 4: 0}},
{0: {0: None, 1: 0, 2: 3, 3: 4, 4: 0},
1: {0: 1, 1: None, 2: 1, 3: 2, 4: 0},
2: {0: 4, 1: 2, 2: None, 3: 2, 4: 3},
3: {0: 4, 1: 2, 2: 3, 3: None, 4: 3},
4: {0: 4, 1: 0, 2: 3, 3: 4, 4: None}})
```

shortest_path_length(*u, v, by_weight=False, bidirectional=True, weight_sum=None*)

Returns the minimal length of paths from u to v: if there is no path from u to v, returns Infinity.

INPUT:

- `by_weight` - if False, uses a breadth first search. If True, takes edge weightings into account, using Dijkstra's algorithm.
- `bidirectional` - if True, the algorithm will expand vertices from u and v at the same time, making two spheres of half the usual radius. This generally doubles the speed (consider the total volume in each case).
- `weight_sum` - if False, returns the number of edges in the path. If True, returns the sum of the weights of these edges. Default behavior is to have the same value as by_weight.

EXAMPLE:

```
sage: D = graphs.DodecahedralGraph()
sage: D.shortest_path_length(4, 9)
5
sage: D.shortest_path_length(5, 5)
0
sage: D.delete_edges(D.edges_incident(13))
sage: D.shortest_path_length(13, 4)
+Infinity
sage: G = Graph( { 0: {1: 1}, 1: {2: 1}, 2: {3: 1}, 3: {4: 2}, 4: {0: 2} }, sparse=True )
sage: G.plot(edge_labels=True).show()
sage: G.shortest_path_length(0, 3)
2
sage: G.shortest_path_length(0, 3, by_weight=True)
3
```

shortest_path_lengths(*u, by_weight=False, weight_sums=None*)

Returns a dictionary of shortest path lengths keyed by targets that are connected by a path from u.

INPUT:

- `by_weight` - if False, uses a breadth first search. If True, takes edge weightings into account, using Dijkstra's algorithm.
- `weight_sums` - if False, returns the number of edges in each path. If True, returns the sum of the weights of these edges. Default behavior is to have the same value as by_weight.

EXAMPLES:

```
sage: D = graphs.DodecahedralGraph()
sage: D.shortest_path_lengths(0)
{0: 0, 1: 1, 2: 2, 3: 2, 4: 3, 5: 4, 6: 3, 7: 3, 8: 2, 9: 2, 10: 1, 11: 2, 12: 3, 13: 3, 14:
sage: G = Graph( { 0: {1: 1}, 1: {2: 1}, 2: {3: 1}, 3: {4: 2}, 4: {0: 2} }, sparse=True )
sage: G.plot(edge_labels=True).show()
sage: G.shortest_path_lengths(0, by_weight=True)
{0: 0, 1: 1, 2: 2, 3: 3, 4: 2}
```

shortest_paths(*u, by_weight=False, cutoff=None*)

Returns a dictionary d of shortest paths d[v] from u to v, for each vertex v connected by a path from u.

INPUT:

- `by_weight` - if False, uses a breadth first search. If True, uses Dijkstra's algorithm to find the shortest paths by weight.
- `cutoff` - integer depth to stop search. Ignored if by_weight is True.

EXAMPLES:

```
sage: D = graphs.DodecahedralGraph()
sage: D.shortest_paths(0)
{0: [0], 1: [0, 1], 2: [0, 1, 2], 3: [0, 19, 3], 4: [0, 19, 3, 4], 5: [0, 19, 3, 4, 5], 6: [
sage: D.shortest_paths(0, cutoff=2)
{0: [0], 1: [0, 1], 2: [0, 1, 2], 3: [0, 19, 3], 8: [0, 1, 8], 9: [0, 10, 9], 10: [0, 10], 1
sage: G = Graph( { 0: {1: 1}, 1: {2: 1}, 2: {3: 1}, 3: {4: 2}, 4: {0: 2} }, sparse=True )
sage: G.plot(edge_labels=True).show()
sage: G.shortest_paths(0, by_weight=True)
{0: [0], 1: [0, 1], 2: [0, 1, 2], 3: [0, 1, 2, 3], 4: [0, 4]}
```

show(***kwds*)

Shows the (di)graph.

For syntax and lengthy documentation, see G.plot?. Any options not used by plot will be passed on to the Graphics.show method.

EXAMPLE:

```
sage: C = graphs.CubeGraph(8)
sage: P = C.plot(vertex_labels=False, vertex_size=0, graph_border=True)
sage: P.show()
```

show3d(*bgcolor=(1, 1, 1), vertex_colors=None, vertex_size=0.059999999999999998, edge_colors=None, edge_size=0.02, edge_size2=0.032500000000000001, pos3d=None, iterations=50, color_by_label=False, engine='jmol', **kwds*)

Plots the graph using Tachyon, and shows the resulting plot.

INPUT:

- `bgcolor` - rgb tuple (default: (1,1,1))
- `vertex_size` - float (default: 0.06)
- `vertex_colors` - optional dictionary to specify vertex colors: each key is a color recognizable by tachyon (rgb tuple (default: (1,0,0))), and each corresponding entry is a list of vertices. If a vertex is not listed, it looks invisible on the resulting plot (it doesn't get drawn).
- `edge_colors` - a dictionary specifying edge colors: each key is a color recognized by tachyon (default: (0,0,0)), and each entry is a list of edges.
- `edge_size` - float (default: 0.02)
- `edge_size2` - float (default: 0.0325), used for Tachyon sleeves
- `pos3d` - a position dictionary for the vertices
- `iterations` - how many iterations of the spring layout algorithm to go through, if applicable
- `engine` - which renderer to use. Options:
- `'jmol'` - default 'tachyon'
- `xres` - resolution
- `yres` - resolution
- `**kwds` - passed on to the Tachyon command

EXAMPLES:

```
sage: G = graphs.CubeGraph(5)
sage: G.show3d(iterations=500, edge_size=None, vertex_size=0.04)
```

We plot a fairly complicated Cayley graph:

```
sage: A5 = AlternatingGroup(5); A5
Alternating group of order 5!/2 as a permutation group
sage: G = A5.cayley_graph()
sage: G.show3d(vertex_size=0.03, edge_size=0.01, edge_size2=0.02, vertex_colors={(1,1,1):G.v
```

Some Tachyon examples:

```
sage: D = graphs.DodecahedralGraph()
sage: D.show3d(engine='tachyon') # long time

sage: G = graphs.PetersenGraph()
sage: G.show3d(engine='tachyon', vertex_colors={(0,0,1):G.vertices()}) # long time

sage: C = graphs.CubeGraph(4)
sage: C.show3d(engine='tachyon', edge_colors={(0,1,0):C.edges()}, vertex_colors={(1,1,1):C.v

sage: K = graphs.CompleteGraph(3)
sage: K.show3d(engine='tachyon', edge_colors={(1,0,0):[(0,1,None)], (0,1,0):[(0,2,None)], (0
```

size()

Returns the number of edges.

EXAMPLE:

```
sage: G = graphs.PetersenGraph()
sage: G.size()
15
```

spectrum(*laplacian=False*)

Returns the spectrum of the graph, the eigenvalues of the adjacency matrix

INPUT:

- `laplacian` - if True, use the Laplacian matrix instead (see self.kirchhoff_matrix())

EXAMPLE:

```
sage: P = graphs.PetersenGraph()
sage: P.spectrum()
[-2.0, -2.0, -2.0, -2.0, 1.0, 1.0, 1.0, 1.0, 1.0, 3.0]
```

Due to numerical imprecision the first entry for the spectrum below is zero or near zero:

```
sage: P.spectrum(laplacian=True)
[..., 2.0, 2.0, 2.0, 2.0, 2.0, 5.0, 5.0, 5.0, 5.0]

sage: D = P.to_directed()
sage: D.delete_edge(7,9)
sage: D.spectrum()
[-2.0, -2.0, -2.0, -1.7..., 0.8..., 1.0, 1.0, 1.0, 1.0, 2.9...]
```

strong_product(*other*)

Returns the strong product of self and other.

The strong product of G and H is the graph L with vertex set V(L) equal to the Cartesian product of the vertices V(G) and V(H), and ((u,v), (w,x)) is an edge iff either - (u, w) is an edge of self and v = x, or - (v, x) is an edge of other and u = w, or - (u, w) is an edge of self and (v, x) is an edge of other. In other words, the edges of the strong product is the union of the edges of the tensor and Cartesian products.

EXAMPLES:

```
sage: Z = graphs.CompleteGraph(2)
sage: C = graphs.CycleGraph(5)
sage: S = C.strong_product(Z); S
Graph on 10 vertices
sage: S.plot().show()

sage: D = graphs.DodecahedralGraph()
sage: P = graphs.PetersenGraph()
sage: S = D.strong_product(P); S
Graph on 200 vertices
sage: S.plot().show()
```

subgraph(*vertices=None, edges=None, inplace=False, vertex_property=None, edge_property=None*)

Returns the subgraph containing the given vertices and edges. If either vertices or edges are not specified, they are assumed to be all vertices or edges. If edges are not specified, returns the subgraph induced by the vertices.

INPUT:

- `inplace` - Using inplace is True will simply delete the extra vertices and edges from the current graph. This will modify the graph.
- `vertices` - Vertices can be a single vertex or an iterable container of vertices, e.g. a list, set, graph, file or numeric array. If not passed, defaults to the entire graph.
- `edges` - As with vertices, edges can be a single edge or an iterable container of edges (e.g., a list, set, file, numeric array, etc.). If not edges are not specified, then all edges are assumed and the returned graph is an induced subgraph. In the case of multiple edges, specifying an edge as (u,v) means to keep all edges (u,v), regardless of the label.

- `vertex_property` - If specified, this is expected to be a function on vertices, which is intersected with the vertices specified, if any are.
- `edge_property` - If specified, this is expected to be a function on edges, which is intersected with the edges specified, if any are.

EXAMPLES:

```
sage: G = graphs.CompleteGraph(9)
sage: H = G.subgraph([0,1,2]); H
Subgraph of (Complete graph): Graph on 3 vertices
sage: G
Complete graph: Graph on 9 vertices
sage: J = G.subgraph(edges=[(0,1)])
sage: J.edges(labels=False)
[(0, 1)]
sage: J.vertices()==G.vertices()
True
sage: G.subgraph([0,1,2], inplace=True); G
Subgraph of (Complete graph): Graph on 3 vertices
sage: G.subgraph()==G
True

sage: D = graphs.CompleteGraph(9).to_directed()
sage: H = D.subgraph([0,1,2]); H
Subgraph of (Complete graph): Digraph on 3 vertices
sage: H = D.subgraph(edges=[(0,1), (0,2)])
sage: H.edges(labels=False)
[(0, 1), (0, 2)]
sage: H.vertices()==D.vertices()
True
sage: D
Complete graph: Digraph on 9 vertices
sage: D.subgraph([0,1,2], inplace=True); D
Subgraph of (Complete graph): Digraph on 3 vertices
sage: D.subgraph()==D
True
```

A more complicated example involving multiple edges and labels.

```
sage: G = Graph(multiedges=True, implementation='networkx')
sage: G.add_edges([(0,1,'a'), (0,1,'b'), (1,0,'c'), (0,2,'d'), (0,2,'e'), (2,0,'f'), (1,2,'g
sage: G.subgraph(edges=[(0,1), (0,2,'d'), (0,2,'not in graph')]).edges()
[(0, 1, 'a'), (0, 1, 'b'), (0, 1, 'c'), (0, 2, 'd')]
sage: J = G.subgraph(vertices=[0,1], edges=[(0,1,'a'), (0,2,'c')])
sage: J.edges()
[(0, 1, 'a')]
sage: J.vertices()
[0, 1]

sage: D = DiGraph(multiedges=True, implementation='networkx')
sage: D.add_edges([(0,1,'a'), (0,1,'b'), (1,0,'c'), (0,2,'d'), (0,2,'e'), (2,0,'f'), (1,2,'g
sage: D.subgraph(edges=[(0,1), (0,2,'d'), (0,2,'not in graph')]).edges()
[(0, 1, 'a'), (0, 1, 'b'), (0, 2, 'd')]
sage: H = D.subgraph(vertices=[0,1], edges=[(0,1,'a'), (0,2,'c')])
sage: H.edges()
[(0, 1, 'a')]
sage: H.vertices()
[0, 1]
```

Using the property arguments:

```
sage: P = graphs.PetersenGraph()
sage: S = P.subgraph(vertex_property = lambda v : v%2 == 0)
sage: S.vertices()
[0, 2, 4, 6, 8]

sage: C = graphs.CubeGraph(2)
sage: S = C.subgraph(edge_property=(lambda e: e[0][0] == e[1][0]))
sage: C.edges()
[('00', '01', None),
 ('10', '00', None),
 ('11', '01', None),
 ('11', '10', None)]
sage: S.edges()
[('00', '01', None), ('11', '10', None)]
```

TESTS: We should delete unused _pos dictionary entries

```
sage: g = graphs.PathGraph(10)
sage: h = g.subgraph([3..5])
sage: h._pos.keys()
[3, 4, 5]
```

tensor_product(*other*)

Returns the tensor product, also called the categorical product, of self and other.

The tensor product of G and H is the graph L with vertex set V(L) equal to the Cartesian product of the vertices V(G) and V(H), and ((u,v), (w,x)) is an edge iff - (u, w) is an edge of self, and - (v, x) is an edge of other.

EXAMPLES:

```
sage: Z = graphs.CompleteGraph(2)
sage: C = graphs.CycleGraph(5)
sage: T = C.tensor_product(Z); T
Graph on 10 vertices
sage: T.plot().show()

sage: D = graphs.DodecahedralGraph()
sage: P = graphs.PetersenGraph()
sage: T = D.tensor_product(P); T
Graph on 200 vertices
sage: T.plot().show()
```

to_simple()

Returns a simple version of itself (i.e., undirected and loops and multiple edges are removed).

EXAMPLE:

```
sage: G = DiGraph(loops=True,multiedges=True,sparse=True)
sage: G.add_edges( [ (0,0), (1,1), (2,2), (2,3,1), (2,3,2), (3,2) ] )
sage: G.edges(labels=False)
[(0, 0), (1, 1), (2, 2), (2, 3), (2, 3), (3, 2)]
sage: H=G.to_simple()
sage: H.edges(labels=False)
[(2, 3)]
sage: H.is_directed()
False
sage: H.allows_loops()
False
sage: H.allows_multiple_edges()
False
```

trace_faces(*comb_emb*)

A helper function for finding the genus of a graph. Given a graph and a combinatorial embedding (rot_sys), this function will compute the faces (returned as a list of lists of edges (tuples) of the particular embedding.

Note - rot_sys is an ordered list based on the hash order of the vertices of graph. To avoid confusion, it might be best to set the rot_sys based on a 'nice_copy' of the graph.

INPUT:

- `comb_emb` - a combinatorial embedding dictionary. Format: v1:[v2,v3], v2:[v1], v3:[v1] (clockwise ordering of neighbors at each vertex.)

EXAMPLES:

```
sage: T = graphs.TetrahedralGraph()
sage: T.trace_faces({0: [1, 3, 2], 1: [0, 2, 3], 2: [0, 3, 1], 3: [0, 1, 2]})
[[(0, 1), (1, 2), (2, 0)],
 [(3, 2), (2, 1), (1, 3)],
 [(2, 3), (3, 0), (0, 2)],
 [(0, 3), (3, 1), (1, 0)]]
```

transitive_closure()

Computes the transitive closure of a graph and returns it. The original graph is not modified.

The transitive closure of a graph G has an edge (x,y) if and only if there is a path between x and y in G.

The transitive closure of any strongly connected component of a graph is a complete graph. In particular, the transitive closure of a connected undirected graph is a complete graph. The transitive closure of a directed acyclic graph is a directed acyclic graph representing the full partial order.

EXAMPLES:

```
sage: g=graphs.PathGraph(4)
sage: g.transitive_closure()==graphs.CompleteGraph(4)
True
sage: g=DiGraph({0:[1,2], 1:[3], 2:[4,5]})
sage: g.transitive_closure().edges(labels=False)
[(0, 1), (0, 2), (0, 3), (0, 4), (0, 5), (1, 3), (2, 4), (2, 5)]
```

transitive_reduction()

Returns a transitive reduction of a graph. The original graph is not modified.

A transitive reduction H of G has a path from x to y if and only if there was a path from x to y in G. Deleting any edge of H destroys this property. A transitive reduction is not unique in general. A transitive reduction has the same transitive closure as the original graph.

A transitive reduction of a complete graph is a tree. A transitive reduction of a tree is itself.

EXAMPLES:

```
sage: g=graphs.PathGraph(4)
sage: g.transitive_reduction()==g
True
sage: g=graphs.CompleteGraph(5)
sage: edges = g.transitive_reduction().edges(); len(edges)
4
sage: g=DiGraph({0:[1,2], 1:[2,3,4,5], 2:[4,5]})
sage: g.transitive_reduction().size()
5
```

union(*other*)

Returns the union of self and other.

If the graphs have common vertices, the common vertices will be identified.

EXAMPLE:

```
sage: G = graphs.CycleGraph(3)
sage: H = graphs.CycleGraph(4)
sage: J = G.union(H); J
Graph on 4 vertices
sage: J.vertices()
[0, 1, 2, 3]
sage: J.edges(labels=False)
[(0, 1), (0, 2), (0, 3), (1, 2), (2, 3)]
```

vertex_boundary(*vertices1, vertices2=None*)

Returns a list of all vertices in the external boundary of vertices1, intersected with vertices2. If vertices2 is None, then vertices2 is the complement of vertices1. This is much faster if vertices1 is smaller than vertices2.

The external boundary of a set of vertices is the union of the neighborhoods of each vertex in the set. Note that in this implementation, since vertices2 defaults to the complement of vertices1, if a vertex v has a loop, then vertex_boundary(v) will not contain v.

In a digraph, the external boundary of a vertex v are those vertices u with an arc (v, u).

EXAMPLE:

```
sage: G = graphs.CubeGraph(4)
sage: l = ['0111', '0000', '0001', '0011', '0010', '0101', '0100', '1111', '1101', '1011', '
sage: G.vertex_boundary(['0000', '1111'], l)
['0111', '0001', '0010', '0100', '1101', '1011']

sage: D = DiGraph({0:[1,2], 3:[0]})
sage: D.vertex_boundary([0])
[1, 2]
```

vertex_iterator(*vertices=None*)

Returns an iterator over the given vertices. Returns False if not given a vertex, sequence, iterator or None. None is equivalent to a list of every vertex. Note that `for v in G` syntax is allowed.

INPUT:

- `vertices` - iterated vertices are these intersected with the vertices of the (di)graph

EXAMPLE:

```
sage: P = graphs.PetersenGraph()
sage: for v in P.vertex_iterator():
...     print v
...
0
1
2
...
8
9

sage: G = graphs.TetrahedralGraph()
sage: for i in G:
...     print i
0
1
2
3
```

Note that since the intersection option is available, the vertex_iterator() function is sub-optimal, speedwise, but note the following optimization:

```
sage: timeit V = P.vertices()                    # not tested
100000 loops, best of 3: 8.85 [micro]s per loop
sage: timeit V = list(P.vertex_iterator())       # not tested
100000 loops, best of 3: 5.74 [micro]s per loop
sage: timeit V = list(P._nxg.adj.iterkeys())     # not tested
100000 loops, best of 3: 3.45 [micro]s per loop
```

In other words, if you want a fast vertex iterator, call the dictionary directly.

vertices(*boundary_first=False*)

Return a list of the vertices.

INPUT:

- `boundary_first` - Return the boundary vertices first.

EXAMPLE:

```
sage: P = graphs.PetersenGraph()
sage: P.vertices()
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

Note that the output of the vertices() function is always sorted. This is sub-optimal, speedwise, but note the following optimizations:

```
sage: timeit V = P.vertices()                      # not tested
100000 loops, best of 3: 8.85 [micro]s per loop
sage: timeit V = list(P.vertex_iterator())         # not tested
100000 loops, best of 3: 5.74 [micro]s per loop
sage: timeit V = list(P._nxg.adj.iterkeys())       # not tested
100000 loops, best of 3: 3.45 [micro]s per loop
```

In other words, if you want a fast vertex iterator, call the dictionary directly.

weighted(*new=None*)

Returns whether the (di)graph is to be considered as a weighted (di)graph.

Note that edge weightings can still exist for (di)graphs G where G.weighted() is False.

EXAMPLE: Here we have two graphs with different labels, but weighted is False for both, so we just check for the presence of edges:

```
sage: G = Graph({0:{1:'a'}}, implementation='networkx')
sage: H = Graph({0:{1:'b'}}, implementation='networkx')
sage: G == H
True
```

Now one is weighted and the other is not, and thus the graphs are not equal.

:: sage: G.weighted(True) sage: H.weighted() False sage: G == H False

However, if both are weighted, then we finally compare 'a' to 'b'.

```
sage: H.weighted(True)
sage: G == H
False
```

weighted_adjacency_matrix(*sparse=True, boundary_first=False*)

Returns the weighted adjacency matrix of the graph. Each vertex is represented by its position in the list returned by the vertices() function.

EXAMPLES:

```
sage: G = Graph(sparse=True, weighted=True)
sage: G.add_edges([(0,1,1),(1,2,2),(0,2,3),(0,3,4)])
sage: M = G.weighted_adjacency_matrix(); M
[0 1 3 4]
```

```
[1 0 2 0]
[3 2 0 0]
[4 0 0 0]
sage: H = Graph(data=M, format='weighted_adjacency_matrix', sparse=True)
sage: H == G
True
```

The following doctest verifies that #4888 is fixed:

```
sage: G = DiGraph({0:{}, 1:{0:1}, 2:{0:1}}, weighted = True)
sage: G.weighted_adjacency_matrix()
[0 0 0]
[1 0 0]
[1 0 0]
```

class Graph(*data=None, pos=None, loops=None, format=None, boundary=, [], weighted=None, implementation='networkx', sparse=True, vertex_labels=True, **kwds*)

Undirected graph.

INPUT:

- `data` - can be any of the following:
  1. A NetworkX digraph
  2. A dictionary of dictionaries
  3. A dictionary of lists
  4. A numpy matrix or ndarray
  5. A Sage adjacency matrix or incidence matrix
  6. A pygraphviz agraph
  7. A SciPy sparse matrix
- `pos` - a positioning dictionary: for example, the spring layout from NetworkX for the 5-cycle is:

```
{0: [-0.91679746, 0.88169588],
 1: [ 0.47294849, 1.125     ],
 2: [ 1.125     ,-0.12867615],
 3: [ 0.12743933,-1.125     ],
 4: [-1.125     ,-0.50118505]}
```

- `name` - (must be an explicitly named parameter, i.e., name="complete") gives the graph a name
- `loops` - boolean, whether to allow loops (ignored if data is an instance of the Graph class)
- `multiedges` - boolean, whether to allow multiple edges (ignored if data is an instance of the Graph class)
- `weighted` - whether graph thinks of itself as weighted or not. See self.weighted()
- `format` - if None, Graph tries to guess- can be several values, including:
  - `'graph6'` - Brendan McKay's graph6 format, in a string (if the string has multiple graphs, the first graph is taken)
  - `'sparse6'` - Brendan McKay's sparse6 format, in a string (if the string has multiple graphs, the first graph is taken)
  - `'adjacency_matrix'` - a square Sage matrix M, with M[i,j] equal to the number of edges {i,j}
  - `'weighted_adjacency_matrix'` - a square Sage matrix M, with M[i,j] equal to the weight of the single edge {i,j}. Given this format, weighted is ignored (assumed True).
  - `'incidence_matrix'` - a Sage matrix, with one column C for each edge, where if C represents {i, j}, C[i] is -1 and C[j] is 1
  - `'elliptic_curve_congruence'` - data must be an iterable container of elliptic curves, and the graph produced has each curve as a vertex (it's Cremona label) and an edge E-F labelled p if and only if E is congruent to F mod p

- `boundary` - a list of boundary vertices, if empty, graph is considered as a 'graph without boundary'
- `implementation` - what to use as a backend for the graph. Currently, the options are either 'networkx' or 'c_graph'
- `sparse` - only for implementation == 'c_graph'. Whether to use sparse or dense graphs as backend. Note that currently dense graphs do not have edge labels, nor can they be multigraphs
- `vertex_labels` - only for implementation == 'c_graph'. Whether to allow any object as a vertex (slower), or only the integers 0, ..., n-1, where n is the number of vertices.

EXAMPLES: We illustrate the first six input formats (the other two involve packages that are currently not standard in Sage):

1. A NetworkX XGraph:

```
sage: import networkx
sage: g = networkx.XGraph({0:[1,2,3], 2:[4]})
sage: Graph(g)
Graph on 5 vertices
```

2. A NetworkX graph:

```
sage: import networkx
sage: g = networkx.Graph({0:[1,2,3], 2:[4]})
sage: DiGraph(g)
Digraph on 5 vertices
```

Note that in all cases, we copy the NetworkX structure.

```
sage: import networkx
sage: g = networkx.Graph({0:[1,2,3], 2:[4]})
sage: G = Graph(g, implementation='networkx')
sage: H = Graph(g, implementation='networkx')
sage: G._backend._nxg is H._backend._nxg
False
```

1. A dictionary of dictionaries:

```
sage: g = Graph({0:{1:'x',2:'z',3:'a'}, 2:{5:'out'}}, implementation='networkx'); g
Graph on 5 vertices
```

The labels ('x', 'z', 'a', 'out') are labels for edges. For example, 'out' is the label for the edge on 2 and 5. Labels can be used as weights, if all the labels share some common parent.

sage: a,b,c,d,e,f = sorted(SymmetricGroup(3)) sage: Graph({b:{d:'c',e:'p'}, c:{d:'p',e:'c'}}) Graph on 4 vertices

2. A dictionary of lists:

```
sage: g = Graph({0:[1,2,3], 2:[4]}); g
Graph on 5 vertices
```

3. A list of vertices and a function describing adjacencies. Note that the list of vertices and the function must be enclosed in a list (i.e., [list of vertices, function]).

Construct the Paley graph over GF(13).

```
sage: g=Graph([GF(13), lambda i,j: i!=j and (i-j).is_square()], implementation='networkx')
sage: g.vertices()
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12]
sage: g.adjacency_matrix()
[0 1 0 1 1 0 0 0 0 1 1 0 1]
```

```
[1 0 1 0 1 1 0 0 0 0 1 1 0]
[0 1 0 1 0 1 1 0 0 0 0 1 1]
[1 0 1 0 1 0 1 1 0 0 0 0 1]
[1 1 0 1 0 1 0 1 1 0 0 0 0]
[0 1 1 0 1 0 1 0 1 1 0 0 0]
[0 0 1 1 0 1 0 1 0 1 1 0 0]
[0 0 0 1 1 0 1 0 1 0 1 1 0]
[0 0 0 0 1 1 0 1 0 1 0 1 1]
[1 0 0 0 0 1 1 0 1 0 1 0 1]
[1 1 0 0 0 0 1 1 0 1 0 1 0]
[0 1 1 0 0 0 0 1 1 0 1 0 1]
[1 0 1 1 0 0 0 0 1 1 0 1 0]
```

Construct the line graph of a complete graph.

```
sage: g=graphs.CompleteGraph(4)
sage: line_graph=Graph([g.edges(labels=false), \
       lambda i,j: len(set(i).intersection(set(j)))>0], \
       implementation='networkx', loops=False)
sage: line_graph.vertices()
[(0, 1), (0, 2), (0, 3), (1, 2), (1, 3), (2, 3)]
sage: line_graph.adjacency_matrix()
[0 1 1 1 1 0]
[1 0 1 1 0 1]
[1 1 0 0 1 1]
[1 1 0 0 1 1]
[1 0 1 1 0 1]
[0 1 1 1 1 0]
```

4.A numpy matrix or ndarray:

```
sage: import numpy
sage: A = numpy.array([[0,1,1],[1,0,1],[1,1,0]])
sage: Graph(A, implementation='networkx')
Graph on 3 vertices
```

5.A graph6 or sparse6 string: Sage automatically recognizes whether a string is in graph6 or sparse6 format:

```
sage: s = ':I`AKGsaOs`cI]Gb~'
sage: Graph(s, sparse=True)
Looped multi-graph on 10 vertices

sage: G = Graph('G?????')
sage: G = Graph("G'?G?C")
...
RuntimeError: The string seems corrupt: valid characters are
?@ABCDEFGHIJKLMNOPQRSTUVWXYZ[\]^_`abcdefghijklmnopqrstuvwxyz{|}~
sage: G = Graph('G??????')
...
RuntimeError: The string (G??????) seems corrupt: for n = 8, the string is too long.

sage: G = Graph(":I'AKGsaOs`cI]Gb~")
...
RuntimeError: The string seems corrupt: valid characters are
?@ABCDEFGHIJKLMNOPQRSTUVWXYZ[\]^_`abcdefghijklmnopqrstuvwxyz{|}~
```

There are also list functions to take care of lists of graphs:

```
sage: s = ':IgMoqoCUOqeb\n:I`AKGsaOs`cI]Gb~\n:I`EDOAEQ?PccSsge\N\n'
sage: graphs_list.from_sparse6(s)
```

```
[Looped multi-graph on 10 vertices, Looped multi-graph on 10 vertices, Looped multi-graph or
```

6.A Sage matrix: Note: If format is not specified, then Sage assumes a symmetric square matrix is an adjacency matrix, otherwise an incidence matrix.

•an adjacency matrix:

```
sage: M = graphs.PetersenGraph().am(); M
[0 1 0 0 1 1 0 0 0 0]
[1 0 1 0 0 0 1 0 0 0]
[0 1 0 1 0 0 0 1 0 0]
[0 0 1 0 1 0 0 0 1 0]
[1 0 0 1 0 0 0 0 0 1]
[1 0 0 0 0 0 0 1 1 0]
[0 1 0 0 0 0 0 0 1 1]
[0 0 1 0 0 1 0 0 0 1]
[0 0 0 1 0 1 1 0 0 0]
[0 0 0 0 1 0 1 1 0 0]
sage: Graph(M)
Graph on 10 vertices

sage: Graph(matrix([[1,2],[2,4]]),loops=True)
Looped multi-graph on 2 vertices

sage: M = Matrix([[0,1,-1],[1,0,-1/2],[-1,-1/2,0]]); M
[   0    1   -1]
[   1    0 -1/2]
[  -1 -1/2    0]
sage: G = Graph(M); G
Graph on 3 vertices
sage: G.weighted()
True
```

•an incidence matrix:

```
sage: M = Matrix(6, [-1,0,0,0,1, 1,-1,0,0,0, 0,1,-1,0,0, 0,0,1,-1,0, 0,0,0,1,-1, 0,0,0,0
[-1  0  0  0  1]
[ 1 -1  0  0  0]
[ 0  1 -1  0  0]
[ 0  0  1 -1  0]
[ 0  0  0  1 -1]
[ 0  0  0  0  0]
sage: Graph(M)
Graph on 6 vertices

sage: Graph(Matrix([[1],[1],[1]]))
...
ValueError: Non-symmetric or non-square matrix assumed to be an incidence matrix: There n
sage: Graph(Matrix([[1],[1],[0]]))
...
ValueError: Non-symmetric or non-square matrix assumed to be an incidence matrix: Each co

sage: M = Matrix([[0,1,-1],[1,0,-1],[-1,-1,0]]); M
[ 0  1 -1]
[ 1  0 -1]
[-1 -1  0]
sage: Graph(M)
Graph on 3 vertices

sage: M = Matrix([[0,1,1],[1,0,0],[0,0,0]]); M
```

```
[0 1 1]
[1 0 0]
[0 0 0]
sage: Graph(M)
...
ValueError: Non-symmetric or non-square matrix assumed to be an incidence matrix: There r

sage: M = Matrix([[0,1,1],[1,0,1],[-1,-1,0]]); M
[ 0  1  1]
[ 1  0  1]
[-1 -1  0]
sage: Graph(M)
...
ValueError: Non-symmetric or non-square matrix assumed to be an incidence matrix: Each c
```

bipartite_color()

Returns a dictionary with vertices as the keys and the color class as the values. Fails with an error if the graph is not bipartite.

EXAMPLE:

```
sage: graphs.CycleGraph(4).bipartite_color()
{0: 1, 1: 0, 2: 1, 3: 0}
sage: graphs.CycleGraph(5).bipartite_color()
...
RuntimeError: Graph is not bipartite.
```

bipartite_sets()

Returns (X,Y) where X and Y are the nodes in each bipartite set of graph G. Fails with an error if graph is not bipartite.

EXAMPLE:

```
sage: graphs.CycleGraph(4).bipartite_sets()
([0, 2], [1, 3])
sage: graphs.CycleGraph(5).bipartite_sets()
...
RuntimeError: Graph is not bipartite.
```

centrality_betweenness(*normalized=True*)

Returns the betweenness centrality (fraction of number of shortest paths that go through each vertex) as a dictionary keyed by vertices. The betweenness is normalized by default to be in range (0,1). This wraps Networkx's implementation of the algorithm described in [1].

Measures of the centrality of a vertex within a graph determine the relative importance of that vertex to its graph. Vertices that occur on more shortest paths between other vertices have higher betweenness than vertices that occur on less.

INPUT:

- `normalized` - boolean (default True) - if set to False, result is not normalized.

REFERENCE:

- [1] Ulrik Brandes. (2003). Faster Evaluation of Shortest-Path Based Centrality Indices. [Online] Available: http://citeseer.nj.nec.com/brandes00faster.html

EXAMPLES:

```
sage: (graphs.ChvatalGraph()).centrality_betweenness()
{0: 0.069696969696969688, 1: 0.069696969696969688, 2: 0.060606060606060601, 3: 0.0606060606
sage: (graphs.ChvatalGraph()).centrality_betweenness(normalized=False)
{0: 7.6666666666666661, 1: 7.6666666666666661, 2: 6.6666666666666661, 3: 6.6666666666666661,
```

```
sage: D = DiGraph({0:[1,2,3], 1:[2], 3:[0,1]})
sage: D.show(figsize=[2,2])
sage: D = D.to_undirected()
sage: D.show(figsize=[2,2])
sage: D.centrality_betweenness()
{0: 0.16666666666666666, 1: 0.16666666666666666, 2: 0.0, 3: 0.0}
```

centrality_closeness(*v=None*)

Returns the closeness centrality (1/average distance to all vertices) as a dictionary of values keyed by vertex. The degree centrality is normalized to be in range (0,1).

Measures of the centrality of a vertex within a graph determine the relative importance of that vertex to its graph. 'Closeness centrality may be defined as the total graph-theoretic distance of a given vertex from all other vertices... Closeness is an inverse measure of centrality in that a larger value indicates a less central actor while a smaller value indicates a more central actor,' [1].

INPUT:

- v - a vertex label (to find degree centrality of only one vertex)

REFERENCE:

- [1] Stephen P Borgatti. (1995). Centrality and AIDS. [Online] Available: http://www.analytictech.com/networks/centaids.htm

EXAMPLES:

```
sage: (graphs.ChvatalGraph()).centrality_closeness()
{0: 0.6111111111111116, 1: 0.6111111111111116, 2: 0.6111111111111116, 3: 0.611111111111
sage: D = DiGraph({0:[1,2,3], 1:[2], 3:[0,1]})
sage: D.show(figsize=[2,2])
sage: D = D.to_undirected()
sage: D.show(figsize=[2,2])
sage: D.centrality_closeness()
{0: 1.0, 1: 1.0, 2: 0.75, 3: 0.75}
sage: D.centrality_closeness(v=1)
1.0
```

centrality_degree(*v=None*)

Returns the degree centrality (fraction of vertices connected to) as a dictionary of values keyed by vertex. The degree centrality is normalized to be in range (0,1).

Measures of the centrality of a vertex within a graph determine the relative importance of that vertex to its graph. Degree centrality measures the number of links incident upon a vertex.

INPUT:

- v - a vertex label (to find degree centrality of only one vertex)

EXAMPLES:

```
sage: (graphs.ChvatalGraph()).centrality_degree()
{0: 0.36363636363636365, 1: 0.36363636363636365, 2: 0.36363636363636365, 3: 0.3636363636363
sage: D = DiGraph({0:[1,2,3], 1:[2], 3:[0,1]})
sage: D.show(figsize=[2,2])
sage: D = D.to_undirected()
sage: D.show(figsize=[2,2])
sage: D.centrality_degree()
{0: 1.0, 1: 1.0, 2: 0.6666666666666663, 3: 0.6666666666666663}
sage: D.centrality_degree(v=1)
1.0
```

chromatic_number()

Returns the minimal number of colors needed to color the vertices of the graph G.

EXAMPLES:

```
sage: G = Graph({0:[1,2,3],1:[2]})
sage: G.chromatic_number()
3
```

chromatic_polynomial()

Returns the chromatic polynomial of the graph G.

EXAMPLES:

```
sage: G = Graph({0:[1,2,3],1:[2]})
sage: factor(G.chromatic_polynomial())
(x - 2) * x * (x - 1)^2

sage: g = graphs.trees(5).next()
sage: g.chromatic_polynomial().factor()
x * (x - 1)^4

sage: seven_acre_wood = sum(graphs.trees(7), Graph())
sage: seven_acre_wood.chromatic_polynomial()
x^77 - 66*x^76 ... - 2515943049305400*x^60 ... - 66*x^12 + x^11

sage: for i in range(2,7):
...       graphs.CompleteGraph(i).chromatic_polynomial().factor()
(x - 1) * x
(x - 2) * (x - 1) * x
(x - 3) * (x - 2) * (x - 1) * x
(x - 4) * (x - 3) * (x - 2) * (x - 1) * x
(x - 5) * (x - 4) * (x - 3) * (x - 2) * (x - 1) * x
```

clique_number(*cliques=None*)

Returns the size of the largest clique of the graph (clique number).

Currently only implemented for undirected graphs. Use to_undirected to convert a digraph to an undirected graph.

INPUT:

- `cliques` - list of cliques (if already computed)

EXAMPLES:

```
sage: C = Graph('DJ{')
sage: C.clique_number()
4
sage: E = C.cliques()
sage: E
[[4, 1, 2, 3], [4, 0]]
sage: C.clique_number(cliques=E)
4
sage: G = Graph({0:[1,2,3], 1:[2], 3:[0,1]})
sage: G.show(figsize=[2,2])
sage: G.clique_number()
3
```

cliques()

Returns the list of maximal cliques. Each maximal clique is represented by a list of vertices.

Currently only implemented for undirected graphs. Use to_undirected to convert a digraph to an undirected graph.

Maximal cliques are the largest complete subgraphs containing a given point. This function is based on Networkx's implementation of the Bron and Kerbosch Algorithm, [1].

REFERENCE:

- [1] Coen Bron and Joep Kerbosch. (1973). Algorithm 457: Finding All Cliques of an Undirected Graph. Commun. ACM. v 16. n 9. pages 575-577. ACM Press. [Online] Available: http://www.ram.org/computing/rambin/rambin.html

EXAMPLES:

```
sage: (graphs.ChvatalGraph()).cliques()
[[0, 1], [0, 4], [0, 6], [0, 9], [2, 1], [2, 3], [2, 6], [2, 8], [3, 4], [3, 7], [3, 9], [5,
sage: G = Graph({0:[1,2,3], 1:[2], 3:[0,1]})
sage: G.show(figsize=[2,2])
sage: G.cliques()
[[0, 1, 2], [0, 1, 3]]
```

cliques_containing_vertex(*vertices=None, cliques=None, with_labels=False*)

Returns the cliques containing each vertex, represented as a list of lists. (Returns a single list if only one input vertex).

Currently only implemented for undirected graphs. Use to_undirected to convert a digraph to an undirected graph.

INPUT:

- `vertices` - the vertices to inspect (default is entire graph)
- `with_labels` - (boolean) default False returns list as above True returns a dictionary keyed by vertex labels
- `cliques` - list of cliques (if already computed)

EXAMPLES:

```
sage: C = Graph('DJ{')
sage: C.cliques_containing_vertex()
[[[4, 0]], [[4, 1, 2, 3]], [[4, 1, 2, 3]], [[4, 1, 2, 3]], [[4, 1, 2, 3], [4, 0]]]
sage: E = C.cliques()
sage: E
[[4, 1, 2, 3], [4, 0]]
sage: C.cliques_containing_vertex(cliques=E)
[[[4, 0]], [[4, 1, 2, 3]], [[4, 1, 2, 3]], [[4, 1, 2, 3]], [[4, 1, 2, 3], [4, 0]]]
sage: F = graphs.Grid2dGraph(2,3)
sage: F.cliques_containing_vertex(with_labels=True)
{(0, 1): [[(0, 1), (0, 0)], [(0, 1), (0, 2)], [(0, 1), (1, 1)]], (1, 2): [[(1, 2), (0, 2)],
sage: F.cliques_containing_vertex(vertices=[(0, 1), (1, 2)])
[[[(0, 1), (0, 0)], [(0, 1), (0, 2)], [(0, 1), (1, 1)]], [[(1, 2), (0, 2)], [(1, 2), (1, 1)]
sage: G = Graph({0:[1,2,3], 1:[2], 3:[0,1]})
sage: G.show(figsize=[2,2])
sage: G.cliques_containing_vertex()
[[[0, 1, 2], [0, 1, 3]], [[0, 1, 2], [0, 1, 3]], [[0, 1, 2]], [[0, 1, 3]]]
```

cliques_get_clique_bipartite(***kwds*)

Returns a bipartite graph constructed such that cliques are the right vertices and the left vertices are retained from the given graph. Right and left vertices are connected if the bottom vertex belongs to the clique represented by a top vertex.

Currently only implemented for undirected graphs. Use to_undirected to convert a digraph to an undirected graph.

EXAMPLES:

```
sage: (graphs.ChvatalGraph()).cliques_get_clique_bipartite()
Bipartite graph on 36 vertices
sage: ((graphs.ChvatalGraph()).cliques_get_clique_bipartite()).show(figsize=[2,2], vertex_si
sage: G = Graph({0:[1,2,3], 1:[2], 3:[0,1]})
sage: G.show(figsize=[2,2])
sage: G.cliques_get_clique_bipartite()
```

```
Bipartite graph on 6 vertices
sage: (G.cliques_get_clique_bipartite()).show(figsize=[2,2])
```

cliques_get_max_clique_graph(*name=''*)

Returns a graph constructed with maximal cliques as vertices, and edges between maximal cliques with common members in the original graph.

Currently only implemented for undirected graphs. Use to_undirected to convert a digraph to an undirected graph.

INPUT:

- `name` - The name of the new graph.

EXAMPLES:

```
sage: (graphs.ChvatalGraph()).cliques_get_max_clique_graph()
Graph on 24 vertices
sage: ((graphs.ChvatalGraph()).cliques_get_max_clique_graph()).show(figsize=[2,2], vertex_si
sage: G = Graph({0:[1,2,3], 1:[2], 3:[0,1]})
sage: G.show(figsize=[2,2])
sage: G.cliques_get_max_clique_graph()
Graph on 2 vertices
sage: (G.cliques_get_max_clique_graph()).show(figsize=[2,2])
```

cliques_number_of(*vertices=None, cliques=None, with_labels=False*)

Returns a list of the number of maximal cliques containing each vertex. (Returns a single value if only one input vertex).

Currently only implemented for undirected graphs. Use to_undirected to convert a digraph to an undirected graph.

INPUT:

- `vertices` - the vertices to inspect (default is entire graph)
- `with_labels` - (boolean) default False returns list as above True returns a dictionary keyed by vertex labels
- `cliques` - list of cliques (if already computed)

EXAMPLES:

```
sage: C = Graph('DJ{')
sage: C.cliques_number_of()
[1, 1, 1, 1, 2]
sage: E = C.cliques()
sage: E
[[4, 1, 2, 3], [4, 0]]
sage: C.cliques_number_of(cliques=E)
[1, 1, 1, 1, 2]
sage: F = graphs.Grid2dGraph(2,3)
sage: F.cliques_number_of(with_labels=True)
{(0, 1): 3, (1, 2): 2, (0, 0): 2, (1, 1): 3, (1, 0): 2, (0, 2): 2}
sage: F.cliques_number_of(vertices=[(0, 1), (1, 2)])
[3, 2]
sage: G = Graph({0:[1,2,3], 1:[2], 3:[0,1]})
sage: G.show(figsize=[2,2])
sage: G.cliques_number_of()
[2, 2, 1, 1]
```

cliques_vertex_clique_number(*vertices=None, with_labels=False, cliques=None*)

Returns a list of sizes of the largest maximal cliques containing each vertex. (Returns a single value if only one input vertex).

Currently only implemented for undirected graphs. Use to_undirected to convert a digraph to an undirected graph.

INPUT:

- `vertices` - the vertices to inspect (default is entire graph)
- `with_labels` - (boolean) default False returns list as above True returns a dictionary keyed by vertex labels
- `cliques` - list of cliques (if already computed)

EXAMPLES:

```
sage: C = Graph('DJ{')
sage: C.cliques_vertex_clique_number()
[2, 4, 4, 4, 4]
sage: E = C.cliques()
sage: E
[[4, 1, 2, 3], [4, 0]]
sage: C.cliques_vertex_clique_number(cliques=E)
[2, 4, 4, 4, 4]
sage: F = graphs.Grid2dGraph(2,3)
sage: F.cliques_vertex_clique_number(with_labels=True)
{(0, 1): 2, (1, 2): 2, (0, 0): 2, (1, 1): 2, (1, 0): 2, (0, 2): 2}
sage: F.cliques_vertex_clique_number(vertices=[(0, 1), (1, 2)])
[2, 2]
sage: G = Graph({0:[1,2,3], 1:[2], 3:[0,1]})
sage: G.show(figsize=[2,2])
sage: G.cliques_vertex_clique_number()
[3, 3, 3, 3]
```

coloring(*hex_colors=False*)

Returns the first (optimal) coloring found.

INPUT:

```
hex_colors -- if True, return a dict which can
              easily be used for plotting
```

EXAMPLES:

```
sage: G = Graph("Fooba")

sage: P = G.coloring(); P
[[1, 2, 3], [0, 5, 6], [4]]
sage: G.plot(partition=P)

sage: H = G.coloring(hex_colors=True)
sage: for c in sorted(H.keys()):
...    print c, H[c]
#0000ff [4]
#00ff00 [1, 2, 3]
#ff0000 [0, 5, 6]
sage: G.plot(vertex_colors=H)
```

eulerian_circuit(*return_vertices=False, labels=True*)

Return a list of edges forming an eulerian circuit if one exists. Otherwise return False.

This is implemented using Fleury's algorithm. This could be extended to find eulerian paths too (check for existence and make sure you start on an odd-degree vertex if one exists).

INPUT:

- `return_vertices` - optionally provide a list of vertices for the path
- `labels` - whether to return edges with labels (3-tuples)

OUTPUT: either ([edges], [vertices]) or [edges] of an Eulerian circuit

EXAMPLES:

```
sage: g=graphs.CycleGraph(5);
sage: g.eulerian_circuit()
[(0, 1, None), (1, 2, None), (2, 3, None), (3, 4, None), (4, 0, None)]
sage: g.eulerian_circuit(labels=False)
[(0, 1), (1, 2), (2, 3), (3, 4), (4, 0)]
sage: g = graphs.CompleteGraph(7)
sage: edges, vertices = g.eulerian_circuit(return_vertices=True)
sage: vertices
[0, 1, 2, 0, 3, 1, 4, 0, 5, 1, 6, 2, 3, 4, 2, 5, 3, 6, 4, 5, 6, 0]
sage: graphs.CompleteGraph(4).eulerian_circuit()
False
```

graph6_string()

Returns the graph6 representation of the graph as an ASCII string. Only valid for simple (no loops, multiple edges) graphs on 0 to 262143 vertices.

EXAMPLE:

```
sage: G = graphs.KrackhardtKiteGraph()
sage: G.graph6_string()
'IvUqwK@?G'
```

graphviz_string()

Returns a representation in the DOT language, ready to render in graphviz.

REFERENCES:

- http://www.graphviz.org/doc/info/lang.html

EXAMPLE:

```
sage: G = Graph({0:{1:None,2:None}, 1:{0:None,2:None}, 2:{0:None,1:None,3:'foo'}, 3:{2:'foo'
sage: s = G.graphviz_string()
sage: s
'graph {\n"0";"1";"2";"3";\n"0"--"1";"0"--"2";"1"--"2";"2"--"3"[label="foo"];\n}'
```

is_bipartite()

Returns True if graph G is bipartite, False if not.

Traverse the graph G with depth-first-search and color nodes. This function uses the corresponding NetworkX function.

EXAMPLE:

```
sage: graphs.CycleGraph(4).is_bipartite()
True
sage: graphs.CycleGraph(5).is_bipartite()
False
```

is_directed()

Since graph is undirected, returns False.

EXAMPLE:

```
sage: Graph().is_directed()
False
```

min_spanning_tree(*weight_function=<function <lambda> at 0x2666d70>, algorithm='Kruskal', starting_vertex=None*)

Returns the edges of a minimum spanning tree, if one exists, otherwise returns False.

INPUT:

- `weight_function` - A function that takes an edge and returns a numeric weight. Defaults to assigning each edge a weight of 1.

- `algorithm` - Three variants of algorithms are implemented: 'Kruskal', 'Prim fringe', and 'Prim edge' (the last two are variants of Prim's algorithm). Defaults to 'Kruskal'. Currently, 'Prim fringe' ignores the labels on the edges.
- `starting_vertex` - The vertex with which to start Prim's algorithm.

OUTPUT: the edges of a minimum spanning tree.

EXAMPLES:

```
sage: g=graphs.CompleteGraph(5)
sage: len(g.min_spanning_tree())
4
sage: weight = lambda e: 1/( (e[0]+1)*(e[1]+1) )
sage: g.min_spanning_tree(weight_function=weight)
[(3, 4, None), (2, 4, None), (1, 4, None), (0, 4, None)]
sage: g.min_spanning_tree(algorithm='Prim edge', starting_vertex=2, weight_function=weight)
[(2, 4, None), (3, 4, None), (1, 3, None), (0, 4, None)]
sage: g.min_spanning_tree(algorithm='Prim fringe', starting_vertex=2, weight_function=weight
[(4, 2), (3, 4), (1, 4), (0, 4)]
```

sparse6_string()

Returns the sparse6 representation of the graph as an ASCII string. Only valid for undirected graphs on 0 to 262143 vertices, but loops and multiple edges are permitted.

EXAMPLE:

```
sage: G = graphs.BullGraph()
sage: G.sparse6_string()
':Da@en'

sage: G = Graph()
sage: G.sparse6_string()
':?'

sage: G = Graph(loops=True, multiedges=True)
sage: Graph(':?') == G
True
```

to_directed(*implementation='networkx'*)

Returns a directed version of the graph. A single edge becomes two edges, one in each direction.

EXAMPLE:

```
sage: graphs.PetersenGraph().to_directed()
Petersen graph: Digraph on 10 vertices
```

to_undirected()

Since the graph is already undirected, simply returns a copy of itself.

EXAMPLE:

```
sage: graphs.PetersenGraph().to_undirected()
Petersen graph: Graph on 10 vertices
```

write_to_eps (*filename, iterations=50*)

Writes a plot of the graph to filename in eps format.

It is relatively simple to include this file in a latex document:

INPUT: filename

- `iterations` - how many iterations of the spring layout algorithm to go through, if applicable

`usepackagegraphics` must appear before the beginning of the document, and `includegraphics filename.eps` will include it in your latex doc. Note: you cannot use pdflatex to print the resulting document, use TeX and Ghostscript or something similar instead.

EXAMPLE:

```
sage: P = graphs.PetersenGraph()
sage: P.write_to_eps(tmp_dir() + 'sage.eps')
```

compare_edges(*x, y*)

Compare edge x to edge y, return -1 if x y, 1 if x y, else 0.

EXAMPLE:

```
sage: G = graphs.PetersenGraph()
sage: E = G.edges()
sage: from sage.graphs.graph import compare_edges
sage: compare_edges(E[0], E[2])
-1
sage: compare_edges(E[0], E[1])
-1
sage: compare_edges(E[0], E[0])
0
sage: compare_edges(E[1], E[0])
1
```

graph_isom_equivalent_non_edge_labeled_graph(*g, partition*)

Helper function for canonical labeling of edge labeled (di)graphs.

Translates to a bipartite incidence-structure type graph appropriate for computing canonical labels of edge labeled graphs. Note that this is actually computationally equivalent to implementing a change on an inner loop of the main algorithm- namely making the refinement procedure sort for each label.

If the graph is a multigraph, it is translated to a non-multigraph, where each edge is labeled with a dictionary describing how many edges of each label were originally there. Then in either case we are working on a graph without multiple edges. At this point, we create another (bipartite) graph, whose left vertices are the original vertices of the graph, and whose right vertices represent the edges. We partition the left vertices as they were originally, and the right vertices by common labels: only automorphisms taking edges to like-labeled edges are allowed, and this additional partition information enforces this on the bipartite graph.

EXAMPLE:

```
sage: G = Graph(multiedges=True, implementation='networkx')
sage: G.add_edges([(0,1,i) for i in range(10)])
sage: G.add_edge(1,2,'string')
sage: G.add_edge(2,3)
sage: from sage.graphs.graph import graph_isom_equivalent_non_edge_labeled_graph
sage: graph_isom_equivalent_non_edge_labeled_graph(G, [G.vertices()])
(Graph on 7 vertices, [[('o', 0), ('o', 1), ('o', 2), ('o', 3)], [('x', 2)], [('x', 0)], [('x',
```

graph_isom_equivalent_non_multi_graph(*g, partition*)

Helper function for canonical labeling of multi-(di)graphs.

The idea for this function is that the main algorithm for computing isomorphism of graphs does not allow multiple edges. Instead of making some very difficult changes to that, we can simply modify the multigraph into a non-multi graph that carries essentially the same information. For each pair of vertices $\{u, v\}$, if there is at most one edge between u and v, we do nothing, but if there are more than one, we split each edge into two, introducing a new vertex. These vertices really represent edges, so we keep them in their own part of a partition - to distinguish them from genuine vertices. Then the canonical label and automorphism group is computed, and in the end, we strip off the parts of the generators that describe how these new vertices move, and we have the automorphism group of the original multi-graph. Similarly, by putting the additional vertices in their own cell of the partition, we guarantee that the relabeling leading to a canonical label moves genuine vertices amongst themselves, and hence the canonical label is still well-defined, when we forget about the additional vertices.

EXAMPLE:

```
sage: from sage.graphs.graph import graph_isom_equivalent_non_multi_graph
sage: G = Graph(multiedges=True)
sage: G.add_edge((0,1,1))
sage: G.add_edge((0,1,2))
sage: G.add_edge((0,1,3))
sage: graph_isom_equivalent_non_multi_graph(G, [[0,1]])
(Graph on 5 vertices, [[('o', 0), ('o', 1)], [('x', 0), ('x', 1), ('x', 2)]])
```

tachyon_vertex_plot(*g, bgcolor=(1, 1, 1), vertex_colors=None, vertex_size=0.059999999999999998, pos3d=None, iterations=50, **kwds*)

Helper function for plotting graphs in 3d with Tachyon. Returns a plot containing only the vertices, as well as the 3d position dictionary used for the plot.

EXAMPLE:

```
sage: G = graphs.TetrahedralGraph()
sage: from sage.graphs.graph import tachyon_vertex_plot
sage: T,p = tachyon_vertex_plot(G)
sage: type(T)
<class 'sage.plot.tachyon.Tachyon'>
sage: type(p)
<type 'dict'>
```

7.2 A collection of constructors of common graphs.

USE:

To see a list of all graph constructors, type "graphs." and then press the tab key. The documentation for each constructor includes information about each graph, which provides a useful reference.

PLOTTING:

All graphs (i.e., networks) have an associated Sage graphics object, which you can display:

```
sage: G = graphs.WheelGraph(15)
sage: P = G.plot()
sage: P.show() # long time
```

If you create a graph in Sage using the `Graph` command, then plot that graph, the positioning of nodes is determined using the spring-layout algorithm. For the special graph constructors, which you get using `graphs.[tab]`, the positions are preset. For example, consider the Petersen graph with default node positioning vs. the Petersen graph constructed by this database:

```
sage: petersen_spring = Graph({0:[1,4,5], 1:[0,2,6], 2:[1,3,7], 3:[2,4,8], 4:[0,3,9], 5:[0,7,8], 6:[1
sage: petersen_spring.show() # long time
sage: petersen_database = graphs.PetersenGraph()
sage: petersen_database.show() # long time
```

For all the constructors in this database (except the octahedral, dodecahedral, random and empty graphs), the position dictionary is filled in, instead of using the spring-layout algorithm.

For further visual examples and explanation, see the docstrings below, particularly for CycleGraph, StarGraph, WheelGraph, CompleteGraph and CompleteBipartiteGraph.

ORGANIZATION:

The constructors available in this database are organized as follows:

```
Basic Structures:
    - BarbellGraph
    - BullGraph
    - CircularLadderGraph
    - ClawGraph
    - CycleGraph
    - DiamondGraph
    - EmptyGraph
    - Grid2dGraph
    - GridGraph
    - HouseGraph
    - HouseXGraph
    - KrackhardtKiteGraph
    - LadderGraph
    - LollipopGraph
    - PathGraph
    - StarGraph
    - WheelGraph
Platonic Solids:
    - TetrahedralGraph
    - HexahedralGraph
    - OctahedralGraph
    - IcosahedralGraph
    - DodecahedralGraph
Named Graphs:
    - ChvatalGraph
    - DesarguesGraph
    - FlowerSnark
    - FruchtGraph
    - HeawoodGraph
    - HoffmanSingletonGraph
    - MoebiusKantorGraph
    - Pappus Graph
    - PetersenGraph
    - ThomsenGraph
Families of Graphs:
    - CirculantGraph
    - CompleteGraph
    - CompleteBipartiteGraph
    - CubeGraph
    - BalancedTree
    - LCFGraph
Pseudofractal Graphs:
    - DorogovtsevGoltsevMendesGraph
Random Graphs:
    - RandomGNP
    - RandomBarabasiAlbert
    - RandomGNM
    - RandomNewmanWattsStrogatz
    - RandomHolmeKim
    - RandomLobster
    - RandomTreePowerlaw
    - RandomRegular
    - RandomShell
Random Directed Graphs:
    - RandomDirectedGN
    - RandomDirectedGNC
    - RandomDirectedGNR
```

```
Graphs with a given degree sequence:
    - DegreeSequence
    - DegreeSequenceConfigurationModel
    - DegreeSequenceTree
    - DegreeSequenceExpected
```

class `DiGraphGenerators`()

A class consisting of constructors for several common digraphs, including orderly generation of isomorphism class representatives.

A list of all graphs and graph structures in this database is available via tab completion. Type "digraphs." and then hit tab to see which graphs are available.

The docstrings include educational information about each named digraph with the hopes that this class can be used as a reference.

The constructors currently in this class include:

```
Random Directed Graphs:
    - RandomDirectedGN
    - RandomDirectedGNC
    - RandomDirectedGNR
```

ORDERLY GENERATION: digraphs(vertices, property=lambda x: True, augment='edges', size=None)

Accesses the generator of isomorphism class representatives. Iterates over distinct, exhaustive representatives.

INPUT:

- `vertices` - natural number
- `property` - any property to be tested on digraphs before generation.
- `augment` - choices:
- `'vertices'` - augments by adding a vertex, and edges incident to that vertex. In this case, all digraphs on up to n=vertices are generated. If for any digraph G satisfying the property, every subgraph, obtained from G by deleting one vertex and only edges incident to that vertex, satisfies the property, then this will generate all digraphs with that property. If this does not hold, then all the digraphs generated will satisfy the property, but there will be some missing.

- 'edges' - augments a fixed number of vertices by adding one edge In this case, all digraphs on exactly n=vertices are generated. If for any graph G satisfying the property, every subgraph, obtained from G by deleting one edge but not the vertices incident to that edge, satisfies the property, then this will generate all digraphs with that property. If this does not hold, then all the digraphs generated will satisfy the property, but there will be some missing.
- implementation - which underlying implementation to use (see DiGraph?)
- sparse - ignored if implementation is not c_graph

EXAMPLES: Print digraphs on 2 or less vertices.

```
sage: for D in digraphs(2, augment='vertices'):
...     print D
...
Digraph on 0 vertices
Digraph on 1 vertex
Digraph on 2 vertices
Digraph on 2 vertices
Digraph on 2 vertices
```

Note that we can also get digraphs with underlying Cython implementation:

```
sage: for D in digraphs(2, augment='vertices', implementation='c_graph'):
...     print D
...
Digraph on 0 vertices
Digraph on 1 vertex
Digraph on 2 vertices
Digraph on 2 vertices
Digraph on 2 vertices
```

Print digraphs on 3 vertices.

```
sage: for D in digraphs(3):
...     print D
Digraph on 3 vertices
Digraph on 3 vertices
...
Digraph on 3 vertices
Digraph on 3 vertices
```

Generate all digraphs with 4 vertices and 3 edges.

```
sage: L = digraphs(4, size=3)
sage: len(list(L))
13
```

Generate all digraphs with 4 vertices and up to 3 edges.

```
sage: L = list(digraphs(4, lambda G: G.size() <= 3))
sage: len(L)
20
sage: graphs_list.show_graphs(L)  # long time
```

Generate all digraphs with degree at most 2, up to 5 vertices.

```
sage: property = lambda G: ( max([G.degree(v) for v in G] + [0]) <= 2 )
sage: L = list(digraphs(5, property, augment='vertices'))
sage: len(L)
75
```

Generate digraphs on the fly: (see http://www.research.att.com/~njas/sequences/A000273)

```
sage: for i in range(0, 5):
...       print len(list(digraphs(i)))
1
1
3
16
218
```

REFERENCE:

ButterflyGraph (*n, vertices='strings'*)

Returns a n-dimensional butterfly graph. The vertices consist of pairs (v,i), where v is an n-dimensional tuple (vector) with binary entries (or a string representation of such) and i is an integer in [0..n]. A directed edge goes from (v,i) to (w,i+1) if v and w are identical except for possibly v[i] != w[i].

A butterfly graph has $(2^n)(n+1)$ vertices and $n2^{n+1}$ edges.

INPUT:

•`vertices` - 'strings' (default) or 'vectors', specifying whether the vertices are zero-one strings or actually tuples over GF(2).

EXAMPLES:

```
sage: digraphs.ButterflyGraph(2).edges(labels=False)
[(('00', 0), ('00', 1)),
(('00', 0), ('10', 1)),
(('00', 1), ('00', 2)),
(('00', 1), ('01', 2)),
(('01', 0), ('01', 1)),
(('01', 0), ('11', 1)),
(('01', 1), ('00', 2)),
(('01', 1), ('01', 2)),
(('10', 0), ('00', 1)),
(('10', 0), ('10', 1)),
(('10', 1), ('10', 2)),
(('10', 1), ('11', 2)),
(('11', 0), ('01', 1)),
(('11', 0), ('11', 1)),
(('11', 1), ('10', 2)),
(('11', 1), ('11', 2))]
sage: digraphs.ButterflyGraph(2,vertices='vectors').edges(labels=False)
[(((0, 0), 0), ((0, 0), 1)),
(((0, 0), 0), ((1, 0), 1)),
(((0, 0), 1), ((0, 0), 2)),
(((0, 0), 1), ((0, 1), 2)),
(((0, 1), 0), ((0, 1), 1)),
(((0, 1), 0), ((1, 1), 1)),
(((0, 1), 1), ((0, 0), 2)),
(((0, 1), 1), ((0, 1), 2)),
(((1, 0), 0), ((0, 0), 1)),
```

```
(((1, 0), 0), ((1, 0), 1)),
(((1, 0), 1), ((1, 0), 2)),
(((1, 0), 1), ((1, 1), 2)),
(((1, 1), 0), ((0, 1), 1)),
(((1, 1), 0), ((1, 1), 1)),
(((1, 1), 1), ((1, 0), 2)),
(((1, 1), 1), ((1, 1), 2))]
```

RandomDirectedGN(*n, kernel=<function <lambda> at 0x266b398>, seed=None*)

Returns a random GN (growing network) digraph with n vertices.

The digraph is constructed by adding vertices with a link to one previously added vertex. The vertex to link to is chosen with a preferential attachment model, i.e. probability is proportional to degree. The default attachment kernel is a linear function of degree. The digraph is always a tree, so in particular it is a directed acyclic graph.

INPUT:

- `n` - number of vertices.
- `kernel` - the attachment kernel
- `seed` - for the random number generator

EXAMPLE:

```
sage: D = digraphs.RandomDirectedGN(25)
sage: D.edges(labels=False)
[(1, 0), (2, 0), (3, 1), (4, 0), (5, 0), (6, 1), (7, 0), (8, 3), (9, 0), (10, 8), (11, 3), (
sage: D.show()  # long time
```

REFERENCE:

- [1] Krapivsky, P.L. and Redner, S. Organization of Growing Random Networks, Phys. Rev. E vol. 63 (2001), p. 066123.

RandomDirectedGNC(*n, seed=None*)

Returns a random GNC (growing network with copying) digraph with n vertices.

The digraph is constructed by adding vertices with a link to one previously added vertex. The vertex to link to is chosen with a preferential attachment model, i.e. probability is proportional to degree. The new vertex is also linked to all of the previously added vertex's successors.

INPUT:

- `n` - number of vertices.
- `seed` - for the random number generator

EXAMPLE:

```
sage: D = digraphs.RandomDirectedGNC(25)
sage: D.edges(labels=False)
[(1, 0), (2, 0), (2, 1), (3, 0), (4, 0), (4, 1), (5, 0), (5, 1), (5, 2), (6, 0), (6, 1), (7,
sage: D.show()  # long time
```

REFERENCE:

- [1] Krapivsky, P.L. and Redner, S. Network Growth by Copying, Phys. Rev. E vol. 71 (2005), p. 036118.

RandomDirectedGNP(*n, p*)

Returns a random digraph on n nodes. Each edge is inserted independently with probability p.

REFERENCES:

- [1] P. Erdos and A. Renyi, On Random Graphs, Publ. Math. 6, 290 (1959).
- [2] E. N. Gilbert, Random Graphs, Ann. Math. Stat., 30, 1141 (1959).

PLOTTING: When plotting, this graph will use the default spring-layout algorithm, unless a position dictionary is specified.

EXAMPLE:

```
sage: digraphs.RandomDirectedGNP(10, .2).num_verts()
10
```

RandomDirectedGNR(*n, p, seed=None*)

Returns a random GNR (growing network with redirection) digraph with n vertices and redirection probability p.

The digraph is constructed by adding vertices with a link to one previously added vertex. The vertex to link to is chosen uniformly. With probability p, the arc is instead redirected to the successor vertex. The digraph is always a tree.

INPUT:

- `n` - number of vertices.
- `p` - redirection probability
- `seed` - for the random number generator.

EXAMPLE:

```
sage: D = digraphs.RandomDirectedGNR(25, .2)
sage: D.edges(labels=False)
[(1, 0), (2, 0), (2, 1), (3, 0), (4, 0), (4, 1), (5, 0), (5, 1), (5, 2), (6, 0), (6, 1), (7,
sage: D.show()  # long time
```

class GraphGenerators()

A class consisting of constructors for several common graphs, as well as orderly generation of isomorphism class representatives.

A list of all graphs and graph structures (other than iso. class rep's) in this database is available via tab completion. Type "graphs." and then hit tab to see which graphs are available.

The docstrings include educational information about each named graph with the hopes that this class can be used as a reference.

For all the constructors in this class (except the octahedral, dodecahedral, random and empty graphs), the position dictionary is filled to override the spring-layout algorithm.

The constructors currently in this class include:

```
Basic Structures:
    - BarbellGraph
    - BullGraph
    - CircularLadderGraph
    - ClawGraph
    - CycleGraph
    - DiamondGraph
    - EmptyGraph
    - Grid2dGraph
    - GridGraph
    - HouseGraph
    - HouseXGraph
    - KrackhardtKiteGraph
    - LadderGraph
    - LollipopGraph
    - PathGraph
```

```
    - StarGraph
    - WheelGraph
Platonic Solids:
    - TetrahedralGraph
    - HexahedralGraph
    - OctahedralGraph
    - IcosahedralGraph
    - DodecahedralGraph
Named Graphs:
    - ChvatalGraph
    - DesarguesGraph
    - FlowerSnark
    - FruchtGraph
    - HeawoodGraph
    - HoffmanSingletonGraph
    - MoebiusKantorGraph
    - PappusGraph
    - PetersenGraph
    - ThomsenGraph
Families of Graphs:
    - CirculantGraph
    - CompleteGraph
    - CompleteBipartiteGraph
    - CubeGraph
    - BalancedTree
    - LCFGraph
Pseudofractal Graphs:
    - DorogovtsevGoltsevMendesGraph
Random Graphs:
    - RandomGNP
    - RandomBarabasiAlbert
    - RandomGNM
    - RandomNewmanWattsStrogatz
    - RandomHolmeKim
    - RandomLobster
    - RandomTreePowerlaw
    - RandomRegular
    - RandomShell
Graphs with a given degree sequence:
    - DegreeSequence
    - DegreeSequenceConfigurationModel
    - DegreeSequenceTree
    - DegreeSequenceExpected
```

ORDERLY GENERATION: graphs(vertices, property=lambda x: True, augment='edges', size=None)

This syntax accesses the generator of isomorphism class representatives. Iterates over distinct, exhaustive representatives.

INPUT:

- `vertices` - natural number
- `property` - any property to be tested on graphs before generation. (Ignored if deg_seq is specified.)
- `augment` - choices:
- `'vertices'` - augments by adding a vertex, and edges incident to that vertex. In this case, all graphs on up to n=vertices are generated. If for any graph G satisfying the property, every subgraph, obtained from G by deleting one vertex and only edges incident to that vertex, satisfies the property, then this will generate

all graphs with that property. If this does not hold, then all the graphs generated will satisfy the property, but there will be some missing.

- `'edges'` - augments a fixed number of vertices by adding one edge In this case, all graphs on exactly n=vertices are generated. If for any graph G satisfying the property, every subgraph, obtained from G by deleting one edge but not the vertices incident to that edge, satisfies the property, then this will generate all graphs with that property. If this does not hold, then all the graphs generated will satisfy the property, but there will be some missing.
- `deg_seq` - a sequence of non-negative integers, or None. If specified, the generated graphs will have these integers for degrees. In this case property and size are both ignored.
- `loops` - whether to allow loops in the graph or not.
- `implementation` - which underlying implementation to use (see Graph?)
- `sparse` - ignored if implementation is not `c_graph`

EXAMPLES: Print graphs on 3 or less vertices.

```
sage: for G in graphs(3, augment='vertices'):
...     print G
Graph on 0 vertices
Graph on 1 vertex
Graph on 2 vertices
Graph on 3 vertices
Graph on 3 vertices
Graph on 3 vertices
Graph on 2 vertices
Graph on 3 vertices
```

Note that we can also get graphs with underlying Cython implementation:

```
sage: for G in graphs(3, augment='vertices', implementation='c_graph'):
...     print G
Graph on 0 vertices
Graph on 1 vertex
Graph on 2 vertices
Graph on 3 vertices
Graph on 3 vertices
Graph on 3 vertices
Graph on 2 vertices
Graph on 3 vertices
```

Print graphs on 3 vertices.

```
sage: for G in graphs(3):
...     print G
Graph on 3 vertices
Graph on 3 vertices
Graph on 3 vertices
Graph on 3 vertices
```

Generate all graphs with 5 vertices and 4 edges.

```
sage: L = graphs(5, size=4)
sage: len(list(L))
6
```

Generate all graphs with 5 vertices and up to 4 edges.

```
sage: L = list(graphs(5, lambda G: G.size() <= 4))
sage: len(L)
14
sage: graphs_list.show_graphs(L) # long time
```

Generate all graphs with up to 5 vertices and up to 4 edges.

```
sage: L = list(graphs(5, lambda G: G.size() <= 4, augment='vertices'))
sage: len(L)
31
sage: graphs_list.show_graphs(L)               # long time
```

Generate all graphs with degree at most 2, up to 6 vertices.

```
sage: property = lambda G: ( max([G.degree(v) for v in G] + [0]) <= 2 )
sage: L = list(graphs(6, property, augment='vertices'))
sage: len(L)
45
```

Generate all bipartite graphs on up to 7 vertices: (see http://www.research.att.com/~njas/sequences/A033995)

```
sage: L = list( graphs(7, lambda G: G.is_bipartite(), augment='vertices') )
sage: [len([g for g in L if g.order() == i]) for i in [1..7]]
[1, 2, 3, 7, 13, 35, 88]
```

Generate all bipartite graphs on exactly 7 vertices:

```
sage: L = list( graphs(7, lambda G: G.is_bipartite()) )
sage: len(L)
88
```

Generate all bipartite graphs on exactly 8 vertices:

```
sage: L = list( graphs(8, lambda G: G.is_bipartite()) ) # long time
sage: len(L)                                            # long time
303
```

Generate graphs on the fly: (see http://www.research.att.com/~njas/sequences/A000088)

```
sage: for i in range(0, 7):
...     print len(list(graphs(i)))
1
1
2
4
11
34
156
```

Generate all simple graphs, allowing loops: (see http://www.research.att.com/~njas/sequences/A000666)

```
sage: L = list(graphs(6,augment='vertices',loops=True))               # long time
sage: for i in [0..6]: print i, len([g for g in L if g.order() == i]) # long time
0 1
1 2
2 6
3 20
4 90
```

```
5 544
6 5096
```

Generate all graphs with a specified degree sequence: (see http://www.research.att.com/~njas/sequences/A002851)

```
sage: for i in [4,6,8]:
...     print i, len([g for g in graphs(i,deg_seq=[3]*i) if g.is_connected()])
4 1
6 2
8 5
sage: for i in [4,6,8]:
...     print i, len([g for g in graphs(i,augment='vertices',deg_seq=[3]*i) if g.is_connected()])
4 1
6 2
8 5

sage: print 10, len([g for g in graphs(10,deg_seq=[3]*10) if g.is_connected()]) # not tested
10 19
```

REFERENCE:

- Brendan D. McKay, Isomorph-Free Exhaustive generation. Journal of Algorithms Volume 26, Issue 2, February 1998, pages 306-324.

BalancedTree(*r, h*)

Returns the perfectly balanced tree of height $h \geq 1$, whose root has degree $r \geq 2$.

The number of vertices of this graph is $1 + r + r^2 + \cdots + r^h$, that is, $\frac{r^{h+1}-1}{r-1}$. The number of edges is one less than the number of vertices.

EXAMPLE: Plot a balanced tree of height 4 with r = 3

```
sage: G = graphs.BalancedTree(3, 5)
sage: G.show()   # long time
```

BarbellGraph(*n1, n2*)

Returns a barbell graph with 2*n1 + n2 nodes. n1 must be greater than or equal to 2.

A barbell graph is a basic structure that consists of a path graph of order n2 connecting two complete graphs of order n1 each.

This constructor depends on NetworkX numeric labels. In this case, the (n1)th node connects to the path graph from one complete graph and the (n1+n2+1)th node connects to the path graph from the other complete graph.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, each barbell graph will be displayed with the two complete graphs in the lower-left and upper-right corners, with the path graph connecting diagonally between the two. Thus the (n1)th node will be drawn at a 45 degree angle from the horizontal right center of the first complete graph, and the (n1+n2+1)th node will be drawn 45 degrees below the left horizontal center of the second complete graph.

EXAMPLES: Construct and show a barbell graph Bar = 4, Bells = 9

```
sage: g = graphs.BarbellGraph(9,4)
sage: g.show() # long time
```

Create several barbell graphs in a Sage graphics array

```
sage: g = []
sage: j = []
sage: for i in range(6):
...     k = graphs.BarbellGraph(i+2,4)
...     g.append(k)
```

```
...
sage: for i in range(2):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

BullGraph()

Returns a bull graph with 5 nodes.

A bull graph is named for its shape. It's a triangle with horns.

This constructor depends on NetworkX numeric labeling.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, the bull graph is drawn as a triangle with the first node (0) on the bottom. The second and third nodes (1 and 2) complete the triangle. Node 3 is the horn connected to 1 and node 4 is the horn connected to node 2.

EXAMPLES: Construct and show a bull graph

```
sage: g = graphs.BullGraph()
sage: g.show() # long time
```

ChvatalGraph()

Returns the Chvatal graph.

The Chvatal graph has 12 vertices. It is a 4-regular, 4-chromatic graph. It is one of the few known graphs to satisfy Grunbaum's conjecture that for every m 1, n 2, there is an m-regular, m-chromatic graph of girth at least n.

EXAMPLE:

```
sage: G = graphs.ChvatalGraph()
sage: G.degree()
[4, 4, 4, 4, 4, 4, 4, 4, 4, 4, 4, 4]
```

CirculantGraph(*n, adjacency*)

Returns a circulant graph with n nodes.

A circulant graph has the property that the vertex i is connected with the vertices i+j and i-j for each j in adj.

INPUT:

- `n` - number of vertices in the graph
- `adjacency` - the list of j values

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, each circulant graph will be displayed with the first (0) node at the top, with the rest following in a counterclockwise manner.

Filling the position dictionary in advance adds O(n) to the constructor.

EXAMPLES: Compare plotting using the predefined layout and networkx:

```
sage: import networkx
sage: n = networkx.cycle_graph(23)
sage: spring23 = Graph(n)
sage: posdict23 = graphs.CirculantGraph(23,2)
sage: spring23.show() # long time
sage: posdict23.show() # long time
```

We next view many cycle graphs as a Sage graphics array. First we use the `CirculantGraph` constructor, which fills in the position dictionary:

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     k = graphs.CirculantGraph(i+3,i)
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

Compare to plotting with the spring-layout algorithm:

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     spr = networkx.cycle_graph(i+3)
...     k = Graph(spr)
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

Passing a 1 into adjacency should give the cycle.

```
sage: graphs.CirculantGraph(6,1)==graphs.CycleGraph(6)
True
sage: graphs.CirculantGraph(7,[1,3]).edges(labels=false)
[(0, 1),
(0, 3),
(0, 4),
(0, 6),
(1, 2),
(1, 4),
(1, 5),
(2, 3),
(2, 5),
(2, 6),
(3, 4),
(3, 6),
(4, 5),
(5, 6)]
```

CircularLadderGraph(*n*)

Returns a circular ladder graph with 2*n nodes.

A Circular ladder graph is a ladder graph that is connected at the ends, i.e.: a ladder bent around so that top meets bottom. Thus it can be described as two parallel cycle graphs connected at each corresponding node pair.

This constructor depends on NetworkX numeric labels.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, the circular ladder graph is displayed as an inner and outer cycle pair, with the first n nodes drawn on the inner circle. The first (0) node is drawn at the top of the inner-circle, moving clockwise after that. The outer circle is drawn with the (n+1)th node at the top, then counterclockwise as well.

EXAMPLES: Construct and show a circular ladder graph with 26 nodes

```
sage: g = graphs.CircularLadderGraph(13)
sage: g.show() # long time
```

Create several circular ladder graphs in a Sage graphics array

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     k = graphs.CircularLadderGraph(i+3)
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

ClawGraph()

Returns a claw graph.

A claw graph is named for its shape. It is actually a complete bipartite graph with (n1, n2) = (1, 3).

PLOTTING: See CompleteBipartiteGraph.

EXAMPLES: Show a Claw graph

```
sage: (graphs.ClawGraph()).show() # long time
```

Inspect a Claw graph

```
sage: G = graphs.ClawGraph()
sage: G
Claw graph: Graph on 4 vertices
```

CompleteBipartiteGraph(*n1, n2*)

Returns a Complete Bipartite Graph sized n1+n2, with each of the nodes [0,(n1-1)] connected to each of the nodes [n1,(n2-1)] and vice versa.

A Complete Bipartite Graph is a graph with its vertices partitioned into two groups, V1 and V2. Each v in V1 is connected to every v in V2, and vice versa.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, each complete bipartite graph will be displayed with the first n1 nodes on the top row (at y=1) from left to right. The remaining n2 nodes appear at y=0, also from left to right. The shorter row (partition with fewer nodes) is stretched to the same length as the longer row, unless the shorter row has 1 node; in which case it is centered. The x values in the plot are in domain [0,maxn1,n2].

In the Complete Bipartite graph, there is a visual difference in using the spring-layout algorithm vs. the position dictionary used in this constructor. The position dictionary flattens the graph and separates the partitioned nodes, making it clear which nodes an edge is connected to. The Complete Bipartite graph plotted with the spring-layout algorithm tends to center the nodes in n1 (see spring_med in examples below), thus overlapping its nodes and edges, making it typically hard to decipher.

Filling the position dictionary in advance adds O(n) to the constructor. Feel free to race the constructors below in the examples section. The much larger difference is the time added by the spring-layout algorithm

when plotting. (Also shown in the example below). The spring model is typically described as $O(n^3)$, as appears to be the case in the NetworkX source code.

EXAMPLES: Two ways of constructing the complete bipartite graph, using different layout algorithms:

```
sage: import networkx
sage: n = networkx.complete_bipartite_graph(389,157); spring_big = Graph(n)    # long time
sage: posdict_big = graphs.CompleteBipartiteGraph(389,157)                     # long time
```

Compare the plotting:

```
sage: n = networkx.complete_bipartite_graph(11,17)
sage: spring_med = Graph(n)
sage: posdict_med = graphs.CompleteBipartiteGraph(11,17)
```

Notice here how the spring-layout tends to center the nodes of n1

```
sage: spring_med.show() # long time
sage: posdict_med.show() # long time
```

View many complete bipartite graphs with a Sage Graphics Array, with this constructor (i.e., the position dictionary filled):

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     k = graphs.CompleteBipartiteGraph(i+1,4)
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

We compare to plotting with the spring-layout algorithm:

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     spr = networkx.complete_bipartite_graph(i+1,4)
...     k = Graph(spr)
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

CompleteGraph(*n*)

Returns a complete graph on n nodes.

A Complete Graph is a graph in which all nodes are connected to all other nodes.

This constructor is dependant on vertices numbered 0 through n-1 in NetworkX complete_graph()

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, each complete graph will be displayed with the first (0) node at the top, with the rest

following in a counterclockwise manner.

In the complete graph, there is a big difference visually in using the spring-layout algorithm vs. the position dictionary used in this constructor. The position dictionary flattens the graph, making it clear which nodes an edge is connected to. But the complete graph offers a good example of how the spring-layout works. The edges push outward (everything is connected), causing the graph to appear as a 3-dimensional pointy ball. (See examples below).

EXAMPLES: We view many Complete graphs with a Sage Graphics Array, first with this constructor (i.e., the position dictionary filled):

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     k = graphs.CompleteGraph(i+3)
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

We compare to plotting with the spring-layout algorithm:

```
sage: import networkx
sage: g = []
sage: j = []
sage: for i in range(9):
...     spr = networkx.complete_graph(i+3)
...     k = Graph(spr)
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

Compare the constructors (results will vary)

```
sage: import networkx
sage: t = cputime()
sage: n = networkx.complete_graph(389); spring389 = Graph(n)
sage: cputime(t)            # random
0.59203700000000126
sage: t = cputime()
sage: posdict389 = graphs.CompleteGraph(389)
sage: cputime(t)            # random
0.6680419999999998
```

We compare plotting:

```
sage: import networkx
sage: n = networkx.complete_graph(23)
sage: spring23 = Graph(n)
```

```
sage: posdict23 = graphs.CompleteGraph(23)
sage: spring23.show() # long time
sage: posdict23.show() # long time
```

CubeGraph(*n*)

AUTHORS:

- Robert Miller

PLOTTING: See commented source code.

EXAMPLES: Plot several n-cubes in a Sage Graphics Array

```
sage: g = []
sage: j = []
sage: for i in range(6):
...     k = graphs.CubeGraph(i+1)
...     g.append(k)
...
sage: for i in range(2):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show(figsize=[6,4]) # long time
```

Use the plot options to display larger n-cubes

```
sage: g = graphs.CubeGraph(9)
sage: g.show(figsize=[12,12],vertex_labels=False, vertex_size=20) # long time
```

CycleGraph(*n*)

Returns a cycle graph with n nodes.

A cycle graph is a basic structure which is also typically called an n-gon.

This constructor is dependant on vertices numbered 0 through n-1 in NetworkX `cycle_graph()`

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, each cycle graph will be displayed with the first (0) node at the top, with the rest following in a counterclockwise manner.

The cycle graph is a good opportunity to compare efficiency of filling a position dictionary vs. using the spring-layout algorithm for plotting. Because the cycle graph is very symmetric, the resulting plots should be similar (in cases of small n).

Filling the position dictionary in advance adds O(n) to the constructor.

EXAMPLES: Compare plotting using the predefined layout and networkx:

```
sage: import networkx
sage: n = networkx.cycle_graph(23)
sage: spring23 = Graph(n)
sage: posdict23 = graphs.CycleGraph(23)
sage: spring23.show() # long time
sage: posdict23.show() # long time
```

We next view many cycle graphs as a Sage graphics array. First we use the `CycleGraph` constructor, which fills in the position dictionary:

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     k = graphs.CycleGraph(i+3)
```

```
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

Compare to plotting with the spring-layout algorithm:

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     spr = networkx.cycle_graph(i+3)
...     k = Graph(spr)
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

DegreeSequence(*deg_sequence*)

Returns a graph with the given degree sequence. Raises a NetworkX error if the proposed degree sequence cannot be that of a graph.

Graph returned is the one returned by the Havel-Hakimi algorithm, which constructs a simple graph by connecting vertices of highest degree to other vertices of highest degree, resorting the remaining vertices by degree and repeating the process. See Theorem 1.4 in [1].

INPUT:

- `deg_sequence` - a list of integers with each entry corresponding to the degree of a different vertex.

EXAMPLES:

```
sage: G = graphs.DegreeSequence([3,3,3,3])
sage: G.edges(labels=False)
[(0, 1), (0, 2), (0, 3), (1, 2), (1, 3), (2, 3)]
sage: G.show()  # long time

sage: G = graphs.DegreeSequence([3,3,3,3,3,3,3,3,3,3,3,3,3,3,3,3,3,3,3,3,3,3])
sage: G.show()  # long time

sage: G = graphs.DegreeSequence([4,4,4,4,4,4,4,4])
sage: G.show()  # long time

sage: G = graphs.DegreeSequence([1,2,3,4,3,4,3,2,3,2,1])
sage: G.show()  # long time
```

REFERENCE:

- [1] Chartrand, G. and Lesniak, L. Graphs and Digraphs. Chapman and Hall/CRC, 1996.

DegreeSequenceConfigurationModel(*deg_sequence, seed=None*)

Returns a random pseudograph with the given degree sequence. Raises a NetworkX error if the proposed degree sequence cannot be that of a graph with multiple edges and loops.

One requirement is that the sum of the degrees must be even, since every edge must be incident with two vertices.

INPUT:

- `deg_sequence` - a list of integers with each entry corresponding to the expected degree of a different vertex.
- `seed` - for the random number generator.

EXAMPLES:

```
sage: G = graphs.DegreeSequenceConfigurationModel([1,1])
sage: G.adjacency_matrix()
[0 1]
[1 0]
```

Note: as of this writing, plotting of loops and multiple edges is not supported, and the output is allowed to contain both types of edges.

```
sage: G = graphs.DegreeSequenceConfigurationModel([3,3,3,3,3,3,3,3,3,3,3,3,3,3,3,3,3,3,3,3])
sage: G.edges(labels=False)
[(0, 2), (0, 10), (0, 15), (1, 6), (1, 16), (1, 17), (2, 5), (2, 19), (3, 7), (3, 14), (3, 1
sage: G.show()  # long time
```

REFERENCE:

- [1] Newman, M.E.J. The Structure and function of complex networks, SIAM Review vol. 45, no. 2 (2003), pp. 167-256.

DegreeSequenceExpected(*deg_sequence, seed=None*)

Returns a random graph with expected given degree sequence. Raises a NetworkX error if the proposed degree sequence cannot be that of a graph.

One requirement is that the sum of the degrees must be even, since every edge must be incident with two vertices.

INPUT:

- `deg_sequence` - a list of integers with each entry corresponding to the expected degree of a different vertex.
- `seed` - for the random number generator.

EXAMPLE:

```
sage: G = graphs.DegreeSequenceExpected([1,2,3,2,3])
sage: G.edges(labels=False)
[(0, 2), (1, 1), (1, 3), (2, 2), (2, 4), (3, 3)]
sage: G.show()  # long time
```

REFERENCE:

- [1] Chung, Fan and Lu, L. Connected components in random graphs with given expected degree sequences. Ann. Combinatorics (6), 2002 pp. 125-145.

DegreeSequenceTree(*deg_sequence*)

Returns a tree with the given degree sequence. Raises a NetworkX error if the proposed degree sequence cannot be that of a tree.

Since every tree has one more vertex than edge, the degree sequence must satisfy len(deg_sequence) - sum(deg_sequence)/2 == 1.

INPUT:

- `deg_sequence` - a list of integers with each entry corresponding to the expected degree of a different vertex.

EXAMPLE:

```
sage: G = graphs.DegreeSequenceTree([3,1,3,3,1,1,1,2,1])
sage: G.show()  # long time
```

DesarguesGraph()

Returns the Desargues graph.

PLOTTING: The layout chosen is the same as on the cover of [1].

EXAMPLE:

```
sage: D = graphs.DesarguesGraph()
sage: L = graphs.LCFGraph(20,[5,-5,9,-9],5)
sage: D.is_isomorphic(L)
True
sage: D.show()  # long time
```

REFERENCE:

- [1] Harary, F. Graph Theory. Reading, MA: Addison-Wesley, 1994.

DiamondGraph()

Returns a diamond graph with 4 nodes.

A diamond graph is a square with one pair of diagonal nodes connected.

This constructor depends on NetworkX numeric labeling.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, the diamond graph is drawn as a diamond, with the first node on top, second on the left, third on the right, and fourth on the bottom; with the second and third node connected.

EXAMPLES: Construct and show a diamond graph

```
sage: g = graphs.DiamondGraph()
sage: g.show() # long time
```

DodecahedralGraph()

Returns a Dodecahedral graph (with 20 nodes)

The dodecahedral graph is cubic symmetric, so the spring-layout algorithm will be very effective for display. It is dual to the icosahedral graph.

PLOTTING: The Dodecahedral graph should be viewed in 3 dimensions. We chose to use the default spring-layout algorithm here, so that multiple iterations might yield a different point of reference for the user. We hope to add rotatable, 3-dimensional viewing in the future. In such a case, a string argument will be added to select the flat spring-layout over a future implementation.

EXAMPLES: Construct and show a Dodecahdedral graph

```
sage: g = graphs.DodecahedralGraph()
sage: g.show() # long time
```

Create several dodecahedral graphs in a Sage graphics array They will be drawn differently due to the use of the spring-layout algorithm

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     k = graphs.DodecahedralGraph()
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
```

```
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

DorogovtsevGoltsevMendesGraph(*n*)

Construct the n-th generation of the Dorogovtsev-Goltsev-Mendes graph.

EXAMPLE:

```
sage: G = graphs.DorogovtsevGoltsevMendesGraph(8)
sage: G.size()
6561
```

REFERENCE:

- [1] Dorogovtsev, S. N., Goltsev, A. V., and Mendes, J. F. F., Pseudofractal scale-free web, Phys. Rev. E 066122 (2002).

EmptyGraph()

Returns an empty graph (0 nodes and 0 edges).

This is useful for constructing graphs by adding edges and vertices individually or in a loop.

PLOTTING: When plotting, this graph will use the default spring-layout algorithm, unless a position dictionary is specified.

EXAMPLES: Add one vertex to an empty graph and then show:

```
sage: empty1 = graphs.EmptyGraph()
sage: empty1.add_vertex()
sage: empty1.show() # long time
```

Use for loops to build a graph from an empty graph:

```
sage: empty2 = graphs.EmptyGraph()
sage: for i in range(5):
...     empty2.add_vertex() # add 5 nodes, labeled 0-4
...
sage: for i in range(3):
...     empty2.add_edge(i,i+1) # add edges {[0:1],[1:2],[2:3]}
...
sage: for i in range(4)[1:]:
...     empty2.add_edge(4,i) # add edges {[1:4],[2:4],[3:4]}
...
sage: empty2.show() # long time
```

FlowerSnark()

Returns a Flower Snark.

A flower snark has 20 vertices. It is part of the class of biconnected cubic graphs with edge chromatic number = 4, known as snarks. (i.e.: the Petersen graph). All snarks are not Hamiltonian, non-planar and have Petersen graph graph minors.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algoirithm. By convention, the nodes are drawn 0-14 on the outer circle, and 15-19 in an inner pentagon.

REFERENCES:

- [1] Weisstein, E. (1999). "Flower Snark - from Wolfram MathWorld". [Online] Available: http://mathworld.wolfram.com/FlowerSnark.html [2007, February 17]

EXAMPLES: Inspect a flower snark:

```
sage: F = graphs.FlowerSnark()
sage: F
Flower Snark: Graph on 20 vertices
sage: F.graph6_string()
'ShCGHC@?GGg@?@?Gp?K??C?CA?G?_G?Cc'
```

Now show it:

```
sage: F.show() # long time
```

FruchtGraph()

Returns a Frucht Graph.

A Frucht graph has 12 nodes and 18 edges. It is the smallest cubic identity graph. It is planar and it is Hamiltonian.

This constructor is dependant on Networkx's numeric labeling.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, the first seven nodes are on the outer circle, with the next four on an inner circle and the last in the center.

REFERENCES:

- [1] Weisstein, E. (1999). "Frucht Graph - from Wolfram MathWorld". [Online] Available: http://mathworld.wolfram.com/FruchtGraph.html [2007, February 17]

EXAMPLES:

```
sage: FRUCHT = graphs.FruchtGraph()
sage: FRUCHT
Frucht graph: Graph on 12 vertices
sage: FRUCHT.graph6_string()
'KhCKM?_EGK?L'
sage: (graphs.FruchtGraph()).show() # long time
```

Grid2dGraph(*n1, n2*)

Returns a 2-dimensional grid graph with n1*n2 nodes (n1 rows and n2 columns).

A 2d grid graph resembles a 2 dimensional grid. All inner nodes are connected to their 4 neighbors. Outer (non-corner) nodes are connected to their 3 neighbors. Corner nodes are connected to their 2 neighbors.

This constructor depends on NetworkX numeric labels.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, nodes are labelled in (row, column) pairs with (0, 0) in the top left corner. Edges will always be horizontal and vertical - another advantage of filling the position dictionary.

EXAMPLES: Construct and show a grid 2d graph Rows = 5, Columns = 7

```
sage: g = graphs.Grid2dGraph(5,7)
sage: g.show() # long time
```

GridGraph(*dim_list*)

Returns an n-dimensional grid graph.

INPUT:

- `dim_list` - a list of integers representing the number of nodes to extend in each dimension.

PLOTTING: When plotting, this graph will use the default spring-layout algorithm, unless a position dictionary is specified.

EXAMPLES:

```
sage: G = graphs.GridGraph([2,3,4])
sage: G.show()  # long time

sage: C = graphs.CubeGraph(4)
sage: G = graphs.GridGraph([2,2,2,2])
sage: C.show()  # long time
sage: G.show()  # long time
```

HeawoodGraph()

Returns a Heawood graph.

The Heawood graph is a cage graph that has 14 nodes. It is a cubic symmetric graph. (See also the Moebius-Kantor graph). It is nonplanar and Hamiltonian. It has diameter = 3, radius = 3, girth = 6, chromatic number = 2. It is 4-transitive but not 5-transitive.

This constructor is dependant on Networkx's numeric labeling.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, the nodes are positioned in a circular layout with the first node appearing at the top, and then continuing counterclockwise.

REFERENCES:

- [1] Weisstein, E. (1999). "Heawood Graph - from Wolfram MathWorld". [Online] Available: http://mathworld.wolfram.com/HeawoodGraph.html [2007, February 17]

EXAMPLES:

```
sage: H = graphs.HeawoodGraph()
sage: H
Heawood graph: Graph on 14 vertices
sage: H.graph6_string()
'MhEGHC@AI?_PC@_G_'
sage: (graphs.HeawoodGraph()).show() # long time
```

HexahedralGraph()

Returns a hexahedral graph (with 8 nodes).

A regular hexahedron is a 6-sided cube. The hexahedral graph corresponds to the connectivity of the vertices of the hexahedron. This graph is equivalent to a 3-cube.

PLOTTING: The hexahedral graph should be viewed in 3 dimensions. We chose to use the default spring-layout algorithm here, so that multiple iterations might yield a different point of reference for the user. We hope to add rotatable, 3-dimensional viewing in the future. In such a case, a string argument will be added to select the flat spring-layout over a future implementation.

EXAMPLES: Construct and show a Hexahedral graph

```
sage: g = graphs.HexahedralGraph()
sage: g.show() # long time
```

Create several hexahedral graphs in a Sage graphics array. They will be drawn differently due to the use of the spring-layout algorithm.

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     k = graphs.HexahedralGraph()
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

HoffmanSingletonGraph()

Returns the Hoffman-Singleton graph.

The Hoffman-Singleton graph is the Moore graph of degree 7, diameter 2 and girth 5. The Hoffman-Singleton theorem states that any Moore graph with girth 5 must have degree 2, 3, 7 or 57. The first three respectively are the pentagon, the Petersen graph, and the Hoffman-Singleton graph. The existence of a Moore graph with girth 5 and degree 57 is still open.

A Moore graph is a graph with diameter d and girth $2d + 1$. This implies that the graph is regular, and distance regular.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. A novel algorithm written by Tom Boothby gives a random layout which is pleasing to the eye.

REFERENCES:

•[1] Godsil, C. and Royle, G. Algebraic Graph Theory. Springer, 2001.

EXAMPLES:

```
sage: HS = graphs.HoffmanSingletonGraph()
sage: Set(HS.degree())
{7}
sage: HS.girth()
5
sage: HS.diameter()
2
sage: HS.num_verts()
50
```

HouseGraph()

Returns a house graph with 5 nodes.

A house graph is named for its shape. It is a triange (roof) over a square (walls).

This constructor depends on NetworkX numeric labeling.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, the house graph is drawn with the first node in the lower-left corner of the house, the second in the lower-right corner of the house. The third node is in the upper-left corner connecting the roof to the wall, and the fourth is in the upper-right corner connecting the roof to the walll. The fifth node is the top of the roof, connected only to the third and fourth.

EXAMPLES: Construct and show a house graph

```
sage: g = graphs.HouseGraph()
sage: g.show() # long time
```

HouseXGraph()

Returns a house X graph with 5 nodes.

A house X graph is a house graph with two additional edges. The upper-right corner is connected to the lower-left. And the upper-left corner is connected to the lower-right.

This constructor depends on NetworkX numeric labeling.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, the house X graph is drawn with the first node in the lower-left corner of the house, the second in the lower-right corner of the house. The third node is in the upper-left corner connecting the roof to the wall, and the fourth is in the upper-right corner connecting the roof to the walll. The fifth node is the top of the roof, connected only to the third and fourth.

EXAMPLES: Construct and show a house X graph

```
sage: g = graphs.HouseXGraph()
sage: g.show() # long time
```

IcosahedralGraph()

Returns an Icosahedral graph (with 12 nodes).

The regular icosahedron is a 20-sided triangular polyhedron. The icosahedral graph corresponds to the connectivity of the vertices of the icosahedron. It is dual to the dodecahedral graph. The icosahedron is symmetric, so the spring-layout algorithm will be very effective for display.

PLOTTING: The Icosahedral graph should be viewed in 3 dimensions. We chose to use the default spring-layout algorithm here, so that multiple iterations might yield a different point of reference for the user. We

hope to add rotatable, 3-dimensional viewing in the future. In such a case, a string argument will be added to select the flat spring-layout over a future implementation.

EXAMPLES: Construct and show an Octahedral graph

```
sage: g = graphs.IcosahedralGraph()
sage: g.show() # long time
```

Create several icosahedral graphs in a Sage graphics array. They will be drawn differently due to the use of the spring-layout algorithm.

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     k = graphs.IcosahedralGraph()
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

KrackhardtKiteGraph()

Returns a Krackhardt kite graph with 10 nodes.

The Krackhardt kite graph was originally developed by David Krackhardt for the purpose of studying social networks. It is used to show the distinction between: degree centrality, betweeness centrality, and closeness centrality. For more information read the plotting section below in conjunction with the example.

REFERENCES:

- [1] Kreps, V. (2002). "Social Network Analysis". [Online] Available: http://www.fsu.edu/~spap/water/network/intro.htm [2007, January 17]

This constructor depends on NetworkX numeric labeling.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, the graph is drawn left to right, in top to bottom row sequence of [2, 3, 2, 1, 1, 1] nodes on each row. This places the fourth node (3) in the center of the kite, with the highest degree. But the fourth node only connects nodes that are otherwise connected, or those in its clique (i.e.: Degree Centrality). The eigth (7) node is where the kite meets the tail. It has degree = 3, less than the average, but is the only connection between the kite and tail (i.e.: Betweenness Centrality). The sixth and seventh nodes (5 and 6) are drawn in the third row and have degree = 5. These nodes have the shortest path to all other nodes in the graph (i.e.: Closeness Centrality). Please execute the example for visualization.

EXAMPLE: Construct and show a Krackhardt kite graph

```
sage: g = graphs.KrackhardtKiteGraph()
sage: g.show() # long time
```

LCFGraph(*n, shift_list, repeats*)

Returns the cubic graph specified in LCF notation.

LCF (Lederberg-Coxeter-Fruchte) notation is a concise way of describing cubic Hamiltonian graphs. The way a graph is constructed is as follows. Since there is a Hamiltonian cycle, we first create a cycle on n nodes. The variable shift_list = [s_0, s_1, ..., s_k-1] describes edges to be created by the following scheme: for each i, connect vertex i to vertex (i + s_i). Then, repeats specifies the number of times to repeat this process, where on the jth repeat we connect vertex (i + j*len(shift_list)) to vertex (i + j*len(shift_list) + s_i).

INPUT:

- n - the number of nodes.
- shift_list - a list of integer shifts mod n.
- repeats - the number of times to repeat the process.

EXAMPLES:

```
sage: G = graphs.LCFGraph(4, [2,-2], 2)
sage: G.is_isomorphic(graphs.TetrahedralGraph())
True

sage: G = graphs.LCFGraph(20, [10,7,4,-4,-7,10,-4,7,-7,4], 2)
sage: G.is_isomorphic(graphs.DodecahedralGraph())
True

sage: G = graphs.LCFGraph(14, [5,-5], 7)
sage: G.is_isomorphic(graphs.HeawoodGraph())
True
```

The largest cubic nonplanar graph of diameter three:

```
sage: G = graphs.LCFGraph(20, [-10,-7,-5,4,7,-10,-7,-4,5,7,-10,-7,6,-5,7,-10,-7,5,-6,7], 1)
sage: G.degree()
[3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3]
sage: G.diameter()
3
sage: G.show()  # long time
```

PLOTTING: LCF Graphs are plotted as an n-cycle with edges in the middle, as described above.

LadderGraph(*n*)

Returns a ladder graph with 2*n nodes.

A ladder graph is a basic structure that is typically displayed as a ladder, i.e.: two parallel path graphs connected at each corresponding node pair.

This constructor depends on NetworkX numeric labels.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, each ladder graph will be displayed horizontally, with the first n nodes displayed left to right on the top horizontal line.

EXAMPLES: Construct and show a ladder graph with 14 nodes

```
sage: g = graphs.LadderGraph(7)
sage: g.show() # long time
```

Create several ladder graphs in a Sage graphics array

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     k = graphs.LadderGraph(i+2)
...     g.append(k)
...
sage: for i in range(3):
```

```
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

LollipopGraph(*n1, n2*)

Returns a lollipop graph with n1+n2 nodes.

A lollipop graph is a path graph (order n2) connected to a complete graph (order n1). (A barbell graph minus one of the bells).

This constructor depends on NetworkX numeric labels.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, the complete graph will be drawn in the lower-left corner with the (n1)th node at a 45 degree angle above the right horizontal center of the complete graph, leading directly into the path graph.

EXAMPLES: Construct and show a lollipop graph Candy = 13, Stick = 4

```
sage: g = graphs.LollipopGraph(13,4)
sage: g.show() # long time
```

Create several lollipop graphs in a Sage graphics array

```
sage: g = []
sage: j = []
sage: for i in range(6):
...     k = graphs.LollipopGraph(i+3,4)
...     g.append(k)
...
sage: for i in range(2):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

MoebiusKantorGraph()

Returns a Moebius-Kantor Graph.

A Moebius-Kantor graph is a cubic symmetric graph. (See also the Heawood graph). It has 16 nodes and 24 edges. It is nonplanar and Hamiltonian. It has diameter = 4, girth = 6, and chromatic number = 2. It is identical to the Generalized Petersen graph, P[8,3].

PLOTTING: Upon construction, the position dictionary is filled to overwrite the spring-layout algorithm. By convention, the first 8 nodes are drawn counter-clockwise in an outer circle, with the remaining eight drawn likewise nested in a smaller circular pattern. The Moebius-Kantor graph is constructed directly below from a dictionary with nodes as keys and entries represented the nodes they are connected to. Please browse this dictionary or display an example to further understand the plotting convention.

REFERENCES:

- [1] Weisstein, E. (1999). "Moebius-Kantor Graph - from Wolfram MathWorld". [Online] Available: http://mathworld.wolfram.com/Moebius-KantorGraph.html [2007, February 17]

EXAMPLES:

```
sage: MK = graphs.MoebiusKantorGraph()
sage: MK
Moebius-Kantor Graph: Graph on 16 vertices
```

```
sage: MK.graph6_string()
'OhCGKE?O@?ACAC@I?Q_AS'
sage: (graphs.MoebiusKantorGraph()).show() # long time
```

OctahedralGraph()

Returns an Octahedral graph (with 6 nodes).

The regular octahedron is an 8-sided polyhedron with triangular faces. The octahedral graph corresponds to the connectivity of the vertices of the octahedron. It is the line graph of the tetrahedral graph. The octahedral is symmetric, so the spring-layout algorithm will be very effective for display.

PLOTTING: The Octahedral graph should be viewed in 3 dimensions. We chose to use the default spring-layout algorithm here, so that multiple iterations might yield a different point of reference for the user. We hope to add rotatable, 3-dimensional viewing in the future. In such a case, a string argument will be added to select the flat spring-layout over a future implementation.

EXAMPLES: Construct and show an Octahedral graph

```
sage: g = graphs.OctahedralGraph()
sage: g.show() # long time
```

Create several octahedral graphs in a Sage graphics array They will be drawn differently due to the use of the spring-layout algorithm

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     k = graphs.OctahedralGraph()
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

PappusGraph()

Returns the Pappus graph, a graph on 18 vertices.

The Pappus graph is cubic, symmetric, and distance-regular.

EXAMPLES:

```
sage: G = graphs.PappusGraph()
sage: G.show()  # long time
sage: L = graphs.LCFGraph(18, [5,7,-7,7,-7,-5], 3)
sage: L.show()  # long time
sage: G.is_isomorphic(L)
True
```

PathGraph(*n, pos=None*)

Returns a path graph with n nodes. Pos argument takes a string which is either 'circle' or 'line', (otherwise the default is used). See the plotting section below for more detail.

A path graph is a graph where all inner nodes are connected to their two neighbors and the two end-nodes are connected to their one inner neighbors. (i.e.: a cycle graph without the first and last node connected).

This constructor depends on NetworkX numeric labels.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, the graph may be drawn in one of two ways: The 'line' argument will draw the graph in a horizontal line (left to right) if there are less than 11 nodes. Otherwise the 'line' argument will append

horizontal lines of length 10 nodes below, alternating left to right and right to left. The 'circle' argument will cause the graph to be drawn in a cycle-shape, with the first node at the top and then about the circle in a clockwise manner. By default (without an appropriate string argument) the graph will be drawn as a 'circle' if 10 n 41 and as a 'line' for all other n.

EXAMPLES: Show default drawing by size: 'line': n 11

```
sage: p = graphs.PathGraph(10)
sage: p.show() # long time
```

'circle': 10 n 41

```
sage: q = graphs.PathGraph(25)
sage: q.show() # long time
```

'line': n 40

```
sage: r = graphs.PathGraph(55)
sage: r.show() # long time
```

Override the default drawing:

```
sage: s = graphs.PathGraph(5,'circle')
sage: s.show() # long time
```

PetersenGraph()

The Petersen Graph is a named graph that consists of 10 vertices and 15 edges, usually drawn as a five-point star embedded in a pentagon.

The Petersen Graph is a common counterexample. For example, it is not Hamiltonian.

PLOTTING: When plotting the Petersen graph with the spring-layout algorithm, we see that this graph is not very symmetric and thus the display may not be very meaningful. Efficiency of construction and plotting is not an issue, as the Petersen graph only has 10 vertices.

Our labeling convention here is to start on the outer pentagon from the top, moving counterclockwise. Then the nodes on the inner star, starting at the top and moving counterclockwise.

EXAMPLES: We compare below the Petersen graph with the default spring-layout versus a planned position dictionary of [x,y] tuples:

```
sage: petersen_spring = Graph({0:[1,4,5], 1:[0,2,6], 2:[1,3,7], 3:[2,4,8], 4:[0,3,9], 5:[0,7
sage: petersen_spring.show() # long time
sage: petersen_database = graphs.PetersenGraph()
sage: petersen_database.show() # long time
```

RandomBarabasiAlbert(*n, m, seed=None*)

Return a random graph created using the Barabasi-Albert preferential attachment model.

A graph with m vertices and no edges is initialized, and a graph of n vertices is grown by attaching new veritces each with m edges that are attached to existing vertices, preferentially with high degree.

INPUT:

- `n` - number of vertices in the graph
- `m` - number of edges to attach from each new node
- `seed` - for random number generator

EXAMPLES:

We show the edge list of a random graph on 6 nodes with m = 2.

```
sage: graphs.RandomBarabasiAlbert(6,2).edges(labels=False)
[(0, 2), (0, 3), (0, 4), (1, 2), (1, 3), (2, 4), (2, 5), (3, 5)]
```

We plot a random graph on 12 nodes with m = 3.

```
sage: ba = graphs.RandomBarabasiAlbert(12,3)
sage: ba.show()  # long time
```

We view many random graphs using a graphics array:

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     k = graphs.RandomBarabasiAlbert(i+3, 3)
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show()  # long time
```

RandomGNM(*n, m, dense=False, seed=None*)

Returns a graph randomly picked out of all graphs on n vertices with m edges.

INPUT:

- `n` - number of vertices.
- `m` - number of edges.
- `dense` - whether to use NetworkX's dense_gnm_random_graph or gnm_random_graph

EXAMPLES: We show the edge list of a random graph on 5 nodes with 10 edges.

```
sage: graphs.RandomGNM(5, 10).edges(labels=False)
[(0, 1), (0, 2), (0, 3), (0, 4), (1, 2), (1, 3), (1, 4), (2, 3), (2, 4), (3, 4)]
```

We plot a random graph on 12 nodes with m = 12.

```
sage: gnm = graphs.RandomGNM(12, 12)
sage: gnm.show()  # long time
```

We view many random graphs using a graphics array:

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     k = graphs.RandomGNM(i+3, i^2-i)
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show()  # long time
```

RandomGNP(*n, p, seed=None, fast=True*)

Returns a Random graph on n nodes. Each edge is inserted independently with probability p.

IMPLEMENTATION: This function calls the NetworkX function `fast_gnp_random_graph`, unless fast==False, then `gnp_random_graph`.

REFERENCES:

- [1] P. Erdos and A. Renyi, On Random Graphs, Publ. Math. 6, 290 (1959).
- [2] E. N. Gilbert, Random Graphs, Ann. Math. Stat., 30, 1141 (1959).

PLOTTING: When plotting, this graph will use the default spring-layout algorithm, unless a position dictionary is specified.

EXAMPLES: We show the edge list of a random graph on 6 nodes with probability $p = .4$:

```
sage: graphs.RandomGNP(6, .4).edges(labels=False)
[(0, 1), (0, 3), (0, 4), (0, 5), (1, 2), (1, 3), (1, 4), (1, 5)]
```

We plot a random graph on 12 nodes with probability $p = .71$:

```
sage: gnp = graphs.RandomGNP(12,.71)
sage: gnp.show() # long time
```

We view many random graphs using a graphics array:

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     k = graphs.RandomGNP(i+3,.43)
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
sage: graphs.RandomGNP(4,1)
Complete graph: Graph on 4 vertices
```

TIMINGS: The following timings compare the speed with fast==False and fast==True for sparse and dense graphs. (It's no different?)

```
sage: t=cputime(); regular_sparse = graphs.RandomGNP(389,.22)
sage: cputime(t)      # slightly random
0.2240130000000029

sage: t=cputime(); fast_sparse =  graphs.RandomGNP(389,.22,fast=True)
sage: cputime(t)      # slightly random
0.22401400000000038

sage: t=cputime(); regular_dense = graphs.RandomGNP(389,.88)     # long time
sage: cputime(t)      # slightly random, long time
0.87205499999999958

sage: t=cputime(); fast_dense = graphs.RandomGNP(389,.88,fast=True)     # long time
sage: cputime(t)      # slightly random, long time
0.90005700000000033
```

RandomHolmeKim(*n, m, p, seed=None*)

Returns a random graph generated by the Holme and Kim algorithm for graphs with powerlaw degree distribution and approximate average clustering.

INPUT:

- n - number of vertices.
- m - number of random edges to add for each new node.
- p - probability of adding a triangle after adding a random edge.

- seed - for the random number generator.

From the NetworkX documentation: The average clustering has a hard time getting above a certain cutoff that depends on m. This cutoff is often quite low. Note that the transitivity (fraction of triangles to possible triangles) seems to go down with network size. It is essentially the Barabasi-Albert growth model with an extra step that each random edge is followed by a chance of making an edge to one of its neighbors too (and thus a triangle). This algorithm improves on B-A in the sense that it enables a higher average clustering to be attained if desired. It seems possible to have a disconnected graph with this algorithm since the initial m nodes may not be all linked to a new node on the first iteration like the BA model.

EXAMPLE: We show the edge list of a random graph on 8 nodes with 2 random edges per node and a probability $p = 0.5$ of forming triangles.

```
sage: graphs.RandomHolmeKim(8, 2, 0.5).edges(labels=False)
[(0, 2), (0, 4), (1, 2), (1, 3), (2, 3), (3, 4), (3, 5), (3, 6), (3, 7), (4, 5), (4, 6)]

sage: G = graphs.RandomHolmeKim(12, 3, .3)
sage: G.show()  # long time
```

REFERENCE:

- [1] Holme, P. and Kim, B.J. Growing scale-free networks with tunable clustering, Phys. Rev. E (2002). vol 65, no 2, 026107.

RandomLobster(*n, p, q, seed=None*)

Returns a random lobster.

A lobster is a tree that reduces to a caterpillar when pruning all leaf vertices. A caterpillar is a tree that reduces to a path when pruning all leaf vertices (q=0).

INPUT:

- n - expected number of vertices in the backbone
- p - probability of adding an edge to the backbone
- q - probability of adding an edge (claw) to the arms
- seed - for the random number generator

EXAMPLE: We show the edge list of a random graph with 3 backbone nodes and probabilities $p = 0.7$ and $q = 0.3$:

```
sage: graphs.RandomLobster(3, 0.7, 0.3).edges(labels=False)
[(0, 1), (1, 2)]

sage: G = graphs.RandomLobster(9, .6, .3)
sage: G.show()  # long time
```

RandomNewmanWattsStrogatz(*n, k, p, seed=None*)

Returns a Newman-Watts-Strogatz small world random graph on n vertices.

From the NetworkX documentation: First create a ring over n nodes. Then each node in the ring is connected with its k nearest neighbors. Then shortcuts are created by adding new edges as follows: for each edge u-v in the underlying "n-ring with k nearest neighbors"; with probability p add a new edge u-w with randomly-chosen existing node w. In contrast with watts_strogatz_graph(), no edges are removed.

INPUT:

- n - number of vertices.
- k - each vertex is connected to its k nearest neighbors
- p - the probability of adding a new edge for each edge
- seed - for the random number generator

EXAMPLE: We show the edge list of a random graph on 7 nodes with 2 "nearest neighbors" and probability $p = 0.2$:

```
sage: graphs.RandomNewmanWattsStrogatz(7, 2, 0.2).edges(labels=False)
[(0, 1), (0, 2), (0, 3), (0, 6), (1, 2), (2, 3), (2, 4), (3, 4), (3, 6), (4, 5), (5, 6)]

sage: G = graphs.RandomNewmanWattsStrogatz(12, 2, .3)
sage: G.show()  # long time
```

REFERENCE:

- [1] Newman, M.E.J., Watts, D.J. and Strogatz, S.H. Random graph models of social networks. Proc. Nat. Acad. Sci. USA 99, 2566-2572.

RandomRegular(*d, n, seed=None*)

Returns a random d-regular graph on n vertices, or returns False on failure.

Since every edge is incident to two vertices, n*d must be even.

INPUT:

- `n` - number of vertices
- `d` - degree
- `seed` - for the random number generator

EXAMPLE: We show the edge list of a random graph with 8 nodes each of degree 3.

```
sage: graphs.RandomRegular(3, 8)
Graph on 0 vertices
sage: graphs.RandomRegular(3, 8)
Graph on 0 vertices
sage: graphs.RandomRegular(3, 8).edges(labels=False)
[(0, 1), (0, 4), (0, 5), (1, 6), (1, 7), (2, 3), (2, 4), (2, 7), (3, 4), (3, 5), (5, 6), (6,

sage: G = graphs.RandomRegular(3, 20)
sage: if G:
...     G.show()  # random output, long time
```

REFERENCES:

- [2] Steger, A. and Wormald, N. Generating random regular graphs quickly. Prob. and Comp. 8 (1999), pp 377-396.

RandomShell(*constructor, seed=None*)

Returns a random shell graph for the constructor given.

INPUT:

- `constructor` - a list of 3-tuples (n,m,d), each representing a shell
- `n` - the number of vertices in the shell
- `m` - the number of edges in the shell
- `d` - the ratio of inter (next) shell edges to intra shell edges
- `seed` - for the random number generator

EXAMPLE:

```
sage: G = graphs.RandomShell([(10,20,0.8),(20,40,0.8)])
sage: G.edges(labels=False)
[(0, 3), (0, 7), (0, 8), (1, 2), (1, 5), (1, 8), (1, 9), (3, 6), (3, 11), (4, 6), (4, 7), (4
sage: G.show()  # long time
```

RandomTreePowerlaw(*n, gamma=3, tries=100, seed=None*)

Returns a tree with a powerlaw degree distribution. Returns False on failure.

From the NetworkX documentation: A trial powerlaw degree sequence is chosen and then elements are swapped with new elements from a powerlaw distribution until the sequence makes a tree (size = order - 1).

INPUT:

- `n` - number of vertices
- `gamma` - exponent of power law
- `tries` - number of attempts to adjust sequence to make a tree
- `seed` - for the random number generator

EXAMPLE: We show the edge list of a random graph with 10 nodes and a power law exponent of 2.

```
sage: graphs.RandomTreePowerlaw(10, 2).edges(labels=False)
[(0, 1), (1, 2), (2, 3), (3, 4), (4, 5), (5, 6), (6, 7), (6, 8), (6, 9)]

sage: G = graphs.RandomTreePowerlaw(15, 2)
sage: if G:
...     G.show()  # random output, long time
```

StarGraph(*n*)

Returns a star graph with n+1 nodes.

A Star graph is a basic structure where one node is connected to all other nodes.

This constructor is dependant on NetworkX numeric labels.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, each star graph will be displayed with the first (0) node in the center, the second node (1) at the top, with the rest following in a counterclockwise manner. (0) is the node connected to all other nodes.

The star graph is a good opportunity to compare efficiency of filling a position dictionary vs. using the spring-layout algorithm for plotting. As far as display, the spring-layout should push all other nodes away from the (0) node, and thus look very similar to this constructor's positioning.

EXAMPLES:

```
sage: import networkx
```

Compare the plots:

```
sage: n = networkx.star_graph(23)
sage: spring23 = Graph(n)
sage: posdict23 = graphs.StarGraph(23)
sage: spring23.show() # long time
sage: posdict23.show() # long time
```

View many star graphs as a Sage Graphics Array

With this constructor (i.e., the position dictionary filled)

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     k = graphs.StarGraph(i+3)
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

Compared to plotting with the spring-layout algorithm

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     spr = networkx.star_graph(i+3)
...     k = Graph(spr)
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

TetrahedralGraph()

Returns a tetrahedral graph (with 4 nodes).

A tetrahedron is a 4-sided triangular pyramid. The tetrahedral graph corresponds to the connectivity of the vertices of the tetrahedron. This graph is equivalent to a wheel graph with 4 nodes and also a complete graph on four nodes. (See examples below).

PLOTTING: The tetrahedral graph should be viewed in 3 dimensions. We chose to use the default spring-layout algorithm here, so that multiple iterations might yield a different point of reference for the user. We hope to add rotatable, 3-dimensional viewing in the future. In such a case, a string argument will be added to select the flat spring-layout over a future implementation.

EXAMPLES: Construct and show a Tetrahedral graph

```
sage: g = graphs.TetrahedralGraph()
sage: g.show() # long time
```

The following example requires networkx:

```
sage: import networkx as NX
```

Compare this Tetrahedral, Wheel(4), Complete(4), and the Tetrahedral plotted with the spring-layout algorithm below in a Sage graphics array:

```
sage: tetra_pos = graphs.TetrahedralGraph()
sage: tetra_spring = Graph(NX.tetrahedral_graph())
sage: wheel = graphs.WheelGraph(4)
sage: complete = graphs.CompleteGraph(4)
sage: g = [tetra_pos, tetra_spring, wheel, complete]
sage: j = []
sage: for i in range(2):
...     n = []
...     for m in range(2):
...         n.append(g[i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

ThomsenGraph()

Returns the Thomsen Graph.

The Thomsen Graph is actually a complete bipartite graph with (n1, n2) = (3, 3). It is also called the Utility graph.

PLOTTING: See CompleteBipartiteGraph.

EXAMPLES:

```
sage: T = graphs.ThomsenGraph()
sage: T
Thomsen graph: Graph on 6 vertices
sage: T.graph6_string()
'EFz_'
sage: (graphs.ThomsenGraph()).show() # long time
```

WheelGraph(*n*)

Returns a Wheel graph with n nodes.

A Wheel graph is a basic structure where one node is connected to all other nodes and those (outer) nodes are connected cyclically.

This constructor depends on NetworkX numeric labels.

PLOTTING: Upon construction, the position dictionary is filled to override the spring-layout algorithm. By convention, each wheel graph will be displayed with the first (0) node in the center, the second node at the top, and the rest following in a counterclockwise manner.

With the wheel graph, we see that it doesn't take a very large n at all for the spring-layout to give a counter-intuitive display. (See Graphics Array examples below).

EXAMPLES: We view many wheel graphs with a Sage Graphics Array, first with this constructor (i.e., the position dictionary filled):

```
sage: g = []
sage: j = []
sage: for i in range(9):
...     k = graphs.WheelGraph(i+3)
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

Next, using the spring-layout algorithm:

```
sage: import networkx
sage: g = []
sage: j = []
sage: for i in range(9):
...     spr = networkx.wheel_graph(i+3)
...     k = Graph(spr)
...     g.append(k)
...
sage: for i in range(3):
...     n = []
...     for m in range(3):
...         n.append(g[3*i + m].plot(vertex_size=50, vertex_labels=False))
...     j.append(n)
...
sage: G = sage.plot.plot.GraphicsArray(j)
sage: G.show() # long time
```

Compare the plotting:

```
sage: n = networkx.wheel_graph(23)
sage: spring23 = Graph(n)
```

```
sage: posdict23 = graphs.WheelGraph(23)
sage: spring23.show() # long time
sage: posdict23.show() # long time
```

nauty_geng(*options=''*)

Calls the geng program in the optional nauty spkg to generate graphs. The options argument is passed straight to nauty.

INPUT:

- `options` - a string passed to the command line of geng. You *must* pass the number of vertices you desire.

EXAMPLES:

```
sage: graph_list = graphs.nauty_geng("-q 3") # requires the optional nauty package
sage: len(graph_list) # requires the optional nauty package
4
```

trees(*vertices*)

Accesses the generator of trees (graphs without cycles). Iterates over distinct, exhaustive representatives.

INPUT:

- `vertices` - natural number

EXAMPLES: Sloane A000055:

```
sage: for i in range(0, 7):
...     print len(list(graphs.trees(i)))
1
1
1
1
2
3
6
sage: for i in range(7, 10):              # long time
...     print len(list(graphs.trees(i))) # long time
11
23
47
```

canaug_traverse_edge(*g, aut_gens, property, dig=False, loops=False, implementation='networkx', sparse=True*)

Main function for exhaustive generation. Recursive traversal of a canonically generated tree of isomorph free graphs satisfying a given property.

INPUT:

- `g` - current position on the tree.
- `aut_gens` - list of generators of Aut(g), in list notation.
- `property` - check before traversing below g.

EXAMPLES:

```
sage: from sage.graphs.graph_generators import canaug_traverse_edge
sage: G = Graph(3)
sage: list(canaug_traverse_edge(G, [], lambda x: True))
[Graph on 3 vertices, ... Graph on 3 vertices]
```

The best way to access this function is through the graphs() iterator:

Print graphs on 3 or less vertices.

```
sage: for G in graphs(3):
...     print G
...
Graph on 3 vertices
Graph on 3 vertices
Graph on 3 vertices
Graph on 3 vertices
```

Print digraphs on 3 or less vertices.

```
sage: for G in digraphs(3):
...     print G
...
Digraph on 3 vertices
Digraph on 3 vertices
...
Digraph on 3 vertices
Digraph on 3 vertices
```

canaug_traverse_vert(*g, aut_gens, max_verts, property, dig=False, loops=False, implementation='networkx', sparse=True*)

Main function for exhaustive generation. Recursive traversal of a canonically generated tree of isomorph free (di)graphs satisfying a given property.

INPUT:

- `g` - current position on the tree.
- `aut_gens` - list of generators of Aut(g), in list notation.
- `max_verts` - when to retreat.
- `property` - check before traversing below g.
- `deg_seq` - specify a degree sequence to try to obtain.

EXAMPLES:

```
sage: from sage.graphs.graph_generators import canaug_traverse_vert
sage: list(canaug_traverse_vert(Graph(), [], 3, lambda x: True))
[Graph on 0 vertices, ... Graph on 3 vertices]
```

The best way to access this function is through the graphs() iterator:

Print graphs on 3 or less vertices.

```
sage: for G in graphs(3, augment='vertices'):
...     print G
...
Graph on 0 vertices
Graph on 1 vertex
Graph on 2 vertices
Graph on 3 vertices
Graph on 3 vertices
Graph on 3 vertices
Graph on 2 vertices
Graph on 3 vertices
```

Print digraphs on 2 or less vertices.

```
sage: for D in digraphs(2, augment='vertices'):
...     print D
...
Digraph on 0 vertices
Digraph on 1 vertex
Digraph on 2 vertices
Digraph on 2 vertices
Digraph on 2 vertices
```

check_aut (*aut_gens, cut_vert, n*)

Helper function for exhaustive generation.

At the start, check_aut is given a set of generators for the automorphism group, aut_gens. We already know we are looking for an element of the auto- morphism group that sends cut_vert to n, and check_aut generates these for the canaug_traverse function.

EXAMPLE: Note that the last two entries indicate that none of the automorphism group has yet been searched - we are starting at the identity [0, 1, 2, 3] and so far that is all we have seen. We return automorphisms mapping 2 to 3.

```
sage: from sage.graphs.graph_generators import check_aut
sage: list( check_aut( [ [0, 3, 2, 1], [1, 0, 3, 2], [2, 1, 0, 3] ], 2, 3))
[[1, 0, 3, 2], [1, 2, 3, 0]]
```

check_aut_edge (*aut_gens, cut_edge, i, j, n, dig=False*)

Helper function for exhaustive generation.

At the start, check_aut_edge is given a set of generators for the automorphism group, aut_gens. We already know we are looking for an element of the auto- morphism group that sends cut_edge to {i, j}, and check_aut generates these for the canaug_traverse function.

EXAMPLE: Note that the last two entries indicate that none of the automorphism group has yet been searched - we are starting at the identity [0, 1, 2, 3] and so far that is all we have seen. We return automorphisms mapping 2 to 3.

```
sage: from sage.graphs.graph_generators import check_aut
sage: list( check_aut( [ [0, 3, 2, 1], [1, 0, 3, 2], [2, 1, 0, 3] ], 2, 3))
[[1, 0, 3, 2], [1, 2, 3, 0]]
```

7.3 N.I.C.E. - Nice (as in open source) Isomorphism Check Engine

Automorphism group computation and isomorphism checking for graphs.

This is an open source implementation of Brendan McKay's algorithm for graph automorphism and isomorphism. McKay released a C version of his algorithm, named nauty (No AUTomorphisms, Yes?) under a license that is not GPL compatible. Although the program is open source, reading the source disallows anyone from recreating anything similar and releasing it under the GPL. Also, many people have complained that the code is difficult to understand. The first main goal of NICE was to produce a genuinely open graph isomorphism program, which has been accomplished. The second goal is for this code to be understandable, so that computed results can be trusted and further derived work will be possible.

To determine the isomorphism type of a graph, it is convenient to define a canonical label for each isomorphism class- essentially an equivalence class representative. Loosely (albeit incorrectly), the canonical label is defined by enumerating all labeled graphs, then picking the maximal one in each isomorphism class. The NICE algorithm is essentially a backtrack search. It searches through the rooted tree of partition nests (where each partition is equitable) for implicit and explicit automorphisms, and uses this information to eliminate large parts of the tree from further

searching. Since the leaves of the search tree are all discrete ordered partitions, each one of these corresponds to an ordering of the vertices of the graph, i.e. another member of the isomorphism class. Once the algorithm has finished searching the tree, it will know which leaf corresponds to the canonical label. In the process, generators for the automorphism group are also produced.

Note:

1. Often we assume that G is a graph on vertices 0,1,...,n-1.
2. There is no s == loads(dumps(s)) type test since none of the classes defined here are meant to be instantiated for longer than the algorithm runs (i.e. pickling is not relevant here).

class `OrbitPartition`()

An OrbitPartition is simply a partition which keeps track of the orbits of the part of the automorphism group so far discovered. Essentially a union-find datastructure.

EXAMPLES:

```
sage: from sage.graphs.graph_isom import OrbitPartition
sage: K = OrbitPartition(20)
sage: K.find(7)
7
sage: K.union_find(7, 12)
sage: K.find(12)
7
sage: J = OrbitPartition(20)
sage: J.is_finer_than(K, 20)
True
sage: K.is_finer_than(J, 20)
False
```

```
sage: from sage.graphs.graph_isom import OrbitPartition
sage: Theta1 = OrbitPartition(10)
sage: Theta2 = OrbitPartition(10)
sage: Theta1.union_find(0,1)
sage: Theta1.union_find(2,3)
sage: Theta1.union_find(3,4)
sage: Theta1.union_find(5,6)
sage: Theta1.union_find(8,9)
sage: Theta2.vee_with(Theta1, 10)
```

```
sage: for i in range(10):
...       print i, Theta2.find(i)
0 0
1 0
2 2
3 2
4 2
5 5
6 5
7 7
8 8
9 8
```

find()

Returns an element of the cell which depends only on the cell.

EXAMPLE:

```
sage: from sage.graphs.graph_isom import OrbitPartition
sage: K = OrbitPartition(20)
```

0 and 1 begin in different cells:

```
sage: K.find(0)
0
sage: K.find(1)
1
```

Now we put them in the same cell:

```
sage: K.union_find(0,1)
sage: K.find(0)
0
sage: K.find(1)
0
```

incorporate_permutation()

Unions the cells of self which contain common elements of some orbit of gamma.

INPUT:

- gamma - a permutation, in list notation

EXAMPLE:

```
sage: from sage.graphs.graph_isom import OrbitPartition
sage: O = OrbitPartition(9)
sage: O.incorporate_permutation([0,1,3,2,5,6,7,4,8])
sage: for i in range(9):
...    print i, O.find(i)
0 0
1 1
2 2
3 2
4 4
5 4
6 4
7 4
8 8
```

is_finer_than()

Partition P is finer than partition Q if every cell of P is a subset of a cell of Q.

EXAMPLE:

```
sage: from sage.graphs.graph_isom import OrbitPartition
sage: K = OrbitPartition(20)
sage: K.find(7)
7
sage: K.union_find(7, 12)
sage: K.find(12)
7
sage: J = OrbitPartition(20)
sage: J.is_finer_than(K, 20)
True
sage: K.is_finer_than(J, 20)
False
```

union_find()

Merges the cells containing a and b.

EXAMPLE:

```
sage: from sage.graphs.graph_isom import OrbitPartition
sage: K = OrbitPartition(20)
```

0 and 1 begin in different cells:

```
sage: K.find(0)
0
sage: K.find(1)
1
```

Now we put them in the same cell:

```
sage: K.union_find(0,1)
sage: K.find(0)
0
sage: K.find(1)
0
```

vee_with()

Merges the minimal number of cells such that other is finer than self.

EXAMPLE:

```
sage: from sage.graphs.graph_isom import OrbitPartition
sage: K = OrbitPartition(20)
sage: K.union_find(7, 12)
sage: J = OrbitPartition(20)
sage: J.is_finer_than(K, 20)
True
sage: K.is_finer_than(J, 20)
False
sage: J.vee_with(K, 20)
sage: K.is_finer_than(J, 20)
True
```

class **PartitionStack**()

TODO: documentation

EXAMPLES:

```
sage: from sage.graphs.graph_isom import PartitionStack
sage: from sage.graphs.base.sparse_graph import SparseGraph
sage: P = PartitionStack([range(9, -1, -1)])
sage: P.set_k(1)
sage: P.sort_by_function(0, [2,1,2,1,2,1,3,4,2,1], 10)
```

```
0
sage: P.set_k(2)
sage: P.sort_by_function(0, [2,1,2,1], 10)
0
sage: P.set_k(3)
sage: P.sort_by_function(4, [2,1,2,1], 10)
4
sage: P.set_k(4)
sage: P.sort_by_function(0, [0,1], 10)
0
sage: P.set_k(5)
sage: P.sort_by_function(2, [1,0], 10)
2
sage: P.set_k(6)
sage: P.sort_by_function(4, [1,0], 10)
4
sage: P.set_k(7)
sage: P.sort_by_function(6, [1,0], 10)
6
sage: P
(5,9,7,1,6,2,8,0,4,3)
(5,9,7,1|6,2,8,0|4|3)
(5,9|7,1|6,2,8,0|4|3)
(5,9|7,1|6,2|8,0|4|3)
(5|9|7,1|6,2|8,0|4|3)
(5|9|7|1|6,2|8,0|4|3)
(5|9|7|1|6|2|8,0|4|3)
(5|9|7|1|6|2|8|0|4|3)
sage: P.is_discrete()
1
sage: P.set_k(6)
sage: P.is_discrete()
0

sage: G = SparseGraph(10)
sage: for i,j,_ in graphs.PetersenGraph().edge_iterator():
...     G.add_arc(i,j)
...     G.add_arc(j,i)
sage: P = PartitionStack(10)
sage: P.set_k(1)
sage: P.split_vertex(0)
sage: P.refine(G, [0], 10, 0, 1)
sage: P
(0,2,3,6,7,8,9,1,4,5)
(0|2,3,6,7,8,9|1,4,5)
sage: P.set_k(2)
sage: P.split_vertex(1)
sage: P.refine(G, [7], 10, 0, 1)
sage: P
(0,3,7,8,9,2,6,1,4,5)
(0|3,7,8,9,2,6|1,4,5)
(0|3,7,8,9|2,6|1|4,5)
```

clear()

Merges all cells in the partition stack.

EXAMPLE:

```
sage: from sage.graphs.graph_isom import PartitionStack
sage: P = PartitionStack([range(9, -1, -1)])
sage: P.set_k(1)
sage: P
(0,9,8,7,6,5,4,3,2,1)
(0,9,8,7,6,5,4,3,2,1)
sage: P.sort_by_function(0, [2,1,2,1,2,1,3,4,2,1], 10)
0
sage: P
(1,9,7,5,0,2,8,6,4,3)
(1,9,7,5|0,2,8,6|4|3)
sage: P
(1,9,7,5,0,2,8,6,4,3)
(1,9,7,5|0,2,8,6|4|3)
sage: P.clear()
sage: P
(1,9,7,5,0,2,8,6,4,3)
(1,9,7,5,0,2,8,6,4,3)
```

degree()

Returns the number of edges in G from self.entries[v] to a vertex in W.

EXAMPLE:

```
sage: from sage.graphs.graph_isom import PartitionStack
sage: from sage.graphs.base.sparse_graph import SparseGraph
sage: P = PartitionStack([range(9, -1, -1)])
sage: P
(0,9,8,7,6,5,4,3,2,1)
sage: G = SparseGraph(10)
sage: G.add_arc(2,9)
sage: G.add_arc(3,9)
sage: G.add_arc(4,9)
sage: P.degree(G, 1, 0)
3
```

is_discrete()

Returns whether the partition consists of only singletons.

EXAMPLE:

```
sage: from sage.graphs.graph_isom import PartitionStack
sage: P = PartitionStack([range(9, -1, -1)])
sage: P.set_k(1)
sage: P.sort_by_function(0, [2,1,2,1,2,1,3,4,2,1], 10)
0
sage: P.set_k(2)
sage: P.sort_by_function(0, [2,1,2,1], 10)
0
sage: P.set_k(3)
sage: P.sort_by_function(4, [2,1,2,1], 10)
4
sage: P.set_k(4)
sage: P.sort_by_function(0, [0,1], 10)
0
sage: P.set_k(5)
sage: P.sort_by_function(2, [1,0], 10)
2
sage: P.set_k(6)
sage: P.sort_by_function(4, [1,0], 10)
```

```
4
sage: P.set_k(7)
sage: P.sort_by_function(6, [1,0], 10)
6
sage: P
(5,9,7,1,6,2,8,0,4,3)
(5,9,7,1|6,2,8,0|4|3)
(5,9|7,1|6,2,8,0|4|3)
(5,9|7,1|6,2|8,0|4|3)
(5|9|7,1|6,2|8,0|4|3)
(5|9|7|1|6,2|8,0|4|3)
(5|9|7|1|6|2|8,0|4|3)
(5|9|7|1|6|2|8|0|4|3)
sage: P.is_discrete()
True
sage: P.set_k(2)
sage: P
(5,9,7,1,6,2,8,0,4,3)
(5,9,7,1|6,2,8,0|4|3)
(5,9|7,1|6,2,8,0|4|3)
sage: P.is_discrete()
False
```

num_cells()

Return the number of cells in the finest partition.

EXAMPLE:

```
sage: from sage.graphs.graph_isom import PartitionStack
sage: P = PartitionStack([range(9, -1, -1)])
sage: P.set_k(1)
sage: P.sort_by_function(0, [2,1,2,1,2,1,3,4,2,1], 10)
0
sage: P
(1,9,7,5,0,2,8,6,4,3)
(1,9,7,5|0,2,8,6|4|3)
sage: P.num_cells()
4
sage: P.set_k(2)
sage: P.sort_by_function(0, [2,1,2,1], 10)
0
sage: P
(5,9,1,7,0,2,8,6,4,3)
(5,9,1,7|0,2,8,6|4|3)
(5,9|1,7|0,2,8,6|4|3)
sage: P.num_cells()
5
```

percolate()

Perform one round of bubble sort, moving the smallest element to the front.

EXAMPLE:

```
sage: from sage.graphs.graph_isom import PartitionStack
sage: P = PartitionStack([range(9, -1, -1)])
sage: P
(0,9,8,7,6,5,4,3,2,1)
sage: P.percolate(2,7)
sage: P
(0,9,3,8,7,6,5,4,2,1)
```

refine()

Implementation of Algorithm 2.5 in [1].

EXAMPLE:

```
sage: from sage.graphs.graph_isom import PartitionStack
sage: from sage.graphs.base.sparse_graph import SparseGraph
sage: P = PartitionStack([range(9, -1, -1)])
sage: P.set_k(1)
sage: P.sort_by_function(0, [2,1,2,1,2,1,3,4,2,1], 10)
0
sage: P.set_k(2)
sage: P.sort_by_function(0, [2,1,2,1], 10)
0
sage: P.set_k(3)
sage: P.sort_by_function(4, [2,1,2,1], 10)
4
sage: P.set_k(4)
sage: P.sort_by_function(0, [0,1], 10)
0
sage: P.set_k(5)
sage: P.sort_by_function(2, [1,0], 10)
2
sage: P.set_k(6)
sage: P.sort_by_function(4, [1,0], 10)
4
sage: P.set_k(7)
sage: P.sort_by_function(6, [1,0], 10)
6
sage: P
(5,9,7,1,6,2,8,0,4,3)
(5,9,7,1|6,2,8,0|4|3)
(5,9|7,1|6,2,8,0|4|3)
(5,9|7,1|6,2|8,0|4|3)
(5|9|7,1|6,2|8,0|4|3)
(5|9|7|1|6,2|8,0|4|3)
(5|9|7|1|6|2|8,0|4|3)
(5|9|7|1|6|2|8|0|4|3)
sage: P.is_discrete()
1
sage: P.set_k(6)
sage: P.is_discrete()
0

sage: G = SparseGraph(10)
sage: for i,j,_ in graphs.PetersenGraph().edge_iterator():
...     G.add_arc(i,j)
...     G.add_arc(j,i)
sage: P = PartitionStack(10)
sage: P.set_k(1)
sage: P.split_vertex(0)
sage: P.refine(G, [0], 10, 0, 1)
sage: P
(0,2,3,6,7,8,9,1,4,5)
(0|2,3,6,7,8,9|1,4,5)
sage: P.set_k(2)
sage: P.split_vertex(1)
sage: P.refine(G, [7], 10, 0, 1)
sage: P
```

```
(0,3,7,8,9,2,6,1,4,5)
(0|3,7,8,9,2,6|1,4,5)
(0|3,7,8,9|2,6|1|4,5)
```

repr_at_k()

Return the k-th line of the representation of self, i.e. the k-th partition in the stack.

EXAMPLE:

```
sage: from sage.graphs.graph_isom import PartitionStack
sage: P = PartitionStack([range(9, -1, -1)])
sage: P.set_k(1)
sage: P.sort_by_function(0, [2,1,2,1,2,1,3,4,2,1], 10)
0
sage: P.set_k(2)
sage: P.sort_by_function(0, [2,1,2,1], 10)
0
sage: P.set_k(3)
sage: P.sort_by_function(4, [2,1,2,1], 10)
4
sage: P.set_k(4)
sage: P.sort_by_function(0, [0,1], 10)
0
sage: P.set_k(5)
sage: P.sort_by_function(2, [1,0], 10)
2
sage: P.set_k(6)
sage: P.sort_by_function(4, [1,0], 10)
4
sage: P.set_k(7)
sage: P.sort_by_function(6, [1,0], 10)
6
sage: P
(5,9,7,1,6,2,8,0,4,3)
(5,9,7,1|6,2,8,0|4|3)
(5,9|7,1|6,2,8,0|4|3)
(5,9|7,1|6,2|8,0|4|3)
(5|9|7,1|6,2|8,0|4|3)
(5|9|7|1|6,2|8,0|4|3)
(5|9|7|1|6|2|8,0|4|3)
(5|9|7|1|6|2|8|0|4|3)

sage: P.repr_at_k(0)
'(5,9,7,1,6,2,8,0,4,3)'
sage: P.repr_at_k(1)
'(5,9,7,1|6,2,8,0|4|3)'
```

sat_225()

Whether the finest partition satisfies the hypotheses of Lemma 2.25 in [1].

EXAMPLE:

```
sage: from sage.graphs.graph_isom import PartitionStack
sage: P = PartitionStack([range(9, -1, -1)])
sage: P
(0,9,8,7,6,5,4,3,2,1)
sage: P.sat_225(10)
False
sage: P.set_k(1)
sage: P.sort_by_function(0, [2,1,2,1,2,1,3,4,2,1], 10)
```

```
0
sage: P
(1,9,7,5,0,2,8,6,4,3)
(1,9,7,5|0,2,8,6|4|3)
sage: P.sat_225(10)
False
sage: P.set_k(2)
sage: P.sort_by_function(0, [2,1,2,1], 10)
0
sage: P
(5,9,1,7,0,2,8,6,4,3)
(5,9,1,7|0,2,8,6|4|3)
(5,9|1,7|0,2,8,6|4|3)
sage: P.sat_225(10)
False
sage: P.set_k(3)
sage: P.sort_by_function(4, [2,1,2,1], 10)
4
sage: P
(5,9,1,7,2,6,0,8,4,3)
(5,9,1,7|2,6,0,8|4|3)
(5,9|1,7|2,6,0,8|4|3)
(5,9|1,7|2,6|0,8|4|3)
sage: P.sat_225(10)
True
```

set_k()

Sets self.k, the index of the finest partition.

```
sage: from sage.graphs.graph_isom import PartitionStack
sage: P = PartitionStack([range(9, -1, -1)])
sage: P.set_k(1)
sage: P.sort_by_function(0, [2,1,2,1,2,1,3,4,2,1], 10)
0
sage: P.set_k(2)
sage: P.sort_by_function(0, [2,1,2,1], 10)
0
sage: P.set_k(3)
sage: P.sort_by_function(4, [2,1,2,1], 10)
4
sage: P.set_k(4)
sage: P.sort_by_function(0, [0,1], 10)
0
sage: P.set_k(5)
sage: P.sort_by_function(2, [1,0], 10)
2
sage: P.set_k(6)
sage: P.sort_by_function(4, [1,0], 10)
4
sage: P.set_k(7)
sage: P.sort_by_function(6, [1,0], 10)
6
sage: P
(5,9,7,1,6,2,8,0,4,3)
(5,9,7,1|6,2,8,0|4|3)
(5,9|7,1|6,2,8,0|4|3)
(5,9|7,1|6,2|8,0|4|3)
(5|9|7,1|6,2|8,0|4|3)
```

```
(5|9|7|1|6,2|8,0|4|3)
(5|9|7|1|6|2|8,0|4|3)
(5|9|7|1|6|2|8|0|4|3)

sage: P.set_k(2)
sage: P
(5,9,7,1,6,2,8,0,4,3)
(5,9,7,1|6,2,8,0|4|3)
(5,9|7,1|6,2,8,0|4|3)
```

sort_by_function()

Sort the cell starting at start using a counting sort, where degrees is the function giving the sort. Result is the cell is subdivided into cells which have elements all of the same 'degree,' in order.

EXAMPLE:

```
sage: from sage.graphs.graph_isom import PartitionStack
sage: P = PartitionStack([range(9, -1, -1)])
sage: P.set_k(1)
sage: P
(0,9,8,7,6,5,4,3,2,1)
(0,9,8,7,6,5,4,3,2,1)
sage: P.sort_by_function(0, [2,1,2,1,2,1,3,4,2,1], 10)
0
sage: P
(1,9,7,5,0,2,8,6,4,3)
(1,9,7,5|0,2,8,6|4|3)
```

split_vertex()

Splits the cell in self(k) containing v, putting new cells in place in self(k).

EXAMPLE:

```
sage: from sage.graphs.graph_isom import PartitionStack
sage: P = PartitionStack([range(9, -1, -1)])
sage: P
(0,9,8,7,6,5,4,3,2,1)
sage: P.split_vertex(2)
sage: P
(2|0,9,8,7,6,5,4,3,1)
```

all_labeled_digraphs()

EXAMPLES:

```
sage: from sage.groups.perm_gps.partn_ref.refinement_graphs import search_tree
sage: from sage.graphs.graph_isom import all_labeled_digraphs
sage: Glist = {}
sage: Giso  = {}
sage: for n in range(1,4):
...       Glist[n] = all_labeled_digraphs(n)
...       Giso[n] = []
...       for g in Glist[n]:
...           a, b = search_tree(g, [range(n)], dig=True)
...           inn = False
...           for gi in Giso[n]:
...               if b == gi:
...                   inn = True
...           if not inn:
...               Giso[n].append(b)
sage: for n in Giso:
```

```
...       print n, len(Giso[n])
1 1
2 3
3 16
```

all_labeled_digraphs_with_loops()

Returns all labeled digraphs on n vertices 0,1,...,n-1. Used in classifying isomorphism types (naive approach), and more importantly in benchmarking the search algorithm.

EXAMPLE:

```
sage: from sage.groups.perm_gps.partn_ref.refinement_graphs import search_tree
sage: from sage.graphs.graph_isom import all_labeled_digraphs_with_loops
sage: Glist = {}
sage: Giso  = {}
sage: for n in range(1,4):
...     Glist[n] = all_labeled_digraphs_with_loops(n)
...     Giso[n] = []
...     for g in Glist[n]:
...         a, b = search_tree(g, [range(n)], dig=True)
...         inn = False
...         for gi in Giso[n]:
...             if b == gi:
...                 inn = True
...         if not inn:
...             Giso[n].append(b)
sage: for n in Giso:
...     print n, len(Giso[n])
1 2
2 10
3 104
```

all_labeled_graphs()

Returns all labeled graphs on n vertices 0,1,...,n-1. Used in classifying isomorphism types (naive approach), and more importantly in benchmarking the search algorithm.

EXAMPLE:

```
sage: from sage.groups.perm_gps.partn_ref.refinement_graphs import search_tree
sage: from sage.graphs.graph_isom import all_labeled_graphs
sage: Glist = {}
sage: Giso  = {}
sage: for n in range(1,5):
...     Glist[n] = all_labeled_graphs(n)
...     Giso[n] = []
...     for g in Glist[n]:
...         a, b = search_tree(g, [range(n)])
...         inn = False
...         for gi in Giso[n]:
...             if b == gi:
...                 inn = True
...         if not inn:
...             Giso[n].append(b)
sage: for n in Giso:
...     print n, len(Giso[n])
1 1
2 2
3 4
4 11
```

```
sage: n = 5
sage: Glist[n] = all_labeled_graphs(n)
sage: Giso[n] = []
sage: for g in Glist[5]:
...     a, b = search_tree(g, [range(n)])
...     inn = False
...     for gi in Giso[n]:
...         if b == gi:
...             inn = True
...     if not inn:
...         Giso[n].append(b)
sage: print n, len(Giso[n]) # long time
5 34
sage: graphs_list.show_graphs(Giso[4])
```

all_ordered_partitions()

Returns all ordered partitions of the set 0,1,...,n-1. Used in benchmarking the search algorithm.

EXAMPLE:

```
sage: from sage.graphs.graph_isom import all_ordered_partitions
sage: all_ordered_partitions(['a', 1, {}])
[[['a'], [1], [{}]],
 [['a'], [{}], [1]],
 [['a'], [{}, 1]],
 [['a'], [1, {}]],
 [[1], ['a'], [{}]],
 [[1], [{}], ['a']],
 [[1], [{}, 'a']],
 [[1], ['a', {}]],
 [[{}], ['a'], [1]],
 [[{}], [1], ['a']],
 [[{}], [1, 'a']],
 [[{}], ['a', 1]],
 [[1, 'a'], [{}]],
 [[{}, 'a'], [1]],
 [['a', 1], [{}]],
 [[{}, 1], ['a']],
 [['a', {}], [1]],
 [[1, {}], ['a']],
 [[{}, 1, 'a']],
 [[1, {}, 'a']],
 [[{}, 'a', 1]],
 [['a', {}, 1]],
 [[1, 'a', {}]],
 [['a', 1, {}]]]
```

kpow()

Returns the subset of the power set of listy consisting of subsets of size k. Used in all_ordered_partitions.

EXAMPLE:

```
sage: from sage.graphs.graph_isom import kpow
sage: kpow(['a', 1, {}], 2)
[[1, 'a'], [{}, 'a'], ['a', 1], [{}, 1], ['a', {}], [1, {}]]
```

orbit_partition()

Assuming that G is a graph on vertices 0,1,...,n-1, and gamma is an element of SymmetricGroup(n), returns the

partition of the vertex set determined by the orbits of gamma, considered as action on the set 1,2,...,n where we take 0 = n. In other words, returns the partition determined by a cyclic representation of gamma.

INPUT:

- `list_perm` - if True, assumes `gamma` is a list representing the map $i \mapsto$ "$gamma$"$[i]$.

EXAMPLES:

```
sage: from sage.graphs.graph_isom import orbit_partition
sage: G = graphs.PetersenGraph()
sage: S = SymmetricGroup(10)
sage: gamma = S('(10,1,2,3,4)(5,6,7)(8,9)')
sage: orbit_partition(gamma)
[[1, 2, 3, 4, 0], [5, 6, 7], [8, 9]]
sage: gamma = S('(10,5)(1,6)(2,7)(3,8)(4,9)')
sage: orbit_partition(gamma)
[[1, 6], [2, 7], [3, 8], [4, 9], [5, 0]]
```

perm_group_elt()

Given a list permutation of the set 0, 1, ..., n-1, returns the corresponding PermutationGroupElement where we take 0 = n.

EXAMPLE:

```
sage: from sage.graphs.graph_isom import perm_group_elt
sage: perm_group_elt([0,2,1])
(1,2)
sage: perm_group_elt([1,2,0])
(1,2,3)
```

search_tree()

Assumes that the vertex set of G is 0,1,...,n-1 for some n.

Note that this conflicts with the SymmetricGroup we are using to represent automorphisms. The solution is to let the group act on the set 1,2,...,n, under the assumption n = 0.

INPUT: lab- if True, return the canonical label in addition to the auto- morphism group. dig- if True, does not use Lemma 2.25 in [1], and the algorithm is valid for digraphs and graphs with loops. dict_rep- if True, explain which vertices are which elements of the set 1,2,...,n in the representation of the automorphism group. certify- if True, return the relabeling from G to its canonical label. Forces lab=True. verbosity- 0 - print nothing 1 - display state trace 2 - with timings 3 - display partition nests 4 - display orbit partition 5 - plot the part of the tree traversed during search

- `use_indicator_function` - option to turn off indicator function (False - slower)
- `sparse` - whether to use sparse or dense representation of the graph (ignored if G is already a CGraph - see sage.graphs.base)
- `base` - whether to return the first sequence of split vertices (used in computing the order of the group)
- `order` - whether to return the order of the automorphism group

STATE DIAGRAM:

```
sage: SD = DiGraph( { 1:[18,2], 2:[5,3], 3:[4,6], 4:[7,2], 5:[4], 6:[13,12], 7:[18,8,10], 8:[6,9
sage: SD.set_edge_label(1, 18, 'discrete')
sage: SD.set_edge_label(4, 7, 'discrete')
sage: SD.set_edge_label(2, 5, 'h = 0')
sage: SD.set_edge_label(7, 18, 'h = 0')
sage: SD.set_edge_label(7, 10, 'aut')
sage: SD.set_edge_label(8, 10, 'aut')
```

```
sage: SD.set_edge_label(8, 9, 'label')
sage: SD.set_edge_label(8, 6, 'no label')
sage: SD.set_edge_label(13, 17, 'k > h')
sage: SD.set_edge_label(13, 14, 'k = h')
sage: SD.set_edge_label(17, 15, 'v_k finite')
sage: SD.set_edge_label(14, 15, 'v_k m.c.r.')
sage: posn = {1:[ 3,-3],  2:[0,2],  3:[0, 13],  4:[3,9],  5:[3,3],  6:[16, 13], 7:[6,1],  8:[6,6
sage: SD.plot(pos=posn, vertex_size=400, vertex_colors={'#FFFFFF':range(1,19)}, edge_labels=True
```

Note: There is a function, called test_refine, that has the same signature as _refine. It calls _refine, then checks to make sure the output is sane. To use this, simply add 'test' to the two places this algorithm calls the function (states 1 and 2).

EXAMPLES: The following example is due to Chris Godsil:

```
sage: HS = graphs.HoffmanSingletonGraph()
sage: clqs = (HS.complement()).cliques()
sage: alqs = [Set(c) for c in clqs if len(c) == 15]
sage: Y = Graph([alqs, lambda s,t: len(s.intersection(t))==0], implementation='networkx')
sage: Y0,Y1 = Y.connected_components_subgraphs()
sage: Y0.is_isomorphic(Y1)
True
sage: Y0.is_isomorphic(HS)
True
```

```
sage: from sage.groups.perm_gps.partn_ref.refinement_graphs import search_tree
sage: from sage.graphs.base.sparse_graph import SparseGraph
sage: from sage.graphs.base.dense_graph import DenseGraph
sage: from sage.groups.perm_gps.permgroup import PermutationGroup
sage: from sage.graphs.graph_isom import perm_group_elt
```

```
sage: G = graphs.DodecahedralGraph()
sage: GD = DenseGraph(20)
sage: GS = SparseGraph(20)
sage: for i,j,_ in G.edge_iterator():
...     GD.add_arc(i,j); GD.add_arc(j,i)
...     GS.add_arc(i,j); GS.add_arc(j,i)
sage: Pi=[range(20)]
sage: a,b = search_tree(G, Pi)

```

```
sage: C = graphs.CubeGraph(1)
sage: gens = search_tree(C, [C.vertices()], lab=False)
sage: PermutationGroup([perm_group_elt(aa) for aa in gens]).order()
2
sage: C = graphs.CubeGraph(2)
sage: gens = search_tree(C, [C.vertices()], lab=False)
sage: PermutationGroup([perm_group_elt(aa) for aa in gens]).order()
8
sage: C = graphs.CubeGraph(3)
sage: gens = search_tree(C, [C.vertices()], lab=False)
sage: PermutationGroup([perm_group_elt(aa) for aa in gens]).order()
48
sage: C = graphs.CubeGraph(4)
sage: gens = search_tree(C, [C.vertices()], lab=False)
sage: PermutationGroup([perm_group_elt(aa) for aa in gens]).order()
384
sage: C = graphs.CubeGraph(5)
sage: gens = search_tree(C, [C.vertices()], lab=False)
```

```
sage: PermutationGroup([perm_group_elt(aa) for aa in gens]).order()
3840
sage: C = graphs.CubeGraph(6)
sage: gens = search_tree(C, [C.vertices()], lab=False)
sage: PermutationGroup([perm_group_elt(aa) for aa in gens]).order()
46080
```

One can also turn off the indicator function (note- this will take longer)

```
sage: D1 = DiGraph({0:[2],2:[0],1:[1]}, loops=True)
sage: D2 = DiGraph({1:[2],2:[1],0:[0]}, loops=True)
sage: a,b = search_tree(D1, [D1.vertices()], use_indicator_function=False)
sage: c,d = search_tree(D2, [D2.vertices()], use_indicator_function=False)
sage: b==d
True
```

Previously a bug, now the output is correct:

```
sage: G = Graph('^?????????????????????{??N??@w??FaGa?PCO@CP?AGa?_QO?Q@G?CcA??cc????Bo????{????F_
sage: perm = {3:15, 15:3}
sage: H = G.relabel(perm, inplace=False)
sage: G.canonical_label() == H.canonical_label()
True
```

Another former bug:

```
sage: Graph('Fll^G').canonical_label()
Graph on 7 vertices
```

```
sage: g = Graph(21)
sage: g.automorphism_group(return_group=False, order=True)
51090942171709440000
```

verify_partition_refinement()

Verify that the refinement is correct.

EXAMPLE:

```
sage: from sage.graphs.graph_isom import PartitionStack
sage: from sage.graphs.base.sparse_graph import SparseGraph
sage: G = SparseGraph(10)
sage: for i,j,_ in graphs.PetersenGraph().edge_iterator():
...     G.add_arc(i,j)
...     G.add_arc(j,i)
sage: P = PartitionStack(10)
sage: P.set_k(1)
sage: P.split_vertex(0)
sage: P.refine(G, [0], 10, 0, 1)
sage: P
(0,2,3,6,7,8,9,1,4,5)
(0|2,3,6,7,8,9|1,4,5)
sage: P.set_k(2)
sage: P.split_vertex(1)
```

Note that this line implicitly tests the function verify_partition_refinement:

```
sage: P.refine(G, [7], 10, 0, 1, test=True)
sage: P
(0,3,7,8,9,2,6,1,4,5)
(0|3,7,8,9,2,6|1,4,5)
(0|3,7,8,9|2,6|1|4,5)
```

7.4 Graph Database Module

INFO:

This module implements classes (GraphDatabase, GraphQuery, GenericGraphQuery) for interfacing with the sqlite database graphs.db.

The GraphDatabase class interfaces with the sqlite database graphs.db. It is an immutable database that inherits from SQLDatabase (see sage.databases.database.py).

The database contains all unlabeled graphs with 7 or fewer nodes. This class will also interface with the optional database package containing all unlabeled graphs with 8 or fewer nodes. The database(s) consists of five tables, and has the structure given by the function graph_info. (For a full description including column data types, create a GraphDatabase instance and call the method get_skeleton).

AUTHORS:

- Emily A. Kirkman (2008-09-20): first version of interactive queries, cleaned up code and generalized many elements to sage.databases.database.py
- Emily A. Kirkman (2007-07-23): inherits GenericSQLDatabase, also added classes: GraphQuery and GenericGraphQuery
- Emily A. Kirkman (2007-05-11): initial sqlite version
- Emily A. Kirkman (2007-02-13): initial version (non-sqlite)

REFERENCES:

- Data provided by Jason Grout (Brigham Young University). [Online] Available: http://math.byu.edu/~grout/graphs/

class GenericGraphQuery(*query_string, database=None, param_tuple=None*)

class GraphDatabase()

interactive_query(*display_cols, **kwds*)

TODO: This function could use improvement. Add full options of typical GraphQuery (i.e.: have it accept list input); and update options in interact to make it less annoying to put in operators.

Generates an interact shell (in the notebook only) that allows the user to manipulate query parameters and see the updated results.

EXAMPLE:

```
sage: D = GraphDatabase()
sage: D.interactive_query(display_cols=['graph6','num_vertices','degree_sequence'],num_edges
<html>...</html>
```

query(*query_dict=None, display_cols=None, **kwds*)

Creates a GraphQuery on this database. For full class details, type GraphQuery? and press shift+enter.

EXAMPLE:

```
sage: D = GraphDatabase()
sage: q = D.query(display_cols=['graph6','num_vertices','degree_sequence'],num_edges=['<=',5
sage: q.show()
Graph6                Num Vertices          Degree Sequence

```

class GraphQuery(*graph_db=None, query_dict=None, display_cols=None, **kwds*)

get_graphs_list()

Returns a list of Sage Graph objects that satisfy the query.

EXAMPLES:

```
sage: Q = GraphQuery(display_cols=['graph6','num_vertices','degree_sequence'],num_edges=['<=
sage: L = Q.get_graphs_list()
sage: L[0]
Graph on 2 vertices
sage: len(L)
35
```

number_of()

Returns the number of graphs in the database that satisfy the query.

EXAMPLES:

```
sage: Q = GraphQuery(display_cols=['graph6','num_vertices','degree_sequence'],num_edges=['<=
sage: Q.number_of()
35
```

query_iterator()

Returns an iterator over the results list of the GraphQuery.

EXAMPLE:

```
sage: Q = GraphQuery(display_cols=['graph6'],num_vertices=7, diameter=5)
sage: for g in Q:
...     print g.graph6_string()
F@?]O
F@OKg
F?`po
F?gqg
FIAHo
F@R@o
FA_pW
FGC{o
FEOhW

sage: Q = GraphQuery(display_cols=['graph6'],num_vertices=7, diameter=5)
sage: it = iter(Q)
sage: while True:
...     try: print it.next().graph6_string()
...     except StopIteration: break
F@?]O
F@OKg
F?`po
F?gqg
FIAHo
F@R@o
FA_pW
FGC{o
FEOhW
```

show(*max_field_size=20, with_picture=False*)

Displays the results of a query in table format.

INPUT:

- `max_field_size` - width of fields in command prompt version
- `with_picture` - whether or not to display results with a picture of the graph (available only in the notebook)

EXAMPLES:

```
sage: G = GraphDatabase()
sage: Q = GraphQuery(G, display_cols=['graph6','num_vertices','aut_grp_size'], num_vertices=
sage: Q.show()
Graph6                Num Vertices          Aut Grp Size
------------------------------------------------------------
C@                    4                     4
C^                    4                     4

sage: R = GraphQuery(G, display_cols=['graph6','num_vertices','degree_sequence'], num_vertic
sage: R.show()
Graph6                Num Vertices          Degree Sequence
------------------------------------------------------------
C?                    4                     [0, 0, 0, 0]
C@                    4                     [0, 0, 1, 1]
CB                    4                     [0, 1, 1, 2]
CK                    4                     [1, 1, 1, 1]
CF                    4                     [1, 1, 1, 3]
CJ                    4                     [0, 2, 2, 2]
CL                    4                     [1, 1, 2, 2]
CN                    4                     [1, 2, 2, 3]
C]                    4                     [2, 2, 2, 2]
C^                    4                     [2, 2, 3, 3]
C~                    4                     [3, 3, 3, 3]
```

Show the pictures (in notebook mode only):

```
sage: S = GraphQuery(G, display_cols=['graph6','aut_grp_size'], num_vertices=4)
sage: S.show(with_picture=True)
...
NotImplementedError: Cannot display plot on command line.
```

Note that pictures can be turned off:

```
sage: S.show(with_picture=False)
Graph6                Aut Grp Size
---------------------------------------
C?                    24
C@                    4
CB                    2
CK                    8
CF                    6
CJ                    6
CL                    2
CN                    2
C]                    8
C^                    4
C~                    24
```

Show your own query (note that the output is not reformatted for generic queries):

```
sage: (GenericGraphQuery('select degree_sequence from degrees where max_degree=2 and min_deg
degree_sequence
--------------------
211
222
2211
2222
21111
22211
```

```

221111
221111
222211
222211
222211
222222
222222
2111111
2221111
2221111
2221111
2222211
2222211
2222211
2222211
2222222
2222222
```

data_to_degseq(*data, graph6=None*)

Takes the database integer data type (one digit per vertex representing its degree, sorted high to low) and converts it to degree sequence list. The graph6 identifier is required for all graphs with no edges, so that the correct number of zeros will be returned.

EXAMPLE:

```
sage: from sage.graphs.graph_database import data_to_degseq
sage: data_to_degseq(3221)
[1, 2, 2, 3]
sage: data_to_degseq(0,'D??')
[0, 0, 0, 0, 0]
```

degseq_to_data(*degree_sequence*)

Takes a degree sequence list (of Integers) and converts to a sorted (max-min) integer data type, as used for faster access in the underlying database.

EXAMPLE:

```
sage: from sage.graphs.graph_database import degseq_to_data
sage: degseq_to_data([2,2,3,1])
3221
```

graph6_to_plot(*graph6*)

Constructs a graph from a graph6 string and returns a Graphics object with arguments preset for show function.

EXAMPLE:

```
sage: from sage.graphs.graph_database import graph6_to_plot
sage: type(graph6_to_plot('D??'))
<class 'sage.plot.plot.Graphics'>
```

graph_db_info(*tablename=None*)

Returns a dictionary of allowed table and column names.

INPUT:

- `tablename` - restricts the output to a single table

EXAMPLE:

```
sage: graph_db_info().keys()
['graph_data', 'degrees', 'spectrum', 'misc', 'aut_grp']

sage: graph_db_info(tablename='graph_data')
['complement_graph6',
 'eulerian',
 'graph6',
 'lovasz_number',
 'num_cycles',
 'num_edges',
 'num_hamiltonian_cycles',
 'num_vertices',
 'perfect',
 'planar']
```

subgraphs_to_query (*subgraphs, db*)

Constructs and returns a GraphQuery object respecting the special input required for the induced_subgraphs parameter. This input can be an individual graph6 string (in which case it is evaluated without the use of this method) or a list of strings. In the latter case, the list should be of one of the following two formats: 1. ['one_of',String,...,String] Will search for graphs containing a subgraph isomorphic to any of the graph6 strings in the list. 2. ['all_of',String,...,String] Will search for graphs containing a subgraph isomorphic to each of the graph6 strings in the list.

This is a helper method called by the GraphQuery constructor to handle this special format. This method should not be used on its own because it doesn't set any display columns in the query string, causing a failure to fetch the data when run.

EXAMPLE:

```
sage: from sage.graphs.graph_database import subgraphs_to_query
sage: gd = GraphDatabase()
sage: q = subgraphs_to_query(['all_of','A?','B?','C?'],gd)
sage: q.get_query_string()
'SELECT , ,, ,,  FROM misc WHERE ( ( misc.induced_subgraphs regexp ? ) AND ( misc.induced_subgra
```

7.5 A module for dealing with lists of graphs.

AUTHORS:

- Robert L. Miller (2007-02-10): initial version
- Emily A. Kirkman (2007-02-13): added show functions (to_graphics_array and show_graphs)

from_graph6 (*data*)

Returns a list of Sage Graphs, given a list of graph6 data.

INPUT:

- `data` - can be a string, a list of strings, or a file stream.

EXAMPLE:

```
sage: l = ['N@@?N@UGAGG?gGlKCMO','XsGGWOW?CC?C@HQKHqOjYKC_uHWGX?P?~TqIKA`OA@SAOEcEA??']
sage: graphs_list.from_graph6(l)
[Graph on 15 vertices, Graph on 25 vertices]
```

from_sparse6(*data*)

Returns a list of Sage Graphs, given a list of sparse6 data.

INPUT:

- `data` - can be a string, a list of strings, or a file stream.

EXAMPLE:

```
sage: l = [':P_`cBaC_ACd`C_@BC`ABDHaEH_@BF_@CHIK_@BCEHKL_BIKM_BFGHI',':f`??KO?B_OOSCGE_?OWONDBO?
sage: graphs_list.from_sparse6(l)
[Looped multi-graph on 17 vertices, Looped multi-graph on 39 vertices]
```

from_whatever(*data*)

Returns a list of Sage Graphs, given a list of whatever kind of data.

INPUT:

- `data` - can be a string, a list of strings, or a file stream, or whatever.

EXAMPLE:

```
sage: l = ['N@@?N@UGAGG?gGlKCMO',':P_`cBaC_ACd`C_@BC`ABDHaEH_@BF_@CHIK_@BCEHKL_BIKM_BFGHI']
sage: graphs_list.from_whatever(l)
[Graph on 15 vertices, Looped multi-graph on 17 vertices]
```

show_graphs(*list, **kwds*)

Shows a maximum of 20 graphs from list in a sage graphics array. If more than 20 graphs are given in the list argument, then it will display one graphics array after another with each containing at most 20 graphs.

Note that if to save the image output from the notebook, you must save each graphics array individually. (There will be a small space between graphics arrays).

INPUT:

- `list` - a list of Sage graphs

GRAPH PLOTTING: Defaults to circular layout for graphs. This allows for a nicer display in a small area and takes much less time to compute than the spring- layout algorithm for many graphs.

EXAMPLES: Create a list of graphs:

```
sage: glist = []
sage: glist.append(graphs.CompleteGraph(6))
sage: glist.append(graphs.CompleteBipartiteGraph(4,5))
sage: glist.append(graphs.BarbellGraph(7,4))
sage: glist.append(graphs.CycleGraph(15))
sage: glist.append(graphs.DiamondGraph())
sage: glist.append(graphs.HouseGraph())
sage: glist.append(graphs.HouseXGraph())
sage: glist.append(graphs.KrackhardtKiteGraph())
sage: glist.append(graphs.LadderGraph(5))
sage: glist.append(graphs.LollipopGraph(5,6))
sage: glist.append(graphs.PathGraph(15))
sage: glist.append(graphs.PetersenGraph())
sage: glist.append(graphs.StarGraph(17))
sage: glist.append(graphs.WheelGraph(9))
```

Check that length is = 20:

```
sage: len(glist)
14
```

Show the graphs in a graphics array:

```
sage: graphs_list.show_graphs(glist)
```

Here's an example where more than one graphics array is used:

```
sage: gq = GraphQuery(display_cols=['graph6'],num_vertices=5)
sage: g = gq.get_graphs_list()
sage: len(g)
34
sage: graphs_list.show_graphs(g)
```

See the .plot() or .show() documentation for an individual graph for options, all of which are available from to_graphics_arrays

```
sage: glist = []
sage: for _ in range(10):
...       glist.append(graphs.RandomLobster(41, .3, .4))
sage: graphs_list.show_graphs(glist, layout='spring', vertex_size=20)
```

to_graph6(*list, file=None, output_list=False*)

Converts a list of Sage graphs to a single string of graph6 graphs. If file is specified, then the string will be written quietly to the file. If output_list is True, then a list of strings will be returned, one string per graph.

INPUT:

- `list` - a Python list of Sage Graphs
- `file` - (optional) a file stream to write to (must be in 'w' mode)
- `output_list` - False - output is a string True - output is a list of strings (ignored if file gets specified)

EXAMPLE:

```
sage: l = [graphs.DodecahedralGraph(), graphs.PetersenGraph()]
sage: graphs_list.to_graph6(l)
'ShCHGD@?K?_@?@?C_GGG@??cG?G?GK_?C\nIheA@GUAo\n'
```

to_graphics_arrays(*list, **kwds*)

Returns a list of Sage graphics arrays containing the graphs in list. The maximum number of graphs per array is 20 (5 rows of 4). Use this function if there are too many graphs for the show_graphs function. The graphics arrays will contain 20 graphs each except potentially the last graphics array in the list.

INPUT:

- `list` - a list of Sage graphs

GRAPH PLOTTING: Defaults to circular layout for graphs. This allows for a nicer display in a small area and takes much less time to compute than the spring- layout algorithm for many graphs.

EXAMPLES:

```
sage: glist = []
sage: for i in range(999):
...     glist.append(graphs.RandomGNP(6,.45))
...
sage: garray = graphs_list.to_graphics_arrays(glist)
```

Display the first graphics array in the list.

```
sage: garray[0].show()
```

Display the last graphics array in the list.

```
sage: garray[len(garray)-1].show()
```

See the .plot() or .show() documentation for an individual graph for options, all of which are available from to_graphics_arrays

```
sage: glist = []
sage: for _ in range(10):
...       glist.append(graphs.RandomLobster(41, .3, .4))
sage: w = graphs_list.to_graphics_arrays(glist, layout='spring', vertex_size=20)
sage: len(w)
1
sage: w[0]
```

to_sparse6 (*list, file=None, output_list=False*)

Converts a list of Sage graphs to a single string of sparse6 graphs. If file is specified, then the string will be written quietly to the file. If output_list is True, then a list of strings will be returned, one string per graph.

INPUT:

- `list` - a Python list of Sage Graphs
- `file` - (optional) a file stream to write to (must be in 'w' mode)
- `output_list` - False - output is a string True - output is a list of strings (ignored if file gets specified)

EXAMPLE:

```
sage: l = [graphs.DodecahedralGraph(), graphs.PetersenGraph()]
sage: graphs_list.to_sparse6(l)
':S_`abcaDe`Fg_HijhKfLdMkNcOjP_BQ\n:I`ES@obGkqegW~\n'
```

CHAPTER

EIGHT

CONSTANTS

8.1 Mathematical constants

The following standard mathematical constants are defined in Sage, along with support for coercing them into GAP, GP/PARI, KASH, Maxima, Mathematica, Maple, Octave, and Singular:

```
sage: pi
pi
sage: e              # base of the natural logarithm
e
sage: NaN            # Not a number
NaN
sage: golden_ratio
golden_ratio
sage: log2           # natural logarithm of the real number 2
log2
sage: euler_gamma    # Euler's gamma constant
euler_gamma
sage: catalan        # the Catalon constant
catalan
sage: khinchin       # Khinchin's constant
khinchin
sage: twinprime
twinprime
sage: merten
merten
sage: brun
brun
```

Support for coercion into the various systems means that if, e.g., you want to create π in Maxima and Singular, you don't have to figure out the special notation for each system. You just type the following:

```
sage: maxima(pi)
%pi
sage: singular(pi)
pi
sage: gap(pi)
pi
sage: gp(pi)
3.1415926535897932384626433832795028842     # 32-bit
3.1415926535897932384626433832795028842   # 64-bit
sage: pari(pi)
3.14159265358979
```

```
sage: kash(pi)                      # optional
3.14159265358979323846264338328
sage: mathematica(pi)               # optional
Pi
sage: maple(pi)                     # optional
Pi
sage: octave(pi)                    # optional
3.14159
```

Arithmetic operations with constants also yield constants, which can be coerced into other systems or evaluated.

```
sage: a = pi + e*4/5; a
pi + 4/5*e
sage: maxima(a)
%pi+4*%e/5
sage: RealField(15)(a)            # 15 *bits* of precision
5.316
sage: gp(a)
5.3162181163570294267508733603616328824    # 64-bit
sage: print mathematica(a)                     # optional
 4 E
 --- + Pi
  5
```

EXAMPLES: Decimal expansions of constants

We can obtain floating point approximations to each of these constants by coercing into the real field with given precision. For example, to 200 decimal places we have the following:

```
sage: R = RealField(200); R
Real Field with 200 bits of precision

sage: R(pi)
3.1415926535897932384626433832795028841971693993751058209749

sage: R(e)
2.7182818284590452353602874713526624977572470936999595749670

sage: R(NaN)
NaN

sage: R(golden_ratio)
1.6180339887498948482045868343656381177203091798057628621354

sage: R(log2)
0.69314718055994530941723212145817656807550013436025525412068

sage: R(euler_gamma)
0.57721566490153286060651209008240243104215933593992359880577

sage: R(catalan)
0.91596559417721901505460351493238411077414937428167213426650
```

```
sage: R(khinchin)

```

class Brun (*name='brun'*)

Brun's constant is the sum of reciprocals of odd twin primes.

It is not known to very high precision; calculating the number using twin primes up to 10^{16} (Sebah 2002) gives the number 1.9021605831040.

EXAMPLES:

```
sage: float(brun)
...
NotImplementedError: brun is only available up to 41 bits
sage: R = RealField(41); R
Real Field with 41 bits of precision
sage: R(brun)
1.90216058310
```

class Catalan (*name='catalan'*)

A number appaering in combinatorics defined as the Dirichlet beta function evaluated at the number 2.

EXAMPLES:

```
sage: catalan^2 + merten
merten + catalan^2
```

class Constant (*name, conversions=None, latex=None, mathml='', domain='complex'*)

domain()

Returns the domain of this constant. This is either positive, real, or complex, and is used by Pynac to make inferences about expressions containing this constant.

EXAMPLES:

```
sage: p = pi.pyobject(); p
pi
sage: type(_)
<class 'sage.symbolic.constants.Pi'>
sage: p.domain()
'positive'
```

expression()

Returns an expression for this constant.

EXAMPLES:

```
sage: a = pi.pyobject()
sage: pi2 = a.expression()
sage: pi2
```

```
pi
sage: pi2 + 2
pi + 2
sage: pi - pi2
0
```

name()

Returns the name of this constant.

EXAMPLES:

```
sage: from sage.symbolic.constants import Constant
sage: c = Constant('c')
sage: c.name()
'c'
```

class E(*name='e'*)

expression()

Note: For e, we don't return a wrapper around a Pynac constant. Instead, we return exp(1) so that Pynac can perform appropiate.

EXAMPLES:

```
sage: e + 2
e + 2
sage: e.operator()
exp
sage: e.operands()
[1]
```

class EulerGamma(*name='euler_gamma'*)

The limiting difference between the harmonic series and the natural logarithm.

EXAMPLES:

```
sage: R = RealField()
sage: R(euler_gamma)
0.577215664901533
sage: R = RealField(200); R
Real Field with 200 bits of precision
sage: R(euler_gamma)
0.57721566490153286060651209008240243104215933593992359880577
sage: eg = euler_gamma + euler_gamma; eg
2*euler_gamma
sage: R(eg)
1.15443132980306572121302418016480486208431867187984719761115
```

class GoldenRatio(*name='golden_ratio'*)

The number (1+sqrt(5))/2

EXAMPLES:

```
sage: gr = golden_ratio
sage: RR(gr)
1.61803398874989
sage: R = RealField(200)
sage: R(gr)
1.61803398874989484820458683436563811772030917980576286213544
```

```
sage: grm = maxima(golden_ratio);grm
(sqrt(5)+1)/2
sage: grm + grm
sqrt(5)+1
sage: float(grm + grm)
3.2360679774997898
```

minpoly(*bits=None, degree=None, epsilon=0*)

EXAMPLES:

```
sage: golden_ratio.minpoly()
x^2 - x - 1
```

class **I_class**(*name='I'*)

expression(*constant=False*)

Returns an Expression for I. If *constnat* is True, then it returns a wrapper around a Pynac constant. If *constant* is False, then it returns a wrapper around a NumberFieldElement.

EXAMPLES:

```
sage: from sage.symbolic.constants import I_class
sage: a = I_class()
sage: I_constant = a.expression(constant=True)
sage: type(I_constant.pyobject())
<class 'sage.symbolic.constants.I_class'>
sage: I_nf = a.expression()
sage: type(I_nf.pyobject())
<type 'sage.rings.number_field.number_field_element_quadratic.NumberFieldElement_quadratic'>
```

class **Khinchin**(*name='khinchin'*)

The geometric mean of the continued fraction expansion of any (almost any) real number.

EXAMPLES:

```
sage: float(khinchin)
2.6854520010653062
sage: m = mathematica(khinchin); m              # optional
Khinchin
sage: m.N(200)                                  # optional
2.6854520010653064453097148354817956938203822939944629530511523455572188595371520028011411749318
2.6854520010653064453097148354817956938203822939944629530511523455572188595371520028011411749318
```

class **LimitedPrecisionConstant**(*name, value, **kwds*)

class **Log2**(*name='log2'*)

The natural logarithm of the real number 2.

EXAMPLES:

```
sage: log2
log2
sage: float(log2)
0.69314718055994529
sage: RR(log2)
0.693147180559945
sage: R = RealField(200); R
Real Field with 200 bits of precision
sage: R(log2)
0.69314718055994530941723212145817656807550013436025525412068
```

```
sage: l = (1-log2)/(1+log2); l
-(log2 - 1)/(log2 + 1)
sage: R(l)
0.18123221829928249948761381864650311423330609774776013488056
sage: maxima(log2)
log(2)
sage: maxima(log2).float()
.6931471805599453
sage: gp(log2)
0.69314718055994530941723212145817656807   # 64-bit
0.69314718055994530941723212             # 32-bit
```

class Merten (*name='merten'*)

The Merten constant is related to the Twin Primes constant and appears in Merten's second theorem.

EXAMPLES:

```
sage: float(merten)
0.26149721284764277
sage: R=RealField(200);R
Real Field with 200 bits of precision
sage: R(merten)
0.26149721284764278375542683860869585905156664826119920619206
```

class NotANumber (*name='NaN'*)

Not a Number

class Pi (*name='pi'*)

class TwinPrime (*name='twinprime'*)

The Twin Primes constant is defined as $\prod 1 - 1/(p-1)^2$ for primes $p > 2$.

EXAMPLES:

```
sage: float(twinprime)
0.66016181584686962
sage: R=RealField(200);R
Real Field with 200 bits of precision
sage: R(twinprime)
0.66016181584686957392781211001455577843262336028473341331945
```

unpickle_Constant (*class_name, name, conversions, latex, mathml, domain*)

EXAMPLES:

```
sage: from sage.symbolic.constants import unpickle_Constant
sage: a = unpickle_Constant('Constant', 'a', {}, 'aa', '', 'positive')
sage: a.domain()
'positive'
sage: latex(a)
aa
```

Note that if the name already appears in the `constants_name_table`, then that will be returned instead of constructing a new object:

```
sage: pi = unpickle_Constant('Pi', 'pi', None, None, None, None)
sage: pi._maxima_init_()
'%pi'
```

CHAPTER

NINE

FUNCTIONS

9.1 Logarithmic functions

class Function_dilog()

class Function_exp()

class Function_log()

class Function_polylog()

ln(*x*)

The natural logarithm of x.

INPUT:

- x - positive real number

OUTPUT:

- ln(x) - real number

EXAMPLES:

```
sage: ln(e^2)
2
sage: ln(2)
log(2)
sage: ln(2.0)
0.693147180559945
```

log(*x*, *base=None*)

Return the logarithm of x to the given base.

Calls the log method of the object x when computing the logarithm, thus allowing use of logarithm on any object containing a log method. In other words, log works on more than just real numbers.

TODO: Add p-adic log example.

EXAMPLES:

```
sage: log(e^2)
2
sage: log(1024, 2); RDF(log(1024, 2))
10
10.0
sage: log(10, 4); RDF(log(10, 4))
```

```
log(10)/log(4)
1.66096404744

sage: log(10, 2)
log(10)/log(2)
sage: n(log(10, 2))
3.32192809488736
sage: log(10, e)
log(10)
sage: n(log(10, e))
2.30258509299405
```

The log function also works in finite fields as long as the base is generator of the multiplicative group:

```
sage: F = GF(13); g = F.multiplicative_generator(); g
2
sage: a = F(8)
sage: log(a,g); g^log(a,g)
3
8
sage: log(a,3)
...
ValueError: base (=3) for discrete log must generate multiplicative group
```

9.2 Hyperbolic Functions

class Function_arccosh()

class Function_arccoth()

class Function_arccsch()

class Function_arcsech()

class Function_arcsinh()

class Function_arctanh()

class Function_cosh()

class Function_coth()

class Function_csch()

class Function_sech()

class Function_sinh()

class Function_tanh()

class HyperbolicFunction()

9.3 Transcendental Functions

class DickmanRhoComputer()

Dickman's function is the continuous function satisfying the differential equation

$$x\rho'(x) + \rho(x-1) = 0$$

with initial conditions $\rho(x) = 1$ for $0 \leq x \leq 1$. It is useful in estimating the frequency of smooth numbers as asymptotically

$$\Psi(a, a^{1/s}) \sim a\rho(s)$$

where $\Psi(a, b)$ is the number of b-smooth numbers less than a.

ALGORITHM:

Dickmans's function is analytic on the interval $[n, n+1]$ for each integer n. To evalute at $n + t, 0 \leq t < 1$, a power series is recursively computed about $n + 1/2$ using the differential equation stated above. As high precision arithmetic may be needed for intermediate results the computed series are cached for later use.

Simple explicit formulas are used for the intervals [0,1] and [1,2].

EXAMPLES:

```
sage: dickman_rho(2)
0.306852819440055
sage: dickman_rho(10)
2.77017183772596e-11
sage: dickman_rho(10.000000000000000000000000000000000000000)
2.7701718377259589887581212006343423263 43e-11
sage: plot(log(dickman_rho(x)), (x, 0, 15))
```

AUTHORS:

- Robert Bradshaw (2008-09)

REFERENCES:

- G. Marsaglia, A. Zaman, J. Marsaglia. "Numerical Solutions to some Classical Differential-Difference Equations." Mathematics of Computation, Vol. 53, No. 187 (1989).

approximate (*x*)

Approximate using de Bruijn's formula

$$\rho(x) \sim \frac{exp(-x\xi + Ei(\xi))}{\sqrt{2\pi x}\xi}$$

which is asymptotically equal to Dickman's function, and is much faster to compute.

REFERENCES:

- N. De Bruijn, "The Asymptotic behavior of a function occuring in the theory of primes." J. Indian Math Soc. v 15. (1951)

EXAMPLES:

```
sage: dickman_rho.approximate(10)
2.41739196365564e-11
sage: dickman_rho(10)
2.77017183772596e-11
sage: dickman_rho.approximate(1000)
4.32938809066403e-3464
```

power_series (*n, abs_prec*)

This function returns the power series about $n+1/2$ used to evaluate Dickman's function. It is scaled such that the interval $[n, n+1]$ corresponds to x in $[-1, 1]$.

INPUT:

- `n` - the lower endpoint of the interval for which this power series holds
- `abs_prec` - the absolute precision of the resulting power series

EXAMPLES:

```
sage: f = dickman_rho.power_series(2, 20); f
-9.9376e-8*x^11 + 3.7722e-7*x^10 - 1.4684e-6*x^9 + 5.8783e-6*x^8 - 0.000024259*x^7 + 0.00010
sage: f(-1), f(0), f(1)
(0.30685, 0.13032, 0.048608)
sage: dickman_rho(2), dickman_rho(2.5), dickman_rho(3)
(0.306852819440055, 0.130319561832251, 0.0486083882911316)
```

Ei (*z*)

Return the value of the complex exponential integral Ei(z) at a complex number z.

> **Warning:** Calculations are done to double precision, and the output is a complex double element, no matter how big the precision of the input is.

EXAMPLES:

```
sage: Ei(10)
2492.22897624
sage: Ei(I)
0.337403922901 + 2.51687939716*I
sage: Ei(3+I)
7.823134676 + 6.09751978399*I
```

The branch cut for this function is along the positive real axis:

```
sage: Ei(3 + 0.1*I)
9.91152770287 + 0.668898200718*I
sage: Ei(3 - 0.1*I)
9.91152770287 + 5.61428710646*I
```

ALGORITHM: Uses scipy's special.exp1 function.

Li (*x, eps_rel=None, err_bound=False*)

Return value of the function Li(x) as a real double field element.

This is the function

$$\int_2^x dt/\log(t).$$

The function Li(x) is an approximation for the number of primes up to x. In fact, the famous Riemann Hypothesis is equivalent to the statement that for $x \geq 2.01$ we have

$$|\pi(x) - Li(x)| \leq \sqrt{x}\log(x).$$

For "small" x, $Li(x)$ is always slightly bigger than $\pi(x)$. However it is a theorem that there are (very large, e.g., around 10^{316}) values of x so that $\pi(x) > Li(x)$. See "A new bound for the smallest x with $\pi(x) > li(x)$", Bays and Hudson, Mathematics of Computation, 69 (2000) 1285-1296.

ALGORITHM: Computed numerically using GSL.

INPUT:

- x - a real number = 2.

OUTPUT:

- x - a real double

EXAMPLES:

```
sage: Li(2)
0.0
sage: Li(5)
2.58942452992
sage: Li(1000)
176.56449421
sage: Li(10^5)
9628.76383727
sage: prime_pi(10^5)
9592
sage: Li(1)
...
ValueError: Li only defined for x at least 2.
```

```
sage: for n in range(1,7):
...     print '%-10s%-10s%-20s'%(10^n, prime_pi(10^n), Li(10^n))
10        4         5.12043572467
100       25        29.080977804
1000      168       176.56449421
10000     1229      1245.09205212
100000    9592      9628.76383727
1000000   78498     78626.5039957
```

exponential_integral_1 (*x, n=0*)

Returns the exponential integral $E_1(x)$. If the optional argument n is given, computes list of the first n values of the exponential integral $E_1(xm)$.

The exponential integral $E_1(x)$ is

$$E_1(x) = \int_x^\infty e^{-t}/t dt$$

INPUT:

- `x` - a positive real number
- `n` - (default: 0) a nonnegative integer; if nonzero, then return a list of values E_1(x*m) for m = 1,2,3,...,n. This is useful, e.g., when computing derivatives of L-functions.

OUTPUT:

- `float` - if n is 0 (the default) or
- `list` - list of floats if n 0

EXAMPLES:

```
sage: exponential_integral_1(2)
0.048900510708061118
sage: w = exponential_integral_1(2,4); w
[0.048900510708061118, 0.003779352409848905, 0.00036008245216265542, 3.7665622843921715e-05] # 3
[0.048900510708061118, 0.003779352409848905, 0.00036008245216265542, 3.7665622843921498e-05] # 64
```

IMPLEMENTATION: We use the PARI C-library functions eint1 and veceint1.

REFERENCE:

- See page 262, Prop 5.6.12, of Cohen's book "A Course in Computational Algebraic Number Theory".

REMARKS: When called with the optional argument n, the PARI C-library is fast for values of n up to some bound, then very very slow. For example, if x=5, then the computation takes less than a second for n=800000, and takes "forever" for n=900000.

gamma_inc(*s*, *t*)
Incomplete Gamma function Gamma(s,t).

EXAMPLES:

```
sage: gamma_inc(CDF(0,1), 3)
0.00320857499337 + 0.0124061858119*I
sage: gamma_inc(3, 3)
0.846380162253687
sage: gamma_inc(RDF(1), 3)
0.0497870683678639
```

incomplete_gamma(*s*, *t*)
Incomplete Gamma function Gamma(s,t).

EXAMPLES:

```
sage: gamma_inc(CDF(0,1), 3)
0.00320857499337 + 0.0124061858119*I
sage: gamma_inc(3, 3)
0.846380162253687
sage: gamma_inc(RDF(1), 3)
0.0497870683678639
```

zeta(*s*)
Riemann zeta function at s with s a real or complex number.

INPUT:

- s - real or complex number

If s is a real number the computation is done using the MPFR library. When the input is not real, the computation is done using the PARI C library.

EXAMPLES:

```
sage: zeta(2)
1.64493406684823
sage: RR = RealField(200)
sage: zeta(RR(2))
1.6449340668482264364724151666460251892189499012067984377356
sage: zeta(I)
zeta(I)
sage: zeta(I).n()
0.00330022368532410 - 0.418155449141322*I
```

zeta_symmetric(*s*)
Completed function $\xi(s)$ that satisfies $\xi(s) = \xi(1-s)$ and has zeros at the same points as the Riemann zeta function.

INPUT:

- s - real or complex number

If s is a real number the computation is done using the MPFR library. When the input is not real, the computation is done using the PARI C library.

More precisely,

$$xi(s) = \gamma(s/2+1) * (s-1) * \pi^{-s/2} * \zeta(s).$$

EXAMPLES:

```
sage: zeta_symmetric(0.7)
0.497580414651127
sage: zeta_symmetric(1-0.7)
0.497580414651127
sage: RR = RealField(200)
sage: zeta_symmetric(RR(0.7))
0.49758041465112690357779107525638385212657443284080589766062
sage: C.<i> = ComplexField()
sage: zeta_symmetric(0.5 + i*14.0)
0.000201294444235258 + 1.49077798716757e-19*I
sage: zeta_symmetric(0.5 + i*14.1)
0.0000489893483255687 + 4.40457132572236e-20*I
sage: zeta_symmetric(0.5 + i*14.2)
-0.0000868931282620101 + 7.11507675693612e-20*I
```

REFERENCE:

•I copied the definition of xi from http://www.math.ubc.ca/~pugh/RiemannZeta/RiemannZetaLong.html

9.4 Piecewise-defined Functions.

Sage implements a very simple class of piecewise-defined functions. Functions may be any type of symbolic expression. Infinite intervals are not supported. The endpoints of each interval must line up.

TODO:

- Implement max/min location and values,
- Need: parent object - ring of piecewise functions
- This class should derive from an element-type class, and should define `_add_`, `_mul_`, etc. That will automatically take care of left multiplication and proper coercion. The coercion mentioned below for scalar mult on right is bad, since it only allows ints and rationals. The right way is to use an element class and only define `_mul_`, and have a parent, so anything gets coerced properly.

AUTHORS:

- David Joyner (2006-04): initial version
- David Joyner (2006-09): added __eq__, extend_by_zero_to, unextend, convolution, trapezoid, trapezoid_integral_approximation, riemann_sum, riemann_sum_integral_approximation, tangent_line fixed bugs in __mul__, __add__
- David Joyner (2007-03): adding Hann filter for FS, added general FS filter methods for computing and plotting, added options to plotting of FS (eg, specifying rgb values arenow allowed). Fixed bug in documentation reported by Pablo De Napoli.
- David Joyner (2007-09): bug fixes due to behaviour of SymbolicArithmetic
- David Joyner (2008-04): fixed docstring bugs reported by J Morrow; added support for laplace transform of functions with infinite support.
- David Joyner (2008-07): fixed a left multiplication bug reported by C. Boncelet (by defining __rmul__ = __mul__).
- Paul Butler (2009-01): added indefinite integration and default_variable

TESTS:

```
sage: R.<x> = QQ[]
sage: f = Piecewise([[(0,1),1*x^0]])
sage: 2*f
Piecewise defined function with 1 parts, [[(0, 1), 2]]
```

Piecewise(*list_of_pairs, var=None*)

Returns a piecewise function from a list of (interval, function) pairs.

`list_of_pairs` is a list of pairs (I, fcn), where fcn is a Sage function (such as a polynomial over RR, or functions using the lambda notation), and I is an interval such as I = (1,3). Two consecutive intervals must share a common endpoint.

If the optional `var` is specified, then any symbolic expressions in the list will be converted to symbolic functions using `fcn.function(var)`. (This says which variable is considered to be "piecewise".)

We assume that these definitions are consistent (ie, no checking is done).

EXAMPLES:

```
sage: f1(x) = -1
sage: f2(x) = 2
sage: f = Piecewise([[(0,pi/2),f1],[(pi/2,pi),f2]])
sage: f(1)
-1
sage: f(3)
2
sage: f = Piecewise([[(0,1),x], [(1,2),x^2]], x); f
Piecewise defined function with 2 parts, [[(0, 1), x |--> x], [(1, 2), x |--> x^2]]
sage: f(0.9)
0.900000000000000
sage: f(1.1)
1.21000000000000
```

class **PiecewisePolynomial**(*list_of_pairs, var=None*)

Returns a piecewise function from a list of (interval, function) pairs.

EXAMPLES:

```
sage: f1(x) = -1
sage: f2(x) = 2
sage: f = Piecewise([[(0,pi/2),f1],[(pi/2,pi),f2]])
sage: f(1)
-1
sage: f(3)
2
```

base_ring()

Returns the base-ring (ie, QQ[x]) - useful when this class is extended.

convolution(*other*)

Returns the convolution function, $f * g(t) = \int_{-\infty}^{\infty} f(u)g(t-u)du$, for compactly supported f, g.

EXAMPLES:

```
sage: x = PolynomialRing(QQ,'x').gen()
sage: f = Piecewise([[(0,1),1*x^0]])  ## example 0
sage: g = f.convolution(f)
sage: h = f.convolution(g)
sage: P = f.plot(); Q = g.plot(rgbcolor=(1,1,0)); R = h.plot(rgbcolor=(0,1,1));
sage: # Type show(P+Q+R) to view
```

```
sage: f = Piecewise([[(0,1),1*x^0],[(1,2),2*x^0],[(2,3),1*x^0]])  ## example 1
sage: g = f.convolution(f)
sage: h = f.convolution(g)
sage: P = f.plot(); Q = g.plot(rgbcolor=(1,1,0)); R = h.plot(rgbcolor=(0,1,1));
sage: # Type show(P+Q+R) to view
sage: f = Piecewise([[(-1,1),1]])                              ## example 2
sage: g = Piecewise([[(0,3),x]])
sage: f.convolution(g)
Piecewise defined function with 3 parts, [[(-1, 1), 0], [(1, 2), -3/2*x], [(2, 4), -3/2*x]]
sage: g = Piecewise([[(0,3),1*x^0],[(3,4),2*x^0]])
sage: f.convolution(g)
Piecewise defined function with 5 parts, [[(-1, 1), x + 1], [(1, 2), 3], [(2, 3), x], [(3, 4
```

cosine_series_coefficient(*n, L*)

Returns the n-th cosine series coefficient of $\cos(n\pi x/L)$, a_n.

INPUT:

- `self` - the function f(x), defined over 0 x L (no checking is done to insure this)
- `n` - an integer n=0
- `L` - (the period)/2

OUTPUT: $a_n = \frac{2}{L}\int_{-L}^{L} f(x)\cos(n\pi x/L)dx$ such that

$$f(x) \sim \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos(\frac{n\pi x}{L}),\ \ 0 < x < L.$$

EXAMPLES:

```
sage: f(x) = x
sage: f = Piecewise([[(0,1),f]])
sage: f.cosine_series_coefficient(2,1)
0
sage: f.cosine_series_coefficient(3,1)
-4/9/pi^2
sage: f1(x) = -1
sage: f2(x) = 2
sage: f = Piecewise([[(0,pi/2),f1],[(pi/2,pi),f2]])
sage: f.cosine_series_coefficient(2,pi)
0
sage: f.cosine_series_coefficient(3,pi)
2/pi
sage: f.cosine_series_coefficient(111,pi)
2/37/pi
sage: f1 = lambda x: x*(pi-x)
sage: f = Piecewise([[(0,pi),f1]])
sage: f.cosine_series_coefficient(0,pi)
1/3*pi^2
```

critical_points()

Return the critical points of this piecewise function.

> **Warning:** Uses maxima, which prints the warning to use results with caution. Only works for piecewise functions whose parts are polynomials with real critical not occurring on the interval endpoints.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: f1 = x^0
```

```
sage: f2 = 10*x - x^2
sage: f3 = 3*x^4 - 156*x^3 + 3036*x^2 - 26208*x
sage: f = Piecewise([[(0,3),f1],[(3,10),f2],[(10,20),f3]])
sage: expected = [5, 12, 13, 14]
sage: all(abs(e-a) < 0.001 for e,a in zip(expected, f.critical_points()))
True
```

default_variable()

Return the default variable. The default variable is defined as the first variable in the first piece uses a variable. If no pieces have a variable (each piece is a constant value), x is returned.

The result is cached.

AUTHOR: Paul Butler

EXAMPLES:

```
sage: f1(x) = 1
sage: f2(x) = 5*x
sage: p = Piecewise([[(0,1),f1],[(1,4),f2]])
sage: p.default_variable()
x
```

derivative()

Returns the derivative (as computed by maxima) Piecewise(I,‘(d/dx)(selfl_I)‘), as I runs over the intervals belonging to self. self must be piecewise polynomial.

EXAMPLES:

```
sage: f1(x) = 1
sage: f2(x) = 1-x
sage: f = Piecewise([[(0,1),f1],[(1,2),f2]])
sage: f.derivative()
Piecewise defined function with 2 parts, [[(0, 1), x |--> 0], [(1, 2), x |--> -1]]
sage: f1(x) = -1
sage: f2(x) = 2
sage: f = Piecewise([[(0,pi/2),f1],[(pi/2,pi),f2]])
sage: f.derivative()
Piecewise defined function with 2 parts, [[(0, 1/2*pi), x |--> 0], [(1/2*pi, pi), x |--> 0]]

sage: f = Piecewise([[(0,1), (x * 2)]], x)
sage: f.derivative()
Piecewise defined function with 1 parts, [[(0, 1), x |--> 2]]
```

domain()

Returns the domain of the function.

EXAMPLES:

```
sage: f1(x) = 1
sage: f2(x) = 1-x
sage: f3(x) = exp(x)
sage: f4(x) = sin(2*x)
sage: f = Piecewise([[(0,1),f1],[(1,2),f2],[(2,3),f3],[(3,10),f4]])
sage: f.domain()
(0, 10)
```

end_points()

Returns a list of all interval endpoints for this function.

EXAMPLES:

```
sage: f1(x) = 1
sage: f2(x) = 1-x
```

```
sage: f3(x) = x^2-5
sage: f = Piecewise([[(0,1),f1],[(1,2),f2],[(2,3),f3]])
sage: f.end_points()
[0, 1, 2, 3]
```

extend_by_zero_to (*xmin=-1000, xmax=1000*)

This function simply returns the piecewise defined function which is extended by 0 so it is defined on all of (xmin,xmax). This is needed to add two piecewise functions in a reasonable way.

EXAMPLES:

```
sage: f1(x) = 1
sage: f2(x) = 1 - x
sage: f = Piecewise([[(0,1),f1],[(1,2),f2]])
sage: f.extend_by_zero_to(-1, 3)
Piecewise defined function with 4 parts, [[(-1, 0), 0], [(0, 1), x |--> 1], [(1, 2), x |-->
```

fourier_series_cosine_coefficient (*n, L*)

Returns the n-th Fourier series coefficient of $\cos(n\pi x/L)$, a_n.

INPUT:

- `self` - the function f(x), defined over -L x L
- `n` - an integer n=0
- `L` - (the period)/2

OUTPUT: $a_n = \frac{1}{L}\int_{-L}^{L} f(x)\cos(n\pi x/L)dx$

EXAMPLES:

```
sage: f(x) = x^2
sage: f = Piecewise([[(-1,1),f]])
sage: f.fourier_series_cosine_coefficient(2,1)
pi^(-2)
sage: f(x) = x^2
sage: f = Piecewise([[(-pi,pi),f]])
sage: f.fourier_series_cosine_coefficient(2,pi)
1
sage: f1(x) = -1
sage: f2(x) = 2
sage: f = Piecewise([[(-pi,pi/2),f1],[(pi/2,pi),f2]])
sage: f.fourier_series_cosine_coefficient(5,pi)
-3/5/pi
```

fourier_series_partial_sum (*N, L*)

Returns the partial sum

$$f(x) \sim \frac{a_0}{2} + \sum_{n=1}^{N}[a_n \cos(\frac{n\pi x}{L}) + b_n \sin(\frac{n\pi x}{L})],$$

as a string.

EXAMPLE:

```
sage: f(x) = x^2
sage: f = Piecewise([[(-1,1),f]])
sage: f.fourier_series_partial_sum(3,1)
-4*cos(pi*x)/pi^2 + cos(2*pi*x)/pi^2 + 1/3
sage: f1(x) = -1
sage: f2(x) = 2
sage: f = Piecewise([[(-pi,pi/2),f1],[(pi/2,pi),f2]])
sage: f.fourier_series_partial_sum(3,pi)
-3*sin(2*x)/pi + 3*sin(x)/pi - 3*cos(x)/pi - 1/4
```

fourier_series_partial_sum_cesaro(*N, L*)

Returns the Cesaro partial sum

$$f(x) \sim \frac{a_0}{2} + \sum_{n=1}^{N} (1 - n/N) * [a_n \cos(\frac{n\pi x}{L}) + b_n \sin(\frac{n\pi x}{L})],$$

as a string. This is a "smoother" partial sum - the Gibbs phenomenon is mollified.

EXAMPLE:

```
sage: f(x) = x^2
sage: f = Piecewise([[(-1,1),f]])
sage: f.fourier_series_partial_sum_cesaro(3,1)
-8/3*cos(pi*x)/pi^2 + 1/3*cos(2*pi*x)/pi^2 + 1/3
sage: f1(x) = -1
sage: f2(x) = 2
sage: f = Piecewise([[(-pi,pi/2),f1],[(pi/2,pi),f2]])
sage: f.fourier_series_partial_sum_cesaro(3,pi)
-sin(2*x)/pi + 2*sin(x)/pi - 2*cos(x)/pi - 1/4
```

fourier_series_partial_sum_filtered(*N, L, F*)

Returns the "filtered" partial sum

$$f(x) \sim \frac{a_0}{2} + \sum_{n=1}^{N} F_n * [a_n \cos(\frac{n\pi x}{L}) + b_n \sin(\frac{n\pi x}{L})],$$

as a string, where $F = [F_1, F_2, ..., F_N]$ is a list of length N consisting of real numbers. This can be used to plot FS solutions to the heat and wave PDEs.

EXAMPLE:

```
sage: f(x) = x^2
sage: f = Piecewise([[(-1,1),f]])
sage: f.fourier_series_partial_sum_filtered(3,1,[1,1,1])
-4*cos(pi*x)/pi^2 + cos(2*pi*x)/pi^2 + 1/3
sage: f1(x) = -1
sage: f2(x) = 2
sage: f = Piecewise([[(-pi,pi/2),f1],[(pi/2,pi),f2]])
sage: f.fourier_series_partial_sum_filtered(3,pi,[1,1,1])
-3*sin(2*x)/pi + 3*sin(x)/pi - 3*cos(x)/pi - 1/4
```

fourier_series_partial_sum_hann(*N, L*)

Returns the Hann-filtered partial sum (named after von Hann, not Hamming)

$$f(x) \sim \frac{a_0}{2} + \sum_{n=1}^{N} H_N(n) * [a_n \cos(\frac{n\pi x}{L}) + b_n \sin(\frac{n\pi x}{L})],$$

as a string, where $H_N(x) = (1+\cos(\pi x/N))/2$. This is a "smoother" partial sum - the Gibbs phenomenon is mollified.

EXAMPLE:

```
sage: f(x) = x^2
sage: f = Piecewise([[(-1,1),f]])
sage: f.fourier_series_partial_sum_hann(3,1)
-3*cos(pi*x)/pi^2 + 1/4*cos(2*pi*x)/pi^2 + 1/3
sage: f1(x) = -1
sage: f2(x) = 2
sage: f = Piecewise([[(-pi,pi/2),f1],[(pi/2,pi),f2]])
sage: f.fourier_series_partial_sum_hann(3,pi)
-3/4*sin(2*x)/pi + 9/4*sin(x)/pi - 9/4*cos(x)/pi - 1/4
```

fourier_series_sine_coefficient(*n, L*)

Returns the n-th Fourier series coefficient of $\sin(n\pi x/L)$, b_n.

INPUT:

- `self` - the function f(x), defined over -L x L
- `n` - an integer n0
- `L` - (the period)/2

OUTPUT: $b_n = \frac{1}{L}\int_{-L}^{L} f(x)\sin(n\pi x/L)dx$

EXAMPLES:

```
sage: f(x) = x^2
sage: f = Piecewise([[(-1,1),f]])
sage: f.fourier_series_sine_coefficient(2,1)  # L=1, n=2
0
```

fourier_series_value(*x, L*)

Returns the value of the Fourier series coefficient of self at x,

$$f(x) \sim \frac{a_0}{2} + \sum_{n=1}^{\infty}[a_n \cos(\frac{n\pi x}{L}) + b_n \sin(\frac{n\pi x}{L})], \quad -L < x < L.$$

This method applies to piecewise non-polynomial functions as well.

INPUT:

- `self` - the function f(x), defined over -L x L
- `x` - a real number
- `L` - (the period)/2

OUTPUT: $(f^*(x+) + f^*(x-)/2$, where f^* denotes the function f extended to $\mathbf{R}$ with period $2L$ (Dirichlet's Theorem for Fourier series).

EXAMPLES:

```
sage: f1(x) = 1
sage: f2(x) = 1-x
sage: f3(x) = exp(x)
sage: f4(x) = sin(2*x)
sage: f = Piecewise([[(-10,1),f1],[(1,2),f2],[(2,3),f3],[(3,10),f4]])
sage: f.fourier_series_value(101,10)
1/2
sage: f.fourier_series_value(100,10)
1
sage: f.fourier_series_value(10,10)
1/2*sin(20) + 1/2
sage: f.fourier_series_value(20,10)
1
sage: f.fourier_series_value(30,10)
1/2*sin(20) + 1/2
sage: f1(x) = -1
sage: f2(x) = 2
sage: f = Piecewise([[(-pi,0),lambda x:0],[(0,pi/2),f1],[(pi/2,pi),f2]])
sage: f.fourier_series_value(-1,pi)
0
sage: f.fourier_series_value(20,pi)
-1
sage: f.fourier_series_value(pi/2,pi)
1/2
```

functions()

Returns the list of functions (the "pieces").

EXAMPLES:

```
sage: f1(x) = 1
sage: f2(x) = 1-x
sage: f3(x) = exp(x)
sage: f4(x) = sin(2*x)
sage: f = Piecewise([[(0,1),f1],[(1,2),f2],[(2,3),f3],[(3,10),f4]])
sage: f.functions()
[x |--> 1, x |--> -x + 1, x |--> e^x, x |--> sin(2*x)]
```

integral (*x=None, a=None, b=None, definite=False*)

By default, returns the indefinite integral of the function. If definite=True is given, returns the definite integral.

AUTHOR:

- Paul Butler

EXAMPLES:

```
sage: f1(x) = 1
sage: f2(x) = 1-x
sage: f = Piecewise([[(0,1),f1],[(1,2),f2]])
sage: f.integral(definite=True)
1/2

sage: f1(x) = -1
sage: f2(x) = 2
sage: f = Piecewise([[(0,pi/2),f1],[(pi/2,pi),f2]])
sage: f.integral(definite=True)
1/2*pi

sage: f1(x) = 2
sage: f2(x) = 3 - x
sage: f = Piecewise([[(-2, 0), f1], [(0, 3), f2]])
sage: f.integral()
Piecewise defined function with 2 parts, [[(-2, 0), x |--> 2*x + 4], [(0, 3), x |--> -1/2*x^

sage: f1(y) = -1
sage: f2(y) = y + 3
sage: f3(y) = -y - 1
sage: f4(y) = y^2 - 1
sage: f5(y) = 3
sage: f = Piecewise([[(-4,-3),f1],[(-3,-2),f2],[(-2,0),f3],[(0,2),f4],[(2,3),f5]])
sage: F = f.integral(y)
sage: F
Piecewise defined function with 5 parts, [[(-4, -3), y |--> -y - 4], [(-3, -2), y |--> 1/2*y
```

Ensure results are consistant with FTC:

```
sage: F(-3) - F(-4)
-1
sage: F(-1) - F(-3)
1
sage: F(2) - F(0)
2/3
sage: f.integral(y, 0, 2)
2/3
sage: F(3) - F(-4)
19/6
sage: f.integral(y, -4, 3)
19/6
sage: f.integral(definite=True)
```

```
19/6

sage: f1(y) = (y+3)^2
sage: f2(y) = y+3
sage: f3(y) = 3
sage: f = Piecewise([[(-infinity, -3), f1], [(-3, 0), f2], [(0, infinity), f3]])
sage: f.integral()
Piecewise defined function with 3 parts, [[(-Infinity, -3), y |--> 1/3*y^3 + 3*y^2 + 9*y + 9

sage: f1(x) = e^(-abs(x))
sage: f = Piecewise([[(-infinity, infinity), f1]])
sage: f.integral(definite=True)
2
sage: f.integral()
Piecewise defined function with 1 parts, [[(-Infinity, +Infinity), x |--> -integrate(e^(-abs
```

intervals()

A piecewise non-polynomial example.

EXAMPLES:

```
sage: f1(x) = 1
sage: f2(x) = 1-x
sage: f3(x) = exp(x)
sage: f4(x) = sin(2*x)
sage: f = Piecewise([[(0,1),f1],[(1,2),f2],[(2,3),f3],[(3,10),f4]])
sage: f.intervals()
[(0, 1), (1, 2), (2, 3), (3, 10)]
```

laplace(*x='x', s='t'*)

Returns the Laplace transform of self with respect to the variable var.

INPUT:

- x - variable of self
- s - variable of Laplace transform.

We assume that a piecewise function is 0 outside of its domain and that the left-most endpoint of the domain is 0.

EXAMPLES:

```
sage: x, s, w = var('x, s, w')
sage: f = Piecewise([[(0,1),1],[(1,2), 1-x]])
sage: f.laplace(x, s)
(s + 1)*e^(-2*s)/s^2 - e^(-s)/s + 1/s - e^(-s)/s^2
sage: f.laplace(x, w)
(w + 1)*e^(-2*w)/w^2 - e^(-w)/w + 1/w - e^(-w)/w^2

sage: y, t = var('y, t')
sage: f = Piecewise([[(1,2), 1-y]])
sage: f.laplace(y, t)
(t + 1)*e^(-2*t)/t^2 - e^(-t)/t^2

sage: s = var('s')
sage: t = var('t')
sage: f1(t) = -t
sage: f2(t) = 2
sage: f = Piecewise([[(0,1),f1],[(1,infinity),f2]])
sage: f.laplace(t,s)
(s + 1)*e^(-s)/s^2 + 2*e^(-s)/s - 1/s^2
```

length()

Retuns the number of pieces of this function.

EXAMPLES:

```
sage: f1(x) = 1
sage: f2(x) = 1 - x
sage: f = Piecewise([[(0,1),f1],[(1,2),f2]])
sage: f.length()
2
```

list()

plot(**args, **kwds*)

Returns the plot of self.

Keyword arguments are passed onto the plot command for each piece of the function. E.g., the plot_points keyword affects each segment of the plot.

EXAMPLES:

```
sage: f1(x) = 1
sage: f2(x) = 1-x
sage: f3(x) = exp(x)
sage: f4(x) = sin(2*x)
sage: f = Piecewise([[(0,1),f1],[(1,2),f2],[(2,3),f3],[(3,10),f4]])
sage: P = f.plot(rgbcolor=(0.7,0.1,0), plot_points=40)
sage: P
```

Remember: to view this, type show(P) or P.save("path/myplot.png") and then open it in a graphics viewer such as GIMP.

plot_fourier_series_partial_sum(*N, L, xmin, xmax, **kwds*)

Plots the partial sum

$$f(x) \sim \frac{a_0}{2} + sum_{n=1}^{N}[a_n \cos(\frac{n\pi x}{L}) + b_n \sin(\frac{n\pi x}{L})],$$

over xmin x xmin.

EXAMPLE:

```
sage: f1(x) = -2
sage: f2(x) = 1
sage: f3(x) = -1
sage: f4(x) = 2
sage: f = Piecewise([[(-pi,-pi/2),f1],[(-pi/2,0),f2],[(0,pi/2),f3],[(pi/2,pi),f4]])
sage: P = f.plot_fourier_series_partial_sum(3,pi,-5,5)     # long time
sage: f1(x) = -1
sage: f2(x) = 2
sage: f = Piecewise([[(-pi,pi/2),f1],[(pi/2,pi),f2]])
sage: P = f.plot_fourier_series_partial_sum(15,pi,-5,5)    # long time
```

Remember, to view this type show(P) or P.save("path/myplot.png") and then open it in a graphics viewer such as GIMP.

plot_fourier_series_partial_sum_cesaro(*N, L, xmin, xmax, **kwds*)

Plots the partial sum

$$f(x) \sim \frac{a_0}{2} + \sum_{n=1}^{N}(1 - n/N) * [a_n \cos(\frac{n\pi x}{L}) + b_n \sin(\frac{n\pi x}{L})],$$

over xmin x xmin. This is a "smoother" partial sum - the Gibbs phenomenon is mollified.

EXAMPLE:

```
sage: f1(x) = -2
sage: f2(x) = 1
sage: f3(x) = -1
sage: f4(x) = 2
sage: f = Piecewise([[(-pi,-pi/2),f1],[(-pi/2,0),f2],[(0,pi/2),f3],[(pi/2,pi),f4]])
sage: P = f.plot_fourier_series_partial_sum_cesaro(3,pi,-5,5)     # long time
sage: f1(x) = -1
sage: f2(x) = 2
sage: f = Piecewise([[(-pi,pi/2),f1],[(pi/2,pi),f2]])
sage: P = f.plot_fourier_series_partial_sum_cesaro(15,pi,-5,5)    # long time
```

Remember, to view this type show(P) or P.save("path/myplot.png") and then open it in a graphics viewer such as GIMP.

plot_fourier_series_partial_sum_filtered(*N, L, F, xmin, xmax, **kwds*)

Plots the partial sum

$$f(x) \sim \frac{a_0}{2} + \sum_{n=1}^{N} F_n * [a_n \cos(\frac{n\pi x}{L}) + b_n \sin(\frac{n\pi x}{L})],$$

over xmin x xmin, where $F = [F_1, F_2, ..., F_N]$ is a list of length N consisting of real numbers. This can be used to plot FS solutions to the heat and wave PDEs.

EXAMPLE:

```
sage: f1(x) = -2
sage: f2(x) = 1
sage: f3(x) = -1
sage: f4(x) = 2
sage: f = Piecewise([[(-pi,-pi/2),f1],[(-pi/2,0),f2],[(0,pi/2),f3],[(pi/2,pi),f4]])
sage: P = f.plot_fourier_series_partial_sum_filtered(3,pi,[1]*3,-5,5)     # long time
sage: f1(x) = -1
sage: f2(x) = 2
sage: f = Piecewise([[(-pi,-pi/2),f1],[(-pi/2,0),f2],[(0,pi/2),f1],[(pi/2,pi),f2]])
sage: P = f.plot_fourier_series_partial_sum_filtered(15,pi,[1]*15,-5,5)    # long time
```

Remember, to view this type show(P) or P.save("path/myplot.png") and then open it in a graphics viewer such as GIMP.

plot_fourier_series_partial_sum_hann(*N, L, xmin, xmax, **kwds*)

Plots the partial sum

$$f(x) \sim \frac{a_0}{2} + \sum_{n=1}^{N} H_N(n) * [a_n \cos(\frac{n\pi x}{L}) + b_n \sin(\frac{n\pi x}{L})],$$

over xmin x xmin, where H_N(x) = (0.5)+(0.5)*cos(x*pi/N) is the N-th Hann filter.

EXAMPLE:

```
sage: f1(x) = -2
sage: f2(x) = 1
sage: f3(x) = -1
sage: f4(x) = 2
sage: f = Piecewise([[(-pi,-pi/2),f1],[(-pi/2,0),f2],[(0,pi/2),f3],[(pi/2,pi),f4]])
sage: P = f.plot_fourier_series_partial_sum_hann(3,pi,-5,5)     # long time
sage: f1(x) = -1
sage: f2(x) = 2
sage: f = Piecewise([[(-pi,pi/2),f1],[(pi/2,pi),f2]])
sage: P = f.plot_fourier_series_partial_sum_hann(15,pi,-5,5)    # long time
```

Remember, to view this type show(P) or P.save("path/myplot.png") and then open it in a graphics viewer such as GIMP.

riemann_sum(*N, mode=None*)

Returns the piecewise line function defined by the Riemann sums in numerical integration based on a subdivision into N subintervals. Set mode="midpoint" for the height of the rectangles to be determined by the midpoint of the subinterval; set mode="right" for the height of the rectangles to be determined by the right-hand endpoint of the subinterval; the default is mode="left" (the height of the rectangles to be determined by the leftt-hand endpoint of the subinterval).

EXAMPLES:

```
sage: f1(x) = x^2
sage: f2(x) = 5-x^2
sage: f = Piecewise([[(0,1),f1],[(1,2),f2]])
sage: f.riemann_sum(6,mode="midpoint")
Piecewise defined function with 6 parts, [[(0, 1/3), 1/36], [(1/3, 2/3), 1/4], [(2/3, 1), 25

sage: f = Piecewise([[(-1,1),(1-x^2).function(x)]])
sage: rsf = f.riemann_sum(7)
sage: P = f.plot(rgbcolor=(0.7,0.1,0.5), plot_points=40)
sage: Q = rsf.plot(rgbcolor=(0.7,0.6,0.6), plot_points=40)
sage: L = add([line([[a,0],[a,f(x=a)]],rgbcolor=(0.7,0.6,0.6)) for (a,b),f in rsf.list()])
sage: P + Q + L

sage: f = Piecewise([[(-1,1),(1/2+x-x^3)]], x) ## example 3
sage: rsf = f.riemann_sum(8)
sage: P = f.plot(rgbcolor=(0.7,0.1,0.5), plot_points=40)
sage: Q = rsf.plot(rgbcolor=(0.7,0.6,0.6), plot_points=40)
sage: L = add([line([[a,0],[a,f(x=a)]],rgbcolor=(0.7,0.6,0.6)) for (a,b),f in rsf.list()])
sage: P + Q + L
```

riemann_sum_integral_approximation(*N, mode=None*)

Returns the piecewise line function defined by the Riemann sums in numerical integration based on a subdivision into N subintervals.

Set mode="midpoint" for the height of the rectangles to be determined by the midpoint of the subinterval; set mode="right" for the height of the rectangles to be determined by the right-hand endpoint of the subinterval; the default is mode="left" (the height of the rectangles to be determined by the leftt-hand endpoint of the subinterval).

EXAMPLES:

```
sage: f1(x) = x^2                    ## example 1
sage: f2(x) = 5-x^2
sage: f = Piecewise([[(0,1),f1],[(1,2),f2]])
sage: f.riemann_sum_integral_approximation(6)
17/6
sage: f.riemann_sum_integral_approximation(6,mode="right")
19/6
sage: f.riemann_sum_integral_approximation(6,mode="midpoint")
3
sage: f.integral(definite=True)
3
```

sine_series_coefficient(*n, L*)

Returns the n-th sine series coefficient of $\sin(n\pi x/L)$, b_n.

INPUT:

- `self` - the function f(x), defined over 0 x L (no checking is done to insure this)
- `n` - an integer n0
- `L` - (the period)/2

OUTPUT:

$b_n = \frac{2}{L}\int_{-L}^{L} f(x)\sin(n\pi x/L)dx$ such that

$$f(x) \sim \sum_{n=1}^{\infty} b_n \sin(\frac{n\pi x}{L}),\ \ 0 < x < L.$$

EXAMPLES:

```
sage: f(x) = 1
sage: f = Piecewise([[(0,1),f]])
sage: f.sine_series_coefficient(2,1)
0
sage: f.sine_series_coefficient(3,1)
4/3/pi
```

tangent_line(*pt*)

Computes the linear function defining the tangent line of the piecewise function self.

EXAMPLES:

```
sage: f1(x) = x^2
sage: f2(x) = 5-x^3+x
sage: f = Piecewise([[(0,1),f1],[(1,2),f2]])
sage: tf = f.tangent_line(0.9) ## tangent line at x=0.9
sage: P = f.plot(rgbcolor=(0.7,0.1,0.5), plot_points=40)
sage: Q = tf.plot(rgbcolor=(0.7,0.2,0.2), plot_points=40)
sage: P + Q
```

trapezoid(*N*)

Returns the piecewise line function defined by the trapezoid rule for numerical integration based on a subdivision into N subintervals.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: f1 = x^2
sage: f2 = 5-x^2
sage: f = Piecewise([[(0,1),f1],[(1,2),f2]])
sage: f.trapezoid(4)
Piecewise defined function with 4 parts, [[(0, 1/2), 1/2*x], [(1/2, 1), 9/2*x - 2], [(1, 3/2

sage: R.<x> = QQ[]
sage: f = Piecewise([[(-1,1),1-x^2]])
sage: tf = f.trapezoid(4)
sage: P = f.plot(rgbcolor=(0.7,0.1,0.5), plot_points=40)
sage: Q = tf.plot(rgbcolor=(0.7,0.6,0.6), plot_points=40)
sage: L = add([line([[a,0],[a,f(a)]],rgbcolor=(0.7,0.6,0.6)) for (a,b),f in tf.list()])
sage: P+Q+L

sage: R.<x> = QQ[]
sage: f = Piecewise([[(-1,1),1/2+x-x^3]]) ## example 3
sage: tf = f.trapezoid(6)
sage: P = f.plot(rgbcolor=(0.7,0.1,0.5), plot_points=40)
sage: Q = tf.plot(rgbcolor=(0.7,0.6,0.6), plot_points=40)
sage: L = add([line([[a,0],[a,f(a)]],rgbcolor=(0.7,0.6,0.6)) for (a,b),f in tf.list()])
sage: P+Q+L
```

trapezoid_integral_approximation(*N*)

Returns the approximation given by the trapezoid rule for numerical integration based on a subdivision into N subintervals.

EXAMPLES:

```
sage: f1(x) = x^2                          ## example 1
sage: f2(x) = 1-(1-x)^2
sage: f = Piecewise([[(0,1),f1],[(1,2),f2]])
sage: P = f.plot(rgbcolor=(0.7,0.1,0.5), plot_points=40)
sage: tf = f.trapezoid(6)
sage: Q = tf.plot(rgbcolor=(0.7,0.6,0.6), plot_points=40)
sage: ta = f.trapezoid_integral_approximation(6)
sage: t = text('trapezoid approximation = %s'%ta, (1.5, 0.25))
sage: a = f.integral(definite=True)
sage: tt = text('area under curve = %s'%a, (1.5, -0.5))
sage: P + Q + t + tt

sage: f = Piecewise([[(0,1),f1],[(1,2),f2]])  ## example 2
sage: tf = f.trapezoid(4)
sage: ta = f.trapezoid_integral_approximation(4)
sage: Q = tf.plot(rgbcolor=(0.7,0.6,0.6), plot_points=40)
sage: t = text('trapezoid approximation = %s'%ta, (1.5, 0.25))
sage: a = f.integral(definite=True)
sage: tt = text('area under curve = %s'%a, (1.5, -0.5))
sage: P+Q+t+tt
```

unextend()

This removes any parts in the front or back of the function which is zero (the inverse to extend_by_zero_to).

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: f = Piecewise([[(-3,-1),1+2+x],[(-1,1),1-x^2]])
sage: e = f.extend_by_zero_to(-10,10); e
Piecewise defined function with 4 parts, [[(-10, -3), 0], [(-3, -1), x + 3], [(-1, 1), -x^2
sage: d = e.unextend(); d
Piecewise defined function with 2 parts, [[(-3, -1), x + 3], [(-1, 1), -x^2 + 1]]
sage: d==f
True
```

which_function(*x0*)

Returns the function piece used to evaluate self at x0.

EXAMPLES:

```
sage: f1(z) = z
sage: f2(x) = 1-x
sage: f3(y) = exp(y)
sage: f4(t) = sin(2*t)
sage: f = Piecewise([[(0,1),f1],[(1,2),f2],[(2,3),f3],[(3,10),f4]])
sage: f.which_function(3/2)
x |--> -x + 1
```

piecewise(*list_of_pairs, var=None*)

Returns a piecewise function from a list of (interval, function) pairs.

`list_of_pairs` is a list of pairs (I, fcn), where fcn is a Sage function (such as a polynomial over RR, or functions using the lambda notation), and I is an interval such as I = (1,3). Two consecutive intervals must share a common endpoint.

If the optional `var` is specified, then any symbolic expressions in the list will be converted to symbolic functions using `fcn.function(var)`. (This says which variable is considered to be "piecewise".)

We assume that these definitions are consistent (ie, no checking is done).

EXAMPLES:

```
sage: f1(x) = -1
sage: f2(x) = 2
sage: f = Piecewise([[(0,pi/2),f1],[(pi/2,pi),f2]])
sage: f(1)
-1
sage: f(3)
2
sage: f = Piecewise([[(0,1),x], [(1,2),x^2]], x); f
Piecewise defined function with 2 parts, [[(0, 1), x |--> x], [(1, 2), x |--> x^2]]
sage: f(0.9)
0.900000000000000
sage: f(1.1)
1.21000000000000
```

9.5 Orthogonal Polynomials

This module wraps some of the orthogonal/special functions in the Maxima package "orthopoly". This package was written by Barton Willis of the University of Nebraska at Kearney. It is released under the terms of the General Public License (GPL). Send Maxima-related bug reports and comments on this module to willisb@unk.edu. In your report, please include Maxima and specfun version information.

- The Chebyshev polynomial of the first kind arises as a solution to the differential equation

  $$(1-x^2)\,y'' - x\,y' + n^2\,y = 0$$

  and those of the second kind as a solution to

  $$(1-x^2)\,y'' - 3x\,y' + n(n+2)\,y = 0.$$

  The Chebyshev polynomials of the first kind are defined by the recurrence relation

  $$T_0(x) = 1\,T_1(x) = x\,T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x).$$

  The Chebyshev polynomials of the second kind are defined by the recurrence relation

  $$U_0(x) = 1\,U_1(x) = 2x\,U_{n+1}(x) = 2xU_n(x) - U_{n-1}(x).$$

  For integers m, n, they satisfy the orthogonality relations

  $$\int_{-1}^{1} T_n(x)T_m(x)\,\frac{dx}{\sqrt{1-x^2}} = \begin{cases} 0 & : n \neq m \\ \pi & : n = m = 0 \\ \pi/2 & : n = m \neq 0 \end{cases}$$

  and

  $$\int_{-1}^{1} U_n(x)U_m(x)\sqrt{1-x^2}\,dx = \frac{\pi}{2}\delta_{m,n}.$$

  They are named after Pafnuty Chebyshev (alternative transliterations: Tchebyshef or Tschebyscheff).

- The Hermite polynomials are defined either by

  $$H_n(x) = (-1)^n e^{x^2/2}\frac{d^n}{dx^n}e^{-x^2/2}$$

(the "probabilists' Hermite polynomials"), or by

$$H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2}$$

(the "physicists' Hermite polynomials"). Sage (via Maxima) implements the latter flavor. These satisfy the orthogonality relation

$$\int_{-\infty}^{\infty} H_n(x) H_m(x)\, e^{-x^2}\, dx = n! 2^n \sqrt{\pi} \delta_{nm}$$

They are named in honor of Charles Hermite.

- Each *Legendre polynomial* $P_n(x)$ is an n-th degree polynomial. It may be expressed using Rodrigues' formula:

$$P_n(x) = (2^n n!)^{-1} \frac{d^n}{dx^n} \left[(x^2-1)^n\right].$$

These are solutions to Legendre's differential equation:

$$\frac{d}{dx}\left[(1-x^2)\frac{d}{dx}P(x)\right] + n(n+1)P(x) = 0.$$

and satisfy the orthogonality relation

$$\int_{-1}^{1} P_m(x) P_n(x)\, dx = \frac{2}{2n+1}\delta_{mn}$$

The *Legendre function of the second kind* $Q_n(x)$ is another (linearly independent) solution to the Legendre differential equation. It is not an ""orthogonal polynomial"" however.

The associated Legendre functions of the first kind $P_\ell^m(x)$ can be given in terms of the "usual" Legendre polynomials by

$$\begin{aligned} P_\ell^m(x) &= (-1)^m (1-x^2)^{m/2} (d^m)/(dx^m) P_\ell(x) \\ &= \tfrac{(-1)^m}{2^\ell \ell!} (1-x^2)^{m/2} \tfrac{d^{(\ell+m)}}{dx^{(\ell+m)}} (x^2-1)^\ell. \end{aligned}$$

Assuming $0 \le m \le \ell$, they satisfy the orthogonality relation:

$$\int_{-1}^{1} P_k^{(m)} P_\ell^{(m)} dx = \frac{2(\ell+m)!}{(2\ell+1)(\ell-m)!}\, \delta_{k,\ell},$$

where $\delta_{k,\ell}$ is the Kronecker delta.

The associated Legendre functions of the second kind $Q_\ell^m(x)$ can be given in terms of the "usual" Legendre polynomials by

$$Q_\ell^m(x) = (-1)^m (1-x^2)^{m/2} (d^m)/(dx^m) Q_\ell(x).$$

They are named after Adrien-Marie Legendre.

- Laguerre polynomials may be defined by the Rodrigues formula

$$L_n(x) = \frac{e^x}{n!}\frac{d^n}{dx^n}\left(e^{-x}x^n\right).$$

They are solutions of Laguerre's equation:

$$x\, y'' + (1-x)\, y' + n\, y = 0$$

and satisfy the orthogonality relation

$$\int_0^\infty L_m(x)L_n(x)e^{-x}\,dx = \delta_{mn}.$$

The generalized Laguerre polynomials may be defined by the Rodrigues formula:

$$L_n^{(\alpha)}(x) = \frac{x^{-\alpha}e^x}{n!}\frac{d^n}{dx^n}\left(e^{-x}x^{n+\alpha}\right).$$

(These are also sometimes called the associated Laguerre polynomials.) The simple Laguerre polynomials are recovered from the generalized polynomials by setting $\alpha = 0$.

They are named after Edmond Laguerre.

- Jacobi polynomials are a class of orthogonal polynomials. They are obtained from hypergeometric series in cases where the series is in fact finite:

$$P_n^{(\alpha,\beta)}(z) = \frac{(\alpha+1)_n}{n!}\,{}_2F_1\left(-n, 1+\alpha+\beta+n; \alpha+1; \frac{1-z}{2}\right),$$

where $()_n$ is Pochhammer's symbol (for the rising factorial), (Abramowitz and Stegun p561.) and thus have the explicit expression

$$P_n^{(\alpha,\beta)}(z) = \frac{\Gamma(\alpha+n+1)}{n!\Gamma(\alpha+\beta+n+1)}\sum_{m=0}^{n}\binom{n}{m}\frac{\Gamma(\alpha+\beta+n+m+1)}{\Gamma(\alpha+m+1)}\left(\frac{z-1}{2}\right)^m.$$

They are named after Carl Jacobi.

- Ultraspherical or Gegenbauer polynomials are given in terms of the Jacobi polynomials $P_n^(\alpha,\beta))(x)$ with $\alpha = \beta = a - 1/2$ by

$$C_n^(a))(x) = \frac{\Gamma(a+1/2)}{\Gamma(2a)}\frac{\Gamma(n+2a)}{\Gamma(n+a+1/2)}P_n^{(a-1/2,a-1/2)}(x).$$

They satisfy the orthogonality relation

$$\int_(-1)^1 (1-x^2)^{a-1/2}C_m^{(a)}(x)C_n^{(a)}(x)\,dx = \delta_{mn}2^(1-2a)\pi\frac{\Gamma(n+2a)}{(n+a)\Gamma^2(a)\Gamma(n+1)},$$

for $a > -1/2$. They are obtained from hypergeometric series in cases where the series is in fact finite:

$$C_n^{(a)}(z) = \frac{(2a)^{\underline{n}}}{n!}\,{}_2F_1\left(-n, 2a+n; a+\frac{1}{2}; \frac{1-z}{2}\right)$$

where $\underline{n}$ is the falling factorial. (See Abramowitz and Stegun p561)

They are named for Leopold Gegenbauer (1849-1903).

For completeness, the Pochhammer symbol, introduced by Leo August Pochhammer, $(x)_n$, is used in the theory of special functions to represent the "rising factorial" or "upper factorial"

$$(x)_n = x(x+1)(x+2)\cdots(x+n-1) = \frac{(x+n-1)!}{(x-1)!}.$$

On the other hand, the "falling factorial" or "lower factorial" is

$$x^{\underline{n}} = \frac{x!}{(x-n)!},$$

in the notation of Ronald L. Graham, Donald E. Knuth and Oren Patashnik in their book Concrete Mathematics.

Note: The first call of any of these will usually cost a bit extra (it loads "specfun", but I'm not sure if that is the real reason). The next call is usually faster but not always.

TODO: Implement associated Legendre polynomials and Zernike polynomials. (Neither is in Maxima.) http://en.wikipedia.org/wiki/Associated_Legendre_polynomials http://en.wikipedia.org/wiki/Zernike_polynomials

AUTHORS:

- David Joyner (2006-06)

chebyshev_T(*n, x*)

Returns the Chebyshev function of the first kind for integers $n > -1$.

REFERENCE:

•AS 22.5.31 page 778 and AS 6.1.22 page 256.

EXAMPLES:

```
sage: x = PolynomialRing(QQ, 'x').gen()
sage: chebyshev_T(2,x)
2*x^2 - 1
```

chebyshev_U(*n, x*)

Returns the Chebyshev function of the second kind for integers $n > -1$.

REFERENCE:

•AS, 22.8.3 page 783 and AS 6.1.22 page 256.

EXAMPLES:

```
sage: x = PolynomialRing(QQ, 'x').gen()
sage: chebyshev_U(2,x)
4*x^2 - 1
```

gegenbauer(*n, a, x*)

Returns the ultraspherical (or Gegenbauer) polynomial for integers $n > -1$.

Computed using Maxima.

REFERENCE:

•AS 22.5.27

EXAMPLES:

```
sage: x = PolynomialRing(QQ, 'x').gen()
sage: ultraspherical(2,3/2,x)
15/2*x^2 - 3/2
sage: ultraspherical(2,1/2,x)
3/2*x^2 - 1/2
sage: ultraspherical(1,1,x)
2*x
sage: t = PolynomialRing(RationalField(),"t").gen()
sage: gegenbauer(3,2,t)
32*t^3 - 12*t
```

gen_laguerre(*n, a, x*)

Returns the generalized Laguerre polynomial for integers $n > -1$. Typically, a = 1/2 or a = -1/2.

REFERENCE:

- table on page 789 in AS.

EXAMPLES:

```
sage: x = PolynomialRing(QQ, 'x').gen()
sage: gen_laguerre(2,1,x)
1/2*x^2 - 3*x + 3
sage: gen_laguerre(2,1/2,x)
1/2*x^2 - 5/2*x + 15/8
sage: gen_laguerre(2,-1/2,x)
1/2*x^2 - 3/2*x + 3/8
sage: gen_laguerre(2,0,x)
1/2*x^2 - 2*x + 1
sage: gen_laguerre(3,0,x)
-1/6*x^3 + 3/2*x^2 - 3*x + 1
```

gen_legendre_P(*n, m, x*)

Returns the generalized (or associated) Legendre function of the first kind for integers $n > -1, m > -1$.

The awkward code for when m is odd and 1 results from the fact that Maxima is happy with, for example, $(1 - t^2)^3/2$, but Sage is not. For these cases the function is computed from the (m-1)-case using one of the recursions satisfied by the Legendre functions.

REFERENCE:

- Gradshteyn and Ryzhik 8.706 page 1000.

EXAMPLES:

```
sage: P.<t> = QQ[]
sage: gen_legendre_P(2, 0, t)
3/2*t^2 - 1/2
sage: gen_legendre_P(2, 0, t) == legendre_P(2, t)
True
sage: gen_legendre_P(3, 1, t)
-3/2*sqrt(-t^2 + 1)*(5*t^2 - 1)
sage: gen_legendre_P(4, 3, t)
(105*t^3 - 105*t)*sqrt(-t^2 + 1)
sage: gen_legendre_P(7, 3, I).expand()
-16695*sqrt(2)
sage: gen_legendre_P(4, 1, 2.5)
-583.562373654533*I
```

gen_legendre_Q(*n, m, x*)

Returns the generalized (or associated) Legendre function of the second kind for integers $n > -1$, $m > -1$.

Maxima restricts m = n. Hence the cases m n are computed using the same recursion used for gen_legendre_P(n,m,x) when m is odd and 1.

EXAMPLES:

```
sage: P.<t> = QQ[]
sage: gen_legendre_Q(2,0,t)
3/4*t^2*log((-t - 1)/(t - 1)) - 3/2*t - 1/4*log((-t - 1)/(t - 1))
sage: gen_legendre_Q(2,0,t) - legendre_Q(2, t)
0
sage: gen_legendre_Q(3,1,0.5)
2.49185259170895
sage: gen_legendre_Q(0, 1, x)
-1/sqrt(-x^2 + 1)
sage: gen_legendre_Q(2, 4, x).factor()
48*x/((x - 1)^2*(x + 1)^2)
```

hermite(*n, x*)

Returns the Hermite polynomial for integers $n > -1$.

REFERENCE:

- AS 22.5.40 and 22.5.41, page 779.

EXAMPLES:

```
sage: x = PolynomialRing(QQ, 'x').gen()
sage: hermite(2,x)
4*x^2 - 2
sage: hermite(3,x)
8*x^3 - 12*x
sage: hermite(3,2)
40
sage: S.<y> = PolynomialRing(RR)
sage: hermite(3,y)
8.00000000000000*y^3 - 12.0000000000000*y
sage: R.<x,y> = QQ[]
sage: hermite(3,y^2)
8*y^6 - 12*y^2
sage: w = var('w')
sage: hermite(3,2*w)
8*(8*w^2 - 3)*w
```

jacobi_P(*n, a, b, x*)

Returns the Jacobi polynomial $P_n^{(a,b)}(x)$ for integers $n > -1$ and a and b symbolic or $a > -1$ and $b > -1$. The Jacobi polynomials are actually defined for all a and b. However, the Jacobi polynomial weight $(1-x)^a(1+x)^b$ isn't integrable for $a \leq -1$ or $b \leq -1$.

REFERENCE:

- table on page 789 in AS.

EXAMPLES:

```
sage: x = PolynomialRing(QQ, 'x').gen()
sage: jacobi_P(2,0,0,x)
3/2*x^2 - 1/2
sage: jacobi_P(2,1,2,1.2)        # random output of low order bits
5.009999999999998
```

laguerre (*n, x*)

Returns the Laguerre polynomial for integers $n > -1$.

REFERENCE:

- AS 22.5.16, page 778 and AS page 789.

EXAMPLES:

```
sage: x = PolynomialRing(QQ, 'x').gen()
sage: laguerre(2,x)
1/2*x^2 - 2*x + 1
sage: laguerre(3,x)
-1/6*x^3 + 3/2*x^2 - 3*x + 1
sage: laguerre(2,2)
-1
```

legendre_P (*n, x*)

Returns the Legendre polynomial of the first kind for integers $n > -1$.

REFERENCE:

- AS 22.5.35 page 779.

EXAMPLES:

```
sage: P.<t> = QQ[]
sage: legendre_P(2,t)
3/2*t^2 - 1/2
sage: legendre_P(3, 1.1)
1.67750000000000
sage: legendre_P(3, 1 + I)
7/2*I - 13/2
sage: legendre_P(3, MatrixSpace(ZZ, 2)([1, 2, -4, 7]))
[-179  242]
[-484  547]
sage: legendre_P(3, GF(11)(5))
8
```

legendre_Q (*n, x*)

Returns the Legendre function of the second kind for integers $n > -1$.

Computed using Maxima.

EXAMPLES:

```
sage: P.<t> = QQ[]
sage: legendre_Q(2, t)
3/4*t^2*log((-t - 1)/(t - 1)) - 3/2*t - 1/4*log((-t - 1)/(t - 1))
sage: legendre_Q(3, 0.5)
-0.198654771479482
sage: legendre_Q(4, 2)

ultraspherical (*n, a, x*)

Returns the ultraspherical (or Gegenbauer) polynomial for integers $n > -1$.

Computed using Maxima.

REFERENCE:

•AS 22.5.27

EXAMPLES:

```
sage: x = PolynomialRing(QQ, 'x').gen()
sage: ultraspherical(2,3/2,x)
15/2*x^2 - 3/2
sage: ultraspherical(2,1/2,x)
3/2*x^2 - 1/2
sage: ultraspherical(1,1,x)
2*x
sage: t = PolynomialRing(RationalField(),"t").gen()
sage: gegenbauer(3,2,t)
32*t^3 - 12*t
```

9.6 Special Functions

AUTHORS:

- David Joyner (2006-13-06): initial version
- David Joyner (2006-30-10): bug fixes to pari wrappers of Bessel functions, hypergeometric_U
- William Stein (2008-02): Impose some sanity checks.
- David Joyner (2008-04-23): addition of elliptic integrals

This module provides easy access to many of Maxima and PARI's special functions.

Maxima's special functions package (which includes spherical harmonic functions, spherical Bessel functions (of the 1st and 2nd kind), and spherical Hankel functions (of the 1st and 2nd kind)) was written by Barton Willis of the University of Nebraska at Kearney. It is released under the terms of the General Public License (GPL).

Support for elliptic functions and integrals was written by Raymond Toy. It is placed under the terms of the General Public License (GPL) that governs the distribution of Maxima.

The (usual) Bessel functions and Airy functions are part of the standard Maxima package. Some Bessel functions also are implemented in Pari. (Caution: The Pari versions are sometimes different than the Maxima version.) For example, the K-Bessel function $K_\nu(z)$ can be computed using either Maxima or Pari, depending on an optional variable you pass to bessel_K.

Next, we summarize some of the properties of the functions implemented here.

- Bessel functions, first defined by the Swiss mathematician Daniel Bernoulli and named after Friedrich Bessel, are canonical solutions y(x) of Bessel's differential equation:

$$x^2\frac{d^2y}{dx^2} + x\frac{dy}{dx} + (x^2 - \alpha^2)y = 0,$$

  for an arbitrary real number α (the order).

- Another important formulation of the two linearly independent solutions to Bessel's equation are the Hankel functions $H_\alpha^{(1)}(x)$ and $H_\alpha^{(2)}(x)$, defined by:

$$H_\alpha^{(1)}(x) = J_\alpha(x) + iY_\alpha(x)$$

$$H_\alpha^{(2)}(x) = J_\alpha(x) - iY_\alpha(x)$$

where i is the imaginary unit (and J_* and Y_* are the usual J- and Y-Bessel functions). These linear combinations are also known as Bessel functions of the third kind; they are two linearly independent solutions of Bessel's differential equation. They are named for Hermann Hankel.

- Airy function The function $Ai(x)$ and the related function $Bi(x)$, which is also called an Airy function, are solutions to the differential equation

$$y'' - xy = 0,$$

known as the Airy equation. They belong to the class of 'Bessel functions of fractional order'. The initial conditions $Ai(0) = (\Gamma(2/3)3^{2/3})^{-1}$, $Ai'(0) = -(\Gamma(1/3)3^{1/3})^{-1}$ define $Ai(x)$. The initial conditions $Bi(0) = 3^{1/2}Ai(0)$, $Bi'(0) = -3^{1/2}Ai'(0)$ define $Bi(x)$.

They are named after the British astronomer George Biddell Airy.

- Spherical harmonics: Laplace's equation in spherical coordinates is:

$$\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial f}{\partial r}\right) + \frac{1}{r^2}\sin\theta\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial f}{\partial\theta}\right) + \frac{1}{r^2\sin^2\theta}\frac{\partial^2 f}{\partial\varphi^2} = 0.$$

Note that the spherical coordinates θ and φ are defined here as follows: θ is the colatitude or polar angle, ranging from $0 \le \theta \le \pi$ and φ the azimuth or longitude, ranging from $0 \le \varphi < 2\pi$.

The general solution which remains finite towards infinity is a linear combination of functions of the form

$$r^{-1-\ell}\cos(m\varphi)P_\ell^m(\cos\theta)$$

and

$$r^{-1-\ell}\sin(m\varphi)P_\ell^m(\cos\theta)$$

where P_ℓ^m are the associated Legendre polynomials, and with integer parameters $\ell \ge 0$ and m from 0 to ℓ. Put in another way, the solutions with integer parameters $\ell \ge 0$ and $-\ell \le m \le \ell$, can be written as linear combinations of:

$$U_{\ell,m}(r,\theta,\varphi) = r^{-1-\ell}Y_\ell^m(\theta,\varphi)$$

where the functions Y are the spherical harmonic functions with parameters ℓ, m, which can be written as:

$$Y_\ell^m(\theta,\varphi) = \sqrt{\frac{(2\ell+1)}{4\pi}\frac{(\ell-m)!}{(\ell+m)!}}\cdot e^{im\varphi}\cdot P_\ell^m(\cos\theta).$$

The spherical harmonics obey the normalisation condition

$$\int_{\theta=0}^{\pi}\int_{\varphi=0}^{2\pi} Y_\ell^m Y_{\ell'}^{m'*}\,d\Omega = \delta_{\ell\ell'}\delta_{mm'} \qquad d\Omega = \sin\theta\,d\varphi\,d\theta.$$

- When solving for separable solutions of Laplace's equation in spherical coordinates, the radial equation has the form:

$$x^2\frac{d^2y}{dx^2} + 2x\frac{dy}{dx} + [x^2 - n(n+1)]y = 0.$$

The spherical Bessel functions j_n and y_n, are two linearly independent solutions to this equation. They are related to the ordinary Bessel functions J_n and Y_n by:

$$j_n(x) = \sqrt{\frac{\pi}{2x}}J_{n+1/2}(x),$$

$$y_n(x) = \sqrt{\frac{\pi}{2x}}Y_{n+1/2}(x) = (-1)^{n+1}\sqrt{\frac{\pi}{2x}}J_{-n-1/2}(x).$$

- For $x > 0$, the confluent hypergeometric function $y = U(a, b, x)$ is defined to be the solution to Kummer's differential equation

$$xy'' + (b - x)y' - ay = 0,$$

which satisfies $U(a, b, x) \sim x^{-a}$, as $x \to \infty$. (There is a linearly independent solution, called Kummer's function $M(a, b, x)$, which is not implemented.)

- Jacobi elliptic functions can be thought of as generalizations of both ordinary and hyperbolic trig functions. There are twelve Jacobian elliptic functions. Each of the twelve corresponds to an arrow drawn from one corner of a rectangle to another.

Each of the corners of the rectangle are labeled, by convention, s, c, d and n. The rectangle is understood to be lying on the complex plane, so that s is at the origin, c is on the real axis, and n is on the imaginary axis. The twelve Jacobian elliptic functions are then pq(x), where p and q are one of the letters s,c,d,n.

The Jacobian elliptic functions are then the unique doubly-periodic, meromorphic functions satisfying the following three properties:

1. There is a simple zero at the corner p, and a simple pole at the corner q.
2. The step from p to q is equal to half the period of the function pq(x); that is, the function pq(x) is periodic in the direction pq, with the period being twice the distance from p to q. Also, pq(x) is also periodic in the other two directions as well, with a period such that the distance from p to one of the other corners is a quarter period.
3. If the function pq(x) is expanded in terms of x at one of the corners, the leading term in the expansion has a coefficient of 1. In other words, the leading term of the expansion of pq(x) at the corner p is x; the leading term of the expansion at the corner q is 1/x, and the leading term of an expansion at the other two corners is 1.

We can write

$$pq(x) = \frac{pr(x)}{qr(x)}$$

where p, q, and r are any of the letters s, c, d, n, with the understanding that $ss = cc = dd = nn = 1$.

Let

$$u = \int_0^\phi \frac{d\theta}{\sqrt{1 - m\sin^2\theta}}$$

Then the *Jacobi elliptic function* $sn(u)$ is given by

$$sn\ u = \sin\phi$$

and $cn(u)$ is given by

$$cn\ u = \cos\phi$$

and

$$dn\ u = \sqrt{1 - m\sin^2\phi}.$$

To emphasize the dependence on m, one can write $sn(u, m)$ for example (and similarly for cn and dn). This is the notation used below.

For a given k with $0 < k < 1$ they therefore are solutions to the following nonlinear ordinary differential equations:

– $\mathrm{sn}\,(x;k)$ solves the differential equations

$$\frac{\mathrm{d}^2y}{\mathrm{d}x^2} + (1+k^2)y - 2k^2y^3 = 0,$$

and

$$\left(\frac{\mathrm{d}y}{\mathrm{d}x}\right)^2 = (1-y^2)(1-k^2y^2).$$

– $\mathrm{cn}\,(x;k)$ solves the differential equations

$$\frac{\mathrm{d}^2y}{\mathrm{d}x^2} + (1-2k^2)y + 2k^2y^3 = 0,$$

and $\left(\frac{\mathrm{d}y}{\mathrm{d}x}\right)^2 = (1-y^2)(1-k^2+k^2y^2)$.

– $\mathrm{dn}\,(x;k)$ solves the differential equations

$$\frac{\mathrm{d}^2y}{\mathrm{d}x^2} - (2-k^2)y + 2y^3 = 0,$$

and $\left(\frac{\mathrm{d}y}{\mathrm{d}x}\right)^2 = y^2(1-k^2-y^2)$.

If $K(m)$ denotes the complete elliptic integral of the first kind (denoted `elliptic_kc`), the elliptic functions $sn(x,m)$ and $cn(x,m)$ have real periods $4K(m)$, whereas $dn(x,m)$ has a period $2K(m)$. The limit $m \to 0$ gives $K(0) = \pi/2$ and trigonometric functions: $sn(x,0) = \sin x$, $cn(x,0) = \cos x$, $dn(x,0) = 1$. The limit $m \to 1$ gives $K(1) \to \infty$ and hyperbolic functions: $sn(x,1) = \tanh x$, $cn(x,1) = \mathrm{sech} x$, $dn(x,1) = \mathrm{sech} x$.

– The incomplete elliptic integrals (of the first kind, etc.) are:

$$\int_0^\phi \frac{1}{\sqrt{1-m\sin(x)^2}}\,dx,$$
$$\int_0^\phi \sqrt{1-m\sin(x)^2}\,dx,$$
$$\int_0^\phi \frac{\sqrt{1-mt^2}}{\sqrt{(1-t^2)}}\,dx,$$
$$\int_0^\phi \frac{1}{\sqrt{1-m\sin(x)^2}\sqrt{1-n\sin(x)^2}}\,dx,$$

and the complete ones are obtained by taking $\phi = \pi/2$.

TODO: Resolve weird bug in commented out code in hypergeometric_U below.

AUTHORS:

- David Joyner and William Stein

Added 16-02-2008 (wdj): optional calls to scipy and replace all '#random' by '...' (both at the request of William Stein)

Warning: SciPy's versions are poorly documented and seem less accurate than the Maxima and Pari versions.

class Bessel(*nu, typ='J', algorithm='pari', prec=53*)

A class implementing the I, J, K, and Y Bessel functions.

EXAMPLES:

```
sage: g = Bessel(2); g
J_{2}
sage: print g
J-Bessel function of order 2
sage: g.plot(0,10)
```

order()

plot(*a, b*)

prec()

system()

type()

class EllipticE()

class EllipticEC()

class EllipticEU()

class EllipticF()

class EllipticKC()

class EllipticPi()

class MaximaFunction(*name, nargs=2, conversions={}*)

airy_ai(*x*)

The function $Ai(x)$ and the related function $Bi(x)$, which is also called an *Airy function*, are solutions to the differential equation

$$y'' - xy = 0,$$

known as the *Airy equation*. The initial conditions $Ai(0) = (\Gamma(2/3)3^{2/3})^{-1}$, $Ai'(0) = -(\Gamma(1/3)3^{1/3})^{-1}$ define $Ai(x)$. The initial conditions $Bi(0) = 3^{1/2}Ai(0)$, $Bi'(0) = -3^{1/2}Ai'(0)$ define $Bi(x)$.

They are named after the British astronomer George Biddell Airy. They belong to the class of "Bessel functions of fractional order".

EXAMPLES:

```
sage: airy_ai(1.0)        # last few digits are random
0.135292416312881400
sage: airy_bi(1.0)        # last few digits are random
1.20742359495287099
```

REFERENCE:

- http://en.wikipedia.org/wiki/Airy_function

airy_bi (x)

The function $Ai(x)$ and the related function $Bi(x)$, which is also called an *Airy function*, are solutions to the differential equation

$$y'' - xy = 0,$$

known as the *Airy equation*. The initial conditions $Ai(0) = (\Gamma(2/3)3^{2/3})^{-1}$, $Ai'(0) = -(\Gamma(1/3)3^{1/3})^{-1}$ define $Ai(x)$. The initial conditions $Bi(0) = 3^{1/2}Ai(0)$, $Bi'(0) = -3^{1/2}Ai'(0)$ define $Bi(x)$.

They are named after the British astronomer George Biddell Airy. They belong to the class of "Bessel functions of fractional order".

EXAMPLES:

```
sage: airy_ai(1)         # last few digits are random
0.135292416312881400
sage: airy_bi(1)         # last few digits are random
1.20742359495287099
```

bessel_I (*nu, z, algorithm='pari', prec=53*)

Implements the "I-Bessel function", or "modified Bessel function, 1st kind", with index (or "order") nu and argument z.

INPUT:

- nu - a real (or complex, for pari) number
- z - a real (positive) algorithm - "pari" or "maxima" or "scipy" prec - real precision (for Pari only)

DEFINITION:

Maxima:

```
 inf
====   - nu - 2 k   nu + 2 k
\     2           z
 >    -------------------
/     k! Gamma(nu + k + 1)
====
k = 0
```

Pari:

```
 inf
====   - 2 k   2 k
\     2       z     Gamma(nu + 1)
 >    -----------------------
/       k! Gamma(nu + k + 1)
====
k = 0
```

Sometimes `bessel_I(nu,z)` is denoted `I_nu(z)` in the literature.

Warning: In Maxima (the manual says) i0 is deprecated but `bessel_i(0,*)` is broken. (Was fixed in recent CVS patch though.)

EXAMPLES:

```
sage: bessel_I(1,1,"pari",500)
0.565159103992485027207696027609863307328899621621092009480294489479255640964371134092664997766
sage: bessel_I(1,1)
0.565159103992485
sage: bessel_I(2,1.1,"maxima")
0.16708949925104...
sage: bessel_I(0,1.1,"maxima")
1.32616018371265...
sage: bessel_I(0,1,"maxima")
1.26606587775200...
sage: bessel_I(1,1,"scipy")
0.565159103992...
```

bessel_J(*nu, z, algorithm='pari', prec=53*)

Return value of the "J-Bessel function", or "Bessel function, 1st kind", with index (or "order") nu and argument z.

```
Defn:
Maxima:
                  inf
                 ====           - nu - 2 k  nu + 2 k
                 \      (-1)^k 2           z
                  >     ------------------------
                 /         k! Gamma(nu + k + 1)
                 ====
                 k = 0

Pari:

                  inf
                 ====           - 2k    2k
                 \      (-1)^k 2      z    Gamma(nu + 1)
                  >     ---------------------------
                 /          k! Gamma(nu + k + 1)
                 ====
                 k = 0
```

Sometimes bessel_J(nu,z) is denoted J_nu(z) in the literature.

Warning: Inaccurate for small values of z.

EXAMPLES:

```
sage: bessel_J(2,1.1)
0.136564153956658
sage: bessel_J(0,1.1)
0.719622018527511
sage: bessel_J(0,1)
0.765197686557967
sage: bessel_J(0,0)
1.00000000000000
```

```
sage: bessel_J(0.1,0.1)
0.777264368097005
```

We check consistency of PARI and Maxima:

```
sage: n(bessel_J(3,10,"maxima"))
0.0583793793051...
sage: n(bessel_J(3,10,"pari"))
0.0583793793051868
sage: bessel_J(3,10,"scipy")
0.0583793793052...
```

bessel_K(*nu, z, algorithm='pari', prec=53*)

Implements the "K-Bessel function", or "modified Bessel function, 2nd kind", with index (or "order") nu and argument z. Defn:

```
 pi*(bessel_I(-nu, z) - bessel_I(nu, z))
-----------------------------------------
             2*sin(pi*nu)
```

if nu is not an integer and by taking a limit otherwise.

Sometimes bessel_K(nu,z) is denoted K_nu(z) in the literature. In Pari, nu can be complex and z must be real and positive.

EXAMPLES:

```
sage: bessel_K(3,2,"scipy")
0.64738539094...
sage: bessel_K(3,2)
0.64738539094...
sage: bessel_K(1,1)
0.60190723019...
sage: bessel_K(1,1,"pari",10)
0.60
sage: bessel_K(1,1,"pari",100)
0.60190723019723457473754000154
```

bessel_Y(*nu, z, algorithm='maxima', prec=53*)

Implements the "Y-Bessel function", or "Bessel function of the 2nd kind", with index (or "order") nu and argument z.

Note: Currently only prec=53 is supported.

Defn:

```
 cos(pi n)*bessel_J(nu, z) - bessel_J(-nu, z)
-----------------------------------------------
                  sin(nu*pi)
```

if nu is not an integer and by taking a limit otherwise.

Sometimes bessel_Y(n,z) is denoted Y_n(z) in the literature.

This is computed using Maxima by default.

EXAMPLES:

```
sage: bessel_Y(2,1.1,"scipy")
-1.4314714939...
sage: bessel_Y(2,1.1)
-1.4314714939590...
sage: bessel_Y(3.001,2.1)
-1.0299574976424...
```

Note: Adding '0'+ inside sage_eval as a temporary bug work-around.

error_fcn(*t*)
The complementary error function $\frac{2}{\sqrt{\pi}} \int_t^\infty e^{-x^2} dx$ (t belongs to RR).

exp_int(*t*)
The exponential integral $\int_x^\infty e^{-x}/x dx$ (t belongs to RR).

hypergeometric_U(*alpha, beta, x, algorithm='pari', prec=53*)
Default is a wrap of Pari's hyperu(alpha,beta,x) function. Optionally, algorithm = "scipy" can be used.

The confluent hypergeometric function $y = U(a, b, x)$ is defined to be the solution to Kummer's differential equation

$$xy'' + (b - x)y' - ay = 0.$$

This satisfies $U(a, b, x) \sim x^{-a}$, as $x \to \infty$, and is sometimes denoted `x^{-a}2_F_0(a,1+a-b,-1/x)`. This is not the same as Kummer's M-hypergeometric function, denoted sometimes as `_1F_1(alpha,beta,x)`, though it satisfies the same DE that U does.

Warning: In the literature, both are called "Kummer confluent hypergeometric" functions.

EXAMPLES:

```
sage: hypergeometric_U(1,1,1,"scipy")
0.596347362323...
sage: hypergeometric_U(1,1,1)
0.59634736232319...
sage: hypergeometric_U(1,1,1,"pari",70)
0.59634736232319407434...
```

inverse_jacobi(*sym, x, m*)
Here sym = "pq", where p,q in c,d,n,s. This returns the value of the inverse Jacobi function $pq^{-1}(x, m)$. There are a total of 12 functions described by this.

EXAMPLES:

```
sage: jacobi("sn",1/2,1/2)
jacobi_sn(1/2, 1/2)
sage: float(jacobi("sn",1/2,1/2))
0.4707504736556572
sage: float(inverse_jacobi("sn",0.47,1/2))
0.49909823132221959
sage: float(inverse_jacobi("sn",0.4707504,0.5))
0.49999991146655481
sage: P = plot(inverse_jacobi('sn', x, 0.5), 0, 1, plot_points=20)
```

Now to view this, just type show(P).

jacobi(*sym, x, m*)
Here sym = "pq", where p,q in c,d,n,s. This returns the value of the Jacobi function pq(x,m), as described in the documentation for Sage's "special" module. There are a total of 12 functions described by this.

EXAMPLES:

```
sage: jacobi("sn",1,1)
tanh(1)
sage: jacobi("cd",1,1/2)
jacobi_cd(1, 1/2)
sage: RDF(jacobi("cd",1,1/2))
0.724009721659
sage: RDF(jacobi("cn",1,1/2)); RDF(jacobi("dn",1,1/2)); RDF(jacobi("cn",1,1/2)/jacobi("dn",1,1/2
0.595976567672
0.823161001632
0.724009721659
sage: jsn = jacobi("sn",x,1)
sage: P = plot(jsn,0,1)
```

To view this, type P.show().

lngamma(*t*)
The principal branch of the logarithm of the Gamma function of t.

meval(*x*)

spherical_bessel_J(*n, var, algorithm='maxima'*)
Returns the spherical Bessel function of the first kind for integers n -1.

Reference: AS 10.1.8 page 437 and AS 10.1.15 page 439.

EXAMPLES:

```
sage: spherical_bessel_J(2,x)
((3/x^2 - 1)*sin(x) - 3*cos(x)/x)/x
```

spherical_bessel_Y(*n, var, algorithm='maxima'*)
Returns the spherical Bessel function of the second kind for integers n -1.

Reference: AS 10.1.9 page 437 and AS 10.1.15 page 439.

EXAMPLES:

```
sage: x = PolynomialRing(QQ, 'x').gen()
sage: spherical_bessel_Y(2,x)
-((3/x^2 - 1)*cos(x) + 3*sin(x)/x)/x
```

spherical_hankel1(*n, var*)
Returns the spherical Hankel function of the first kind for integers $n > -1$, written as a string. Reference: AS 10.1.36 page 439.

EXAMPLES:

```
sage: spherical_hankel1(2, x)
(I*x^2 - 3*x - 3*I)*e^(I*x)/x^3
```

spherical_hankel2(*n, x*)
Returns the spherical Hankel function of the second kind for integers n -1, written as a string. Reference: AS 10.1.17 page 439.

EXAMPLES:

```
sage: spherical_hankel2(2, x)
(-I*x^2 - 3*x + 3*I)*e^(-I*x)/x^3
```

Here I = sqrt(-1).

spherical_harmonic(*m, n, x, y*)

Returns the spherical Harmonic function of the second kind for integers $n > -1$, $|m| \leq n$. Reference: Merzbacher 9.64.

EXAMPLES:

```
sage: x,y = var('x,y')
sage: spherical_harmonic(3,2,x,y)
1/8*sqrt(7)*sqrt(30)*e^(2*I*y)*sin(x)^2*cos(x)/sqrt(pi)
sage: spherical_harmonic(3,2,1,2)
1/8*sqrt(7)*sqrt(30)*e^(4*I)*sin(1)^2*cos(1)/sqrt(pi)
```

CHAPTER

TEN

BASIC STRUCTURES

10.1 Abstract base class for Sage objects

class SageObject()

category()

db()

Dumps self into the Sage database. Use db(name) by itself to reload.

The database directory is `$HOME/.sage/db`

dump()

Same as self.save(filename, compress)

dumps()

Dump self to a string s, which can later be reconstituted as self using loads(s).

rename()

Change self so it prints as x, where x is a string.

Note: This is *only* supported for Python classes that derive from SageObject.

EXAMPLES:

```
sage: x = PolynomialRing(QQ,'x').gen()
sage: g = x^3 + x - 5
sage: g
x^3 + x - 5
sage: g.rename('a polynomial')
sage: g
a polynomial
sage: g + x
x^3 + 2*x - 5
sage: h = g^100
sage: str(h)[:20]
'x^300 + 100*x^298 - '
sage: h.rename('x^300 + ...')
sage: h
x^300 + ...
```

Real numbers are not Python classes, so rename is not supported:

```
sage: a = 3.14
sage: type(a)
<type 'sage.rings.real_mpfr.RealLiteral'>
sage: a.rename('pi')
```

```
...
NotImplementedError: object does not support renaming: 3.14000000000000
```

Note: The reason C-extension types are not supported by default is if they were then every single one would have to carry around an extra attribute, which would be slower and waste a lot of memory.

To support them for a specific class, add a `cdef public __custom_name` attribute.

reset_name()

save()

Save self to the given filename.

EXAMPLES:

```
sage: f = x^3 + 5
sage: f.save(SAGE_TMP + '/file')
sage: load(SAGE_TMP + '/file.sobj')
x^3 + 5
```

version()

The version of Sage.

Call this to save the version of Sage in this object. If you then save and load this object it will know in what version of Sage it was created.

This only works on Python classes that derive from SageObject.

dumps()

Dump obj to a string s. To recover obj, use `loads(s)`.

See Also:

`dumps()`

EXAMPLES:

```
sage: a = 2/3
sage: s = dumps(a)
sage: print len(s)
49
sage: loads(s)
2/3
```

load()

Load Sage object from the file with name filename, which will have an .sobj extension added if it doesn't have one.

Note: There is also a special Sage command (that is not available in Python) called load that you use by typing

```
sage: load filename.sage           # not tested
```

The documentation below is not for that command. The documentation for load is almost identical to that for attach. Type attach? for help on attach.

This also loads a ".sobj" file over a network by specifying the full URL. (Setting "verbose = False" suppresses the loading progress indicator.)

EXAMPLE:

```
sage: u = 'http://sage.math.washington.edu/home/was/db/test.sobj'
sage: s = load(u)                                                  # optional - internet
Attempting to load remote file: http://sage.math.washington.edu/home/was/db/test.sobj
Loading: [.]
sage: s                                                            # optional - internet
'hello SAGE'
```

loads()

Recover an object x that has been dumped to a string s using `s = dumps(x)`.

See Also:

`dumps()`

EXAMPLES:

```
sage: a = matrix(2, [1,2,3,-4/3])
sage: s = dumps(a)
sage: loads(s)
[   1    2]
[   3 -4/3]
```

If compress is True (the default), it will try to decompress the data with zlib and with bz2 (in turn); if neither succeeds, it will assume the data is actually uncompressed. If compress=False is explicitly specified, then no decompression is attempted.

```
sage: v = [1..10]
sage: loads(dumps(v, compress=False)) == v
True
sage: loads(dumps(v, compress=False), compress=True) == v
True
sage: loads(dumps(v, compress=True), compress=False)
...
UnpicklingError: invalid load key, 'x'.
```

picklejar()

Create pickled sobj of obj in dir, with name the absolute value of the hash of the pickle of obj. This is used in conjection with sage.structure.sage_object.unpickle_all.

To use this to test the whole Sage library right now, set the environment variable SAGE_PICKLE_JAR, which will make it so dumps will by default call picklejar with the default dir. Once you do that and doctest Sage, you'll find that the SAGE_ROOT/tmp/ contains a bunch of pickled objects along with corresponding txt descriptions of them. Use the sage.structure.sage_object.unpickle_all to see if they unpickle later.

INPUTS:

- `obj` - a pickleable object
- `dir` - a string or None; if None defaults to `SAGE_ROOT/tmp/pickle_jar-version`

EXAMPLES:

```
sage: dir = tmp_dir()
sage: sage.structure.sage_object.picklejar(1,dir)
sage: len(os.listdir(dir))
2
```

register_unpickle_override()

Python pickles include the module and class name of classes. This means that rearranging the Sage source can invalidate old pickles. To keep the old pickles working, you can call register_unpickle_override with an old module name and class name, and the Python callable (function, class with __call__ method, etc.) to use for unpickling. (If this callable is a value in some module, you can specify the module name and class name, for the benefit of explain_pickle(..., in_current_sage=True).)

EXAMPLES:

```
sage: from sage.structure.sage_object import unpickle_override, register_unpickle_override
sage: unpickle_global('sage.rings.integer', 'Integer')
<type 'sage.rings.integer.Integer'>
```

Now we horribly break the pickling system:

sage: register_unpickle_override('sage.rings.integer', 'Integer', Rational, call_name=('sage.rings.rational', 'Rational')) sage: unpickle_global('sage.rings.integer', 'Integer') <type 'sage.rings.rational.Rational'>

And we reach into the internals and put it back:

sage: del unpickle_override[('sage.rings.integer', 'Integer')] sage: unpickle_global('sage.rings.integer', 'Integer') <type 'sage.rings.integer.Integer'>

save()

Save obj to the file with name filename, which will have an .sobj extension added if it doesn't have one. This will *replace* the contents of filename.

EXAMPLES:

```
sage: a = matrix(2, [1,2,3,-5/2])
sage: save(a, 'test.sobj')
sage: load('test')
[   1    2]
[   3 -5/2]
sage: E = EllipticCurve([-1,0])
sage: P = plot(E)
sage: save(P, 'test')
sage: save(P, filename="sage.png", xmin=-2)
sage: print load('test.sobj')
Graphics object consisting of 2 graphics primitives
sage: save("A python string", './test')
sage: load('./test.sobj')
'A python string'
sage: load('./test')
'A python string'
```

unpickle_all()

Unpickle all sobj's in the given directory, reporting failures as they occur. Also printed the number of successes and failure.

INPUT:

- `dir` - string; a directory or name of a .tar.bz2 file that decompresses to give a directory full of pickles.

EXAMPLES:

```
sage: dir = tmp_dir()
sage: sage.structure.sage_object.picklejar('hello', dir)
sage: sage.structure.sage_object.unpickle_all(dir)
Successfully unpickled 1 objects.
Failed to unpickle 0 objects.
```

We unpickle the standard pickle jar. This doctest tests that all "standard pickles" unpickle. Every so often the standard pickle jar should be updated by running the doctest suite with the environment variable SAGE_PICKLE_JAR set, then copying the files from SAGE_ROOT/tmp/pickle_jar* into the standard pickle jar.

```
sage: std = os.environ['SAGE_DATA'] + '/extcode/pickle_jar/pickle_jar.tar.bz2'
sage: sage.structure.sage_object.unpickle_all(std)
doctest:...: DeprecationWarning: RQDF is deprecated; use RealField(212) instead.
Successfully unpickled 572 objects.
Failed to unpickle 0 objects.
```

unpickle_global()

Given a module name and a name within that module (typically a class name), retrieve the corresponding object. This normally just looks up the name in the module, but it can be overridden by register_unpickle_override. This is used in the Sage unpickling mechanism, so if the Sage source code organization changes, register_unpickle_override can allow old pickles to continue to work.

EXAMPLES:

```
sage: from sage.structure.sage_object import unpickle_override, register_unpickle_override
sage: unpickle_global('sage.rings.integer', 'Integer')
<type 'sage.rings.integer.Integer'>
```

Now we horribly break the pickling system:

sage: register_unpickle_override('sage.rings.integer', 'Integer', Rational, call_name=('sage.rings.rational', 'Rational')) sage: unpickle_global('sage.rings.integer', 'Integer') <type 'sage.rings.rational.Rational'>

And we reach into the internals and put it back:

sage: del unpickle_override[('sage.rings.integer', 'Integer')] sage: unpickle_global('sage.rings.integer', 'Integer') <type 'sage.rings.integer.Integer'>

10.2 Base class for parent objects with generators.

Note: This class is being deprecated, see `sage.structure.parent.Parent` and `sage.structure.category_object.CategoryObject` for the new model.

Many parent objects in Sage are equipped with generators, which are special elements of the object. For example, the polynomial ring $\mathbf{Z}[x, y, z]$ is generated by x, y, and z. In Sage the i^{th} generator of an object `X` is obtained using the notation `X.gen(i)`. From the Sage interactive prompt, the shorthand notation `X.i` is also allowed.

REQUIRED: A class that derives from ParentWithGens *must* define the ngens() and gen(i) methods.

OPTIONAL: It is also good if they define gens() to return all gens, but this is not necessary.

The `gens` function returns a tuple of all generators, the `ngens` function returns the number of generators.

The `_assign_names` functions is for internal use only, and is called when objects are created to set the generator names. It can only be called once.

The following examples illustrate these functions in the context of multivariate polynomial rings and free modules.

EXAMPLES:

```
sage: R = PolynomialRing(ZZ, 3, 'x')
sage: R.ngens()
3
sage: R.gen(0)
x0
sage: R.gens()
(x0, x1, x2)
sage: R.variable_names()
('x0', 'x1', 'x2')
```

This example illustrates generators for a free module over $\mathbf{Z}$.

```
sage: M = FreeModule(ZZ, 4)
sage: M
Ambient free module of rank 4 over the principal ideal domain Integer Ring
sage: M.ngens()
4
sage: M.gen(0)
(1, 0, 0, 0)
sage: M.gens()
((1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1))
```

class ParentWithAdditiveAbelianGens()

generator_orders()

class ParentWithGens()

gen()

gens()
Return a tuple whose entries are the generators for this object, in order.

hom()
Return the unique homomorphism from self to codomain that sends `self.gens()` to the entries of `im_gens`. Raises a TypeError if there is no such homomorphism.

INPUT:

- `im_gens` - the images in the codomain of the generators of this object under the homomorphism
- `codomain` - the codomain of the homomorphism
- `check` - whether to verify that the images of generators extend to define a map (using only canonical coercisions).

OUTPUT:

- a homomorphism self –> codomain

Note: As a shortcut, one can also give an object X instead of `im_gens`, in which case return the (if it exists) natural map to X.

EXAMPLE: Polynomial Ring We first illustrate construction of a few homomorphisms involving a polynomial ring.

```
sage: R.<x> = PolynomialRing(ZZ)
sage: f = R.hom([5], QQ)
sage: f(x^2 - 19)
6

sage: R.<x> = PolynomialRing(QQ)
sage: f = R.hom([5], GF(7))
...
TypeError: images do not define a valid homomorphism

sage: R.<x> = PolynomialRing(GF(7))
sage: f = R.hom([3], GF(49,'a'))
sage: f
Ring morphism:
  From: Univariate Polynomial Ring in x over Finite Field of size 7
  To:   Finite Field in a of size 7^2
  Defn: x |--> 3
sage: f(x+6)
2
```

```
sage: f(x^2+1)
3
```

EXAMPLE: Natural morphism

```
sage: f = ZZ.hom(GF(5))
sage: f(7)
2
sage: f
Ring Coercion morphism:
  From: Integer Ring
  To:   Finite Field of size 5
```

There might not be a natural morphism, in which case a TypeError exception is raised.

```
sage: QQ.hom(ZZ)
...
TypeError: Natural coercion morphism from Rational Field to Integer Ring not defined.
```

ngens()

class **ParentWithMultiplicativeAbelianGens**()

generator_orders()

is_ParentWithAdditiveAbelianGens()

Return True if x is a parent object with additive abelian generators, i.e., derives from `sage.structure.parent.ParentWithAdditiveAbelianGens` and False otherwise.

EXAMPLES:

```
sage: from sage.structure.parent_gens import is_ParentWithAdditiveAbelianGens
sage: is_ParentWithAdditiveAbelianGens(QQ)
False
sage: is_ParentWithAdditiveAbelianGens(QQ^3)
True
```

is_ParentWithGens()

Return True if x is a parent object with generators, i.e., derives from `sage.structure.parent.ParentWithGens` and False otherwise.

EXAMPLES:

```
sage: from sage.structure.parent_gens import is_ParentWithGens
sage: is_ParentWithGens(QQ['x'])
True
sage: is_ParentWithGens(CC)
True
sage: is_ParentWithGens(Primes())
False
```

is_ParentWithMultiplicativeAbelianGens()

Return True if x is a parent object with additive abelian generators, i.e., derives from `sage.structure.parent.ParentWithMultiplicativeAbelianGens` and False otherwise.

EXAMPLES:

```
sage: from sage.structure.parent_gens import is_ParentWithMultiplicativeAbelianGens
sage: is_ParentWithMultiplicativeAbelianGens(QQ)
False
```

```
sage: is_ParentWithMultiplicativeAbelianGens(DirichletGroup(11))
True
```

class localvars()

Context manager for safely temporarily changing the variables names of an object with generators.

Objects with named generators are globally unique in SAGE. Sometimes, though, it is very useful to be able to temporarily display the generators differently. The new Python `with` statement and the localvars context manager make this easy and safe (and fun!)

Suppose X is any object with generators. Write

```
with localvars(X, names[, latex_names] [,normalize=False]):
     some code
     ...
```

and the indented code will be run as if the names in X are changed to the new names. If you give normalize=True, then the names are assumed to be a tuple of the correct number of strings.

If you're writing Python library code, you currently have to put `from __future__ import with_statement` in your file in order to use the `with` statement. This restriction will disappear in Python 2.6.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: with localvars(R, 'z,w'):
...       print x^3 + y^3 - x*y
...
z^3 + w^3 - z*w
```

Note: I wrote this because it was needed to print elements of the quotient of a ring R by an ideal I using the print function for elements of R. See the code in `quotient_ring_element.pyx`.

AUTHOR:

- William Stein (2006-10-31)

normalize_names()

Return a tuple of strings of variable names of length ngens given the input names.

INPUT:

- `ngens` - integer
- `names`
  - tuple or list of strings, such as ('x', 'y')
  - a string prefix, such as 'alpha'
  - string of single character names, such as 'xyz'

EXAMPLES:

```
sage: from sage.structure.parent_gens import normalize_names as nn
sage: nn(1, 'a')
('a',)
sage: nn(2, 'zzz')
('zzz0', 'zzz1')
sage: nn(2, 'ab')
('a', 'b')
sage: nn(3, ('a', 'bb', 'ccc'))
('a', 'bb', 'ccc')
```

```
sage: nn(4, ['a1', 'a2', 'b1', 'b11'])
('a1', 'a2', 'b1', 'b11')
```

TESTS:

```
sage: nn(2, 'z1')
('z10', 'z11')
sage: PolynomialRing(QQ, 2, 'alpha0')
Multivariate Polynomial Ring in alpha00, alpha01 over Rational Field
```

10.3 Formal sums

AUTHORS:

- David Harvey (2006-09-20): changed FormalSum not to derive from "list" anymore, because that breaks new Element interface
- Nick Alexander (2006-12-06): added test cases.
- William Stein (2006, 2009): wrote the first version in 2006, documented it in 2009.

FUNCTIONS:

- **`FormalSums(ring)` – create the module of formal finite sums with** coefficients in the given ring.
- `FormalSum(list of pairs (coeff, number))` – create a formal sum

EXAMPLES:

```
sage: A = FormalSum([(1, 2/3)]); A
2/3
sage: B = FormalSum([(3, 1/5)]); B
3*1/5
sage: -B
-3*1/5
sage: A + B
3*1/5 + 2/3
sage: A - B
-3*1/5 + 2/3
sage: B*3
9*1/5
sage: 2*A
2*2/3
sage: list(2*A + A)
[(3, 2/3)]
```

TESTS:

```
sage: R = FormalSums(QQ)
sage: loads(dumps(R)) == R
True
sage: a = R(2/3) + R(-5/7); a
-5/7 + 2/3
sage: loads(dumps(a)) == a
True
```

class FormalSum(*x, parent=Abelian Group of all Formal Finite Sums over Integer Ring, check=True, reduce=True*)
A formal sum over a ring.

reduce()
EXAMPLES:

```
sage: a = FormalSum([(-2,3), (2,3)], reduce=False); a
-2*3 + 2*3
sage: a.reduce()
sage: a
0
```

FormalSums(*R=Integer Ring*)
Return the R-module of finite formal sums with coefficients in R.

INPUT: R – a ring (default: ZZ)

EXAMPLES:

```
sage: FormalSums()
Abelian Group of all Formal Finite Sums over Integer Ring
sage: FormalSums(ZZ[sqrt(2)])
Abelian Group of all Formal Finite Sums over Order in Number Field in sqrt2 with defining polync
sage: FormalSums(GF(9,'a'))
Abelian Group of all Formal Finite Sums over Finite Field in a of size 3^2
```

class FormalSums_generic(*base=Integer Ring*)

base_extend(*R*)
EXAMPLES:

```
sage: FormalSums(ZZ).base_extend(GF(7))
Abelian Group of all Formal Finite Sums over Finite Field of size 7
```

get_action_impl(*other, op, self_is_left*)
EXAMPLES:

```
sage: A = FormalSums(RR).get_action(RR); A      # indirect doctest
Right scalar multiplication by Real Field with 53 bits of precision on Abelian Group of all

sage: A = FormalSums(ZZ).get_action(QQ); A
Right scalar multiplication by Rational Field on Abelian Group of all Formal Finite Sums ove
with precomposition on left by Call morphism:
  From: Abelian Group of all Formal Finite Sums over Integer Ring
  To:   Abelian Group of all Formal Finite Sums over Rational Field
sage: A = FormalSums(QQ).get_action(ZZ); A
Right scalar multiplication by Integer Ring on Abelian Group of all Formal Finite Sums over
```

10.4 Factorizations

The `Factorization` class provides a structure for holding quite general lists of objects with integer multiplicities. These may hold the results of an arithmetic or algebraic factorization, where the objects may be primes or irreducible polynomials and the multiplicities are the (non-zero) exponents in the factorization. For other types of example, see below.

`Factorization` class objects contain a `list`, so can be printed nicely and be manipulated like a list of prime-exponent pairs, or easily turned into a plain list. For example, we factor the integer -45:

```
sage: F = factor(-45)
```

This returns an object of type `Factorization`:

```
sage: type(F)
<class 'sage.structure.factorization.Factorization'>
```

It prints in a nice factored form:

```
sage: F
-1 * 3^2 * 5
```

There is an underlying list representation, emph{which ignores the unit part} (!).

```
sage: list(F)
[(3, 2), (5, 1)]
```

A `Factorization` is not actually a list:

```
sage: isinstance(F, list)
False
```

However, we can access the `Factorization` F itself as if it were a list:

```
sage: F[0]
(3, 2)
sage: F[1]
(5, 1)
```

To get at the unit part, use the `Factorization.unit()` function:

```
sage: F.unit()
-1
```

All factorizations are immutable. Thus if you write a function that returns a cached version of a factorization, you do not have to return a copy.

```
sage: F = factor(-12); F
-1 * 2^2 * 3
sage: F[0] = (5,4)
...
TypeError: 'Factorization' object does not support item assignment
```

EXAMPLES:

This more complicated example involving polynomials also illustrates +that the unit part is not discarded from factorizations.

```
sage: x = QQ['x'].0
sage: f = -5*(x-2)*(x-3)
sage: f
-5*x^2 + 25*x - 30
sage: F = f.factor(); F
(-5) * (x - 3) * (x - 2)
sage: F.unit()
```

```
-5
sage: expand(F)
-5*x^2 + 25*x - 30
```

The underlying list is the list of pairs (p_i, e_i), where each p_i is a 'prime' and each e_i is an integer. The unit part is discarded by the list.

```
sage: list(F)
[(x - 3, 1), (x - 2, 1)]
sage: len(F)
2
sage: F[1]
(x - 2, 1)
```

In the ring $\mathbf{Z}[x]$, the integer -5 is not a unit, so the factorization has three factors:

```
sage: x = ZZ['x'].0
sage: f = -5*(x-2)*(x-3)
sage: f
-5*x^2 + 25*x - 30
sage: F = f.factor(); F
(-1) * 5 * (x - 3) * (x - 2)
sage: F.universe()
Univariate Polynomial Ring in x over Integer Ring
sage: F.unit()
-1
sage: list(F)
[(5, 1), (x - 3, 1), (x - 2, 1)]
sage: expand(F)
-5*x^2 + 25*x - 30
sage: len(F)
3
```

On the other hand, -1 is a unit in $\mathbf{Z}$, so it is included in the unit.

```
sage: x = ZZ['x'].0
sage: f = -1*(x-2)*(x-3)
sage: F = f.factor(); F
(-1) * (x - 3) * (x - 2)
sage: F.unit()
-1
sage: list(F)
[(x - 3, 1), (x - 2, 1)]
```

Factorizations can involve fairly abstract mathematical objects:

```
sage: F = ModularSymbols(11,4).factorization()
sage: F
(Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 6 for Gamma_0(11) of w
(Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 6 for Gamma_0(11) of w
(Modular Symbols subspace of dimension 2 of Modular Symbols space of dimension 6 for Gamma_0(11) of w
sage: type(F)
<class 'sage.structure.factorization.Factorization'>

sage: K.<a> = NumberField(x^2 + 3); K
```

```
Number Field in a with defining polynomial x^2 + 3
sage: f = K.factor(15); f
(Fractional ideal (1/2*a - 3/2))^2 * (Fractional ideal (5))
sage: f.universe()
Monoid of ideals of Number Field in a with defining polynomial x^2 + 3
sage: f.unit()
Fractional ideal (1)
sage: g=K.factor(9); g
(Fractional ideal (1/2*a - 3/2))^4
sage: f.lcm(g)
(Fractional ideal (1/2*a - 3/2))^4 * (Fractional ideal (5))
sage: f.gcd(g)
(Fractional ideal (1/2*a - 3/2))^2
sage: f.is_integral()
True
```

TESTS:

```
sage: F = factor(-20); F
-1 * 2^2 * 5
sage: G = loads(dumps(F)); G
-1 * 2^2 * 5
sage: G == F
True
sage: G is F
False
```

AUTHORS:

- William Stein (2006-01-22): added unit part as suggested by David Kohel.
- William Stein (2008-01-17): wrote much of the documentation and fixed a couple of bugs.
- Nick Alexander (2008-01-19): added support for non-commuting factors.
- John Cremona (2008-08-22): added division, lcm, gcd, is_integral and universe functions

class **Factorization**(*x, unit=None, cr=False, sort=True, simplify=True*)

A formal factorization of an object.

EXAMPLES:

```
sage: N = 2006
sage: F = N.factor(); F
2 * 17 * 59
sage: F.unit()
1
sage: F = factor(-2006); F
-1 * 2 * 17 * 59
sage: F.unit()
-1
sage: loads(F.dumps()) == F
True
sage: F = Factorization([(x,1/3)])
...
TypeError: powers of factors must be integers
```

base_change(*U*)

Return the factorization self, with its factors (including the unit part) coerced into the universe U.

EXAMPLES:

```
sage: F = factor(2006)
sage: F.universe()
Integer Ring
sage: P.<x> = ZZ[]
sage: F.base_change(P).universe()
Univariate Polynomial Ring in x over Integer Ring
```

This method will return a TypeError if the coercion is not possible:

```
sage: g = x^2 - 1
sage: F = factor(g); F
(x - 1) * (x + 1)
sage: F.universe()
Univariate Polynomial Ring in x over Integer Ring
sage: F.base_change(ZZ)
...
TypeError: Impossible to coerce the factors of (x - 1) * (x + 1) into Integer Ring
```

expand()

Same as `value()`, so this returns the product of the factors, multiplied out.

EXAMPLES:

```
sage: x = polygen(QQ, 'x')
sage: F = factor(-x^5 + 1); F
(-1) * (x - 1) * (x^4 + x^3 + x^2 + x + 1)
sage: F.expand()
-x^5 + 1
```

gcd(*other*)

Return the gcd of two factorizations.

If the two factorizations have different universes, this method will attempt to find a common universe for the gcd. A TypeError is raised if this is impossible.

EXAMPLES:

```
sage: factor(-30).gcd(factor(-160))
2 * 5
sage: factor(gcd(-30,160))
2 * 5

sage: R.<x> = ZZ[]
sage: (factor(-20).gcd(factor(5*x+10))).universe()
Univariate Polynomial Ring in x over Integer Ring
```

is_commutative()

Return True if my factors commute.

EXAMPLES:

```
sage: F = factor(2006)
sage: F.is_commutative()
True
sage: K = QuadraticField(23, 'a')
sage: F = K.factor(13)
sage: F.is_commutative()
True
sage: R.<x,y,z> = FreeAlgebra(QQ, 3)
```

```
sage: F = Factorization([(z, 2)], 3)
sage: F.is_commutative()
False
sage: (F*F^-1).is_commutative()
False
```

is_integral()

Return True iff all exponents of this Factorization are non-negative

EXAMPLES:

```
sage: F = factor(-10); F
-1 * 2 * 5
sage: F.is_integral()
True

sage: F = factor(-10) / factor(16); F
-1 * 2^-3 * 5
sage: F.is_integral()
False
```

lcm(*other*)

Return the lcm of two factorizations.

If the two factorizations have different universes, this method will attempt to find a common universe for the lcm. A TypeError is raised if this is impossible.

EXAMPLES:

```
sage: factor(-10).lcm(factor(-16))
2^4 * 5
sage: factor(lcm(-10,16))
2^4 * 5

sage: R.<x> = ZZ[]
sage: (factor(-20).lcm(factor(5*x+10))).universe()
Univariate Polynomial Ring in x over Integer Ring
```

prod()

Same as `value()`.

EXAMPLES:

```
sage: F = factor(100)
sage: F.prod()
100
```

simplify()

Combine adjacent products that commute as much as possible.

TESTS:

```
sage: R.<x,y> = FreeAlgebra(ZZ, 2)
sage: F = Factorization([(x,3), (y, 2), (y,2)], simplify=False); F
x^3 * y^2 * y^2
sage: F.simplify(); F
x^3 * y^4
sage: F * Factorization([(y, -2)], 2)
(2) * x^3 * y^2
```

sort(*_cmp=None*)

Sort the factors in this factorization.

INPUT:

- _cmp - (default: None) comparison function

OUTPUT:

- changes this factorization to be sorted

If _cmp is None, we determine the comparison function as follows: If the prime in the first factor has a dimension method, then we sort based first on *dimension* then on the exponent. If there is no dimension method, we next attempt to sort based on a degree method, in which case, we sort based first on *degree*, then exponent to break ties when two factors have the same degree, and if those match break ties based on the actual prime itself. If there is no degree method, we sort based on dimension.

EXAMPLES: We create a factored polynomial:

```
sage: x = polygen(QQ,'x')
sage: F = factor(x^3 + 1); F
(x + 1) * (x^2 - x + 1)
```

Then we sort it but using the negated version of the standard Python cmp function:

```
sage: F.sort(_cmp = lambda x,y: -cmp(x,y))
sage: F
(x^2 - x + 1) * (x + 1)
```

unit()

Return the unit part of this factorization.

EXAMPLES: We create a polynomial over the real double field and factor it:

```
sage: x = polygen(RDF, 'x')
sage: F = factor(-2*x^2 - 1); F
(-2.0) * (1.0*x^2 + 0.5)
```

Note that the unit part of the factorization is -2.0.

```
sage: F.unit()
-2.0

sage: F = factor(-2006); F
-1 * 2 * 17 * 59
sage: F.unit()
-1
```

universe()

Return the parent structure of my factors.

Note: This used to be called `base_ring`, but the universe of a factorization need not be a ring.

EXAMPLES:

```
sage: F = factor(2006)
sage: F.universe()
Integer Ring

sage: R.<x,y,z> = FreeAlgebra(QQ, 3)
sage: F = Factorization([(z, 2)], 3)
sage: (F*F^-1).universe()
Free Algebra on 3 generators (x, y, z) over Rational Field

sage: F = ModularSymbols(11,4).factorization()
sage: F.universe()
```

value()

Return the product of the factors in the factorization, multiplied out.

EXAMPLES:

```
sage: F = factor(2006); F
2 * 17 * 59
sage: F.value()
2006

sage: R.<x,y> = FreeAlgebra(ZZ, 2)
sage: F = Factorization([(x,3), (y, 2), (x,1)]); F
x^3 * y^2 * x
sage: F.value()
x^3*y^2*x
```

10.5 Elements

AUTHORS:

- David Harvey (2006-10-16): changed CommutativeAlgebraElement to derive from CommutativeRingElement instead of AlgebraElement
- David Harvey (2006-10-29): implementation and documentation of new arithmetic architecture
- William Stein (2006-11): arithmetic architecture – pushing it through to completion.
- Gonzalo Tornaria (2007-06): recursive base extend for coercion – lots of tests

10.5.1 The Abstract Element Class Hierarchy

This is the abstract class hierarchy, i.e., these are all abstract base classes.

```
SageObject
    Element
        ModuleElement
            RingElement
                CommutativeRingElement
                    IntegralDomainElement
                        DedekindDomainElement
                            PrincipalIdealDomainElement
                                EuclideanDomainElement
                    FieldElement
                        FiniteFieldElement
                    CommutativeAlgebraElement
                AlgebraElement   (note -- can't derive from module, since no multiple inheritence)
                    CommutativeAlgebra ??? (should be removed from element.pxd)
                    Matrix
                InfinityElement
                    PlusInfinityElement
                    MinusInfinityElement
            AdditiveGroupElement
            Vector

        MonoidElement
            MultiplicativeGroupElement
```

10.5.2 How to Define a New Element Class

Elements typically define a method `_new_c`, e.g.,

```
cdef _new_c(self, defining data):
    cdef FreeModuleElement_generic_dense x
    x = PY_NEW(FreeModuleElement_generic_dense)
    x._parent = self._parent
    x._entries = v
```

that creates a new sibling very quickly from defining data with assumed properties.

Sage has a special system in place for handling arithmetic operations for all Element subclasses. There are various rules that must be followed by both arithmetic implementors and callers.

A quick summary for the impatient:

- To implement addition for any Element class, override def _add_().
- If you want to add x and y, whose parents you know are IDENTICAL, you may call _add_(x, y). This will be the fastest way to guarantee that the correct implementation gets called. Of course you can still always use "x + y".

Now in more detail. The aims of this system are to provide (1) an efficient calling protocol from both python and cython, (2) uniform coercion semantics across Sage, (3) ease of use, (4) readability of code.

We will take addition of RingElements as an example; all other operators and classes are similar. There are four relevant functions.

- **def RingElement.__add__**

  This function is called by python or pyrex when the binary "+" operator is encountered. It ASSUMES that at least one of its arguments is a RingElement; only a really twisted programmer would violate this condition. It has a fast pathway to deal with the most common case where the arguments have the same parent. Otherwise, it uses the coercion module to work out how to make them have the same parent. After any necessary coercions have been performed, it calls _add_ to dispatch to the correct underlying addition implementation.

  Note that although this function is declared as def, it doesn't have the usual overheads associated with python functions (either for the caller or for __add__ itself). This is because python has optimised calling protocols for such special functions.

- **def RingElement._add_**

  This is the function you should override to implement addition in a python subclass of RingElement.

  Warning: if you override this in a *Cython* class, it won't get called. You should override _add_ instead. It is especially important to keep this in mind whenever you move a class down from Python to Cython.

  The two arguments to this function are guaranteed to have the SAME PARENT. Its return value MUST have the SAME PARENT as its arguments.

  If you want to add two objects from python, and you know that their parents are the same object, you are encouraged to call this function directly, instead of using "x + y".

  The default implementation of this function is to call _add_, so if no-one has defined a python implementation, the correct pyrex implementation will get called.

- **cpdef RingElement._add_**

  This is the function you should override to implement addition in a pyrex subclass of RingElement.

The two arguments to this function are guaranteed to have the SAME PARENT. Its return value MUST have the SAME PARENT as its arguments.

The default implementation of this function is to raise a NotImplementedError, which will happen if no-one has supplied implementations of either _add_.

For speed, there are also **inplace** version of the arithmetic commands. DD NOT call them directly, they may mutate the object and will be called when and only when it has been determined that the old object will no longer be accessible from the calling function after this operation.

- **def RingElement._iadd_**

  This is the function you should override to inplace implement addition in a Python subclass of RingElement.

  The two arguments to this function are guaranteed to have the SAME PARENT. Its return value MUST have the SAME PARENT as its arguments.

  The default implementation of this function is to call _add_, so if no-one has defined a Python implementation, the correct Cython implementation will get called.

class AdditiveGroupElement()
Generic element of an additive group.

order()
Return additive order of element

class AlgebraElement()

class CoercionModel()
Most basic coersion scheme. If it doesn't already match, throw an error.

bin_op()

canonical_coercion()

class CommutativeAlgebra()

class CommutativeAlgebraElement()

class CommutativeRingElement()

divides()
Return True if self divides x.

EXAMPLES:

```
sage: P.<x> = PolynomialRing(QQ)
sage: x.divides(x^2)
True
sage: x.divides(x^2+2)
False
sage: (x^2+2).divides(x)
False
sage: P.<x> = PolynomialRing(ZZ)
sage: x.divides(x^2)
True
sage: x.divides(x^2+2)
False
sage: (x^2+2).divides(x)
False
```

inverse_mod()
Return an inverse of self modulo the ideal I, if defined, i.e., if I and self together generate the unit ideal.

mod()

Return a representative for self modulo the ideal I (or the ideal generated by the elements of I if I is not an ideal.)

EXAMPLE: Integers Reduction of 5 modulo an ideal:

```
sage: n = 5
sage: n.mod(3*ZZ)
2
```

Reduction of 5 modulo the ideal generated by 3:

```
sage: n.mod(3)
2
```

Reduction of 5 modulo the ideal generated by 15 and 6, which is (3).

```
sage: n.mod([15,6])
2
```

EXAMPLE: Univiate polynomials

```
sage: R.<x> = PolynomialRing(QQ)
sage: f = x^3 + x + 1
sage: f.mod(x + 1)
-1
```

When little is implemented about a given ring, then mod may return simply return f. For example, reduction is not implemented for $\mathbf{Z}[x]$ yet. (TODO!)

sage: R.<x> = PolynomialRing(ZZ) sage: f = x^3 + x + 1 sage: f.mod(x + 1) x^3 + x + 1

EXAMPLE: Multivariate polynomials We reduce a polynomial in two variables modulo a polynomial and an ideal:

```
sage: R.<x,y,z> = PolynomialRing(QQ, 3)
sage: (x^2 + y^2 + z^2).mod(x+y+z)
2*y^2 + 2*y*z + 2*z^2
```

Notice above that x is eliminated. In the next example, both y and z are eliminated:

```
sage: (x^2 + y^2 + z^2).mod( (x - y, y - z) )
3*z^2
sage: f = (x^2 + y^2 + z^2)^2; f
x^4 + 2*x^2*y^2 + y^4 + 2*x^2*z^2 + 2*y^2*z^2 + z^4
sage: f.mod( (x - y, y - z) )
9*z^4
```

In this example y is eliminated:

```
sage: (x^2 + y^2 + z^2).mod( (x^3, y - z) )
x^2 + 2*z^2
```

class DedekindDomainElement()

class Element()

Generic element of a structure. All other types of elements (RingElement, ModuleElement, etc) derive from this type.

Subtypes must either call __init__() to set _parent, or may set _parent themselves if that would be more efficient.

base_extend()

base_ring()

Returns the base ring of this element's parent (if that makes sense).

category()

is_zero()
Return True if self equals self.parent()(0). The default implementation is to fall back to 'not self.__nonzero__'.

> **Warning:** Do not re-implement this method in your subclass but implement __nonzero__ instead.

n()
Return a numerical approximation of x with at least prec bits of precision.

EXAMPLES:

```
sage: (2/3).n()
0.666666666666667
sage: a = 2/3
sage: pi.n(digits=10)
3.141592654
sage: pi.n(prec=20)    # 20 bits
3.1416
```

parent()
Returns parent of this element; or, if the optional argument x is supplied, the result of coercing x into the parent of this element.

subs()
Substitutes given generators with given values while not touching other generators. This is a generic wrapper around __call__. The syntax is meant to be compatible with the corresponding method for symbolic expressions.

INPUT:

- in_dict - (optional) dictionary of inputs
- **kwds - named parameters

OUTPUT:

- new object if substitution is possible, otherwise self.

EXAMPLES:

```
sage: x, y = PolynomialRing(ZZ,2,'xy').gens()
sage: f = x^2 + y + x^2*y^2 + 5
sage: f((5,y))
25*y^2 + y + 30
sage: f.subs({x:5})
25*y^2 + y + 30
sage: f.subs(x=5)
25*y^2 + y + 30
sage: (1/f).subs(x=5)
1/(25*y^2 + y + 30)
sage: Integer(5).subs(x=4)
5
```

substitute()
This is an alias for self.subs().

INPUT:

- in_dict - (optional) dictionary of inputs
- **kwds - named parameters

OUTPUT:

- new object if substitution is possible, otherwise self.

EXAMPLES:

```
sage: x, y = PolynomialRing(ZZ,2,'xy').gens()
sage: f = x^2 + y + x^2*y^2 + 5
sage: f((5,y))
25*y^2 + y + 30
sage: f.substitute({x:5})
25*y^2 + y + 30
sage: f.substitute(x=5)
25*y^2 + y + 30
sage: (1/f).substitute(x=5)
1/(25*y^2 + y + 30)
sage: Integer(5).substitute(x=4)
5
```

class EuclideanDomainElement()

degree()

leading_coefficient()

quo_rem()

class FieldElement()

divides()

Check whether self divides other, for field elements.

Since this is a field, all values divide all other values, except that zero does not divide any non-zero values.

EXAMPLES:

```
sage: K.<rt3> = QQ[sqrt(3)]
sage: K(0).divides(rt3)
False
sage: rt3.divides(K(17))
True
sage: K(0).divides(K(0))
True
sage: rt3.divides(K(0))
True
```

is_unit()

Return True if self is a unit in its parent ring.

EXAMPLES:

```
sage: a = 2/3; a.is_unit()
True
```

On the other hand, 2 is not a unit, since its parent is ZZ.

```
sage: a = 2; a.is_unit()
False
sage: parent(a)
Integer Ring
```

However, a is a unit when viewed as an element of QQ:

```
sage: a = QQ(2); a.is_unit()
True
```

quo_rem()

class FiniteFieldElement()

additive_order()

Return the additive order of this finite field element.

EXAMPLES:

```
sage: k.<a> = FiniteField(2^12, 'a')
sage: b = a^3 + a + 1
sage: b.additive_order()
2
sage: k(0).additive_order()
1
```

charpoly()

Return the characteristic polynomial of self as a polynomial with given variable.

INPUT:

- var - string (default: 'x')
- algorithm - string (default: 'matrix')
  - 'matrix' - return the charpoly computed from the matrix of left multiplication by self
  - 'pari' – use pari's charpoly routine on polymods, which is not very good except in small cases

The result is not cached.

EXAMPLES:

```
sage: k.<a> = GF(19^2)
sage: parent(a)
Finite Field in a of size 19^2
sage: a.charpoly('X')
X^2 + 18*X + 2
sage: a^2 + 18*a + 2
0
sage: a.charpoly('X', algorithm='pari')
X^2 + 18*X + 2
```

frobenius()

Return the $(p^k)^{th}$ power of self, where p is the characteristic of the field.

INPUT:

- k - integer (default: 1, must fit in C int type)

Note that if k is negative, then this computes the appropriate root.

EXAMPLES:

```
sage: F.<a> = GF(29^2)
sage: z = a^2 + 5*a + 1
sage: z.pth_power()
19*a + 20
sage: z.pth_power(10)
10*a + 28
sage: z.pth_power(-10) == z
True
sage: F.<b> = GF(2^12)
sage: y = b^3 + b + 1
sage: y == (y.pth_power(-3))^(2^3)
True
sage: y.pth_power(2)
b^7 + b^6 + b^5 + b^4 + b^3 + b
```

matrix()

See _matrix_().

EXAMPLE:

```
sage: k.<a> = GF(2^16)
sage: e = a^2 + 1
sage: e.matrix() # random-ish error message
doctest:1: DeprecationWarning:The function matrix is replaced by _matrix_.
[1 0 0 0 0 0 0 0 0 0 0 0 0 0 1 0]
[0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 1]
[1 0 1 0 0 0 0 0 0 0 0 0 0 0 1 0]
[0 1 0 1 0 0 0 0 0 0 0 0 0 0 1 1]
[0 0 1 0 1 0 0 0 0 0 0 0 0 0 0 1]
[0 0 0 1 0 1 0 0 0 0 0 0 0 0 1 0]
[0 0 0 0 1 0 1 0 0 0 0 0 0 0 0 1]
[0 0 0 0 0 1 0 1 0 0 0 0 0 0 0 0]
[0 0 0 0 0 0 1 0 1 0 0 0 0 0 0 0]
[0 0 0 0 0 0 0 1 0 1 0 0 0 0 0 0]
[0 0 0 0 0 0 0 0 1 0 1 0 0 0 0 0]
[0 0 0 0 0 0 0 0 0 1 0 1 0 0 0 0]
[0 0 0 0 0 0 0 0 0 0 1 0 1 0 0 0]
[0 0 0 0 0 0 0 0 0 0 0 1 0 1 0 0]
[0 0 0 0 0 0 0 0 0 0 0 0 1 0 1 0]
[0 0 0 0 0 0 0 0 0 0 0 0 0 1 0 1]
```

minimal_polynomial()

Returns the minimal polynomial of this element (over the corresponding prime subfield).

EXAMPLES:

```
sage: k.<a> = FiniteField(3^4)
sage: parent(a)
Finite Field in a of size 3^4
sage: b=a**20;p=charpoly(b,"y");p
y^4 + 2*y^2 + 1
sage: factor(p)
(y^2 + 1)^2
sage: b.minimal_polynomial('y')
y^2 + 1
```

minpoly()

Returns the minimal polynomial of this element (over the corresponding prime subfield).

EXAMPLES:

```
sage: k.<a> = FiniteField(19^2)
sage: parent(a)
Finite Field in a of size 19^2
sage: b=a**20;p=b.charpoly("x");p
x^2 + 15*x + 4
sage: factor(p)
(x + 17)^2
sage: b.minpoly('x')
x + 17
```

multiplicative_order()

Return the multiplicative order of this field element.

norm()

Return the norm of self down to the prime subfield.

This is the product of the Galois conjugates of self.

EXAMPLES:

```
sage: S.<b> = GF(5^2); S
Finite Field in b of size 5^2
```

```
sage: b.norm()
2
sage: b.charpoly('t')
t^2 + 4*t + 2
```

Next we consider a cubic extension:

```
sage: S.<a> = GF(5^3); S
Finite Field in a of size 5^3
sage: a.norm()
2
sage: a.charpoly('t')
t^3 + 3*t + 3
sage: a * a^5 * (a^25)
2
```

nth_root()

Returns an nth root of self.

INPUT:

- n - integer >= 1 (must fit in C int type)
- extend - bool (default: True); if True, return an nth root in an extension ring, if necessary. Otherwise, raise a ValueError if the root is not in the base ring. Warning: this option is not implemented!
- all - bool (default: False); if True, return all nth roots of self, instead of just one.

OUTPUT:

If self has an nth root, returns one (if all == False) or a list of all of them (if all == True). Otherwise, raises a ValueError (if extend = False) or a NotImplementedError (if extend = True).

Warning: The 'extend' option is not implemented (yet).

AUTHOR:

- David Roe (2007-10-3)

pth_power()

Return the $(p^k)^{th}$ power of self, where p is the characteristic of the field.

INPUT:

- k - integer (default: 1, must fit in C int type)

Note that if k is negative, then this computes the appropriate root.

EXAMPLES:

```
sage: F.<a> = GF(29^2)
sage: z = a^2 + 5*a + 1
sage: z.pth_power()
19*a + 20
sage: z.pth_power(10)
10*a + 28
sage: z.pth_power(-10) == z
True
sage: F.<b> = GF(2^12)
sage: y = b^3 + b + 1
sage: y == (y.pth_power(-3))^(2^3)
True
sage: y.pth_power(2)
b^7 + b^6 + b^5 + b^4 + b^3 + b
```

pth_root()

Return the $(p^k)^{th}$ root of self, where p is the characteristic of the field.

INPUT:

- k - integer (default: 1, must fit in C int type)

Note that if k is negative, then this computes the appropriate power.

EXAMPLES:

```
sage: F.<b> = GF(2^12)
sage: y = b^3 + b + 1
sage: y == (y.pth_root(3))^(2^3)
True
sage: y.pth_root(2)
b^11 + b^10 + b^9 + b^7 + b^5 + b^4 + b^2 + b
```

trace()

Return the trace of this element, which is the sum of the Galois conjugates.

EXAMPLES:

```
sage: S.<a> = GF(5^3); S
Finite Field in a of size 5^3
sage: a.trace()
0
sage: a.charpoly('t')
t^3 + 3*t + 3
sage: a + a^5 + a^25
0
sage: z = a^2 + a + 1
sage: z.trace()
2
sage: z.charpoly('t')
t^3 + 3*t^2 + 2*t + 2
sage: z + z^5 + z^25
2
```

vector()

See _vector_().

EXAMPLE:

```
sage: k.<a> = GF(2^16)
sage: e = a^2 + 1
sage: e.vector() # random-ish error message
doctest:1: DeprecationWarning:The function vector is replaced by _vector_.
(1, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0)
```

class **InfinityElement**()

class **IntegralDomainElement**()

is_nilpotent()

class **Matrix**()

class **MinusInfinityElement**()

class **ModuleElement**()

Generic element of a module.

additive_order()

Return the additive order of self.

order()

Return the additive order of self.

class **MonoidElement**()

Generic element of a monoid.

multiplicative_order()
Return the multiplicative order of self.

order()
Return the multiplicative order of self.

class MultiplicativeGroupElement()
Generic element of a multiplicative group.

order()
Return the multiplicative order of self.

class PlusInfinityElement()

class PrincipalIdealDomainElement()

gcd()
Returns the gcd of self and right, or 0 if both are 0.

lcm()
Returns the least common multiple of self and right.

xgcd()
Return the extended gcd of self and other, i.e., elements r, s, t such that .. math:

```
r = s \cdot self + t \cdot other.
```

Note: There is no guarantee on minimality of the cofactors. In the integer case, see documentation for Integer._xgcd() to obtain minimal cofactors.

class RingElement()

abs()
Return the absolute value of self. (This just calls the __abs__ method, so it is equivalent to the abs() built-in function.)
EXAMPLES:

```
sage: RR(-1).abs()
1.00000000000000
sage: ZZ(-1).abs()
1
sage: CC(I).abs()
1.00000000000000
sage: Mod(-15, 37).abs()
...
ArithmeticError: absolute valued not defined on integers modulo n.
```

additive_order()
Return the additive order of self.

is_nilpotent()
Return True if self is nilpotent, i.e., some power of self is 0.

is_one()

is_unit()

multiplicative_order()
Return the multiplicative order of self, if self is a unit, or raise `ArithmeticError` otherwise.

order()
Return the additive order of self.
This is deprecated; use `additive_order` instead.
EXAMPLES:

```
sage: a = Integers(12)(5)
sage: a.order()
doctest... DeprecationWarning: The function order is deprecated for ring elements; use addit
12
```

class Vector()

bin_op()

canonical_coercion()

canonical_coercion(x,y) is what is called before doing an arithmetic operation between x and y. It returns a pair (z,w) such that z is got from x and w from y via canonical coercion and the parents of z and w are identical.

EXAMPLES:

```
sage: A = Matrix([[0,1],[1,0]])
sage: canonical_coercion(A,1)
([0 1]
[1 0], [1 0]
[0 1])
```

coerce_cmp()

coercion_traceback()

This function is very helpful in debugging coercion errors. It prints the tracebacks of all the errors caught in the coercion detection. Note that failure is cached, so some errors may be omitted the second time around (as it remembers not to retry failed paths for speed reasons.

EXAMPLES:

```
sage: 1 + 1/5
6/5
sage: coercion_traceback()  # Should be empty, as all went well.
sage: 1/5 + GF(5).gen()
...
TypeError: unsupported operand parent(s) for '+': 'Rational Field' and 'Finite Field of size 5'
sage: coercion_traceback()
...
TypeError: no common canonical parent for objects with parents: 'Rational Field' and 'Finite Fie
```

gcd()

generic_power()

Computes a^n, where n is an integer, and a is an object which supports multiplication. Optionally an additional argument, which is used in the case that n == 0:

- one - the "unit" element, returned directly (can be anything)

If this is not supplied, int(1) is returned.

EXAMPLES:

```
sage: from sage.structure.element import generic_power
sage: generic_power(int(12),int(0))
1
sage: generic_power(int(0),int(100))
0
sage: generic_power(Integer(10),Integer(0))
1
sage: generic_power(Integer(0),Integer(23))
0
```

```
sage: sum([generic_power(2,i) for i in range(17)]) #test all 4-bit combinations
131071
sage: F = Zmod(5)
sage: a = generic_power(F(2), 5); a
2
sage: a.parent() is F
True
sage: a = generic_power(F(1), 2)
sage: a.parent() is F
True

sage: generic_power(int(5), 0)
1
```

get_coercion_model()
Return the global coercion model.

EXAMPLES:

```
sage: import sage.structure.element as e
sage: cm = e.get_coercion_model()
sage: cm
<sage.structure.coerce.CoercionModel_cache_maps object at ...>
```

is_AdditiveGroupElement()
Return True if x is of type AdditiveGroupElement.

is_AlgebraElement()
Return True if x is of type AlgebraElement.

is_CommutativeAlgebraElement()
Return True if x is of type CommutativeAlgebraElement.

is_CommutativeRingElement()
Return True if x is of type CommutativeRingElement.

is_DedekindDomainElement()
Return True if x is of type DedekindDomainElement.

is_Element()
Return True if x is of type Element.

EXAMPLES:

```
sage: from sage.structure.element import is_Element
sage: is_Element(2/3)
True
sage: is_Element(QQ^3)
False
```

is_EuclideanDomainElement()
Return True if x is of type EuclideanDomainElement.

is_FieldElement()
Return True if x is of type FieldElement.

is_InfinityElement()
Return True if x is of type InfinityElement.

is_IntegralDomainElement()
Return True if x is of type IntegralDomainElement.

is_Matrix()

is_ModuleElement()
Return True if x is of type ModuleElement.

This is even faster than using isinstance inline.

EXAMPLES:

```
sage: from sage.structure.element import is_ModuleElement
sage: is_ModuleElement(2/3)
True
sage: is_ModuleElement((QQ^3).0)
True
sage: is_ModuleElement('a')
False
```

is_MonoidElement()
Return True if x is of type MonoidElement.

is_MultiplicativeGroupElement()
Return True if x is of type MultiplicativeGroupElement.

is_PrincipalIdealDomainElement()
Return True if x is of type PrincipalIdealDomainElement.

is_RingElement()
Return True if x is of type RingElement.

is_Vector()

lcm()

make_element()
This function is only here to support old pickles.

Pickling functionality is moved to Element.{__getstate__,__setstate__} functions.

parent()

py_scalar_to_element()

set_coercion_model()

xgcd()

10.6 UniqueRepresentation

class **UniqueRepresentation**()
Classes derived from UniqueRepresentation inherit a unique representation behavior for their instances.

EXAMPLES:

The short story: to construct a class whose instances have a unique representation behavior one just have to do:

```
sage: class MyClass(UniqueRepresentation):
...       # all the rest as usual
...       pass
```

Everything below is for the curious or for advanced usage.

What is unique representation?

Instances of a class have a *unique representation behavior* when several instances constructed with the same arguments share the same memory representation. For example, calling twice:

```
sage: f = GF(7)
sage: g = GF(7)
```

to create the finite field of order 7 actually gives back the same object:

```
sage: f == g
True
sage: f is g
True
```

This is a standard design pattern. Besides saving memory, it allows for sharing cached data (say representation theoretical information about a group) as well as for further optimizations (fast hashing, equality testing). This behaviour is typically desirable for parents and categories. It can also be useful for intensive computations where one wants to cache all the operations on a small set of elements (say the multiplication table of a small group), and access this cache as quickly as possible.

The `UniqueRepresentation` and `UniqueFactory` classes provide two alternative implementations of this design pattern. Both implementations have their own merits. `UniqueRepresentation` is very easy to use: a class just needs to derive from it, or make sure some of its super classes does. For basic usage . Also, it groups together the class and the factory in a single gadget; in the example above, one would want to do:

```
sage: isinstance(f, GF)          # todo: not implemented
True
```

but this does not work, because GF is only the factory.

On the other hand the `UniqueRepresentation` class is more intrusive, as it imposes a behavior (and a metaclass) to all the subclasses. Its implementation is also more technical, which leads to some subtleties.

EXAMPLES:

We start with a simple class whose constructor takes a single value as argument (TODO: find a more meaningful example):

```
sage: class MyClass(UniqueRepresentation):
...       def __init__(self, value):
...           self.value = value
...
```

Two coexisting instances of MyClass created with the same argument data are guaranteed to share the same identity:

```
sage: x = MyClass(1)
sage: y = MyClass(1)
sage: x is y
True
sage: z = MyClass(2)
sage: x is z
False
```

In particular, modifying any one of them modifies the other (reference effect):

```
sage: x.value = 3
sage: x.value, y.value
(3, 3)
sage: y.value = 1
sage: x.value, y.value
(1, 1)
```

Unless overriden by the derived class, equality testing is implemented by comparing identities, which is as fast as it can get:

```
sage: x == y
True
sage: z = MyClass(2)
sage: x == z, x is z
(False, False)
```

Similarly, the identity is used as hash function, which is also as fast as it can get. However this means that the hash function may change in between Sage sessions, or even within the same Sage session (see below). Subclasses should overload `__hash__()` if this could be a problem.

The arguments can consist of any combination of positional or keyword arguements, as taken by a usual `__init__()` function. However, all values passed in should be hashable:

```
sage: MyClass(value = [1,2,3])
...
TypeError: list objects are unhashable
```

Argument preprocessing

Sometimes, one wants to do some preprocessing on the arguments, to put them in some canonical form. The following example illustrates how to achieve this; it takes as argument any iterable, and canonicalizes it into a tuple (which is hashable!):

```
sage: class MyClass2(UniqueRepresentation):
...       @staticmethod
...       def __classcall__(cls, iterable):
...           t = tuple(iterable)
...           return super(MyClass2, cls).__classcall__(cls, t)
...
...       def __init__(self, value):
...           self.value = value
...
sage: x = MyClass2([1,2,3])
sage: y = MyClass2(tuple([1,2,3]))
sage: z = MyClass2(i for i in [1,2,3])
sage: x.value
(1, 2, 3)
sage: x is y, y is z
(True, True)
```

A similar situation arises when the constructor accepts default values for some of its parameters. Alas, the obvious implementation does not work:

```
sage: class MyClass3(UniqueRepresentation):
...       def __init__(self, value = 3):
...           self.value = value
```

```
...
sage: MyClass3(3) is MyClass3()
False
```

Instead, one should do:

```
sage: class MyClass3(UniqueRepresentation):
...       @staticmethod
...       def __classcall__(cls, value = 3):
...           return super(MyClass3, cls).__classcall__(cls, value)
...
...       def __init__(self, value):
...           self.value = value
...
sage: MyClass3(3) is MyClass3()
True
```

A bit of explanation is in order. First, the call `MyClass2([1,2,3])` triggers a call to `MyClass2.__classcall__(MyClass2, [1,2,3])`. This is an extension of the standard Python behavior, needed by `UniqueRepresentation`, and implemented by the `ClasscallMetaclass`. Then, `MyClass2.__classcall__` does the desired transformations on the arguments. Finally, it uses `super` to call the default implementation of `__classcall__` provided by `UniqueRepresentation`. This one in turn handles the caching and, if needed, constructs and initializes a new object in the class using `__new__()` and `__init__()` as usual.

Constraints:

- `__classcall__()` is a staticmethod (like, implicitly, `__new__()`)
- the preprocessing on the arguments should be idempotent. Namely, If `MyClass2.__classcall__()` calls `UniqueRepresentation.__classcall__(<some_arguments>)`, then it should accept <some_arguments> as its own input, and pass it down unmodified to `UniqueRepresentation.__classcall__()`.
- `MyClass2.__classcall__()` should return the result of `UniqueRepresentation.__classcall__()` without modifying it.

Other than that `MyClass2.__classcall__()` may play any tricks, like acting as a Factory and returning object from other classes.

Unique representation and mutability

`UniqueRepresentation` is primarily intended for implementing objects which are (at least semantically) immutable. This is in particular assumed by the default implementations of `copy` and `deepcopy`:

```
sage: copy(x) is x
True
sage: from copy import deepcopy
sage: deepcopy(x) is x
True
```

Using `UniqueRepresentation` on mutable objects may lead to subtle behavior:

```
sage: t = MyClass(3)
sage: z = MyClass(2)
sage: t.value = 2
```

Now x and z have the same data structure, but are not considered as equal:

```
sage: t.value == z.value
True
sage: t == z
False
```

More on unique representation and identity

UniqueRepresentation is implemented by mean of a cache. This cache uses weak references so that, when all other references to, say, MyClass(1) have been deleted, the instance is actually deleted from memory. A later call to MyClass(1) reconstructs the instance from scratch, *most likely with a different id*.

TODO: add an example illustrating this behavior

Unique representation and pickling

The default Python pickling implementation (by reconstructing an object from its class and dictionary, see "The pickle protocol" in the Python Library Reference) does not preserves unique representation, as Python has no chance to know whether and where the same object already exists.

UniqueRepresentation tries to ensure appropriate pickling by implementing a __reduce__() method returning the arguments passed to the constructor:

```
sage: import __main__              # Fake MyClass being defined in a python module
sage: __main__.MyClass = MyClass
sage: x = MyClass(1)
sage: loads(dumps(x)) is x
True
```

UniqueRepresentation uses the __reduce__() pickle protocol rather than __getnewargs__() because the later does not handle keyword arguments:

```
sage: x = MyClass(value = 1)
sage: x.__reduce__()
(<function unreduce at ...>, (<class '__main__.MyClass'>, (), {'value': 1}))
sage: x is loads(dumps(x))
True
```

Caveat: the default implementation of __reduce__() in UniqueRepresentation requires to store the constructor's arguments in the instance dictionary upon construction:

sage: x.__dict__ {'_reduction': (<class '__main__.MyClass'>, (), {'value': 1}), 'value': 1}

It is often easy in a derived subclass to reconstruct the constructors arguments from the instance data structure. When this is the case, __reduce__() should be overriden; automagically the arguments won't be stored anymore:

sage: class MyClass3(UniqueRepresentation): ... def __init__(self, value): ... self.value = value ... ... def __reduce__(self): ... return (MyClass3, (self.value,)) ... sage: import __main__; __main__.MyClass3 = MyClass3 # Fake MyClass3 being defined in a python module sage: x = MyClass3(1) sage: loads(dumps(x)) is x True sage: x.__dict__ {'value': 1}

Migrating classes to `UniqueRepresentation` and unpickling

We check that, when migrating a class to `UniqueRepresentation`, older pickle can still be reasonably unpickled. Let us create a (new style) class, and pickle one of its instances:

```
sage: class MyClass4(object):
...       def __init__(self, value):
...           self.value = value
...
sage: import __main__; __main__.MyClass4 = MyClass4  # Fake MyClass4 being defined in a python m
sage: pickle = dumps(MyClass4(1))
```

It can be unpickled:

```
sage: y = loads(pickle)
sage: y.value
1
```

Now, we upgrade the class to derive from `UniqueRepresentation`:

```
sage: class MyClass4(UniqueRepresentation, object):
...       def __init__(self, value):
...           self.value = value
sage: import __main__; __main__.MyClass4 = MyClass4  # Fake MyClass4 being defined in a python m
sage: __main__.MyClass4 = MyClass4
```

The pickle can still be unpickled:

```
sage: y = loads(pickle)
sage: y.value
1
```

Note however that, for the reasons explained above, unique representation is not guaranteed in this case:

```
sage: y is MyClass4(1)
False
```

Todo: illustrate how this can be fixed on a case by case basis.

Now, we redo the same test for a class deriving from SageObject:

```
sage: class MyClass4(SageObject):
...       def __init__(self, value):
...           self.value = value
sage: import __main__; __main__.MyClass4 = MyClass4  # Fake MyClass4 being defined in a python m
sage: pickle = dumps(MyClass4(1))

sage: class MyClass4(UniqueRepresentation, SageObject):
...       def __init__(self, value):
...           self.value = value
sage: __main__.MyClass4 = MyClass4
sage: y = loads(pickle)
sage: y.value
1
```

Caveat: unpickling instances of a formerly old-style class is not supported yet by default:

```
sage: class MyClass4:
...       def __init__(self, value):
...           self.value = value
sage: import __main__; __main__.MyClass4 = MyClass4  # Fake MyClass4 being defined in a python m
sage: pickle = dumps(MyClass4(1))

sage: class MyClass4(UniqueRepresentation, SageObject):
...       def __init__(self, value):
...           self.value = value
sage: __main__.MyClass4 = MyClass4
sage: y = loads(pickle)  # todo: not implemented
sage: y.value            # todo: not implemented
1
```

Rationale for the current implementation

`UniqueRepresentation` and derived classes use the `ClasscallMetaclass` of the standard Python type. The following example explains why.

We define a variant of `MyClass` where the calls to `__init__()` are traced:

```
sage: class MyClass(UniqueRepresentation):
...       def __init__(self, value):
...           print "initializing object"
...           self.value = value
...
```

Let us create an object twice:

```
sage: x = MyClass(1)
initializing object
sage: z = MyClass(1)
```

As desired the __init__ method was only called the first time, which is an important feature.

As far as we can tell, this is not achievable while just using `__new__()` and `__init__()` (as defined by type; see Section "Basic Customization" in the Python Reference Manual). Indeed, `__init__()` is called systematically on the result of `__new__()` whenever the result is an instance of the class.

Another difficulty is that argument preprocessing (as in the example above) cannot be handled by `__new__()`, since the unprocessed arguments will be passed down to `__init__()`.

TESTS:

For the record, this test did fail with previous implementation attempts:

```
sage: class bla(UniqueRepresentation, SageObject):
...       pass
...
sage: b = bla()
```

unreduce(*cls, args, keywords*)
Calls a class on the given arguments:

```
sage: sage.structure.unique_representation.unreduce(Integer, (1,), {})
1
```

Todo: should reuse something preexisting ...

10.7 Mutability Cython Implementation

class Mutability()

is_immutable()
Return True if this object is immutable (can not be changed) and False if it is not.
To make this object immutable use self.set_immutable().
EXAMPLE:

```
sage: v = Sequence([1,2,3,4/5])
sage: v[0] = 5
sage: v
[5, 2, 3, 4/5]
sage: v.is_immutable()
False
sage: v.set_immutable()
sage: v.is_immutable()
True
```

is_mutable()

set_immutable()
Make this object immutable, so it can never again be changed.
EXAMPLES:

```
sage: v = Sequence([1,2,3,4/5])
sage: v[0] = 5
sage: v
[5, 2, 3, 4/5]
sage: v.set_immutable()
sage: v[3] = 7
...
ValueError: object is immutable; please change a copy instead.
```

10.8 Sequences

A mutable sequence of elements with a common guaranteed category, which can be set immutable.

Sequence derives from list, so has all the functionality of lists and can be used wherever lists are used. When a sequence is created without explicitly given the common universe of the elements, the constructor coerces the first and second element to some *canonical* common parent, if possible, then the second and third, etc. If this is possible, it then coerces everything into the canonical parent at the end. (Note that canonical coercion is very restrictive.) The sequence then has a function `universe()` which returns either the common canonical parent (if the coercion succeeded), or the category of all objects (Objects()). So if you have a list v and type

sage: v = [1, 2/3, 5] sage: w = Sequence(v) sage: w.universe() Rational Field

then since `w.universe()` is $\mathbf{Q}$, you're guaranteed that all elements of w are rationals:

sage: v[0].parent() Integer Ring sage: w[0].parent() Rational Field

If you do assignment to w this property of being rationals is guaranteed to be preserved.

sage: w[0] = 2 sage: w[0].parent() Rational Field sage: w[0] = 'hi' Traceback (most recent call last): ... TypeError: unable to convert hi to a rational

However, if you do `w = Sequence(v)` and the resulting universe is `Objects()`, the elements are not guaranteed to have any special parent. This is what should happen, e.g., with finite field elements of different characteristics:

```
sage: v = Sequence([GF(3)(1), GF(7)(1)])
sage: v.universe()
Category of objects
```

You can make a list immutable with `v.freeze()`. Assignment is never again allowed on an immutable list.

Creation of a sequence involves making a copy of the input list, and substantial coercions. It can be greatly sped up by explicitly specifying the universe of the sequence:

```
sage: v = Sequence(range(10000), universe=ZZ)
```

TESTS:

```
sage: v = Sequence([1..5])
sage: loads(dumps(v)) == v
True
```

class Sequence (*x, universe=None, check=True, immutable=False, cr=False, cr_str=None, use_sage_types=False*)

A mutable list of elements with a common guaranteed universe, which can be set immutable.

A universe is either an object that supports coercion (e.g., a parent), or a category.

INPUT:

- `x` - a list or tuple instance
- `universe` - (default: None) the universe of elements; if None determined using canonical coercions and the entire list of elements. If list is empty, is category Objects() of all objects.
- `check` – (default: True) whether to coerce the elements of x into the universe
- `immutable` - (default: True) whether or not this sequence is immutable
- `cr` - (default: False) if True, then print a carriage return after each comma when printing this sequence.
- **`use_sage_types` – (default: False) if True, coerce the** builtin Python numerical types int, long, float, complex to the corresponding Sage types (this makes functions like vector() more flexible)

OUTPUT:

- a sequence

EXAMPLES:

```
sage: v = Sequence(range(10))
sage: v.universe()
<type 'int'>
sage: v
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

We can request that the builtin Python numerical types be coerced to Sage objects:

```
sage: v = Sequence(range(10), use_sage_types=True)
sage: v.universe()
Integer Ring
sage: v
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

You can also use seq for "Sequence", which is identical to using Sequence:

```
sage: v = seq([1,2,1/1]); v
[1, 2, 1]
sage: v.universe()
Rational Field
sage: v.parent()
Category of sequences in Rational Field
sage: v.parent()([3,4/3])
[3, 4/3]
```

Note that assignment coerces if possible,

```
sage: v = Sequence(range(10), ZZ)
sage: a = QQ(5)
sage: v[3] = a
sage: parent(v[3])
Integer Ring
sage: parent(a)
Rational Field
sage: v[3] = 2/3
...
TypeError: no conversion of this rational to integer
```

Sequences can be used absolutely anywhere lists or tuples can be used:

```
sage: isinstance(v, list)
True
```

Sequence can be immutable, so entries can't be changed:

```
sage: v = Sequence([1,2,3], immutable=True)
sage: v.is_immutable()
True
sage: v[0] = 5
...
ValueError: object is immutable; please change a copy instead.
```

Only immutable sequences are hashable (unlike Python lists), though the hashing is potentially slow, since it first involves conversion of the sequence to a tuple, and returning the hash of that.

```
sage: v = Sequence(range(10), ZZ, immutable=True)
sage: hash(v)
1591723448              # 32-bit
-4181190870548101704    # 64-bit
```

If you really know what you are doing, you can circumvent the type checking (for an efficiency gain):

```
sage: list.__setitem__(v, int(1), 2/3)         # bad circumvention
sage: v
[0, 2/3, 2, 3, 4, 5, 6, 7, 8, 9]
sage: list.__setitem__(v, int(1), int(2))      # not so bad circumvention
```

You can make a sequence with a new universe from an old sequence.

```
sage: w = Sequence(v, QQ)
sage: w
[0, 2, 2, 3, 4, 5, 6, 7, 8, 9]
sage: w.universe()
Rational Field
```

```
sage: w[1] = 2/3
sage: w
[0, 2/3, 2, 3, 4, 5, 6, 7, 8, 9]
```

Sequences themselves live in a category, the category of all sequences in the given universe.

```
sage: w.category()
Category of sequences in Rational Field
```

This is also the parent of any sequence:

```
sage: w.parent()
Category of sequences in Rational Field
```

The default universe for any sequence, if no compatible parent structure can be found, is the universe of all Sage objects.

This example illustrates how every element of a list is taken into account when constructing a sequence.

```
sage: v = Sequence([1,7,6,GF(5)(3)]); v
[1, 2, 1, 3]
sage: v.universe()
Finite Field of size 5
sage: v.parent()
Category of sequences in Finite Field of size 5
sage: v.parent()([7,8,9])
[2, 3, 4]
```

append(*x*)

EXAMPLES: sage: v = Sequence([1,2,3,4], immutable=True) sage: v.append(34) Traceback (most recent call last): ... ValueError: object is immutable; please change a copy instead. sage: v = Sequence([1/3,2,3,4]) sage: v.append(4) sage: type(v[4]) <type 'sage.rings.rational.Rational'>

category()

EXAMPLES:

```
sage: Sequence([1,2/3,-2/5]).category()
Category of sequences in Rational Field
```

extend(*iterable*)

Extend list by appending elements from the iterable.

EXAMPLES:

```
sage: B = Sequence([1,2,3])
sage: B.extend(range(4))
sage: B
[1, 2, 3, 0, 1, 2, 3]
```

insert(*index, object*)

Insert object before index.

EXAMPLES:

```
sage: B = Sequence([1,2,3])
sage: B.insert(10, 5)
sage: B
[1, 2, 3, 5]
```

is_immutable()
Return True if this object is immutable (can not be changed) and False if it is not.
To make this object immutable use `set_immutable()`.
EXAMPLE:

```
sage: v = Sequence([1,2,3,4/5])
sage: v[0] = 5
sage: v
[5, 2, 3, 4/5]
sage: v.is_immutable()
False
sage: v.set_immutable()
sage: v.is_immutable()
True
```

is_mutable()
EXAMPLES:

```
sage: a = Sequence([1,2/3,-2/5])
sage: a.is_mutable()
True
sage: a[0] = 100
sage: type(a[0])
<type 'sage.rings.rational.Rational'>
sage: a.set_immutable()
sage: a[0] = 50
...
ValueError: object is immutable; please change a copy instead.
sage: a.is_mutable()
False
```

parent()
EXAMPLES:

```
sage: Sequence([1,2/3,-2/5]).parent()
Category of sequences in Rational Field
```

pop(*index=-1*)
Remove and return item at index (default last)
EXAMPLES:

```
sage: B = Sequence([1,2,3])
sage: B.pop(1)
2
sage: B
[1, 3]
```

remove(*value*)
Remove first occurrence of value
EXAMPLES:

```
sage: B = Sequence([1,2,3])
sage: B.remove(2)
sage: B
[1, 3]
```

reverse()
Reverse the elements of self, in place.
EXAMPLES:

```
sage: B = Sequence([1,2,3])
sage: B.reverse(); B
[3, 2, 1]
```

set_immutable()
Make this object immutable, so it can never again be changed.
EXAMPLES:

```
sage: v = Sequence([1,2,3,4/5])
sage: v[0] = 5
sage: v
[5, 2, 3, 4/5]
sage: v.set_immutable()
sage: v[3] = 7
...
ValueError: object is immutable; please change a copy instead.
```

sort(*cmp=None, key=None, reverse=False*)
Sort this list *IN PLACE*.
cmp(x, y) -> -1, 0, 1
EXAMPLES:

```
sage: B = Sequence([3,2,1/5])
sage: B.sort()
sage: B
[1/5, 2, 3]
sage: B.sort(reverse=True); B
[3, 2, 1/5]
sage: B.sort(cmp = lambda x,y: cmp(y,x)); B
[3, 2, 1/5]
sage: B.sort(cmp = lambda x,y: cmp(y,x), reverse=True); B
[1/5, 2, 3]
```

universe()
EXAMPLES:

```
sage: Sequence([1,2/3,-2/5]).universe()
Rational Field
sage: Sequence([1,2/3,'-2/5']).universe()
Category of objects
```

class **seq**(*x, universe=None, check=True, immutable=False, cr=False, cr_str=None, use_sage_types=False*)
A mutable list of elements with a common guaranteed universe, which can be set immutable.

A universe is either an object that supports coercion (e.g., a parent), or a category.

INPUT:

- `x` - a list or tuple instance
- `universe` - (default: None) the universe of elements; if None determined using canonical coercions and the entire list of elements. If list is empty, is category Objects() of all objects.
- `check` – (default: True) whether to coerce the elements of x into the universe
- `immutable` - (default: True) whether or not this sequence is immutable
- `cr` - (default: False) if True, then print a carriage return after each comma when printing this sequence.
- **`use_sage_types` – (default: False) if True, coerce the** builtin Python numerical types int, long, float, complex to the corresponding Sage types (this makes functions like vector() more flexible)

OUTPUT:

- a sequence

EXAMPLES:

```
sage: v = Sequence(range(10))
sage: v.universe()
<type 'int'>
sage: v
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

We can request that the builtin Python numerical types be coerced to Sage objects:

```
sage: v = Sequence(range(10), use_sage_types=True)
sage: v.universe()
Integer Ring
sage: v
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

You can also use seq for "Sequence", which is identical to using Sequence:

```
sage: v = seq([1,2,1/1]); v
[1, 2, 1]
sage: v.universe()
Rational Field
sage: v.parent()
Category of sequences in Rational Field
sage: v.parent()([3,4/3])
[3, 4/3]
```

Note that assignment coerces if possible,

```
sage: v = Sequence(range(10), ZZ)
sage: a = QQ(5)
sage: v[3] = a
sage: parent(v[3])
Integer Ring
sage: parent(a)
Rational Field
sage: v[3] = 2/3
...
TypeError: no conversion of this rational to integer
```

Sequences can be used absolutely anywhere lists or tuples can be used:

```
sage: isinstance(v, list)
True
```

Sequence can be immutable, so entries can't be changed:

```
sage: v = Sequence([1,2,3], immutable=True)
sage: v.is_immutable()
True
sage: v[0] = 5
...
ValueError: object is immutable; please change a copy instead.
```

Only immutable sequences are hashable (unlike Python lists), though the hashing is potentially slow, since it first involves conversion of the sequence to a tuple, and returning the hash of that.

```
sage: v = Sequence(range(10), ZZ, immutable=True)
sage: hash(v)
1591723448              # 32-bit
-4181190870548101704    # 64-bit
```

If you really know what you are doing, you can circumvent the type checking (for an efficiency gain):

```
sage: list.__setitem__(v, int(1), 2/3)         # bad circumvention
sage: v
[0, 2/3, 2, 3, 4, 5, 6, 7, 8, 9]
sage: list.__setitem__(v, int(1), int(2))      # not so bad circumvention
```

You can make a sequence with a new universe from an old sequence.

```
sage: w = Sequence(v, QQ)
sage: w
[0, 2, 2, 3, 4, 5, 6, 7, 8, 9]
sage: w.universe()
Rational Field
sage: w[1] = 2/3
sage: w
[0, 2/3, 2, 3, 4, 5, 6, 7, 8, 9]
```

Sequences themselves live in a category, the category of all sequences in the given universe.

```
sage: w.category()
Category of sequences in Rational Field
```

This is also the parent of any sequence:

```
sage: w.parent()
Category of sequences in Rational Field
```

The default universe for any sequence, if no compatible parent structure can be found, is the universe of all Sage objects.

This example illustrates how every element of a list is taken into account when constructing a sequence.

```
sage: v = Sequence([1,7,6,GF(5)(3)]); v
[1, 2, 1, 3]
sage: v.universe()
Finite Field of size 5
sage: v.parent()
Category of sequences in Finite Field of size 5
sage: v.parent()([7,8,9])
[2, 3, 4]
```

append(*x*)

EXAMPLES: sage: v = Sequence([1,2,3,4], immutable=True) sage: v.append(34) Traceback (most recent call last): ... ValueError: object is immutable; please change a copy instead. sage: v = Sequence([1/3,2,3,4]) sage: v.append(4) sage: type(v[4]) <type 'sage.rings.rational.Rational'>

category()

EXAMPLES:

```
sage: Sequence([1,2/3,-2/5]).category()
Category of sequences in Rational Field
```

extend(*iterable*)
Extend list by appending elements from the iterable.
EXAMPLES:

```
sage: B = Sequence([1,2,3])
sage: B.extend(range(4))
sage: B
[1, 2, 3, 0, 1, 2, 3]
```

insert(*index, object*)
Insert object before index.
EXAMPLES:

```
sage: B = Sequence([1,2,3])
sage: B.insert(10, 5)
sage: B
[1, 2, 3, 5]
```

is_immutable()
Return True if this object is immutable (can not be changed) and False if it is not.
To make this object immutable use `set_immutable()`.
EXAMPLE:

```
sage: v = Sequence([1,2,3,4/5])
sage: v[0] = 5
sage: v
[5, 2, 3, 4/5]
sage: v.is_immutable()
False
sage: v.set_immutable()
sage: v.is_immutable()
True
```

is_mutable()
EXAMPLES:

```
sage: a = Sequence([1,2/3,-2/5])
sage: a.is_mutable()
True
sage: a[0] = 100
sage: type(a[0])
<type 'sage.rings.rational.Rational'>
sage: a.set_immutable()
sage: a[0] = 50
...
ValueError: object is immutable; please change a copy instead.
sage: a.is_mutable()
False
```

parent()
EXAMPLES:

```
sage: Sequence([1,2/3,-2/5]).parent()
Category of sequences in Rational Field
```

pop(*index=-1*)
Remove and return item at index (default last)
EXAMPLES:

```
sage: B = Sequence([1,2,3])
sage: B.pop(1)
2
sage: B
[1, 3]
```

remove(*value*)

Remove first occurrence of value

EXAMPLES:

```
sage: B = Sequence([1,2,3])
sage: B.remove(2)
sage: B
[1, 3]
```

reverse()

Reverse the elements of self, in place.

EXAMPLES:

```
sage: B = Sequence([1,2,3])
sage: B.reverse(); B
[3, 2, 1]
```

set_immutable()

Make this object immutable, so it can never again be changed.

EXAMPLES:

```
sage: v = Sequence([1,2,3,4/5])
sage: v[0] = 5
sage: v
[5, 2, 3, 4/5]
sage: v.set_immutable()
sage: v[3] = 7
...
ValueError: object is immutable; please change a copy instead.
```

sort(*cmp=None, key=None, reverse=False*)

Sort this list *IN PLACE*.

cmp(x, y) -> -1, 0, 1

EXAMPLES:

```
sage: B = Sequence([3,2,1/5])
sage: B.sort()
sage: B
[1/5, 2, 3]
sage: B.sort(reverse=True); B
[3, 2, 1/5]
sage: B.sort(cmp = lambda x,y: cmp(y,x)); B
[3, 2, 1/5]
sage: B.sort(cmp = lambda x,y: cmp(y,x), reverse=True); B
[1/5, 2, 3]
```

universe()

EXAMPLES:

```
sage: Sequence([1,2/3,-2/5]).universe()
Rational Field
sage: Sequence([1,2/3,'-2/5']).universe()
Category of objects
```

10.9 A class for wrapping Sage or Python objects as Sage elements

class ElementWrapper(*value, parent*)

A class for wrapping Sage or Python objects as Sage elements

EXAMPLES:

```
sage: o = ElementWrapper("bla", parent=ZZ); o
'bla'
sage: isinstance(o, sage.structure.element.Element)
True
sage: o.parent()
Integer Ring
sage: o.value
'bla'
```

This is of course a meaningless example: *bla* is not an element of `ZZ`.

Note that `o` is not *an instance of* `str`, but rather *contains a* `str`. Therefore, `o` does not inherit the string methods. On the other hand, it is provided with reasonable default implementations for equality testing, hashing, etc.

The typical use case of *ElementWrapper* is for trivially constructing new element classes from preexisting Sage or Python classes, with a containment relation. Here we construct the tropical monoid of integers endowed with `min` as multiplication. There, it is desirable *not* to inherit the `factor` method from Integer:

```
sage: class MinMonoid(Parent):
...       def _repr_(self):
...           return "The min monoid"
...
sage: M = MinMonoid()
sage: class MinMonoidElement(ElementWrapper):
...       wrapped_class = Integer
...
...       def __mul__(self, other):
...           return MinMonoidElement(min(self.value, other.value), parent = self.parent())
sage: x = MinMonoidElement(5, parent = M); x
5
sage: x.parent()
The min monoid
sage: x.value
5
sage: y = MinMonoidElement(3, parent = M)
sage: x * y
3
```

This example was voluntarily kept to a bare minimum. See the (upcoming) examples in the categories for several full featured applications.

Caveat: the order between the value and the parent argument is likely to change shortly. At this point, all the code using it in the Sage library will be updated. There will be no transition period.

wrapped_class()

The most base type

10.10 Sets

AUTHORS:

- William Stein (2005) - first version
- William Stein (2006-02-16) - large number of documentation and examples; improved code
- Mike Hansen (2007-3-25) - added differences and symmetric differences; fixed operators

EnumeratedSet(*X*)

Return the enumerated set associated to X.

The input object X must be finite.

EXAMPLES:

```
sage: EnumeratedSet([1,1,2,3])
{1, 2, 3}
sage: EnumeratedSet(ZZ)
...
ValueError: X (=Integer Ring) must be finite
```

Set(*X*)

Create the underlying set of X.

If X is a list, tuple, Python set, or `X.is_finite()` is true, this returns a wrapper around Python's enumerated immutable frozenset type with extra functionality. Otherwise it returns a more formal wrapper.

If you need the functionality of mutable sets, use Python's builtin set type.

EXAMPLES:

```
sage: X = Set(GF(9,'a'))
sage: X
{0, 1, 2, a, a + 1, a + 2, 2*a, 2*a + 1, 2*a + 2}
sage: type(X)
<class 'sage.sets.set.Set_object_enumerated'>
sage: Y = X.union(Set(QQ))
sage: Y
Set-theoretic union of {0, 1, 2, a, a + 1, a + 2, 2*a, 2*a + 1, 2*a + 2} and Set of elements of
sage: type(Y)
<class 'sage.sets.set.Set_object_union'>
```

Usually sets can be used as dictionary keys.

```
sage: d={Set([2*I,1+I]):10}
sage: d                    # key is randomly ordered
{{I + 1, 2*I}: 10}
sage: d[Set([1+I,2*I])]
10
sage: d[Set((1+I,2*I))]
10
```

The original object is often forgotten.

```
sage: v = [1,2,3]
sage: X = Set(v)
sage: X
{1, 2, 3}
sage: v.append(5)
sage: X
{1, 2, 3}
sage: 5 in X
False
```

Set also accepts iterators, but be careful to only give *finite* sets.

```
sage: list(Set(iter([1, 2, 3, 4, 5])))
[1, 2, 3, 4, 5]
```

class Set_object(*X*)

A set attached to an almost arbitrary object.

EXAMPLES:

```
sage: K = GF(19)
sage: Set(K)
{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18}
sage: S = Set(K)

sage: latex(S)
\left\{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18\right\}
sage: loads(S.dumps()) == S
True

sage: latex(Set(ZZ))
\Bold{Z}
```

cardinality()

Return the cardinality of this set, which is either an integer or Infinity.

EXAMPLES:

```
sage: Set(ZZ).cardinality()
+Infinity
sage: Primes().cardinality()
+Infinity
sage: Set(GF(5)).cardinality()
5
sage: Set(GF(5^2,'a')).cardinality()
25
```

difference(*X*)

Return the intersection of self and X.

EXAMPLES:

```
sage: X = Set(ZZ).difference(Primes())
sage: 4 in X
True
sage: 3 in X
False

sage: 4/1 in X
True

sage: X = Set(GF(9,'b')).difference(Set(GF(27,'c')))
sage: X
{0, 1, 2, b, b + 1, b + 2, 2*b, 2*b + 1, 2*b + 2}

sage: X = Set(GF(9,'b')).difference(Set(GF(27,'b')))
sage: X
{0, 1, 2, b, b + 1, b + 2, 2*b, 2*b + 1, 2*b + 2}
```

intersection(*X*)

Return the intersection of self and X.

EXAMPLES:

```
sage: X = Set(ZZ).intersection(Primes())
sage: 4 in X
False
sage: 3 in X
True

sage: 2/1 in X
True

sage: X = Set(GF(9,'b')).intersection(Set(GF(27,'c')))
sage: X
{}

sage: X = Set(GF(9,'b')).intersection(Set(GF(27,'b')))
sage: X
{}
```

is_finite()

EXAMPLES:

```
sage: Set(QQ).is_finite()
False
sage: Set(GF(250037)).is_finite()
True
sage: Set(Integers(2^1000000)).is_finite()
True
sage: Set([1,'a',ZZ]).is_finite()
True
```

object()

Return underlying object.

EXAMPLES:

```
sage: X = Set(QQ)
sage: X.object()
Rational Field
sage: X = Primes()
sage: X.object()
Set of all prime numbers: 2, 3, 5, 7, ...
```

subsets(*size=None*)

Return the Subset object representing the subsets of a set. If size is specified, return the subsets of that size.

EXAMPLES:

```
sage: X = Set([1,2,3])
sage: list(X.subsets())
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
sage: list(X.subsets(2))
[{1, 2}, {1, 3}, {2, 3}]
```

symmetric_difference(*X*)

Returns the symmetric difference of self and X.

EXAMPLES:

```
sage: X = Set([1,2,3]).symmetric_difference(Set([3,4]))
sage: X
{1, 2, 4}
```

union(*X*)
Return the union of self and X.

EXAMPLES:

```
sage: Set(QQ).union(Set(ZZ))
Set-theoretic union of Set of elements of Rational Field and Set of elements of Integer Ring
sage: Set(QQ) + Set(ZZ)
Set-theoretic union of Set of elements of Rational Field and Set of elements of Integer Ring
sage: X = Set(QQ).union(Set(GF(3))); X
Set-theoretic union of Set of elements of Rational Field and {0, 1, 2}
sage: 2/3 in X
True
sage: GF(3)(2) in X
True
sage: GF(5)(2) in X
False
sage: Set(GF(7)) + Set(GF(3))
{0, 1, 2, 3, 4, 5, 6, 1, 2, 0}
```

class **Set_object_difference**(*X*, *Y*)
Formal difference of two sets.

cardinality()
This tries to return the cardinality of this formal intersection.

Note that this is not likely to work in very much generality, and may just hang if either set involved is infinite.

EXAMPLES:

```
sage: X = Set(GF(13)).difference(Set(Primes()))
sage: X.cardinality()
8
```

class **Set_object_enumerated**(*X*)
A finite enumerated set.

cardinality()
EXAMPLES:

```
sage: Set([1,1]).cardinality()
1
```

difference(*other*)
Returns the set difference self-other.

EXAMPLES:

```
sage: X = Set([1,2,3,4])
sage: Y = Set([1,2])
sage: X.difference(Y)
{3, 4}
sage: Z = Set(ZZ)
sage: W = Set([2.5, 4, 5, 6])
sage: W.difference(Z)
{2.50000000000000}
```

frozenset()
Return the Python frozenset object associated to this set, which is an immutable set (hence hashable).

EXAMPLES:

```
sage: X = Set(GF(8,'c'))
sage: X
```

```
{0, 1, c, c + 1, c^2, c^2 + 1, c^2 + c, c^2 + c + 1}
sage: s = X.set(); s
set([0, 1, c, c + 1, c^2, c^2 + 1, c^2 + c, c^2 + c + 1])
sage: hash(s)
...
TypeError: set objects are unhashable
sage: s = X.frozenset(); s
frozenset([0, 1, c, c + 1, c^2, c^2 + 1, c^2 + c, c^2 + c + 1])
sage: hash(s)
-1390224788            # 32-bit
 561411537695332972    # 64-bit
sage: type(s)
<type 'frozenset'>
```

intersection(*other*)

Return the intersection of self and other.

EXAMPLES:

```
sage: X = Set(GF(8,'c'))
sage: Y = Set([GF(8,'c').0, 1, 2, 3])
sage: X.intersection(Y)
{1, c}
```

set()

Return the Python set object associated to this set.

Python has a notion of finite set, and often Sage sets have an associated Python set. This function returns that set.

EXAMPLES:

```
sage: X = Set(GF(8,'c'))
sage: X
{0, 1, c, c + 1, c^2, c^2 + 1, c^2 + c, c^2 + c + 1}
sage: X.set()
set([0, 1, c, c + 1, c^2, c^2 + 1, c^2 + c, c^2 + c + 1])
sage: type(X.set())
<type 'set'>
sage: type(X)
<class 'sage.sets.set.Set_object_enumerated'>
```

symmetric_difference(*other*)

Returns the set difference self-other.

EXAMPLES:

```
sage: X = Set([1,2,3,4])
sage: Y = Set([1,2])
sage: X.symmetric_difference(Y)
{3, 4}
sage: Z = Set(ZZ)
sage: W = Set([2.5, 4, 5, 6])
sage: U = W.symmetric_difference(Z)
sage: 2.5 in U
True
sage: 4 in U
False
sage: V = Z.symmetric_difference(W)
sage: V == U
True
sage: 2.5 in V
```

```
True
sage: 6 in V
False
```

union(*other*)

Return the union of self and other.

EXAMPLES:

```
sage: X = Set(GF(8,'c'))
sage: Y = Set([GF(8,'c').0, 1, 2, 3])
sage: X
{0, 1, c, c + 1, c^2, c^2 + 1, c^2 + c, c^2 + c + 1}
sage: Y
{1, c, 3, 2}
sage: X.union(Y)
{0, 1, c, c + 1, c^2, c^2 + 1, c^2 + c, c^2 + c + 1, 2, 3}
```

class Set_object_intersection(*X*, *Y*)

Formal intersection of two sets.

cardinality()

This tries to return the cardinality of this formal intersection.

Note that this is not likely to work in very much generality, and may just hang if either set involved is infinite.

EXAMPLES:

```
sage: X = Set(GF(13)).intersection(Set(ZZ))
sage: X.cardinality()
13
```

class Set_object_symmetric_difference(*X*, *Y*)

Formal symmetric difference of two sets.

cardinality()

This tries to return the cardinality of this formal symmetric difference.

Note that this is not likely to work in very much generality, and may just hang if either set involved is infinite.

EXAMPLES:

```
sage: X = Set(GF(13)).symmetric_difference(Set(range(5)))
sage: X.cardinality()
8
```

class Set_object_union(*X*, *Y*)

A formal union of two sets.

cardinality()

Return the cardinality of this set.

EXAMPLES:

```
sage: X = Set(GF(3)).union(Set(GF(2)))
sage: X
{0, 1, 2, 0, 1}
sage: X.cardinality()
5

sage: X = Set(GF(3)).union(Set(ZZ))
sage: X.cardinality()
+Infinity
```

is_Set(*x*)

Returns true if x is a Sage Set (not to be confused with a Python 2.4 set).

EXAMPLES:

```
sage: from sage.sets.set import is_Set
sage: is_Set([1,2,3])
False
sage: is_Set(set([1,2,3]))
False
sage: is_Set(Set([1,2,3]))
True
sage: is_Set(Set(QQ))
True
sage: is_Set(Primes())
True
```

10.11 The set of prime numbers

Primes()

Return the set of prime numbers.

EXAMPLES:

```
sage: P = Primes(); P
Set of all prime numbers: 2, 3, 5, 7, ...
```

We show various methods about the primes:

```
sage: P.cardinality()
+Infinity
sage: R = Primes()
sage: P == R
True
sage: 5 in P
True
sage: 100 in P
False
```

class **Primes_class**()

The set of prime numbers.

EXAMPLES:

```
sage: P = Primes(); P
Set of all prime numbers: 2, 3, 5, 7, ...
sage: loads(P.dumps()) == P
True
```

cardinality()

There is no largest prime number, so we say the set has infinite cardinality.

EXAMPLES:

```
sage: P = Primes()
sage: P.cardinality()
+Infinity
```

10.12 Families

A Family is an associative container which models a family $(f_i)_{i \in I}$. Then, `f[i]` returns the element of the family indexed by `i`. Whenever available, set and combinatorial class operations (counting, iteration, listing) on the family are induced from those of the index set. Families should be created through the `Family()` function.

AUTHORS:

- Nicolas Thiery (2008-02): initial release
- Florent Hivert (2008-04): various fixes, cleanups and improvements.

class AbstractFamily()

The abstract class for family

Any family belongs to a class which inherits from `AbstractFamily`.

hidden_keys()

Returns the hidden keys of the family, if any.

EXAMPLES:

```
sage: f = Family({3: 'a', 4: 'b', 7: 'd'})
sage: f.hidden_keys()
[]
```

map(*f, name=None*)

Returns the family $(f(\texttt{self}[i]))_{i \in I}$, where I is the index set of self.

TODO: good name?

EXAMPLES:

```
sage: f = Family({3: 'a', 4: 'b', 7: 'd'})
sage: g = f.map(lambda x: x+'1')
sage: list(g)
['a1', 'b1', 'd1']
```

zip(*f, other, name=None*)

Given two families with same index set I (and same hidden keys if relevant), returns the family $(f(self[i], other[i]))_{i \in I}$

TODO: generalize to any number of families and merge with map?

EXAMPLES:

```
sage: f = Family({3: 'a', 4: 'b', 7: 'd'})
sage: g = Family({3: '1', 4: '2', 7: '3'})
sage: h = f.zip(lambda x,y: x+y, g)
sage: list(h)
['a1', 'b2', 'd3']
```

Family(*indices, function=None, hidden_keys=, [], hidden_function=None, lazy=False, name=None*)

A Family is an associative container which models a family $(f_i)_{i \in I}$. Then, f[i] returns the element of the family indexed by i. Whenever available, set and combinatorial class operations (counting, iteration, listing) on the family are induced from those of the index set.

There are several available implementations (classes) for different usages; Family serves as a factory, and will create instances of the appropriate classes depending on its arguments.

EXAMPLES:

In its simplest form, a list l or a tuple by itself is considered as the family $(l[i]_{i \in I})$ where I is the range $0 \ldots, len(l)$. So Family(l) returns the corresponding family.

```
sage: f = Family([1,2,3])
sage: f
Family (1, 2, 3)
sage: f = Family((1,2,3))
sage: f
Family (1, 2, 3)
```

A family can also be constructed from a dictionary t. The resulting family is very close to t, except that the elements of the family are the values of t. Here, we define the family $(f_i)_{i\in\{3,4,7\}}$ with f_3='a', f_4='b', and f_7='d':

```
sage: f = Family({3: 'a', 4: 'b', 7: 'd'})
sage: f
Finite family {3: 'a', 4: 'b', 7: 'd'}
sage: f[7]
'd'
sage: len(f)
3
sage: list(f)
['a', 'b', 'd']
sage: [ x for x in f ]
['a', 'b', 'd']
sage: f.keys()
[3, 4, 7]
sage: 'b' in f
True
sage: 'e' in f
False
```

A family can also be constructed by its index set I and a function f, as in $(f(i))_{i\in I}$:

```
sage: f = Family([3,4,7], lambda i: 2*i)
sage: f
Finite family {3: 6, 4: 8, 7: 14}
sage: f.keys()
[3, 4, 7]
sage: f[7]
14
sage: list(f)
[6, 8, 14]
sage: [x for x in f]
[6, 8, 14]
sage: len(f)
3
```

By default, all images are computed right away, and stored in an internal dictionary:

```
sage: f = Family((3,4,7), lambda i: 2*i)
sage: f
Finite family {3: 6, 4: 8, 7: 14}
```

Note that this requires all the elements of the list to be hashable. One can ask instead for the images $f(i)$ to be computed lazily, when needed:

```
sage: f = Family([3,4,7], lambda i: 2r*i, lazy=True)
sage: f
Lazy family (<lambda>(i))_{i in [3, 4, 7]}
sage: f[7]
```

```
14
sage: list(f)
[6, 8, 14]
sage: [x for x in f]
[6, 8, 14]
```

This allows in particular for modeling infinite families:

```
sage: f = Family(ZZ, lambda i: 2r*i, lazy=True)
sage: f
Lazy family (<lambda>(i))_{i in Integer Ring}
sage: f.keys()
Integer Ring
sage: f[1]
2
sage: f[-5]
-10
sage: i = iter(f)
sage: i.next(), i.next(), i.next(), i.next(), i.next()
(0, 2, -2, 4, -4)
```

Note that the `lazy` keyword parameter is only needed to force laziness. Usually it is automatically set to a correct default value (ie: `False` for finite data structures and true for CombinatorialClasses:

```
sage: f == Family(ZZ, lambda i: 2r*i)
True
```

Beware that for those kind of families len(f) is not supposed to work. As a replacement, use the .cardinality() method:

```
sage: f = Family(Permutations(3), attrcall("to_lehmer_code"))
sage: list(f)
[[0, 0, 0], [0, 1, 0], [1, 0, 0], [1, 1, 0], [2, 0, 0], [2, 1, 0]]
sage: f.cardinality()
6
```

Caveat: Only certain families with lazy behavior can be pickled. In particular, only functions that work with Sage's pickle_function and unpickle_function (in sage.misc.fpickle) will correctly unpickle. The following two work:

```
sage: f = Family(Permutations(3), lambda p: p.to_lehmer_code()); f
Lazy family (<lambda>(i))_{i in Standard permutations of 3}
sage: f == loads(dumps(f))
True

sage: f = Family(Permutations(3), attrcall("to_lehmer_code")); f
Lazy family (i.to_lehmer_code())_{i in Standard permutations of 3}
sage: f == loads(dumps(f))
True
```

But this one don't:

```
sage: def plus_n(n): return lambda x: x+n
sage: f = Family([1,2,3], plus_n(3), lazy=True); f
Lazy family (<lambda>(i))_{i in [1, 2, 3]}
sage: f == loads(dumps(f))
...
ValueError: Cannot pickle code objects from closures
```

Finally, it can occasionally be useful to add some hidden elements in a family, which are accessible as f[i], but do not appear in the keys or the container operations:

```
sage: f = Family([3,4,7], lambda i: 2*i, hidden_keys=[2])
sage: f
Finite family {3: 6, 4: 8, 7: 14}
sage: f.keys()
[3, 4, 7]
sage: f.hidden_keys()
[2]
sage: f[7]
14
sage: f[2]
4
sage: list(f)
[6, 8, 14]
sage: [x for x in f]
[6, 8, 14]
sage: len(f)
3
```

The following example illustrates when the function is actually called:

```
sage: def compute_value(i):
...       print('computing 2*'+str(i))
...       return 2*i
sage: f = Family([3,4,7], compute_value, hidden_keys=[2])
computing 2*3
computing 2*4
computing 2*7
sage: f
Finite family {3: 6, 4: 8, 7: 14}
sage: f.keys()
[3, 4, 7]
sage: f.hidden_keys()
[2]
sage: f[7]
14
sage: f[2]
computing 2*2
4
sage: f[2]
4
sage: list(f)
[6, 8, 14]
sage: [x for x in f]
[6, 8, 14]
sage: len(f)
3
```

Here is a close variant where the function for the hidden keys is different from that for the other keys:

```
sage: f = Family([3,4,7], lambda i: 2*i, hidden_keys=[2], hidden_function = lambda i: 3*i)
sage: f
Finite family {3: 6, 4: 8, 7: 14}
sage: f.keys()
[3, 4, 7]
sage: f.hidden_keys()
[2]
```

```
sage: f[7]
14
sage: f[2]
6
sage: list(f)
[6, 8, 14]
sage: [x for x in f]
[6, 8, 14]
sage: len(f)
3
```

Family behaves the same way with FiniteCombinatorialClass instances and lists. This feature will eventually disappear when FiniteCombinatorialClass won't be needed anymore.

```
sage: f = Family(FiniteCombinatorialClass([1,2,3]))
sage: f
Combinatorial class with elements in [1, 2, 3]

sage: f = Family(FiniteCombinatorialClass([3,4,7]), lambda i: 2*i)
sage: f
Finite family {3: 6, 4: 8, 7: 14}
sage: f.keys()
[3, 4, 7]
sage: f[7]
14
sage: list(f)
[6, 8, 14]
sage: [x for x in f]
[6, 8, 14]
sage: len(f)
3
```

TESTS:

```
sage: f = Family({1:'a', 2:'b', 3:'c'})
sage: f
Finite family {1: 'a', 2: 'b', 3: 'c'}
sage: f[2]
'b'
sage: loads(dumps(f)) == f
True

sage: f = Family({1:'a', 2:'b', 3:'c'}, lazy=True)
Traceback (most recent call last):
ValueError: lazy keyword only makes sense together with function keyword !

sage: f = Family(range(1,27), lambda i: chr(i+96))
sage: f
    Finite family {1: 'a', 2: 'b', 3: 'c', 4: 'd', 5: 'e', 6: 'f', 7: 'g', 8: 'h', 9: 'i', 10: '
sage: f[2]
'b'
```

The factory `Family` is supposed to be idempotent. We test this feature here:

```
sage: from sage.sets.family import FiniteFamily, LazyFamily, TrivialFamily
sage: f = FiniteFamily({3: 'a', 4: 'b', 7: 'd'})
sage: g = Family(f)
sage: f == g
True

sage: f = Family([3,4,7], lambda i: 2r*i, hidden_keys=[2])
sage: g = Family(f)
sage: f == g
True

sage: f = LazyFamily([3,4,7], lambda i: 2r*i)
sage: g = Family(f)
sage: f == g
True

sage: f = TrivialFamily([3,4,7])
sage: g = Family(f)
sage: f == g
True
```

class FiniteFamily (*dictionary, keys=None*)

A FiniteFamily is an associative container which models a finite family $(f_i)_{i \in I}$. Its elements f_i are therefore its values. Instances should be created via the Family factory, which see for further examples and tests.

EXAMPLES: We define the family $(f_i)_{i \in \{3,4,7\}}$ with f_3=a, f_4=b, and f_7=d

```
sage: from sage.sets.family import FiniteFamily
sage: f = FiniteFamily({3: 'a', 4: 'b', 7: 'd'})
```

Individual elements are accessible as in a usual dictionary:

```
sage: f[7]
'd'
```

And the other usual dictionary operations are also available:

```
sage: len(f)
3
sage: f.keys()
[3, 4, 7]
```

However f behaves as a container for the f_i's:

```
sage: list(f)
['a', 'b', 'd']
sage: [ x for x in f ]
['a', 'b', 'd']
```

cardinality()

Returns the number of elements in self.

EXAMPLES:

```
sage: from sage.sets.family import FiniteFamily
sage: f = FiniteFamily({3: 'a', 4: 'b', 7: 'd'})
sage: f.cardinality()
3
```

class FiniteFamilyWithHiddenKeys(*dictionary, hidden_keys, hidden_function*)

A close variant of FiniteFamily where the family contains some hidden keys whose corresponding values are computed lazily (and remembered). Instances should be created via the Family factory, which see for examples and tests.

Caveat: Only instances of this class whose functions are compatible with sage.misc.fpickle can be pickled.

hidden_keys()

Returns self's hidden keys.

EXAMPLES:

```
sage: f = Family([3,4,7], lambda i: 2*i, hidden_keys=[2])
sage: f.hidden_keys()
[2]
```

class LazyFamily(*set, function, name=None*)

A LazyFamily(I, f) is an associative container which models the (possibly infinite) family $(f(i))_{i \in I}$.

Instances should be created via the Family factory, which see for examples and tests.

cardinality()

Return the number of elements in self.

EXAMPLES:

```
sage: from sage.sets.family import LazyFamily
sage: f = LazyFamily([3,4,7], lambda i: 2*i)
sage: f.cardinality()
3
```

keys()

Returns self's keys.

EXAMPLES:

```
sage: from sage.sets.family import LazyFamily
sage: f = LazyFamily([3,4,7], lambda i: 2*i)
sage: f.keys()
[3, 4, 7]
```

class TrivialFamily(*enumeration*)

`TrivialFamily(c)` turn the container c into a family indexed by the set $0, \ldots, len(c)$. The container c can be either a list or a tuple.

Instances should be created via the Family factory, which see for examples and tests.

cardinality()

Return the number of elements in self.

EXAMPLES:

```
sage: from sage.sets.family import TrivialFamily
sage: f = TrivialFamily([3,4,7])
sage: f.cardinality()
3
```

keys()

Returns self's keys.

EXAMPLES:

```
sage: from sage.sets.family import TrivialFamily
sage: f = TrivialFamily([3,4,7])
sage: f.keys()
[0, 1, 2]
```

10.13 Base class for parent objects

CLASS HIEARCHY:

```
SageObject
    CategoryObject
        Parent
```

TESTS: This came up in some subtle bug once.

```
sage: gp(2) + gap(3)
5
```

class EltPair()

class Parent()

Parents are the Sage/mathematical analogues of container objects in computer science.

Internal invariants: • self._element_init_pass_parent == guess_pass_parent(self, self._element_constructor) Ensures that self.__call__ passes down the parent properly to self._element_constructor. See #5979.

Hom()

Return the homspace `Hom(self, codomain, cat)` of all homomorphisms from self to codomain in the category cat. The default category is `category'()`.

EXAMPLES:

```
sage: R.<x,y> = PolynomialRing(QQ, 2)
sage: R.Hom(QQ)
Set of Homomorphisms from Multivariate Polynomial Ring in x, y over Rational Field to Ration
```

Homspaces are defined for very general Sage objects, even elements of familiar rings.

```
sage: n = 5; Hom(n,7)
Set of Morphisms from 5 to 7 in Category of elements of Integer Ring
sage: z=(2/3); Hom(z,8/1)
Set of Morphisms from 2/3 to 8 in Category of elements of Rational Field
```

This example illustrates the optional third argument:

```
sage: QQ.Hom(ZZ, Sets())
Set of Morphisms from Rational Field to Integer Ring in Category of sets
```

an_element()

Implementation of a function that returns an element (often non-trivial) of a parent object. This is cached. Parent structures that are should override `_an_element_()` instead.

EXAMPLES:

```
sage: CDF.an_element()
1.0*I
sage: ZZ[['t']].an_element()
t
```

coerce()

Return x as an element of self, if and only if there is a canonical coercion from the parent of x to self.

EXAMPLES:

```
sage: QQ.coerce(ZZ(2))
2
sage: ZZ.coerce(QQ(2))
...
TypeError: no canonical coercion from Rational Field to Integer Ring
```

We make an exception for zero:

```
sage: V = GF(7)^7
sage: V.coerce(0)
(0, 0, 0, 0, 0, 0, 0)
```

coerce_embedding()

Returns the embedding of self into some other parent, if such a parent exists.

This does not mean that there are no coercion maps from self into other fields, this is simply a specific morphism specified out of self and ususally denotes a special relationship (e.g. sub-objects, choice of completion, etc.)

EXAMPLES:

coerce_map_from()

This returns a Map object to coerce from S to self if one exists, or None if no such coercion exists.

EXAMPLES:

```
sage: ZZ.coerce_map_from(int)
Native morphism:
  From: Set of Python objects of type 'int'
  To:   Integer Ring
sage: QQ.coerce_map_from(ZZ)
Natural morphism:
  From: Integer Ring
  To:   Rational Field
```

construction()

Returns a pair (functor, parent) such that functor(parent) return self. If this ring does not have a functorial construction, return None.

EXAMPLES:

```
sage: QQ.construction()
(FractionField, Integer Ring)
sage: f, R = QQ['x'].construction()
sage: f
Poly[x]
sage: R
Rational Field
sage: f(R)
Univariate Polynomial Ring in x over Rational Field
```

convert_map_from()

This function returns a Map from S to self, which may or may not succeed on all inputs. If a coercion map from S to self exists, then the it will be returned. If a coercion from self to S exists, then it will attempt to return a section of that map.

Under the new coercion model, this is the fastest way to convert elements of S to elements of self (short of manually constructing the elements) and is used by __call__.

EXAMPLES:

```
sage: m = ZZ.convert_map_from(QQ)
sage: m(-35/7)
-5
```

```
sage: parent(m(-35/7))
Integer Ring
```

get_action()

Returns an action of self on S or S on self.

To provide additional actions, override _get_action_().

TESTS:

```
sage: M = QQ['y']^3
sage: M.get_action(ZZ['x']['y'])
Right scalar multiplication by Univariate Polynomial Ring in y over Univariate Polynomial Ri
sage: M.get_action(ZZ['x']) # should be None
```

has_coerce_map_from()

Return True if there is a natural map from S to self. Otherwise, return False.

EXAMPLES:

```
sage: RDF.has_coerce_map_from(QQ)
True
sage: RDF.has_coerce_map_from(QQ['x'])
False
sage: RDF['x'].has_coerce_map_from(QQ['x'])
True
sage: RDF['x,y'].has_coerce_map_from(QQ['x'])
True
```

hom()

Return the unique homomorphism from self to codomain that sends `self.gens()` to the entries of `im_gens`. Raises a TypeError if there is no such homomorphism.

INPUT:

- `im_gens` - the images in the codomain of the generators of this object under the homomorphism
- `codomain` - the codomain of the homomorphism
- `check` - whether to verify that the images of generators extend to define a map (using only canonical coercisions).

OUTPUT:

- a homomorphism self –> codomain

Note: As a shortcut, one can also give an object X instead of `im_gens`, in which case return the (if it exists) natural map to X.

EXAMPLE: Polynomial Ring We first illustrate construction of a few homomorphisms involving a polynomial ring.

```
sage: R.<x> = PolynomialRing(ZZ)
sage: f = R.hom([5], QQ)
sage: f(x^2 - 19)
6

sage: R.<x> = PolynomialRing(QQ)
sage: f = R.hom([5], GF(7))
...
TypeError: images do not define a valid homomorphism

sage: R.<x> = PolynomialRing(GF(7))
sage: f = R.hom([3], GF(49,'a'))
sage: f
Ring morphism:
```

```
  From: Univariate Polynomial Ring in x over Finite Field of size 7
  To:   Finite Field in a of size 7^2
  Defn: x |--> 3
sage: f(x+6)
2
sage: f(x^2+1)
3
```

EXAMPLE: Natural morphism

```
sage: f = ZZ.hom(GF(5))
sage: f(7)
2
sage: f
Ring Coercion morphism:
  From: Integer Ring
  To:   Finite Field of size 5
```

There might not be a natural morphism, in which case a TypeError exception is raised.

```
sage: QQ.hom(ZZ)
...
TypeError: Natural coercion morphism from Rational Field to Integer Ring not defined.
```

is_exact()

Return True if elements of this ring are represented exactly, i.e., there is no precision loss when doing arithmetic.

NOTE: This defaults to true, so even if it does return True you have no guarantee (unless the ring has properly overloaded this).

EXAMPLES: sage: QQ.is_exact() True sage: ZZ.is_exact() True sage: Qp(7).is_exact() False sage: Zp(7, type='capped-abs').is_exact() False

list()

Return a list of all elements in this object, if possible (the object must define an iterator).

Set_PythonType()

Return the (unique) Parent that represents the set of Python objects of a specified type.

EXAMPLES:

```
sage: from sage.structure.parent import Set_PythonType
sage: Set_PythonType(list)
Set of Python objects of type 'list'
sage: Set_PythonType(list) is Set_PythonType(list)
True
sage: S = Set_PythonType(tuple)
sage: S([1,2,3])
(1, 2, 3)
```

class **Set_PythonType_class**()

cardinality()

EXAMPLES:

```
sage: S = sage.structure.parent.Set_PythonType(bool)
sage: S.cardinality()
2
sage: S = sage.structure.parent.Set_PythonType(int)
sage: S.cardinality()
4294967296                          # 32-bit
```

```
18446744073709551616              # 64-bit
sage: S = sage.structure.parent.Set_PythonType(float)
sage: S.cardinality()
18437736874454810627
sage: S = sage.structure.parent.Set_PythonType(long)
sage: S.cardinality()
+Infinity
```

object()
EXAMPLES:

```
sage: S = sage.structure.parent.Set_PythonType(tuple)
sage: S.object()
<type 'tuple'>
```

class **Set_generic**()
Abstract base class for sets.

category()
The category that this set belongs to, which is the category of all sets.
EXAMPLES:

```
sage: Set(QQ).category()
Category of sets
```

object()

is_Parent()
Return True if x is a parent object, i.e., derives from sage.structure.parent.Parent and False otherwise.
EXAMPLES:

```
sage: from sage.structure.parent import is_Parent
sage: is_Parent(2/3)
False
sage: is_Parent(ZZ)
True
sage: is_Parent(Primes())
True
```

normalize_names()
TESTS:

```
sage: sage.structure.parent.normalize_names(5, 'x')
('x0', 'x1', 'x2', 'x3', 'x4')
sage: sage.structure.parent.normalize_names(2, ['x','y'])
('x', 'y')
```

10.14 The Coercion Model

The coercion model manages how elements of one parent get related to elements of another. For example, the integer 2 can canonically be viewed as an element of the rational numbers. (The Parent of a non-element is its Python type.)

```
sage: ZZ(2).parent()
Integer Ring
sage: QQ(2).parent()
Rational Field
```

The most prominent role of the coercion model is to make sense of binary operations between elements that have distinct parents. It does this by finding a parent where both elements make sense, and doing the operation there. For example:

```
sage: a = 1/2; a.parent()
Rational Field
sage: b = ZZ[x].gen(); b.parent()
Univariate Polynomial Ring in x over Integer Ring
sage: a+b
x + 1/2
sage: (a+b).parent()
Univariate Polynomial Ring in x over Rational Field
```

If there is a coercion (see below) from one of the parents to the other, the operation is always performed in the codomain of that coercion. Otherwise a reasonable attempt to create a new parent with coercion maps from both original parents is made. The results of these discoveries are cached. On failure, a TypeError is always raised.

Some arithmetic operations (such as multiplication) can indicate an action rather than arithmetic in a common parent. For example:

```
sage: E = EllipticCurve('37a')
sage: P = E(0,0)
sage: 5*P
(1/4 : -5/8 : 1)
```

where there is action of $\mathbf{Z}$ on the points of E given by the additive group law. Parents can specify how they act on or are acted upon by other parents.

There are two kinds of ways to get from one parent to another, coercions and conversions.

Coercions are canonical (possibly modulo a finite number of deterministic choices) morphisms, and the set of all coercions between all parents forms a commuting diagram (modulo possibly rounding issues). $\mathbf{Z} \to \mathbf{Q}$ is an example of a coercion. These are invoked implicitly by the coercion model.

Conversions try to construct an element out of their input if at all possible. Examples include sections of coercions, creating an element from a string or list, etc. and may fail on some inputs of a given type while succeeding on others (i.e. they may not be defined on the whole domain). Conversions are always explicitly invoked, and never used by the coercion model to resolve binary operations.

For more information on how to specify coercions, conversions, and actions, see the documentation for Parent.

class CoercionModel_cache_maps()

See also sage.categories.pushout

EXAMPLES:

```
sage: f = ZZ['t','x'].0 + QQ['x'].0 + CyclotomicField(13).gen(); f
t + x + (zeta13)
sage: f.parent()
Multivariate Polynomial Ring in t, x over Cyclotomic Field of order 13 and degree 12
sage: ZZ['x','y'].0 + ~Frac(QQ['y']).0
(x*y + 1)/y
sage: MatrixSpace(ZZ['x'], 2, 2)(2) + ~Frac(QQ['x']).0
[(2*x + 1)/x           0]
[          0 (2*x + 1)/x]
sage: f = ZZ['x,y,z'].0 + QQ['w,x,z,a'].0; f
w + x
sage: f.parent()
Multivariate Polynomial Ring in w, x, y, z, a over Rational Field
```

```
sage: ZZ['x,y,z'].0 + ZZ['w,x,z,a'].1
2*x
```

AUTHOR:

- Robert Bradshaw

analyse()

Emulate the process of doing arithmetic between xp and yp, returning a list of steps and the parent that the result will live in. The `explain` function is easier to use, but if one wants access to the acutal morphism and action objects (rather than their string representations) then this is the function to use.

EXAMPLES:

```
sage: cm = sage.structure.element.get_coercion_model()
sage: steps, res = cm.analyse(GF(7), ZZ)
sage: print steps
['Coercion on right operand via', Natural morphism:
  From: Integer Ring
  To:   Finite Field of size 7, 'Arithmetic performed after coercions.']
sage: print res
Finite Field of size 7
sage: f = steps[1]; type(f)
<type 'sage.rings.integer_mod.Integer_to_IntegerMod'>
sage: f(100)
2
```

bin_op()

Execute the operation op on x and y. It first looks for an action corresponding to op, and failing that, it tries to coerces x and y into the a common parent and calls op on them.

If it cannot make sense of the operation, a TypeError is raised.

INPUT:

- `x` - the left operand
- `y` - the right operand
- `op` - a python function taking 2 arguments

  Note: op is often an arithmitic operation, but need not be so.

EXAMPLES:

```
sage: cm = sage.structure.element.get_coercion_model()
sage: cm.bin_op(1/2, 5, operator.mul)
5/2
```

The operator can be any callable:

```
set Rational Field Integer Ring <function <lambda> at 0xc0b2270> None None
(Rational Field, Rational Field)
sage: R.<x> = ZZ['x']
sage: cm.bin_op(x^2-1, x+1, gcd)
x + 1
```

Actions are detected and performed:

```
sage: M = matrix(ZZ, 2, 2, range(4))
sage: V = vector(ZZ, [5,7])
sage: cm.bin_op(M, V, operator.mul)
(7, 31)
```

TESTS:

```
sage: class Foo:
...       def __rmul__(self, left):
...           return 'hello'
...
sage: H = Foo()
sage: print int(3)*H
hello
sage: print Integer(3)*H
hello
sage: print H*3
...
TypeError: unsupported operand parent(s) for '*': '<type 'instance'>' and 'Integer Ring'

sage: class Nonsense:
...       def __init__(self, s):
...           self.s = s
...       def __repr__(self):
...           return self.s
...       def __mul__(self, x):
...           return Nonsense(self.s + chr(x%256))
...       __add__ = __mul__
...       def __rmul__(self, x):
...           return Nonsense(chr(x%256) + self.s)
...       __radd__ = __rmul__
...
sage: a = Nonsense('blahblah')
sage: a*80
blahblahP
sage: 80*a
Pblahblah
sage: a+80
blahblahP
sage: 80+a
Pblahblah
```

canonical_coercion()

Given two elements x and y, with parents S and R respectively, find a common parent Z such that there are coercions $f : S \mapsto Z$ and $g : R \mapsto Z$ and return $f(x), g(y)$ which will have the same parent.

Raises a type error if no such Z can be found.

EXAMPLES:

```
sage: cm = sage.structure.element.get_coercion_model()
sage: cm.canonical_coercion(mod(2, 10), 17)
(2, 7)
sage: x, y = cm.canonical_coercion(1/2, matrix(ZZ, 2, 2, range(4)))
sage: x
[1/2   0]
[  0 1/2]
sage: y
[0 1]
[2 3]
sage: parent(x) is parent(y)
True
```

There is some support for non-Sage datatypes as well:

```
sage: x, y = cm.canonical_coercion(int(5), 10)
sage: type(x), type(y)
(<type 'sage.rings.integer.Integer'>, <type 'sage.rings.integer.Integer'>)
```

```
sage: x, y = cm.canonical_coercion(int(5), complex(3))
sage: type(x), type(y)
(<type 'complex'>, <type 'complex'>)

sage: class MyClass:
...       def _sage_(self):
...           return 13
sage: a, b = cm.canonical_coercion(MyClass(), 1/3)
sage: a, b
(13, 1/3)
sage: type(a)
<type 'sage.rings.rational.Rational'>
```

We also make an exception for 0, even if ZZ does not map in:

```
sage: canonical_coercion(vector([1, 2, 3]), 0)
((1, 2, 3), (0, 0, 0))
```

coercion_maps()

Give two parents R and S, return a pair of coercion maps $f : R \to Z$ and $g : S \to Z$, if such a Z can be found.

In the (common) case that $R = Z$ or $S = Z$ then `None` is returned for f or g respectively rather than constructing (and subsequently calling) the identity morphism.

If no suitable f, g can be found, a single None is returned. This result is cached.

EXAMPLES:

```
sage: cm = sage.structure.element.get_coercion_model()
sage: f, g = cm.coercion_maps(ZZ, QQ)
sage: print f
Natural morphism:
  From: Integer Ring
  To:   Rational Field
sage: print g
None

sage: f, g = cm.coercion_maps(ZZ['x'], QQ)
sage: print f
Conversion map:
  From: Univariate Polynomial Ring in x over Integer Ring
  To:   Univariate Polynomial Ring in x over Rational Field
sage: print g
Polynomial base injection morphism:
  From: Rational Field
  To:   Univariate Polynomial Ring in x over Rational Field

sage: cm.coercion_maps(QQ, GF(7)) == None
True
```

Note that to break symmetry, if there is a coercion map in both directions, the parent on the left is used:

```
sage: V = QQ^3
sage: W = V.__class__(QQ, 3)
sage: V == W
True
sage: V is W
False
sage: cm = sage.structure.element.get_coercion_model()
sage: cm.coercion_maps(V, W)
```

```
(None,
 Call morphism:
  From: Vector space of dimension 3 over Rational Field
  To:   Vector space of dimension 3 over Rational Field)
sage: cm.coercion_maps(W, V)
(None,
 Call morphism:
  From: Vector space of dimension 3 over Rational Field
  To:   Vector space of dimension 3 over Rational Field)
sage: v = V([1,2,3])
sage: w = W([1,2,3])
sage: parent(v+w) is V
True
sage: parent(w+v) is W
True
```

discover_action()

INPUT

- R - the left Parent (or type)
- S - the right Parent (or type)
- op - the operand, typically an element of the operator module.

OUTPUT:

- An action A such that s op r is given by A(s,r).

The steps taken are illistrated below.

EXAMPLES:

```
sage: P.<x> = ZZ['x']
sage: P.get_action(ZZ)
Right scalar multiplication by Integer Ring on Univariate Polynomial Ring in x over Integer
sage: ZZ.get_action(P) is None
True
sage: cm = sage.structure.element.get_coercion_model()
```

If R or S is a Parent, ask it for an action by/on R:

```
sage: cm.discover_action(ZZ, P, operator.mul)
Left scalar multiplication by Integer Ring on Univariate Polynomial Ring in x over Integer R
```

If R or S a type, recursively call get_action with the Sage versions of R and/or S:

```
sage: cm.discover_action(P, int, operator.mul)
Right scalar multiplication by Integer Ring on Univariate Polynomial Ring in x over Integer
with precomposition on right by Native morphism:
  From: Set of Python objects of type 'int'
  To:   Integer Ring
```

If op in an inplace operation, look for the non-inplace action:

```
sage: cm.discover_action(P, ZZ, operator.imul)
Right scalar multiplication by Integer Ring on Univariate Polynomial Ring in x over Integer
```

If op is division, look for action on right by inverse:

```
sage: cm.discover_action(P, ZZ, operator.div)
Right inverse action by Rational Field on Univariate Polynomial Ring in x over Integer Ring
with precomposition on right by Natural morphism:
  From: Integer Ring
  To:   Rational Field
```

discover_coercion()

This actually implements the finding of coercion maps as described in the `coercion_maps` method.

EXAMPLES:

```
sage: cm = sage.structure.element.get_coercion_model()
```

If R is S, then two identity morphisms suffice:

```
sage: cm.discover_coercion(SR, SR)
(None, None)
```

If there is a coercion map either direction, use that:

```
sage: cm.discover_coercion(ZZ, QQ)
(Natural morphism:
  From: Integer Ring
  To:   Rational Field, None)
sage: cm.discover_coercion(RR, QQ)
(None,
 Generic map:
  From: Rational Field
  To:   Real Field with 53 bits of precision)
```

Otherwise, try and compute an appropriate cover:

```
sage: cm.discover_coercion(ZZ['x,y'], RDF)
(Call morphism:
  From: Multivariate Polynomial Ring in x, y over Integer Ring
  To:   Multivariate Polynomial Ring in x, y over Real Double Field,
 Call morphism:
  From: Real Double Field
  To:   Multivariate Polynomial Ring in x, y over Real Double Field)
```

Sometimes there is a reasonable "cover," but no canonical coercion:

```
sage: sage.categories.pushout.pushout(QQ, QQ^3)
Vector space of dimension 3 over Rational Field
sage: print cm.discover_coercion(QQ, QQ^3)
None
```

division_parent()

Deduces where the result of division in parent lies by calculating the inverse of `parent.one_element()` or `parent.an_element()`.

The result is cached.

EXAMPLES:

```
sage: cm = sage.structure.element.get_coercion_model()
sage: cm.division_parent(ZZ)
Rational Field
sage: cm.division_parent(QQ)
Rational Field
sage: cm.division_parent(ZZ['x'])
Fraction Field of Univariate Polynomial Ring in x over Integer Ring
sage: cm.division_parent(GF(41))
Finite Field of size 41
sage: cm.division_parent(Integers(100))
Ring of integers modulo 100
sage: cm.division_parent(SymmetricGroup(5))
Symmetric group of order 5! as a permutation group
```

exception_stack()

Returns the list of exceptions that were caught in the course of executing the last binary operation. Useful

for diagnosis when user-defined maps or actions raise exceptions that are caught in the course of coercion detection.

If all went well, this should be the empty list. If things aren't happening as you expect, this is a good place to check. See also `coercion_traceback()`.

EXAMPLES:

```
sage: cm = sage.structure.element.get_coercion_model()
sage: 1/2 + 2
5/2
sage: cm.exception_stack()
[]
sage: 1/2 + GF(3)(2)
...
TypeError: unsupported operand parent(s) for '+': 'Rational Field' and 'Finite Field of size
```

Now see what the actual problem was:

```
sage: import traceback
sage: cm.exception_stack()
[(<type 'exceptions.TypeError'>, TypeError("BUG: the base_extend method must be defined for
sage: print ''.join(sum([traceback.format_exception(*info) for info in cm.exception_stack()]
...
TypeError: no common canonical parent for objects with parents: 'Rational Field' and 'Finite
```

This is typically accessed via the `coercion_traceback()` function.

```
sage: coercion_traceback()
...
TypeError: no common canonical parent for objects with parents: 'Rational Field' and 'Finite
```

explain()

This function can be used to understand what coercions will happen for an arithmetic operation between xp and yp (which may be either elements or parents). If the parent of the result can be determined then it will be returned.

EXAMPLES:

```
sage: cm = sage.structure.element.get_coercion_model()

sage: cm.explain(ZZ, ZZ)
Identical parents, arithmetic performed immediately.
Result lives in Integer Ring
Integer Ring

sage: cm.explain(QQ, int)
Coercion on right operand via
    Native morphism:
      From: Set of Python objects of type 'int'
      To:   Rational Field
Arithmetic performed after coercions.
Result lives in Rational Field
Rational Field

sage: cm.explain(ZZ['x'], QQ)
Action discovered.
    Right scalar multiplication by Rational Field on Univariate Polynomial Ring in x over In
Result lives in Univariate Polynomial Ring in x over Rational Field
Univariate Polynomial Ring in x over Rational Field

sage: cm.explain(ZZ['x'], QQ, operator.add)
Coercion on left operand via
```

```
    Conversion map:
      From: Univariate Polynomial Ring in x over Integer Ring
      To:   Univariate Polynomial Ring in x over Rational Field
Coercion on right operand via
    Polynomial base injection morphism:
      From: Rational Field
      To:   Univariate Polynomial Ring in x over Rational Field
Arithmetic performed after coercions.
Result lives in Univariate Polynomial Ring in x over Rational Field
Univariate Polynomial Ring in x over Rational Field
```

Sometimes with non-sage types there is not enough information to deduce what will actually happen:

```
sage: cm.explain(RealField(100), float, operator.add)
Right operand is numeric, will attempt coercion in both directions.
Unknown result parent.
sage: parent(RealField(100)(1) + float(1))
<type 'float'>
sage: cm.explain(QQ, float, operator.add)
Right operand is numeric, will attempt coercion in both directions.
Unknown result parent.
sage: parent(QQ(1) + float(1))
<type 'float'>
```

Special care is taken to deal with division:

```
sage: cm.explain(ZZ, ZZ, operator.div)
Identical parents, arithmetic performed immediately.
Result lives in Rational Field
Rational Field

sage: cm.explain(ZZ['x'], QQ['x'], operator.div)
Coercion on left operand via
    Conversion map:
      From: Univariate Polynomial Ring in x over Integer Ring
      To:   Univariate Polynomial Ring in x over Rational Field
Arithmetic performed after coercions.
Result lives in Fraction Field of Univariate Polynomial Ring in x over Rational Field
Fraction Field of Univariate Polynomial Ring in x over Rational Field

sage: cm.explain(int, ZZ, operator.div)
Coercion on left operand via
    Native morphism:
      From: Set of Python objects of type 'int'
      To:   Integer Ring
Arithmetic performed after coercions.
Result lives in Rational Field
Rational Field

sage: cm.explain(ZZ['x'], ZZ, operator.div)
Action discovered.
    Right inverse action by Rational Field on Univariate Polynomial Ring in x over Integer R
    with precomposition on right by Natural morphism:
      From: Integer Ring
      To:   Rational Field
Result lives in Univariate Polynomial Ring in x over Rational Field
Univariate Polynomial Ring in x over Rational Field
```

Note: This function is accurate only in so far as analyse is kept in sync with the `bin_op()` and `canonical_coercion()` which are kept seperate for maximal efficiency.

get_action()

Get the action of R on S or S on R associated to the operation op.

EXAMPLES:

```
sage: cm = sage.structure.element.get_coercion_model()
sage: cm.get_action(ZZ['x'], ZZ, operator.mul)
Right scalar multiplication by Integer Ring on Univariate Polynomial Ring in x over Integer
sage: cm.get_action(ZZ['x'], ZZ, operator.imul)
Right scalar multiplication by Integer Ring on Univariate Polynomial Ring in x over Integer
sage: cm.get_action(ZZ['x'], QQ, operator.mul)
Right scalar multiplication by Rational Field on Univariate Polynomial Ring in x over Intege
sage: cm.get_action(QQ['x'], int, operator.mul)
Right scalar multiplication by Integer Ring on Univariate Polynomial Ring in x over Rational
with precomposition on right by Native morphism:
  From: Set of Python objects of type 'int'
  To:   Integer Ring

sage: R.<x> = QQ['x']
sage: A = cm.get_action(R, ZZ, operator.div); A
Right inverse action by Rational Field on Univariate Polynomial Ring in x over Rational Fiel
with precomposition on right by Natural morphism:
  From: Integer Ring
  To:   Rational Field
sage: A(x+10, 5)
1/5*x + 2
```

get_cache()

This returns the current cache of coercion maps and actions, primarily useful for debugging and introspection.

EXAMPLES:

```
sage: 1 + 1/2
3/2
sage: cm = sage.structure.element.get_coercion_model()
sage: maps, actions = cm.get_cache()
```

Now lets see what happens when we do a binary operations with an integer and a rational:

```
sage: left_morphism, right_morphism = maps[ZZ, QQ]
sage: print left_morphism
Natural morphism:
  From: Integer Ring
  To:   Rational Field
sage: print right_morphism
None
```

We can see that it coerces the left operand from an integer to a rational, and doesn't do anything to the right.

Now for some actions:

```
sage: R.<x> = ZZ['x']
sage: 1/2 * x
1/2*x
sage: maps, actions = cm.get_cache()
sage: act = actions[QQ, R, operator.mul]; act
Left scalar multiplication by Rational Field on Univariate Polynomial Ring in x over Integer
sage: act.actor()
Rational Field
sage: act.domain()
Univariate Polynomial Ring in x over Integer Ring
```

```
sage: act.codomain()
Univariate Polynomial Ring in x over Rational Field
sage: act(1/5, x+10)
1/5*x + 2
```

get_stats()

This returns the state of the cache of coercion maps and actions, primarily useful for debugging and introspection. If a class is not part of the coercion system, we should call the __rmul__ method when it makes sense.

The coercion maps are stored in a specialized TripleDict hashtable, and the stats returned are (min, avg, max) of the number of items per bucket. The lower the better.

EXAMPLES:

```
sage: cm = sage.structure.element.get_coercion_model()
sage: cm.get_stats()                # random
((0, 0.16058394160583941, 2), (0, 0.13138686131386862, 3))
```

reset_cache()

Clear the coercion cache.

This should have no impact on the result of arithmetic operations, as the exact same coercions and actions will be re-discovered when needed.

It may be useful for debugging, and may also free some memory.

EXAMPLES:

```
sage: cm = sage.structure.element.get_coercion_model()
sage: cm.get_stats()                # random
((0, 0.3307086614173229, 3), (0, 0.1496062992125984, 2))
sage: cm.reset_cache()
sage: cm.get_stats()
((0, 0.0, 0), (0, 0.0, 0))
```

verify_action()

Verify that `action` takes an element of R on the left and S on the right, raising an error if not.

This is used for consistency checking in the coercion model.

EXAMPLES:

```
sage: R.<x> = ZZ['x']
sage: cm = sage.structure.element.get_coercion_model()
sage: cm.verify_action(R.get_action(QQ), R, QQ, operator.mul)
Right scalar multiplication by Rational Field on Univariate Polynomial Ring in x over Intege
sage: cm.verify_action(R.get_action(QQ), RDF, R, operator.mul)
...
RuntimeError: There is a BUG in the coercion model:
    Action found for R <built-in function mul> S does not have the correct domains
    R = Real Double Field
    S = Univariate Polynomial Ring in x over Integer Ring
    (should be Univariate Polynomial Ring in x over Integer Ring, Rational Field)
    action = Right scalar multiplication by Rational Field on Univariate Polynomial Ring in
```

verify_coercion_maps()

Make sure this is a valid pair of homomorphisms from R and S to a common parent. This function is used to protect the user against buggy parents.

EXAMPLES:

```
sage: cm = sage.structure.element.get_coercion_model()
sage: homs = QQ.coerce_map_from(ZZ), None
sage: cm.verify_coercion_maps(ZZ, QQ, homs) == homs
```

```
        True
        sage: homs = QQ.coerce_map_from(ZZ), RR.coerce_map_from(QQ)
        sage: cm.verify_coercion_maps(ZZ, QQ, homs) == homs
        ...
        RuntimeError: ('BUG in coercion model, codomains must be identical', Natural morphism:
          From: Integer Ring
          To:   Rational Field, Generic map:
          From: Rational Field
          To:   Real Field with 53 bits of precision)
```

parent()

py_scalar_parent()

Returns the Sage equivalent of the given python type, if one exists. If there is no equivalent, return None.

EXAMPLES:

```
sage: from sage.structure.coerce import py_scalar_parent
sage: py_scalar_parent(int)
Integer Ring
sage: py_scalar_parent(long)
Integer Ring
sage: py_scalar_parent(float)
Real Double Field
sage: py_scalar_parent(complex)
Complex Double Field
sage: py_scalar_parent(dict),
(None,)
```

10.15 Coerce actions

class IntegerMulAction()

class LAction()

class LeftModuleAction()

class ModuleAction()

codomain()

The codomain of self, which may or may not be equal to the domain.

EXAMPLES:

```
sage: from sage.structure.coerce_actions import LeftModuleAction
sage: A = LeftModuleAction(QQ, ZZ['x,y,z'])
sage: A.codomain()
Multivariate Polynomial Ring in x, y, z over Rational Field
```

domain()

The domain of self, which is the module that is being acted on.

EXAMPLES:

```
sage: from sage.structure.coerce_actions import LeftModuleAction
sage: A = LeftModuleAction(QQ, ZZ['x,y,z'])
sage: A.domain()
Multivariate Polynomial Ring in x, y, z over Integer Ring
```

class PyScalarAction()

class RAction()

class RightModuleAction()

is_inplace

parent()

10.16 Coerce maps

class CCallableConvertMap_class()

class CallableConvertMap()

class DefaultConvertMap()
This morphism simply calls the codomain's element_constructor method, passing in the codomain as the first argument.

class DefaultConvertMap_unique()
This morphism simply defers action to the codomain's element_constructor method, WITHOUT passing in the codomain as the first argument.

This is used for creating elements that don't take a parent as the first argument to their __init__ method, for example, Integers, Rationals, Algebraic Reals... all have a unique parent. It is also used when the element_constructor is a bound method (whose self argument is assumed to be bound to the codomain).

class ListMorphism()

class NamedConvertMap()
This is used for creating a elements via the _xxx_ methods.

For example, many elements implement an _integer_ method to convert to ZZ, or a _rational_ method to convert to QQ.

method_name

class TryMap()

test_CCallableConvertMap()
For testing CCallableConvertMap_class.

TESTS:

```
sage: from sage.structure.coerce_maps import test_CCallableConvertMap
sage: f = test_CCallableConvertMap(ZZ, 'test'); f
Conversion via c call 'test' map:
  From: Integer Ring
  To:   Integer Ring
sage: f(3)
24
sage: f(9)
720
```

CHAPTER

ELEVEN

MISCELLANEOUS

11.1 Miscellaneous functions

AUTHORS:

- William Stein
- William Stein (2006-04-26): added workaround for Windows where most users's home directory has a space in it.
- Robert Bradshaw (2007-09-20): Ellipsis range/iterator.

class AttrCallObject (*name, args, kwds*)

alarm (*seconds*)
Raise a KeyboardInterrupt exception in a given number of seconds. This is useful for automatically interrupting long computations and can be trapped using exception handling (just catch KeyboardInterrupt).

INPUT:

- `seconds` - integer

TESTS:

```
sage: try: alarm(1); sleep(2)
... except KeyboardInterrupt: print "Alarm went off"
Alarm went off
```

assert_attribute (*x, attr, init=None*)
If the object x has the attribute attr, do nothing. If not, set x.attr to init.

attrcall (*name, *args, **kwds*)
Returns a callable which takes in an object, gets the method named name from that object, and calls it with the specified arguments and keywords.

INPUT:

- `name` - a string of the name of the method you want to call
- `args, kwds` - arguments and keywords to be passed to the methdod

EXAMPLES:

```
sage: f = attrcall('r_core', 3); f
*.r_core(3)
sage: [f(p) for p in Partitions(5)]
[[2], [1, 1], [1, 1], [3, 1, 1], [2], [2], [1, 1]]
```

branch_current_hg()
Return the current hg Mercurial branch name. If the branch is 'main', which is the default branch, then just '' is returned.

branch_current_hg_notice(*branch*)
Return a string describing the current branch and that the library is being loaded. This is called by the `SAGE_ROOT/local/bin/sage-sage` script.

INPUT:

- `string` - a representation of the name of the Sage library branch.

OUTPUT: string

Note: If the branch is main, then return an empty string.

class **cached_attribute**(*method, name=None*)
Computes attribute value and caches it in the instance.

class **cached_class_attribute**(*method, name=None*)
Computes attribute value and caches it in the class.

cancel_alarm()

cmp_props(*left, right, props*)

coeff_repr(*c, is_latex=False*)

cputime(*t=0*)
Return the time in CPU second since Sage started, or with optional argument t, return the time since time t. This is how much time Sage has spent using the CPU. It does not count time spent by subprocesses spawned by Sage (e.g., Gap, Singular, etc.).

This is done via a call to resource.getrusage, so it avoids the wraparound problems in time.clock() on Cygwin.

INPUT:

- `t` - (optional) float, time in CPU seconds

OUTPUT:

- `float` - time in CPU seconds

EXAMPLES:

```
sage: t = cputime()
sage: F = factor(2^199-1)
sage: cputime(t)          # somewhat random
0.29000000000000004

sage: w = walltime()
sage: F = factor(2^199-1)
sage: walltime(w)         # somewhat random
0.8823847770690918
```

delete_tmpfiles()

deprecation(*message*)
Issue a deprecation warning.

EXAMPLE:

```
sage: def foo():
...     sage.misc.misc.deprecation("The function foo is replaced by bar.")
...
sage: def my_function():
...     foo()
...
sage: my_function() # random: I don't know how to test the output.
doctest:1: DeprecationWarning: The function foo is replaced by bar.
```

ellipsis_iter(**args, **kwds*)

Same as ellipsis_range, but as an iterator (and may end with an Ellipsis).

See also ellipsis_range.

Use (1,2,...) notation.

EXAMPLES:

```
sage: A = ellipsis_iter(1,2,Ellipsis)
sage: [A.next() for _ in range(10)]
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
sage: A.next()
11
sage: A = ellipsis_iter(1,3,5,Ellipsis)
sage: [A.next() for _ in range(10)]
[1, 3, 5, 7, 9, 11, 13, 15, 17, 19]
sage: A = ellipsis_iter(1,2,Ellipsis,5,10,Ellipsis)
sage: [A.next() for _ in range(10)]
[1, 2, 3, 4, 5, 10, 11, 12, 13, 14]
```

TESTS:

These were carefully chosen tests, only to be changed if the semantics of ellipsis ranges change. In otherwords, if they don't pass it's probably a bug in the implementation, not in the doctest.

```
sage: list(1,..,10)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
sage: list(1,3,..,10)
[1, 3, 5, 7, 9]
sage: list(1,..,10,..,20)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20]
sage: list(1,3,..,10,..,20)
[1, 3, 5, 7, 9, 10, 12, 14, 16, 18, 20]
sage: list(1,3,..,10,10,..,20)
[1, 3, 5, 7, 9, 10, 12, 14, 16, 18, 20]
sage: list(0,2,..,10,10,..,20,20,..,25)
[0, 2, 4, 6, 8, 10, 10, 12, 14, 16, 18, 20, 20, 22, 24]
sage: list(10,..,1)
[]
sage: list(10,11,..,1)
[]
sage: list(10,9,..,1)
[10, 9, 8, 7, 6, 5, 4, 3, 2, 1]
sage: list(100,..,10,..,20)
[10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20]
sage: list(0,..,10,..,-20)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
sage: list(100,..,10,..,-20)
[]
```

```
sage: list(100,102,..,10,..,20)
[10, 12, 14, 16, 18, 20]
```

ellipsis_range(**args, **kwds*)

Return arithmetic sequence determined by the numeric arguments and ellipsis. Best illustrated by examples.

Use [1,2,..,n] notation.

EXAMPLES:

```
sage: ellipsis_range(1,Ellipsis,11,100)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 100]
sage: ellipsis_range(0,2,Ellipsis,10,Ellipsis,20)
[0, 2, 4, 6, 8, 10, 12, 14, 16, 18, 20]
sage: ellipsis_range(0,2,Ellipsis,11,Ellipsis,20)
[0, 2, 4, 6, 8, 10, 11, 13, 15, 17, 19]
sage: ellipsis_range(0,2,Ellipsis,11,Ellipsis,20, step=3)
[0, 2, 5, 8, 11, 14, 17, 20]
sage: ellipsis_range(10,Ellipsis,0)
[]
```

TESTS: These were carefully chosen tests, only to be changed if the semantics of ellipsis ranges change. In otherwords, if they don't pass it's probably a bug in the implementation, not in the doctest.

Note 10 only appears once (though it is in both ranges).

```
sage: ellipsis_range(0,Ellipsis,10,Ellipsis,20,step=2)
[0, 2, 4, 6, 8, 10, 12, 14, 16, 18, 20]
```

Sometimes one or more ranges is empty.

```
sage: ellipsis_range(100,Ellipsis,10,Ellipsis,20,step=2)
[10, 12, 14, 16, 18, 20]
sage: ellipsis_range(0,Ellipsis,10,Ellipsis,-20,step=2)
[0, 2, 4, 6, 8, 10]
sage: ellipsis_range(100,Ellipsis,10,Ellipsis,-20,step=2)
[]
```

We always start on the leftmost point of the range.

```
sage: ellipsis_range(0,Ellipsis,10,Ellipsis,20,step=3)
[0, 3, 6, 9, 10, 13, 16, 19]
sage: ellipsis_range(100,Ellipsis,10,Ellipsis,20,step=3)
[10, 13, 16, 19]
sage: ellipsis_range(0,Ellipsis,10,Ellipsis,-20,step=3)
[0, 3, 6, 9]
sage: ellipsis_range(100,Ellipsis,10,Ellipsis,-20,step=3)
[]
sage: ellipsis_range(0,1,Ellipsis,-10)
[]
sage: ellipsis_range(0,1,Ellipsis,-10,step=1)
[0]
sage: ellipsis_range(100,0,1,Ellipsis,-10)
[100]
```

Note the duplicate 5 in the output.

```
sage: ellipsis_range(0,Ellipsis,5,5,Ellipsis,10)
[0, 1, 2, 3, 4, 5, 5, 6, 7, 8, 9, 10]
```

Examples in which the step determines the parent of the elements:

```
sage: [1..3, step=0.5]
[1.00000000000000, 1.50000000000000, 2.00000000000000, 2.50000000000000, 3.00000000000000]
sage: v = [1..5, step=1/1]; v
[1, 2, 3, 4, 5]
sage: parent(v[2])
Rational Field
```

embedded()

Return True if this copy of Sage is running embedded in the Sage notebook.

EXAMPLES:

```
sage: sage.misc.misc.embedded()     # output True if in the notebook
False
```

exists(*S, P*)

If S contains an element x such that P(x) is True, this function returns True and the element x. Otherwise it returns False and None.

Note that this function is NOT suitable to be used in an if-statement or in any place where a boolean expression is expected. For those situations, use the Python built-in

any(P(x) for x in S)

INPUT:

- `S` - object (that supports enumeration)
- `P` - function that returns True or False

OUTPUT:

- `bool` - whether or not P is True for some element x of S
- `object` - x

EXAMPLES: lambda functions are very useful when using the exists function:

```
sage: exists([1,2,5], lambda x : x > 7)
(False, None)
sage: exists([1,2,5], lambda x : x > 3)
(True, 5)
```

The following example is similar to one in the MAGMA handbook. We check whether certain integers are a sum of two (small) cubes:

```
sage: cubes = [t**3 for t in range(-10,11)]
sage: exists([(x,y) for x in cubes for y in cubes], lambda v : v[0]+v[1] == 218)
(True, (-125, 343))
sage: exists([(x,y) for x in cubes for y in cubes], lambda v : v[0]+v[1] == 219)
(False, None)
```

forall(*S, P*)

If P(x) is true every x in S, return True and None. If there is some element x in S such that P is not True, return False and x.

Note that this function is NOT suitable to be used in an if-statement or in any place where a boolean expression is expected. For those situations, use the Python built-in

all(P(x) for x in S)

INPUT:

- S - object (that supports enumeration)
- P - function that returns True or False

OUTPUT:

- bool - whether or not P is True for all elements of S
- object - x

EXAMPLES: lambda functions are very useful when using the forall function. As a toy example we test whether certain integers are greater than 3.

```
sage: forall([1,2,5], lambda x : x > 3)
(False, 1)
sage: forall([1,2,5], lambda x : x > 0)
(True, None)
```

Next we ask whether every positive integer less than 100 is a product of at most 2 prime factors:

```
sage: forall(range(1,100),  lambda n : len(factor(n)) <= 2)
(False, 30)
```

The answer is no, and 30 is a counterexample. However, every positive integer 100 is a product of at most 3 primes.

```
sage: forall(range(1,100),  lambda n : len(factor(n)) <= 3)
(True, None)
```

generic_cmp(*x, y*)

Compare x and y and return -1, 0, or 1.

This is similar to x.__cmp__(y), but works even in some cases when a .__cmp__ method isn't defined.

get_verbose()

Return the global Sage verbosity level.

INPUT: int level: an integer between 0 and 2, inclusive.

OUTPUT: changes the state of the verbosity flag.

EXAMPLES:

```
sage: get_verbose()
0
sage: set_verbose(2)
sage: get_verbose()
2
sage: set_verbose(0)
```

get_verbose_files()

getitem(*v, n*)

Variant of getitem that coerces to an int if a TypeError is raised.

(This is not needed anymore - classes should define an __index__ method.)

Thus, e.g., getitem(v,n) will work even if v is a Python list and n is a Sage integer.

EXAMPLES:

```
sage: v = [1,2,3]
```

The following used to fail in Sage <= 1.3.7. Now it works fine:

```
sage: v[ZZ(1)]
2
```

This always worked.

```
sage: getitem(v, ZZ(1))
2
```

graphics_filename(*ext='png'*)
Return the next available canonical filename for a plot/graphics file.

is_in_string(*line, pos*)
Returns True if the character at position pos in line occurs within a string.

EXAMPLES: sage: from sage.misc.misc import is_in_string sage: line = 'test('#')' sage: is_in_string(line, line.rfind('#')) True sage: is_in_string(line, line.rfind(')')) False

class lazy_prop(*calculate_function*)

newton_method_sizes(*N*)
Returns a sequence of integers $1 = a_1 \leq a_2 \leq \cdots \leq a_n = N$ such that $a_j = \lceil a_{j+1}/2 \rceil$ for all j.

This is useful for Newton-style algorithms that double the precision at each stage. For example if you start at precision 1 and want an answer to precision 17, then it's better to use the intermediate stages 1, 2, 3, 5, 9, 17 than to use 1, 2, 4, 8, 16, 17.

INPUT:

- N - positive integer

EXAMPLES:

```
sage: newton_method_sizes(17)
[1, 2, 3, 5, 9, 17]
sage: newton_method_sizes(16)
[1, 2, 4, 8, 16]
sage: newton_method_sizes(1)
[1]
```

AUTHORS:

- David Harvey (2006-09-09)

pad_zeros(*s, size=3*)
EXAMPLES:

```
sage: pad_zeros(100)
'100'
sage: pad_zeros(10)
'010'
sage: pad_zeros(10, 5)
'00010'
sage: pad_zeros(389, 5)
'00389'
sage: pad_zeros(389, 10)
'0000000389'
```

powerset(*X*)
Iterator over the *list* of all subsets of the iterable X, in no particular order. Each list appears exactly once, up to order.

INPUT:

- X - an iterable

OUTPUT: iterator of lists

EXAMPLES:

```
sage: list(powerset([1,2,3]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]
sage: [z for z in powerset([0,[1,2]])]
[[], [0], [[1, 2]], [0, [1, 2]]]
```

Iterating over the power set of an infinite set is also allowed:

```
sage: i = 0
sage: for x in powerset(ZZ):
...     if i > 10:
...         break
...     else:
...         i += 1
...     print x,
[] [0] [1] [0, 1] [-1] [0, -1] [1, -1] [0, 1, -1] [2] [0, 2] [1, 2]
```

You may also use subsets as an alias for powerset:

```
sage: subsets([1,2,3])   # random object location in output
<generator object at 0xaeae418c>
sage: list(subsets([1,2,3]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]

The reason we return lists instead of sets is that the elements of
sets must be hashable and many structures on which one wants the
powerset consist of non-hashable objects.
```

AUTHORS:

- William Stein
- Nils Bruin (2006-12-19): rewrite to work for not-necessarily finite objects X.

prop(*f*)

random_sublist(*X*, *s*)

Return a pseudo-random sublist of the list X where the probability of including a particular element is s.

INPUT:

- X - list
- s - floating point number between 0 and 1

OUTPUT: list

EXAMPLES:

```
sage: S = [1,7,3,4,18]
sage: random_sublist(S, 0.5)
[1, 3, 4]
sage: random_sublist(S, 0.5)
[1, 3]
```

repr_lincomb(*symbols, coeffs, is_latex=False*)

Compute a string representation of a linear combination of some formal symbols.

INPUT:

- `symbols` - list of symbols
- `coeffs` - list of coefficients of the symbols

OUTPUT:

- `str` - a string

EXAMPLES:

```
sage: repr_lincomb(['a','b','c'], [1,2,3])
'a + 2*b + 3*c'
sage: repr_lincomb(['a','b','c'], [1,'2+3*x',3])
'a + (2+3*x)*b + 3*c'
sage: repr_lincomb(['a','b','c'], ['1+x^2','2+3*x',3])
'(1+x^2)*a + (2+3*x)*b + 3*c'
sage: repr_lincomb(['a','b','c'], ['1+x^2','-2+3*x',3])
'(1+x^2)*a + (-2+3*x)*b + 3*c'
sage: repr_lincomb(['a','b','c'], [1,-2,-3])
'a - 2*b - 3*c'
sage: t = PolynomialRing(RationalField(),'t').gen()
sage: repr_lincomb(['a', 's', ''], [-t,t-2,t**2+2])
'-t*a + (t-2)*s + (t^2+2)'
```

set_verbose(*level, files='all'*)

Set the global Sage verbosity level.

INPUT:

- `level` - an integer between 0 and 2, inclusive.
- **`files` (default: 'all'): list of files to make verbose, or** 'all' to make ALL files verbose (the default).

OUTPUT: changes the state of the verbosity flag and possibly appends to the list of files that are verbose.

EXAMPLES:

```
sage: set_verbose(2)
sage: verbose("This is Sage.", level=1)  # not tested
VERBOSE1 (?): This is Sage.
sage: verbose("This is Sage.", level=2)  # not tested
VERBOSE2 (?): This is Sage.
sage: verbose("This is Sage.", level=3)  # not tested
[no output]
sage: set_verbose(0)
```

set_verbose_files(*file_name*)

sourcefile(*object*)

Work out which source or compiled file an object was defined in.

srange(*start, end=None, step=1, universe=None, check=True, include_endpoint=False, endpoint_tolerance=1.0000000000000001e-05*)

Return list of numbers `a, a+step, ..., a+k*step`, where `a+k*step < b` and `a+(k+1)*step >= b` over exact rings, and makes a best attempt for inexact rings (see note below).

This provides one way to iterate over Sage integers as opposed to Python int's. It also allows you to specify step sizes for such an iteration. Note, however, that what is returned is a full list of Integers and not an iterator. It is potentially much slower than the Python range function, depending on the application. The function xsrange() provides an iterator with similar functionality which would usually be more efficient than using srange().

INPUT:

- `a` - number

- b - number (default: None)
- step - number (default: 1)
- universe - Parent or type where all the elements should live (default: deduce from inputs)
- check - make sure a, b, and step all lie in the same universe
- include_endpoint - whether or not to include the endpoint (default: False)
- endpoint_tolerance - used to determine whether or not the endpoint is hit for inexact rings (default 1e-5)

OUTPUT:

- list

If b is None, then b is set equal to a and a is set equal to the 0 in the parent of b.

Unlike range, a and b can be any type of numbers, and the resulting list involves numbers of that type.

Note: The list elements are computed via repeated addition rather than multiplication, which may produce slightly different results with inexact rings. For example:

```
sage: sum([1.1] * 10) == 1.1 * 10
False
```

Also, the question of whether the endpoint is hit exactly for a given `a + k*step` is fuzzy for an inexact ring. If `a + k*step = b` for some k within `endpoint_tolerance` of being integral, it is considered an exact hit, thus avoiding spurious values falling just below the endpoint.

Note: This function is called `srange` to distinguish it from the builtin Python `range` command. The s at the beginning of the name stands for "Sage".

EXAMPLES:

```
sage: v = srange(5); v
[0, 1, 2, 3, 4]
sage: type(v[2])
<type 'sage.rings.integer.Integer'>
sage: srange(1, 10)
[1, 2, 3, 4, 5, 6, 7, 8, 9]
sage: srange(10, 1, -1)
[10, 9, 8, 7, 6, 5, 4, 3, 2]
sage: srange(10,1,-1, include_endpoint=True)
[10, 9, 8, 7, 6, 5, 4, 3, 2, 1]
sage: srange(1, 10, universe=RDF)
[1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0]

sage: srange(1, 10, 1/2)
[1, 3/2, 2, 5/2, 3, 7/2, 4, 9/2, 5, 11/2, 6, 13/2, 7, 15/2, 8, 17/2, 9, 19/2]
sage: srange(1, 5, 0.5)
[1.00000000000000, 1.50000000000000, 2.00000000000000, 2.50000000000000, 3.00000000000000, 3.500
sage: srange(0, 1, 0.4)
[0.000000000000000, 0.400000000000000, 0.800000000000000]
sage: srange(1.0, 5.0, include_endpoint=True)
[1.00000000000000, 2.00000000000000, 3.00000000000000, 4.00000000000000, 5.00000000000000]
sage: srange(1.0, 1.1)
[1.00000000000000]
sage: srange(1.0, 1.0)
[]
sage: V = VectorSpace(QQ, 2)
sage: srange(V([0,0]), V([5,5]), step=V([2,2]))
[(0, 0), (2, 2), (4, 4)]
```

Including the endpoint:: sage: srange(0, 10, step=2, include_endpoint=True) [0, 2, 4, 6, 8, 10] sage: srange(0, 10, step=3, include_endpoint=True) [0, 3, 6, 9]

Try some inexact rings:

```
sage: srange(0.5, 1.1, 0.1, universe=RDF, include_endpoint=False)
[0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
sage: srange(0.5, 1, 0.1, universe=RDF, include_endpoint=False)
[0.5, 0.6, 0.7, 0.8, 0.9]
sage: srange(0.5, 0.9, 0.1, universe=RDF, include_endpoint=False)
[0.5, 0.6, 0.7, 0.8]
sage: srange(0, 1.1, 0.1, universe=RDF, include_endpoint=True)
[0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0, 1.1]
sage: srange(0, 0.2, 0.1, universe=RDF, include_endpoint=True)
[0.0, 0.1, 0.2]
sage: srange(0, 0.3, 0.1, universe=RDF, include_endpoint=True)
[0.0, 0.1, 0.2, 0.3]
```

strunc(*s, n=60*)

Truncate at first space after position n, adding '...' if nontrivial truncation.

subsets(*X*)

Iterator over the *list* of all subsets of the iterable X, in no particular order. Each list appears exactly once, up to order.

INPUT:

- X - an iterable

OUTPUT: iterator of lists

EXAMPLES:

```
sage: list(powerset([1,2,3]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]
sage: [z for z in powerset([0,[1,2]])]
[[], [0], [[1, 2]], [0, [1, 2]]]
```

Iterating over the power set of an infinite set is also allowed:

```
sage: i = 0
sage: for x in powerset(ZZ):
...     if i > 10:
...         break
...     else:
...         i += 1
...     print x,
[] [0] [1] [0, 1] [-1] [0, -1] [1, -1] [0, 1, -1] [2] [0, 2] [1, 2]
```

You may also use subsets as an alias for powerset:

```
sage: subsets([1,2,3])    # random object location in output
<generator object at 0xaeae418c>
sage: list(subsets([1,2,3]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]

The reason we return lists instead of sets is that the elements of
sets must be hashable and many structures on which one wants the
powerset consist of non-hashable objects.
```

AUTHORS:

- William Stein
- Nils Bruin (2006-12-19): rewrite to work for not-necessarily finite objects X.

sxrange(*start, end=None, step=1, universe=None, check=True, include_endpoint=False, endpoint_tolerance=1.0000000000000001e-05*)

Return an iterator over numbers `a, a+step, ..., a+k*step`, where `a+k*step < b` and `a+(k+1)*step > b`.

INPUT: universe – Parent or type where all the elements should live (default: deduce from inputs) check – make sure a, b, and step all lie in the same universe include_endpoint – whether or not to include the endpoint (default: False) endpoint_tolerance – used to determine whether or not the endpoint is hit for inexact rings (default 1e-5)

- `a` - number
- `b` - number
- `step` - number (default: 1)

OUTPUT: iterator

Unlike range, a and b can be any type of numbers, and the resulting iterator involves numbers of that type.

See Also:

`srange()`

Note: This function is called `xsrange` to distinguish it from the builtin Python `xrange` command.

EXAMPLES:

```
sage: list(xsrange(1,10))
[1, 2, 3, 4, 5, 6, 7, 8, 9]
sage: Q = RationalField()
sage: list(xsrange(1, 10, Q('1/2')))
[1, 3/2, 2, 5/2, 3, 7/2, 4, 9/2, 5, 11/2, 6, 13/2, 7, 15/2, 8, 17/2, 9, 19/2]
sage: list(xsrange(1, 5, 0.5))
[1.00000000000000, 1.50000000000000, 2.00000000000000, 2.50000000000000, 3.00000000000000, 3.500
sage: list(xsrange(0, 1, 0.4))
[0.000000000000000, 0.400000000000000, 0.800000000000000]
```

Negative ranges are also allowed:

```
sage: list(xrange(4,1,-1))
[4, 3, 2]
sage: list(sxrange(4,1,-1))
[4, 3, 2]
sage: list(sxrange(4,1,-1/2))
[4, 7/2, 3, 5/2, 2, 3/2]
```

tmp_dir(*name='dir'*)

Create and return a temporary directory in `$HOME/.sage/temp/hostname/pid/`

tmp_filename(*name='tmp'*)

to_gmp_hex(*n*)

todo(*mesg=''*)

typecheck(*x, C, var='x'*)

Check that x is of instance C. If not raise a TypeError with an error message.

union(*x, y=None*)

Return the union of x and y, as a list. The resulting list need not be sorted and can change from call to call.

INPUT:

- x - iterable
- y - iterable (may optionally omitted)

OUTPUT: list

EXAMPLES:

```
sage: answer = union([1,2,3,4], [5,6]); answer
[1, 2, 3, 4, 5, 6]
sage: union([1,2,3,4,5,6], [5,6]) == answer
True
sage: union((1,2,3,4,5,6), [5,6]) == answer
True
sage: union((1,2,3,4,5,6), set([5,6])) == answer
True
```

uniq(*x*)

Return the sublist of all elements in the list x that is sorted and is such that the entries in the sublist are unique.

EXAMPLES:

```
sage: v = uniq([1,1,8,-5,3,-5,'a','x','a'])
sage: v             # potentially random ordering of output
['a', 'x', -5, 1, 3, 8]
sage: set(v) == set(['a', 'x', -5, 1, 3, 8])
True
```

unset_verbose_files(*file_name*)

verbose(*mesg='', t=0, level=1, caller_name=None*)

Print a message if the current verbosity is at least level.

INPUT:

- mesg - str, a message to print
- t - int, optional, if included, will also print cputime(t), - which is the time since time t. Thus t should have been obtained with t=cputime()
- level - int, (default: 1) the verbosity level of what we are printing
- caller_name - string (default: None), the name of the calling function; in most cases Python can deduce this, so it need not be provided.

OUTPUT: possibly prints a message to stdout; also returns cputime()

EXAMPLE:

```
sage: set_verbose(1)
sage: t = cputime()
sage: t = verbose("This is Sage.", t, level=1, caller_name="william")       # not tested
VERBOSE1 (william): This is Sage. (time = 0.0)
sage: set_verbose(0)
```

walltime(*t=0*)

Return the wall time in second, or with optional argument t, return the wall time since time t. "Wall time" means the time on a wall clock, i.e., the actual time.

INPUT:

- t - (optional) float, time in CPU seconds

OUTPUT:

- float - time in seconds

EXAMPLES:

```
sage: w = walltime()
sage: F = factor(2^199-1)
sage: walltime(w)    # somewhat random
0.8823847770690918
```

word_wrap(*s, ncols=85*)

xsrange(*start, end=None, step=1, universe=None, check=True, include_endpoint=False, endpoint_tolerance=1.0000000000000001e-05*)

Return an iterator over numbers a, a+step, ..., a+k*step, where a+k*step < b and a+(k+1)*step > b.

INPUT: universe – Parent or type where all the elements should live (default: deduce from inputs) check – make sure a, b, and step all lie in the same universe include_endpoint – whether or not to include the endpoint (default: False) endpoint_tolerance – used to determine whether or not the endpoint is hit for inexact rings (default 1e-5)

- a - number
- b - number
- step - number (default: 1)

OUTPUT: iterator

Unlike range, a and b can be any type of numbers, and the resulting iterator involves numbers of that type.

See Also:

srange()

Note: This function is called xsrange to distinguish it from the builtin Python xrange command.

EXAMPLES:

```
sage: list(xsrange(1,10))
[1, 2, 3, 4, 5, 6, 7, 8, 9]
sage: Q = RationalField()
sage: list(xsrange(1, 10, Q('1/2')))
[1, 3/2, 2, 5/2, 3, 7/2, 4, 9/2, 5, 11/2, 6, 13/2, 7, 15/2, 8, 17/2, 9, 19/2]
sage: list(xsrange(1, 5, 0.5))
[1.00000000000000, 1.50000000000000, 2.00000000000000, 2.50000000000000, 3.00000000000000, 3.500
sage: list(xsrange(0, 1, 0.4))
[0.000000000000000, 0.400000000000000, 0.800000000000000]
```

Negative ranges are also allowed:

```
sage: list(xrange(4,1,-1))
[4, 3, 2]
sage: list(sxrange(4,1,-1))
[4, 3, 2]
sage: list(sxrange(4,1,-1/2))
[4, 7/2, 3, 5/2, 2, 3/2]
```

11.2 Sage package management commands

A Sage package has the extension .spkg. It is a tarball that is (usually) bzip2 compressed that contains arbitrary data and an spkg-install file. An Sage package typically has the following components:

- spkg-install - shell script that is run to install the package
- Sage.txt - file that describes how the package was made, who maintains it, etc.
- sage - directory with extra patched version of files that needed during the install

Use the `install_package` command to install a new package, and use `optional_packages` to list all optional packages available on the central Sage server. The `upgrade` command upgrades all *standard* packages - there is no auto-upgrade command for optional packages.

All package management can also be done via the Sage command line.

experimental_packages()

Return two lists. The first contains the installed and the second contains the not-installed experimental packages that are available from the Sage repository. You must have an internet connection.

OUTPUT:

•installed experimental packages (as a list)

•NOT installed experimental packages (as a list)

Use `install_package(package_name)` to install or re-install a given package.

See Also:

`install_package()`, `upgrade()`

install_all_optional_packages(*force=True, dry_run=False*)

Install all available optional spkg's in the official Sage spkg repository. Returns a list of all spkg's that *fail* to install.

INPUT: **force – bool (default: True); whether to force reinstall of** spkg's that are already installed.

dry_run – bool (default: False); if True, just list the packages that would be installed in order, but don't actually install them.

OUTPUT: list of strings

NOTE: This is designed mainly for testing purposes. This also doesn't do anything with respect to dependencies – the packages are installed in alphabetical order. Dependency issues will be dealt with in a future version.

AUTHOR: – William Stein (2008-12)

EXAMPLES: sage: sage.misc.package.install_all_optional_packages(dry_run=True) # optional - internet Installing ... []

install_package(*package=None, force=False*)

Install a package or return a list of all packages that have been installed into this Sage install.

You must have an internet connection. Also, you will have to restart Sage for the changes to take affect.

It is not needed to provide the version number.

INPUT:

•`package` - optional; if specified, install the given package. If not, list all installed packages.

IMPLEMENTATION: calls 'sage -f'.

See Also:

`optional_packages()`, `upgrade()`

is_package_installed(*package*)
Return true if a package starting with the given string is installed.

EXAMPLES:

```
sage: is_package_installed('sage')
True
```

optional_packages()
Return two lists. The first contains the installed and the second contains the not-installed optional packages that are available from the Sage repository. You must have an internet connection.

OUTPUT:

- installed optional packages (as a list)
- NOT installed optional packages (as a list)

Use `install_package(package_name)` to install or re-install a given package.

See Also:

`install_package()`, `upgrade()`

package_mesg(*package_name*)

standard_packages()
Return two lists. The first contains the installed and the second contains the not-installed standard packages that are available from the Sage repository. You must have an internet connection.

OUTPUT:

- installed standard packages (as a list)
- NOT installed standard packages (as a list)

Use `install_package(package_name)` to install or re-install a given package.

See Also:

`install_package()`, `upgrade()`

upgrade()
Download and build the latest version of Sage.

You must have an internet connection. Also, you will have to restart Sage for the changes to take affect.

This upgrades to the latest version of core packages (optional packages are not automatically upgraded).

This will not work on systems that don't have a C compiler.

See Also:

`install_package()`, `optional_packages()`

11.3 A tool for inspecting Python pickles

AUTHORS:

- Carl Witty (2009-03)

The explain_pickle function takes a pickle and produces Sage code that will evaluate to the contents of the pickle. Ideally, the combination of explain_pickle to produce Sage code and sage_eval to evaluate the code would be a 100% compatible implementation of cPickle's unpickler; this is almost the case now.

EXAMPLES:

```
sage: explain_pickle(dumps(12345))
pg_make_integer = unpickle_global('sage.rings.integer', 'make_integer')
pg_make_integer('c1p')
sage: explain_pickle(dumps(polygen(QQ)))
pg_Polynomial_rational_dense = unpickle_global('sage.rings.polynomial.polynomial_element_generic', 'P
pg_PolynomialRing = unpickle_global('sage.rings.polynomial.polynomial_ring_constructor', 'PolynomialR
pg_RationalField = unpickle_global('sage.rings.rational_field', 'RationalField')
pg = unpickle_instantiate(pg_RationalField, ())
pg_make_rational = unpickle_global('sage.rings.rational', 'make_rational')
pg_Polynomial_rational_dense(pg_PolynomialRing(pg, 'x', None, False), [pg_make_rational('0'), pg_make
sage: sage_eval(explain_pickle(dumps(polygen(QQ)))) == polygen(QQ)
True
```

By default (as above) the code produced contains calls to several utility functions (unpickle_global, etc.); this is done so that the code is truly equivalent to the pickle. If the pickle can be loaded into a future version of Sage, then the code that explain_pickle produces today should work in that future Sage as well.

It is also possible to produce simpler code, that is tied to the current version of Sage; here are the above two examples again:

```
sage: explain_pickle(dumps(12345), in_current_sage=True)
from sage.rings.integer import make_integer
make_integer('c1p')
sage: explain_pickle(dumps(polygen(QQ)), in_current_sage=True)
from sage.rings.polynomial.polynomial_element_generic import Polynomial_rational_dense
from sage.rings.rational import make_rational
Polynomial_rational_dense(PolynomialRing(RationalField(), 'x', None, False), [make_rational('0'), mak
```

The explain_pickle function has several use cases.

- Write pickling support for your classes

  You can use explain_pickle to see what will happen when a pickle is unpickled. Consider: is this sequence of commands something that can be easily supported in all future Sage versions, or does it expose internal design decisions that are subject to change?

- Debug old pickles

  If you have a pickle from an old version of Sage that no longer unpickles, you can use explain_pickle to see what it is trying to do, to figure out how to fix it.

- Use explain_pickle in doctests to help maintenance

  If you have a `loads(dumps(S))` doctest, you could also add an `explain_pickle(dumps(S))` doctest. Then if something changes in a way that would invalidate old pickles, the output of `explain_pickle` will also change. At that point, you can add the previous output of `explain_pickle` as a new set of doctests (and then update the :obj‘explain_pickle‘ doctest to use the new output), to ensure that old pickles will continue to work. (These problems will also be caught using the `picklejar`, but having the tests directly in the relevant module is clearer.)

As mentioned above, there are several output modes for `explain_pickle`, that control fidelity versus simplicity of the output. For example, the GLOBAL instruction takes a module name and a class name and produces the corresponding class. So GLOBAL of `sage.rings.integer`, `Integer` is approximately equivalent to `sage.rings.integer.Integer`.

However, this class lookup process can be customized (using sage.structure.sage_object.register_unpickle_override). For instance, if some future version of Sage renamed `sage/rings/integer.pyx` to

sage/rings/knuth_was_here.pyx, old pickles would no longer work unless register_unpickle_override was used; in that case, GLOBAL of 'sage.rings.integer', 'integer' would mean sage.rings.knuth_was_here.integer.

By default, explain_pickle will map this GLOBAL instruction to unpickle_global('sage.rings.integer', 'integer'). Then when this code is evaluated, unpickle_global will look up the current mapping in the register_unpickle_override table, so the generated code will continue to work even in hypothetical future versions of Sage where integer.pyx has been renamed.

If you pass the flag in_current_sage=True, then explain_pickle will generate code that may only work in the current version of Sage, not in future versions. In this case, it would generate:

```
from sage.rings.integer import integer
```

and if you ran explain_pickle in hypothetical future sage, it would generate:

```
from sage.rings.knuth_was_here import integer
```

but the current code wouldn't work in the future sage.

If you pass the flag default_assumptions=True, then explain_pickle will generate code that would work in the absence of any special unpickling information. That is, in either current Sage or hypothetical future Sage, it would generate:

```
from sage.rings.integer import integer
```

The intention is that default_assumptions output is prettier (more human-readable), but may not actually work; so it is only intended for human reading.

There are several functions used in the output of explain_pickle. Here I give a brief description of what they usually do, as well as how to modify their operation (for instance, if you're trying to get old pickles to work).

- unpickle_global(module, classname): unpickle_global('sage.foo.bar', 'baz') is usually equivalent to sage.foo.bar.baz, but this can be customized with register_unpickle_override.
- unpickle_newobj(klass, args): Usually equivalent to klass.__new__(klass, *args). If klass is a Python class, then you can define __new__() to control the result (this result actually need not be an instance of klass). (This doesn't work for Cython classes.)
- unpickle_build(obj, state): If obj has a __setstate__() method, then this is equivalent to obj.__setstate__(state). Otherwise uses state to set the attributes of obj. Customize by defining __setstate__().
- unpickle_instantiate(klass, args): Usually equivalent to klass(*args). Cannot be customized.
- unpickle_appends(lst, vals): Appends the values in vals to lst. If not isinstance(lst, list), can be customized by defining a append() method.

class EmptyNewstyleClass()
A featureless new-style class (inherits from object); used for testing explain_pickle.

class EmptyOldstyleClass()
A featureless old-style class (does not inherit from object); used for testing explain_pickle.

class PickleDict(*items*)
An object which can be used as the value of a PickleObject. The items is a list of key-value pairs, where the keys and values are SageInputExpressions. We use this to help construct dictionary literals, instead of always starting with an empty dictionary and assigning to it.

class PickleExplainer(*sib, in_current_sage=False, default_assumptions=False, pedantic=False*)

An interpreter for the pickle virtual machine, that executes symbolically and constructs SageInputExpressions instead of directly constructing values.

APPEND()

TESTS:

```
sage: from sage.misc.explain_pickle import *
sage: test_pickle(['a'])
    0: \x80 PROTO      2
    2: ]    EMPTY_LIST
    3: q    BINPUT     1
    5: U    SHORT_BINSTRING 'a'
    8: a    APPEND
    9: .    STOP
highest protocol among opcodes = 2
explain_pickle in_current_sage=True/False:
['a']
result: ['a']
```

As shown above, we prefer to create a list literal. This is not possible if the list is recursive:

```
sage: v = []
sage: v.append(v)
sage: test_pickle(v)
    0: \x80 PROTO      2
    2: ]    EMPTY_LIST
    3: q    BINPUT     1
    5: h    BINGET     1
    7: a    APPEND
    8: .    STOP
highest protocol among opcodes = 2
explain_pickle in_current_sage=True/False:
si = []
list.append(si, si)
si
result: [[...]]
```

APPENDS()

TESTS:

```
sage: from sage.misc.explain_pickle import *
sage: test_pickle(['a', 'b'])
    0: \x80 PROTO      2
    2: ]    EMPTY_LIST
    3: q    BINPUT     1
    5: (    MARK
    6: U        SHORT_BINSTRING 'a'
    9: U        SHORT_BINSTRING 'b'
   12: e        APPENDS    (MARK at 5)
   13: .    STOP
highest protocol among opcodes = 2
explain_pickle in_current_sage=True/False:
['a', 'b']
result: ['a', 'b']
```

As shown above, we prefer to create a list literal. This is not possible if the list is recursive:

```
sage: v = []
sage: v.append(v)
sage: v.append(v)
```

```
sage: test_pickle(v)
    0: \x80 PROTO      2
    2: ]    EMPTY_LIST
    3: q    BINPUT     1
    5: (    MARK
    6: h        BINGET     1
    8: h        BINGET     1
   10: e        APPENDS    (MARK at 5)
   11: .    STOP
highest protocol among opcodes = 2
explain_pickle in_current_sage=True/False:
si = []
list.extend(si, [si, si])
si
result: [[...], [...]]
```

BINFLOAT(*f*)

TESTS:

```

GLOBAL (*name*)

TESTS:

```
sage: from sage.misc.explain_pickle import *
```

We've used register_unpickle_override so that unpickle_global will map TestGlobalOldName to TestGlobalNewName.

```
sage: test_pickle(TestGlobalOldName())
    0: \x80 PROTO      2
    2: c    GLOBAL     'sage.misc.explain_pickle TestGlobalOldName'
   46: q    BINPUT     1
   48: )    EMPTY_TUPLE
   49: \x81 NEWOBJ
   50: q    BINPUT     2
   52: }    EMPTY_DICT
   53: q    BINPUT     3
   55: b    BUILD
   56: .    STOP
highest protocol among opcodes = 2
explain_pickle in_current_sage=True:
from sage.misc.explain_pickle import TestGlobalNewName
unpickle_newobj(TestGlobalNewName, ())
explain_pickle in_current_sage=False:
pg_TestGlobalOldName = unpickle_global('sage.misc.explain_pickle', 'TestGlobalOldName')
si = unpickle_newobj(pg_TestGlobalOldName, ())
```

```
unpickle_build(si, {})
si
result: TestGlobalNewName
```

Note that default_assumptions blithely assumes that it should use the old name, giving code that doesn't actually work as desired:

```
sage: explain_pickle(dumps(TestGlobalOldName()), default_assumptions=True)
from sage.misc.explain_pickle import TestGlobalOldName
unpickle_newobj(TestGlobalOldName, ())
```

A class name need not be a valid identifier:

```
sage: sage.misc.explain_pickle.__dict__['funny$name'] = TestGlobalFunnyName # see comment at
sage: test_pickle((TestGlobalFunnyName(), TestGlobalFunnyName()))
    0: \x80 PROTO      2

SETITEM()

TESTS:

```
sage: import pickle
sage: from sage.misc.explain_pickle import *
sage: test_pickle(pickle.dumps({'a': 'b'}))
    0: (    MARK
    1: d        DICT       (MARK at 0)
    2: p    PUT        0
    5: S    STRING     'a'
   10: p    PUT        1
   13: S    STRING     'b'
   18: p    PUT        2
   21: s    SETITEM
   22: .    STOP
highest protocol among opcodes = 0
explain_pickle in_current_sage=True/False:
{'a':'b'}
result: {'a': 'b'}
```

We see above that we output the result as a dictionary literal, when possible. This is impossible when a key or value is recursive. First we test recursive values:

```
sage: value_rec = dict()
sage: value_rec['circular'] = value_rec
sage: test_pickle(pickle.dumps(value_rec))
    0: (    MARK
    1: d        DICT       (MARK at 0)
    2: p    PUT        0
    5: S    STRING     'circular'
   17: p    PUT        1
   20: g    GET        0
   23: s    SETITEM
   24: .    STOP
highest protocol among opcodes = 0
explain_pickle in_current_sage=True/False:
si = {}
si['circular'] = si
si
result: {'circular': {...}}
```

Then we test recursive keys:

```
sage: key_rec = dict()
sage: key = EmptyNewstyleClass()
sage: key.circular = key_rec
sage: key_rec[key] = 'circular'
sage: test_pickle(pickle.dumps(key_rec))
    0: (    MARK
    1: d        DICT       (MARK at 0)
    2: p    PUT        0

result: ('a', 'b', 'c')
```

UNICODE(*s*)

TESTS:

```
sage: import pickle
sage: from sage.misc.explain_pickle import *
sage: test_pickle(pickle.dumps(u'hi\u1234\U00012345'))
    0: V    UNICODE    u'hi\u1234\U00012345'
   20: p    PUT        0
   23: .    STOP
highest protocol among opcodes = 0
explain_pickle in_current_sage=True/False:
u'hi\u1234\U00012345'
result: u'hi\u1234\U00012345'
```

check_value(*v*)

Check that the given value is either a SageInputExpression or a PickleObject. Used for internal sanity checking.

EXAMPLES:

```
sage: from sage.misc.explain_pickle import *
sage: from sage.misc.sage_input import SageInputBuilder
sage: sib = SageInputBuilder()
sage: pe = PickleExplainer(sib, in_current_sage=True, default_assumptions=False, pedantic=Tr
sage: pe.check_value(7)
...
AssertionError
sage: pe.check_value(sib(7))
```

is_mutable_pickle_object(*v*)

Test whether a PickleObject is mutable (has never been converted to a SageInputExpression).

EXAMPLES:

```
sage: from sage.misc.explain_pickle import *
sage: from sage.misc.sage_input import SageInputBuilder
sage: sib = SageInputBuilder()
sage: pe = PickleExplainer(sib, in_current_sage=True, default_assumptions=False, pedantic=Tr
sage: v = PickleObject(1, sib(1))
sage: pe.is_mutable_pickle_object(v)
True
sage: sib(v)
{atomic:1}
sage: pe.is_mutable_pickle_object(v)
False
```

pop()

Pop a value from the virtual machine's stack, and return it.

EXAMPLES:

```
sage: from sage.misc.explain_pickle import *
sage: from sage.misc.sage_input import SageInputBuilder
sage: sib = SageInputBuilder()
sage: pe = PickleExplainer(sib, in_current_sage=True, default_assumptions=False, pedantic=Tr
sage: pe.push(sib(7))
sage: pe.pop()
{atomic:7}
```

pop_to_mark()

Pop all values down to the 'mark' from the virtual machine's stack, and return the values as a list.

EXAMPLES:

```
sage: from sage.misc.explain_pickle import *
sage: from sage.misc.sage_input import SageInputBuilder
sage: sib = SageInputBuilder()
sage: pe = PickleExplainer(sib, in_current_sage=True, default_assumptions=False, pedantic=Tr
sage: pe.push_mark()
sage: pe.push(sib(7))
sage: pe.push(sib('hello'))
sage: pe.pop_to_mark()
[{atomic:7}, {atomic:'hello'}]
```

push(*v*)

Push a value onto the virtual machine's stack.

EXAMPLES:

```
sage: from sage.misc.explain_pickle import *
sage: from sage.misc.sage_input import SageInputBuilder
sage: sib = SageInputBuilder()
sage: pe = PickleExplainer(sib, in_current_sage=True, default_assumptions=False, pedantic=Tr
sage: pe.push(sib(7))
sage: pe.stack[-1]
{atomic:7}
```

push_and_share(*v*)

Push a value onto the virtual machine's stack; also mark it as shared for sage_input if we are in pedantic mode.

EXAMPLES:

```
sage: from sage.misc.explain_pickle import *
sage: from sage.misc.sage_input import SageInputBuilder
sage: sib = SageInputBuilder()
sage: pe = PickleExplainer(sib, in_current_sage=True, default_assumptions=False, pedantic=Tr
sage: pe.push_and_share(sib(7))
sage: pe.stack[-1]
{atomic:7}
sage: pe.stack[-1]._sie_share
True
```

push_mark()

Push a 'mark' onto the virtual machine's stack.

EXAMPLES:

```
sage: from sage.misc.explain_pickle import *
sage: from sage.misc.sage_input import SageInputBuilder
sage: sib = SageInputBuilder()
sage: pe = PickleExplainer(sib, in_current_sage=True, default_assumptions=False, pedantic=Tr
sage: pe.push_mark()
sage: pe.stack[-1]
'mark'
sage: pe.stack[-1] is the_mark
True
```

run_pickle(*p*)

Given an (uncompressed) pickle as a string, run the pickle in this virtual machine. Once a STOP has been executed, return the result (a SageInputExpression representing code which, when evaluated, will give the value of the pickle).

EXAMPLES:

```
sage: from sage.misc.explain_pickle import *
sage: from sage.misc.sage_input import SageInputBuilder
sage: sib = SageInputBuilder()
sage: pe = PickleExplainer(sib, in_current_sage=True, default_assumptions=False, pedantic=Tr
sage: sib(pe.run_pickle('T\5\0\0\0hello.'))
{atomic:'hello'}
```

share(*v*)

Mark a sage_input value as shared, if we are in pedantic mode.

EXAMPLES:

```
sage: from sage.misc.explain_pickle import *
sage: from sage.misc.sage_input import SageInputBuilder
sage: sib = SageInputBuilder()
sage: pe = PickleExplainer(sib, in_current_sage=True, default_assumptions=False, pedantic=Tr
sage: v = sib(7)
```

```
sage: v._sie_share
False
sage: pe.share(v)
{atomic:7}
sage: v._sie_share
True
```

class PickleInstance(*klass*)
An object which can be used as the value of a PickleObject. Unlike other possible values of a PickleObject, a PickleInstance doesn't represent an exact value; instead, it gives the class (type) of the object.

class PickleObject(*value, expression*)
Pickles have a stack-based virtual machine. The explain_pickle pickle interpreter mostly uses SageInputExpressions, from sage_input, as the stack values. However, sometimes we want some more information about the value on the stack, so that we can generate better (prettier, less confusing) code. In such cases, we push a PickleObject instead of a SageInputExpression. A PickleObject contains a value (which may be a standard Python value, or a PickleDict or PickleInstance), an expression (a SageInputExpression), and an "immutable" flag (which checks whether this object has been converted to a SageInputExpression; if it has, then we must not mutate the object, since the SageInputExpression would not reflect the changes).

class TestAppendList()
A subclass of list, with deliberately-broken append and extend methods. Used for testing explain_pickle.

append()
A deliberately broken append method.
EXAMPLES:

```
sage: from sage.misc.explain_pickle import *
sage: v = TestAppendList()
sage: v.append(7)
...
TypeError: append() takes exactly 1 argument (2 given)
```

We can still append by directly using the list method: sage: list.append(v, 7) sage: v [7]

extend()
A deliberately broken extend method.
EXAMPLES:

```
sage: from sage.misc.explain_pickle import *
sage: v = TestAppendList()
sage: v.extend([3,1,4,1,5,9])
...
TypeError: extend() takes exactly 1 argument (2 given)
```

We can still extend by directly using the list method: sage: list.extend(v, (3,1,4,1,5,9)) sage: v [3, 1, 4, 1, 5, 9]

class TestAppendNonlist()
A list-like class, carefully designed to test exact unpickling behavior. Used for testing explain_pickle.

class TestBuild()
A simple class with a __getstate__ but no __setstate__. Used for testing explain_pickle.

class TestBuildSetstate()
A simple class with a __getstate__ and a __setstate__. Used for testing explain_pickle.

class TestGlobalFunnyName()
A featureless new-style class which has a name that's not a legal Python identifier.
EXAMPLES:

```
sage: from sage.misc.explain_pickle import *
sage: globals()['funny$name'] = TestGlobalFunnyName # see comment at end of file
sage: TestGlobalFunnyName.__name__
'funny$name'
sage: globals()['funny$name'] is TestGlobalFunnyName
True
```

class TestGlobalNewName()
A featureless new-style class. When you try to unpickle an instance of TestGlobalOldName, it is redirected to create an instance of this class instead. Used for testing explain_pickle.

EXAMPLES: sage: from sage.misc.explain_pickle import * sage: loads(dumps(TestGlobalOldName())) TestGlobalNewName

class TestGlobalOldName()
A featureless new-style class. When you try to unpickle an instance of this class, it is redirected to create a TestGlobalNewName instead. Used for testing explain_pickle.

EXAMPLES:

```
sage: from sage.misc.explain_pickle import *
sage: loads(dumps(TestGlobalOldName()))
TestGlobalNewName
```

class TestReduceGetinitargs()
An old-style class with a __getinitargs__ method. Used for testing explain_pickle.

class TestReduceNoGetinitargs()
An old-style class with no __getinitargs__ method. Used for testing explain_pickle.

explain_pickle(*pickle=None, file=None, compress=True, **kwargs*)
Explain a pickle. That is, produce source code such that evaluating the code is equivalent to loading the pickle. Feeding the result of `explain_pickle` to `sage_eval` should be totally equivalent to loading the `pickle` with `cPickle`.

INPUTS:

- `pickle` – the pickle to explain, as a string (default: None)
- `file` – a filename of a pickle (default: None)
- **`compress` – if False, don't attempt to decompress the pickle** (default: True)
- **`in_current_sage` – if True, produce potentially simpler code that is** tied to the current version of Sage. (default: False)
- **`default_assumptions` – if True, produce potentially simpler code that** assumes that generic unpickling code will be used. This code may not actually work. (default: False)
- **`eval` – if True, then evaluate the resulting code and return the** evaluated result. (default: False)
- **`preparse` – if True, then produce code to be evaluated with** Sage's preparser; if False, then produce standard Python code; if None, then produce code that will work either with or without the preparser. (default: True)
- **`pedantic` – if True, then carefully ensures that the result has** at least as much sharing as the result of cPickle (it may have more, for immutable objects). (default: False)

Exactly one of `pickle` (a string containing a pickle) or `file` (the filename of a pickle) must be provided.

EXAMPLES:

```
sage: explain_pickle(dumps({('a', 'b'): [1r, 2r]}))
{('a', 'b'):[1r, 2r]}
sage: explain_pickle(dumps(RR(pi)), in_current_sage=True)
from sage.rings.real_mpfr import __create__RealNumber_version0
from sage.rings.real_mpfr import __create__RealField_version0
__create__RealNumber_version0(__create__RealField_version0(53r, False, 'RNDN'), '3.4gvml245kc0@0
sage: s = 'hi'
sage: explain_pickle(dumps((s, s)))
('hi', 'hi')
sage: explain_pickle(dumps((s, s)), pedantic=True)
si = 'hi'
(si, si)
sage: explain_pickle(dumps(5r))
5r
sage: explain_pickle(dumps(5r), preparse=False)
5
sage: explain_pickle(dumps(5r), preparse=None)
int(5)
sage: explain_pickle(dumps(22/7))
pg_make_rational = unpickle_global('sage.rings.rational', 'make_rational')
pg_make_rational('m/7')
sage: explain_pickle(dumps(22/7), in_current_sage=True)
from sage.rings.rational import make_rational
make_rational('m/7')
sage: explain_pickle(dumps(22/7), default_assumptions=True)
from sage.rings.rational import make_rational
make_rational('m/7')
```

explain_pickle_string(*pickle, in_current_sage=False, default_assumptions=False, eval=False, preparse=True, pedantic=False*)

This is a helper function for explain_pickle. It takes a decompressed pickle string as input; other than that, its options are all the same as explain_pickle.

EXAMPLES:

```
sage: sage.misc.explain_pickle.explain_pickle_string(dumps("Hello, world", compress=False))
'Hello, world'
```

(See the documentation for `explain_pickle` for many more examples.)

name_is_valid(*name*)

Test whether a string is a valid Python identifier. (We use a conservative test, that only allows ASCII identifiers.)

EXAMPLES:

```
sage: from sage.misc.explain_pickle import name_is_valid
sage: name_is_valid('fred')
True
sage: name_is_valid('Yes!ValidName')
False
sage: name_is_valid('_happy_1234')
True
```

test_pickle(*p, verbose_eval=False, pedantic=False, args=()*)

Tests explain_pickle on a given pickle p. p can be:

- a string containing an uncompressed pickle (which will always end with a '.')

- a string containing a pickle fragment (not ending with '.') test_pickle will synthesize a pickle that will push args onto the stack (using persistent IDs), run the pickle fragment, and then STOP (if the string 'mark' occurs in args, then a mark will be pushed)
- an arbitrary object; test_pickle will pickle the object

Once it has a pickle, test_pickle will print the pickle's disassembly, run explain_pickle with in_current_sage=True and False, print the results, evaluate the results, unpickle the object with cPickle, and compare all three results.

If verbose_eval is True, then test_pickle will print messages before evaluating the pickles; this is to allow for tests where the unpickling prints messages (to verify that the same operations occur in all cases).

EXAMPLES:

```
sage: from sage.misc.explain_pickle import *
sage: test_pickle(['a'])
    0: \x80 PROTO      2
    2: ]    EMPTY_LIST
    3: q    BINPUT     1
    5: U    SHORT_BINSTRING 'a'
    8: a    APPEND
    9: .    STOP
highest protocol among opcodes = 2
explain_pickle in_current_sage=True/False:
['a']
result: ['a']
```

unpickle_appends(*lst, vals*)

Given a list (or list-like object) and a sequence of values, appends the values to the end of the list. This is careful to do so using the exact same technique that cPickle would use. Used by `explain_pickle`.

EXAMPLES:

```
sage: v = []
sage: unpickle_appends(v, (1, 2, 3))
sage: v
[1, 2, 3]
```

unpickle_build(*obj, state*)

Set the state of an object. Used by `explain_pickle`.

EXAMPLES:

```
sage: from sage.misc.explain_pickle import *
sage: v = EmptyNewstyleClass()
sage: unpickle_build(v, {'hello': 42})
sage: v.hello
42
```

unpickle_extension(*code*)

Takes an integer index and returns the extension object with that index. Used by `explain_pickle`.

EXAMPLES:

```
sage: from copy_reg import *
sage: add_extension('sage.misc.explain_pickle', 'EmptyNewstyleClass', 42)
sage: unpickle_extension(42)
<class 'sage.misc.explain_pickle.EmptyNewstyleClass'>
sage: remove_extension('sage.misc.explain_pickle', 'EmptyNewstyleClass', 42)
```

unpickle_instantiate(*fn, args*)
Instantiate a new object of class fn with arguments args. Almost always equivalent to `fn(*args)`. Used by `explain_pickle`.

EXAMPLES:

```
sage: unpickle_instantiate(Integer, ('42',))
42
```

unpickle_newobj(*klass, args*)
Create a new object; this corresponds to the C code klass->tp_new(klass, args, NULL). Used by `explain_pickle`.

EXAMPLES: sage: unpickle_newobj(tuple, ([1, 2, 3],)) (1, 2, 3)

unpickle_persistent(*s*)
Takes an integer index and returns the persistent object with that index; works by calling whatever callable is stored in unpickle_persistent_loader. Used by `explain_pickle`.

EXAMPLES:

```
sage: import sage.misc.explain_pickle
sage: sage.misc.explain_pickle.unpickle_persistent_loader = lambda n: n+7
sage: unpickle_persistent(35)
42
```

11.4 Get resource usage of process

AUTHORS:

- William Stein (2006-03-04): initial versoin

VmB(*VmKey*)
Function used internally by this module.

get_memory_usage(*t=None*)
Return memory usage.

INPUT:

- `t` - None or output of previous call; (only used on Linux)

OUTPUT:

- `Linux` - Returns float number (in megabytes)
- `OS X` - returns string (VSIZE column of top)
- `other` - not implemented for any other operating systems

EXAMPLES:

We test that memory usage doesn't change instantly:

```
sage: t = get_memory_usage()
sage: get_memory_usage(t)          # amount of memory more than when we defined t.
0.0
```

linux_memory_usage()
Return memory usage in megabytes.

top()
Return the top output line that contains this running Sage process.

EXAMPLES: sage: top() # random output '72373 python 0.0% 0:01.36 1 14+ 1197 39M+ 34M+ 55M+ 130M+'

11.5 Multidimensional enumeration

AUTHORS:

- Joel B. Mohler (2006-10-12)
- William Stein (2006-07-19)
- Jon Hanke

cartesian_product_iterator(*X*)
Iterate over the Cartesian product.

INPUT:

•X - list or tuple of lists

OUTPUT: iterator over the cartesian product of the elements of X

EXAMPLES:

```
sage: list(cartesian_product_iterator([[1,2], ['a','b']]))
[(1, 'a'), (1, 'b'), (2, 'a'), (2, 'b')]
```

mrange(*sizes, typ=<type 'list'>*)
Return the multirange list with given sizes and type.

This is the list version of xmrange. Use xmrange for the iterator.

More precisely, return the iterator over all objects of type typ of n-tuples of Python ints with entries between 0 and the integers in the sizes list. The iterator is empty if sizes is empty or contains any non-positive integer.

INPUT:

•sizes - a list of nonnegative integers

•typ - (default: list) a type or class; more generally, something that can be called with a list as input.

OUTPUT: a list

EXAMPLES:

```
sage: mrange([3,2])
[[0, 0], [0, 1], [1, 0], [1, 1], [2, 0], [2, 1]]
sage: mrange([3,2], tuple)
[(0, 0), (0, 1), (1, 0), (1, 1), (2, 0), (2, 1)]
sage: mrange([3,2], sum)
[0, 1, 1, 2, 2, 3]
```

Examples that illustrate empty multi-ranges.

```
sage: mrange([])
[]
sage: mrange([5,3,-2])
[]
sage: mrange([5,3,0])
[]
```

AUTHORS:

- Jon Hanke
- William Stein

mrange_iter(*iter_list, typ=<type 'list'>*)

Return the multirange list derived from the given list of iterators.

This is the list version of xmrange_iter. Use xmrange_iter for the iterator.

More precisely, return the iterator over all objects of type typ of n-tuples of Python ints with entries between 0 and the integers in the sizes list. The iterator is empty if sizes is empty or contains any non-positive integer.

INPUT:

- `sizes` - a list of nonnegative integers
- `typ` - (default: list) a type or class; more generally, something that can be called with a list as input.

OUTPUT: a list

EXAMPLES:

```
sage: mrange_iter([range(3),[0,2]])
[[0, 0], [0, 2], [1, 0], [1, 2], [2, 0], [2, 2]]
sage: mrange_iter([['Monty','Flying'],['Python','Circus']], tuple)
[('Monty', 'Python'), ('Monty', 'Circus'), ('Flying', 'Python'), ('Flying', 'Circus')]
sage: mrange_iter([[2,3,5,7],[1,2]], sum)
[3, 4, 4, 5, 6, 7, 8, 9]
```

Examples that illustrate empty multi-ranges.

```
sage: mrange_iter([])
[]
sage: mrange_iter([range(5),xrange(3),xrange(-2)])
[]
sage: mrange_iter([range(5),range(3),range(0)])
[]
```

AUTHORS:

- Joel B. Mohler

class xmrange(*sizes, typ=<type 'list'>*)

Return the multirange iterate with given sizes and type.

More precisely, return the iterator over all objects of type typ of n-tuples of Python ints with entries between 0 and the integers in the sizes list. The iterator is empty if sizes is empty or contains any non-positive integer.

Use mrange for the non-iterator form.

INPUT:

- `sizes` - a list of nonnegative integers
- `typ` - (default: list) a type or class; more generally, something that can be called with a list as input.

OUTPUT: a generator

EXAMPLES: We create multi-range iterators, print them and also iterate through a tuple version.

```
sage: z = xmrange([3,2]);z
xmrange([3, 2])
sage: z = xmrange([3,2], tuple);z
xmrange([3, 2], <type 'tuple'>)
sage: for a in z:
...     print a
(0, 0)
(0, 1)
(1, 0)
(1, 1)
(2, 0)
(2, 1)
```

We illustrate a few more iterations.

```
sage: list(xmrange([3,2]))
[[0, 0], [0, 1], [1, 0], [1, 1], [2, 0], [2, 1]]
sage: list(xmrange([3,2], tuple))
[(0, 0), (0, 1), (1, 0), (1, 1), (2, 0), (2, 1)]
```

Here we compute the sum of each element of the multi-range iterator:

```
sage: list(xmrange([3,2], sum))
[0, 1, 1, 2, 2, 3]
```

Next we compute the product:

```
sage: list(xmrange([3,2], prod))
[0, 0, 0, 1, 0, 2]
```

Examples that illustrate empty multi-ranges.

```
sage: list(xmrange([]))
[]
sage: list(xmrange([5,3,-2]))
[]
sage: list(xmrange([5,3,0]))
[]
```

We use a multi-range iterator to iterate through the cartesian product of sets.

```
sage: X = ['red', 'apple', 389]
sage: Y = ['orange', 'horse']
sage: for i,j in xmrange([len(X), len(Y)]):
...     print (X[i], Y[j])
('red', 'orange')
('red', 'horse')
('apple', 'orange')
('apple', 'horse')
(389, 'orange')
(389, 'horse')
```

AUTHORS:

- Jon Hanke

•William Stein

class xmrange_iter(*iter_list, typ=<type 'list'>*)

Return the multirange iterate derived from the given iterators and type.

Note: This basically gives you the cartesian product of sets.

More precisely, return the iterator over all objects of type typ of n-tuples of Python ints with entries between 0 and the integers in the sizes list. The iterator is empty if sizes is empty or contains any non-positive integer.

Use mrange_iter for the non-iterator form.

INPUT:

- `list_iter` - a list of objects usable as iterators (possibly lists)
- `typ` - (default: list) a type or class; more generally, something that can be called with a list as input.

OUTPUT: a generator

EXAMPLES: We create multi-range iterators, print them and also iterate through a tuple version.

```
sage: z = xmrange_iter([xrange(3),xrange(2)]);z
xmrange_iter([xrange(3), xrange(2)])
sage: z = xmrange_iter([range(3),range(2)], tuple);z
xmrange_iter([[0, 1, 2], [0, 1]], <type 'tuple'>)
sage: for a in z:
...     print a
(0, 0)
(0, 1)
(1, 0)
(1, 1)
(2, 0)
(2, 1)
```

We illustrate a few more iterations.

```
sage: list(xmrange_iter([range(3),range(2)]))
[[0, 0], [0, 1], [1, 0], [1, 1], [2, 0], [2, 1]]
sage: list(xmrange_iter([range(3),range(2)], tuple))
[(0, 0), (0, 1), (1, 0), (1, 1), (2, 0), (2, 1)]
```

Here we compute the sum of each element of the multi-range iterator:

```
sage: list(xmrange_iter([range(3),range(2)], sum))
[0, 1, 1, 2, 2, 3]
```

Next we compute the product:

```
sage: list(xmrange_iter([range(3),range(2)], prod))
[0, 0, 0, 1, 0, 2]
```

Examples that illustrate empty multi-ranges.

```
sage: list(xmrange_iter([]))
[]
sage: list(xmrange_iter([xrange(5),xrange(3),xrange(-2)]))
[]
sage: list(xmrange_iter([xrange(5),xrange(3),xrange(0)]))
[]
```

We use a multi-range iterator to iterate through the cartesian product of sets.

```
sage: X = ['red', 'apple', 389]
sage: Y = ['orange', 'horse']
sage: for i,j in xmrange_iter([X, Y], tuple):
...     print (i, j)
('red', 'orange')
('red', 'horse')
('apple', 'orange')
('apple', 'horse')
(389, 'orange')
(389, 'horse')
```

11.6 Installing shortcut scripts

install_scripts(*bin_directory=None*)

Run this command as `install_scripts(bin_directory)` to create scripts in the given bin directory that, independently of Sage, run various software components included with Sage: ['gap', 'gp', 'singular', 'maxima', 'M2', 'kash', 'mwrank', 'ipython', 'hg', 'hgmerge', 'R']

This command:

- verbosely tell you which scripts it adds, and
- will *not* overwrite any scripts you already have in the given bin directory.

INPUT:

- `bin_directory` - string; the directory into which to put the scripts

OUTPUT: Verbosely prints what it is doing and creates files in bin_directory that are world executable and readable.

Note: You may need to run Sage as root in order to run `install_scripts` successfully, since the user running Sage will need write permissions on `bin_directory`.

AUTHORS:

- William Stein: code / design
- Arthur Gaer: design

11.7 Sage Interface to the HG/Mercurial Revision Control System

These functions make setup and use of source control with Sage easier, using the distributed Mercurial HG source control system. To learn about Mercurial, see http://www.selenic.com/mercurial/wiki/ , in particular Understanding-Mercurial .

This system should all be fully usable from the Sage notebook (except for merging, currently). This system should all be mostly usable from the Sage notebook.

- Use `hg_sage.record()` to record all of your changes.
- Use `hg_sage.bundle('filename')` to bundle them up to send them.
- Use `hg_sage.inspect('filename.hg')` to inspect a bundle.

- Use `hg_sage.unbundle('filename.hg')` to import a bundle into your repository.
- Use `hg_sage.pull()` to synchronize with the latest official stable Sage changesets.

class HG(*dir, name, pull_url, push_url, target=None, cloneable=False, obj_name=''*)

add(*files, options=''*)

Add the given list of files (or file) or directories to your HG repository. They must exist already.

To see a list of files that haven't been added to the repository do self.status(). They will appear with an explanation point next them.

Add needs to be called whenever you add a new file or directory to your project. Of course, it also needs to be called when you first create the project, to let hg know which files should be kept track of.

INPUT:

- `files` - list or string; name of file or directory.
- `options` - string (e.g., '-dry-run')

apply(*bundle, update=True, options=''*)

Apply patches from a hg patch to the repository.

If the bundle is a .patch file, instead call the import_patch method. To see what is in a bundle before applying it, using self.incoming(bundle).

INPUT:

- `bundle` - an hg bundle (created with the bundle command)
- `update` - if True (the default), update the working directory after unbundling.

browse(*port=8200, address='localhost', open_viewer=True, options=''*)

Start a web server for this repository.

This server is very nice - you can browse all files in the repository, see their changelogs, see who wrote any given line, etc. Very nice.

INPUT:

- `port` - port that the server will listen on
- `address` - (default: 'localhost') address to listen on
- `open_viewer` - boolean (default: True); whether to pop up the web page
- `options` - a string passed directly to hg's serve command.

bundle(*filename, options='', url=None, base=None, to=None*)

Create an hg changeset bundle with the given filename against the repository at the given url (which is by default the 'official' Sage repository, unless push_url() is changed in a setup file).

If you have internet access, it's best to just do `hg_sage.bundle(filename)`. If you don't find a revision r that you and the person unbundling both have (by looking at `hg_sage.log()`), then do `hg_sage.bundle(filename, base=r)`.

Use self.inspect('file.bundle') to inspect the resulting bundle.

This is a file that you should probably send to William Stein (wstein@gmail.com), post to a web page, or send to sage-devel. It will be written to the current directory.

INPUT:

- `filename` - output file in which to put bundle
- `options` - pass to hg
- `url` - url to bundle against (default: SAGE_SERVER, or push_url())
- `base` - a base changeset revision number to bundle against (doesn't require internet access)

changes(*branches=None, keyword=None, limit=None, rev=None, merges=True, only_merges=False, patch=None, template=False, include=None, exclude=None, verbose=False*)

Display the change log for this repository. This is a list of changesets ordered by revision number.

By default this command outputs: changeset id and hash, tags, non-trivial parents, user, date and time, and a summary for each commit.

INPUT:

- `branches` - (string, default: None) show given branches
- `keyword` - (string, default: None) search for a keyword
- `limit` - (integer, default: None, or 20 in notebook mdoe) limit number of changes displayed
- `rev` - (integer) show the specified revision
- `merges` - (bool, default: True) whether or not to show merges
- `only_merges` - (bool, default: False) if true, show only merges
- `patch` - (string, default: None) show given patch
- `template` - (string, default: None) display with template
- `include` - (string, default: None) include names matching the given patterns
- `exclude` - (string, default: None) exclude names matching the given patterns
- `verbose` - (bool, default: False) If true, the list of changed files and full commit message is shown.

checkout (*options=''*)

update or merge working directory

Update the working directory to the specified revision.

If there are no outstanding changes in the working directory and there is a linear relationship between the current version and the requested version, the result is the requested version.

To merge the working directory with another revision, use the merge command.

By default, update will refuse to run if doing so would require merging or discarding local changes.

aliases: up, checkout, co

INPUT:

- `options` - string (default: ''):

```
-C --clean  overwrite locally modified files
-d --date   tipmost revision matching date
-r --rev    revision
```

ci (*files='', comment=None, options='', diff=True*)

Commit your changes to the repository.

Quit out of the editor without saving to not record your changes.

INPUT:

- `files` - space separated string of file names (optional) If specified only those files are commited. The path must be absolute or relative to self.dir().
- **`comment` - optional changeset comment. If you don't give** it you will be dumped into an editor. If you're using the Sage notebook, you *must* specify a comment.
- `options` - string:

```
-A --addremove  mark new/missing files as added/removed before committing
-m --message    use <text> as commit message
-l --logfile    read the commit message from <file>
-d --date       record datecode as commit date
-u --user       record user as commiter
-I --include    include names matching the given patterns
-X --exclude    exclude names matching the given patterns
```

- `diff` - (default: True) if True show diffs between your repository and your working repository before recording changes.

Note: If you create new files you should first add them with the add method.

clone (*name, rev=None*)

Clone the current branch of the Sage library, and make it active.

Only available for the `hg_sage` repository.

Use `hg_sage.switch('branch_name')` to switch to a different branch. You must restart Sage after switching.

INPUT:

- `name` - string
- `rev` - integer or None (default)

If rev is None, clones the latest recorded version of the repository. This is very fast, e.g., about 30-60 seconds (including any build). If a specific revision is specified, cloning may take much longer (e.g., 5 minutes), since all Pyrex code has to be regenerated and compiled.

EXAMPLES:

Make a clone of the repository called testing. A copy of the current repository will be created in a directory sage-testing, then SAGE_ROOT/devel/sage will point to sage-testing, and when you next restart Sage that's the version you'll be using.

```
sage: hg_sage.clone('testing')     # not tested
...
```

Make a clone of the repository as it was at revision 1328.

```
sage: hg_sage.clone('testing', 1328)     # not tested
...
```

co (*options=''*)

update or merge working directory

Update the working directory to the specified revision.

If there are no outstanding changes in the working directory and there is a linear relationship between the current version and the requested version, the result is the requested version.

To merge the working directory with another revision, use the merge command.

By default, update will refuse to run if doing so would require merging or discarding local changes.

aliases: up, checkout, co

INPUT:

- `options` - string (default: ''):

```
-C --clean   overwrite locally modified files
-d --date    tipmost revision matching date
-r --rev     revision
```

commit (*files='', comment=None, options='', diff=True*)

Commit your changes to the repository.

Quit out of the editor without saving to not record your changes.

INPUT:

- `files` - space separated string of file names (optional) If specified only those files are commited. The path must be absolute or relative to self.dir().
- **`comment` - optional changeset comment. If you don't give** it you will be dumped into an editor. If you're using the Sage notebook, you *must* specify a comment.
- `options` - string:

```
-A --addremove  mark new/missing files as added/removed before committing
-m --message    use <text> as commit message
-l --logfile    read the commit message from <file>
-d --date       record datecode as commit date
-u --user       record user as commiter
-I --include    include names matching the given patterns
-X --exclude    exclude names matching the given patterns
```

- `diff` - (default: True) if True show diffs between your repository and your working repository before recording changes.

Note: If you create new files you should first add them with the add method.

current_branch (*print_flag=True*)

Lists the current branch.

diff(*files=”, rev=None*)

Show differences between revisions for the specified files as a unified diff.

By default this command tells you exactly what you have changed in your working repository since you last commited changes.

INPUT:

- `files` - space separated list of files (relative to self.dir())
- `rev` - None or a list of integers.

Differences between files are shown using the unified diff format.

When two revision arguments are given, then changes are shown between those revisions. If only one revision is specified then that revision is compared to the working directory, and, when no revisions are specified, the working directory files are compared to its parent.

dir()

Return the directory where this repository is located.

export(*revs, filename=None, text=False, options=”*)

Export patches with the changeset header and diffs for one or more revisions.

If multiple revisions are given, one plain text unified diff file is generated for each one. These files should be applied using import_patch in order from smallest to largest revision number. The information shown in the changeset header is: author, changeset hash, parent and commit comment.

Note: If you are sending a patch to somebody using export and it depends on previous patches, make sure to include those revisions too! Alternatively, use the `bundle()` method, which includes enough information to patch against the default repository (but is an annoying and mysterious binary file).

INPUT:

- `revs` - integer or list of integers (revision numbers); use the log() method to see these numbers.
- `filename` - (default: ‘%R.patch’) The name of the file is given using a format string. The formatting rules are as follows:

```
%%   literal "%" character
%H   changeset hash (40 bytes of hexadecimal)
%N   number of patches being generated
%R   changeset revision number
%b   basename of the exporting repository
%h   short-form changeset hash (12 bytes of hexadecimal)
%n   zero-padded sequence number, starting at 1
```

- `options` - string (default: ‘’)
  - **–’**`-a -text’` - treat all files as text
  - **–’**`-switch-parent’` - diff against the second parent

  Without the `-a` option, export will avoid generating diffs of files it detects as binary. With `-a`, export will generate a diff anyway, probably with undesirable results.
  With the `-switch-parent` option, the diff will be against the second parent. It can be useful to review a merge.

head(*options=”*)

show current repository heads

Show all repository head changesets.

Repository “heads” are changesets that don’t have children changesets. They are where development generally takes place and are the usual targets for update and merge operations.

INPUT:

- `options` - string (default: ‘’):

```
-r --rev       show only heads which are descendants of rev
   --style     display using template map file
   --template  display with template
```

heads(*options=''*)

show current repository heads

Show all repository head changesets.

Repository "heads" are changesets that don't have children changesets. They are where development generally takes place and are the usual targets for update and merge operations.

INPUT:

•`options` - string (default: ''):

```
-r --rev       show only heads which are descendants of rev
   --style     display using template map file
   --template  display with template
```

help(*cmd=''*)

Return help about the given command, or if cmd is omitted a list of commands.

If this hg object is called hg_sage, then you call a command using `hg_sage('usual hg command line notation')`

history(*branches=None, keyword=None, limit=None, rev=None, merges=True, only_merges=False, patch=None, template=False, include=None, exclude=None, verbose=False*)

Display the change log for this repository. This is a list of changesets ordered by revision number.

By default this command outputs: changeset id and hash, tags, non-trivial parents, user, date and time, and a summary for each commit.

INPUT:

•`branches` - (string, default: None) show given branches

•`keyword` - (string, default: None) search for a keyword

•`limit` - (integer, default: None, or 20 in notebook mdoe) limit number of changes displayed

•`rev` - (integer) show the specified revision

•`merges` - (bool, default: True) whether or not to show merges

•`only_merges` - (bool, default: False) if true, show only merges

•`patch` - (string, default: None) show given patch

•`template` - (string, default: None) display with template

•`include` - (string, default: None) include names matching the given patterns

•`exclude` - (string, default: None) exclude names matching the given patterns

•`verbose` - (bool, default: False) If true, the list of changed files and full commit message is shown.

import_patch(*filename, options=''*)

Import an ordered set of patches from patch file, i.e., a plain text file created using the export command.

If there are outstanding changes in the working directory, import will abort unless given the -f flag.

If imported patch was generated by the export command, user and description from patch override values from message headers and body. Values given as options with -m and -u override these.

INPUT:

•`filename` - string

•`options` - string (default: ''):

```
options: [-p NUM] [-b BASE] [-m MESSage] [-f] PATCH...
  -p --strip         directory strip option for patch. This has the same meaning as the
  -m --message       use text as commit message
  -b --base          base path
  -f --force         skip check for outstanding uncommitted changes
```

ALIASES: patch

incoming(*source, options='-p'*)

Show new changesets found in the given source and display the corresponding diffs. This even works if the

source is a bundle file (ends in .hg or .bundle). This is great because it lets you "see inside" the myserious binary-only .hg files.

Show new changesets found in the specified path/URL or the default pull location. These are the changesets that would be pulled if a pull was requested.

For remote repository, using -bundle avoids downloading the changesets twice if the incoming is followed by a pull.

See pull for valid source format details.

ALIAS: inspect

INPUT:

- `filename` - string
- `options` - (default: '-p'):

```
string '[-p] [-n] [-M] [-r REV] ...'
  -M --no-merges       do not show merges
  -f --force           run even when remote repository is unrelated
  --style              display using template map file
  -n --newest-first    show newest record first
  --bundle             file to store the bundles into
  -p --patch           show patch
  -r --rev             a specific revision you would like to pull
  --template           display with template
  -e --ssh             specify ssh command to use
  --remotecmd          specify hg command to run on the remote side
```

inspect(*source, options='-p'*)

Show new changesets found in the given source and display the corresponding diffs. This even works if the source is a bundle file (ends in .hg or .bundle). This is great because it lets you "see inside" the myserious binary-only .hg files.

Show new changesets found in the specified path/URL or the default pull location. These are the changesets that would be pulled if a pull was requested.

For remote repository, using -bundle avoids downloading the changesets twice if the incoming is followed by a pull.

See pull for valid source format details.

ALIAS: inspect

INPUT:

- `filename` - string
- `options` - (default: '-p'):

```
string '[-p] [-n] [-M] [-r REV] ...'
  -M --no-merges       do not show merges
  -f --force           run even when remote repository is unrelated
  --style              display using template map file
  -n --newest-first    show newest record first
  --bundle             file to store the bundles into
  -p --patch           show patch
  -r --rev             a specific revision you would like to pull
  --template           display with template
  -e --ssh             specify ssh command to use
  --remotecmd          specify hg command to run on the remote side
```

list_branches(*print_flag=True*)

Print all branches in the current Sage installation.

log(*branches=None, keyword=None, limit=None, rev=None, merges=True, only_merges=False, patch=None, template=False, include=None, exclude=None, verbose=False*)

Display the change log for this repository. This is a list of changesets ordered by revision number.

By default this command outputs: changeset id and hash, tags, non-trivial parents, user, date and time, and a summary for each commit.

INPUT:

- `branches` - (string, default: None) show given branches
- `keyword` - (string, default: None) search for a keyword
- `limit` - (integer, default: None, or 20 in notebook mdoe) limit number of changes displayed
- `rev` - (integer) show the specified revision
- `merges` - (bool, default: True) whether or not to show merges
- `only_merges` - (bool, default: False) if true, show only merges
- `patch` - (string, default: None) show given patch
- `template` - (string, default: None) display with template
- `include` - (string, default: None) include names matching the given patterns
- `exclude` - (string, default: None) exclude names matching the given patterns
- `verbose` - (bool, default: False) If true, the list of changed files and full commit message is shown.

merge(*options=''*)

Merge working directory with another revision

Merge the contents of the current working directory and the requested revision. Files that changed between either parent are marked as changed for the next commit and a commit must be performed before any further updates are allowed.

INPUT:

- `options` - default: '':

```
-f --force  force a merge with outstanding changes
-r --rev    revision to merge
```

move(*src, dest, options=''*)

Move (rename) the given file, from src to dest. This command takes effect in the next commit.

INPUT:

- `src, dest` - strings that define a file, relative to self.dir()
- `options`:

```
-A --after    record a rename that has already occurred
-f --force    forcibly copy over an existing managed file
-n --dry-run  do not perform actions, just print output
```

mv(*src, dest, options=''*)

Move (rename) the given file, from src to dest. This command takes effect in the next commit.

INPUT:

- `src, dest` - strings that define a file, relative to self.dir()
- `options`:

```
-A --after    record a rename that has already occurred
-f --force    forcibly copy over an existing managed file
-n --dry-run  do not perform actions, just print output
```

outgoing(*url=None, opts=''*)

Use this to find changsets that are in your branch, but not in the specified destination repository. If no destination is specified, the official repository is used. By default, push_url() is used.

From the Mercurial documentation:

> Show changesets not found in the specified destination repository or the default push location.
> These are the changesets that would be pushed if a push was requested.
> See push() for valid destination format details.

INPUT:

- `url` - (Default: self.push_url()) the official repository
  - –http://[user@]host[:port]/[path]
  - –https://[user@]host[:port]/[path]
  - –ssh://[user@]host[:port]/[path]
  - –local directory (starting with a /)
  - –name of a branch (for hg_sage); no /'s
- `options` - (Default: None):

```
-M --no-merges     do not show merges
-f --force         run even when remote repository is unrelated
-p --patch         show patch
--style            display using template map file
-r --rev           a specific revision you would like to push
-n --newest-first  show newest record first
--template         display with template
-e --ssh           specify ssh command to use
--remotecmd        specify hg command to run on the remote side
```

patch (*filename, options=''*)

Import an ordered set of patches from patch file, i.e., a plain text file created using the export command.

If there are outstanding changes in the working directory, import will abort unless given the -f flag.

If imported patch was generated by the export command, user and description from patch override values from message headers and body. Values given as options with -m and -u override these.

INPUT:

- `filename` - string
- `options` - string (default: ''):

```
options: [-p NUM] [-b BASE] [-m MESSage] [-f] PATCH...
  -p --strip         directory strip option for patch. This has the same meaning as the
  -m --message       use text as commit message
  -b --base          base path
  -f --force         skip check for outstanding uncommitted changes
```

ALIASES: patch

pull (*url=None, options='-u'*)

Pull all new patches from the repository at the given url, or use the default 'official' repository if no url is specified.

INPUT:

- `url` - (Default: self.push_url()) the official repository
  - –http://[user@]host[:port]/[path]
  - –https://[user@]host[:port]/[path]
  - –ssh://[user@]host[:port]/[path]
  - –local directory (starting with a /)
  - –name of a branch (for hg_sage); no /'s
- `options` - (Default: '-u'):

```
-u --update     update the working directory to tip after pull
-e --ssh        specify ssh command to use
-f --force      run even when remote repository is unrelated
-r --rev        a specific revision you would like to pull
--remotecmd     specify hg command to run on the remote side
```

Some notes about using SSH with Mercurial:

- SSH requires an accessible shell account on the destination machine and a copy of hg in the remote path or specified with as remotecmd.
- path is relative to the remote user's home directory by default. Use an extra slash at the start of a path to specify an absolute path: ssh://example.com//tmp/repository
- Mercurial doesn't use its own compression via SSH; the right thing to do is to configure it in your /.ssh/ssh_config, e.g.:

```
Host *.mylocalnetwork.example.com
  Compression off
Host *
  Compression on
```

Alternatively specify 'ssh -C' as your ssh command in your hgrc or with the -ssh command line option.

pull_url()
Return the default 'master url' for this repository.

push(*url=None, options=''*)
Push all new patches from the repository to the given destination.

INPUT:

- `url` - (Default: self.push_url()) the official repository
  - http://[user@]host[:port]/[path]
  - https://[user@]host[:port]/[path]
  - ssh://[user@]host[:port]/[path]
  - local directory (starting with a /)
  - name of a branch (for hg_sage); no /'s
- `options` - (Default: '-u'):

```
-e --ssh        specify ssh command to use
-f --force      run even when remote repository is unrelated
-r --rev        a specific revision you would like to pull
--remotecmd     specify hg command to run on the remote side
```

Some notes about using SSH with Mercurial:

- SSH requires an accessible shell account on the destination machine and a copy of hg in the remote path or specified with as remotecmd.
- path is relative to the remote user's home directory by default. Use an extra slash at the start of a path to specify an absolute path: ssh://example.com//tmp/repository
- Mercurial doesn't use its own compression via SSH; the right thing to do is to configure it in your /.ssh/ssh_config, e.g.:

```
Host *.mylocalnetwork.example.com
  Compression off
Host *
  Compression on
```

Alternatively specify 'ssh -C' as your ssh command in your hgrc or with the -ssh command line option.

push_url()
Return the default url for uploading this repository.

record(*files='', comment=None, options='', diff=True*)
Commit your changes to the repository.

Quit out of the editor without saving to not record your changes.

INPUT:

- `files` - space separated string of file names (optional) If specified only those files are commited. The path must be absolute or relative to self.dir().

- **`comment` - optional changeset comment. If you don't give** it you will be dumped into an editor. If you're using the Sage notebook, you *must* specify a comment.
- `options` - string:

```
-A --addremove  mark new/missing files as added/removed before committing
-m --message    use <text> as commit message
-l --logfile    read the commit message from <file>
-d --date       record datecode as commit date
-u --user       record user as commiter
-I --include    include names matching the given patterns
-X --exclude    exclude names matching the given patterns
```

- `diff` - (default: True) if True show diffs between your repository and your working repository before recording changes.

Note: If you create new files you should first add them with the add method.

`remove` (*files, options=''*)

Remove the given list of files (or file) or directories from your HG repository.

INPUT:

- `files` - list or string; name of file or directory.
- `options` - string (e.g., '-f')

`rename` (*src, dest, options=''*)

Move (rename) the given file, from src to dest. This command takes effect in the next commit.

INPUT:

- `src, dest` - strings that define a file, relative to self.dir()
- `options`:

```
-A --after    record a rename that has already occurred
-f --force    forcibly copy over an existing managed file
-n --dry-run  do not perform actions, just print output
```

`revert` (*files='', options='', rev=None*)

Revert files or dirs to their states as of some revision

With no revision specified, revert the named files or directories to the contents they had in the parent of the working directory. This restores the contents of the affected files to an unmodified state. If the working directory has two parents, you must explicitly specify the revision to revert to.

Modified files are saved with a .orig suffix before reverting. To disable these backups, use -no-backup.

Using the -r option, revert the given files or directories to their contents as of a specific revision. This can be helpful to 'roll back' some or all of a change that should not have been committed.

Revert modifies the working directory. It does not commit any changes, or change the parent of the working directory. If you revert to a revision other than the parent of the working directory, the reverted files will thus appear modified afterwards.

If a file has been deleted, it is recreated. If the executable mode of a file was changed, it is reset.

If names are given, all files matching the names are reverted.

If no arguments are given, all files in the repository are reverted.

OPTIONS:

```
   --no-backup  do not save backup copies of files
-I --include    include names matching given patterns
-X --exclude    exclude names matching given patterns
-n --dry-run    do not perform actions, just print output
```

`rm` (*files, options=''*)

Remove the given list of files (or file) or directories from your HG repository.

INPUT:

- `files` - list or string; name of file or directory.
- `options` - string (e.g., '-f')

rollback()
Remove recorded patches without changing the working copy.

save(*filename, options='', url=None, base=None, to=None*)
Create an hg changeset bundle with the given filename against the repository at the given url (which is by default the 'official' Sage repository, unless push_url() is changed in a setup file).

If you have internet access, it's best to just do `hg_sage.bundle(filename)`. If you don't find a revision r that you and the person unbundling both have (by looking at `hg_sage.log()`), then do `hg_sage.bundle(filename, base=r)`.

Use self.inspect('file.bundle') to inspect the resulting bundle.

This is a file that you should probably send to William Stein (wstein@gmail.com), post to a web page, or send to sage-devel. It will be written to the current directory.

INPUT:

- `filename` - output file in which to put bundle
- `options` - pass to hg
- `url` - url to bundle against (default: SAGE_SERVER, or push_url())
- `base` - a base changeset revision number to bundle against (doesn't require internet access)

send(*filename, options='', url=None, base=None, to=None*)
Create an hg changeset bundle with the given filename against the repository at the given url (which is by default the 'official' Sage repository, unless push_url() is changed in a setup file).

If you have internet access, it's best to just do `hg_sage.bundle(filename)`. If you don't find a revision r that you and the person unbundling both have (by looking at `hg_sage.log()`), then do `hg_sage.bundle(filename, base=r)`.

Use self.inspect('file.bundle') to inspect the resulting bundle.

This is a file that you should probably send to William Stein (wstein@gmail.com), post to a web page, or send to sage-devel. It will be written to the current directory.

INPUT:

- `filename` - output file in which to put bundle
- `options` - pass to hg
- `url` - url to bundle against (default: SAGE_SERVER, or push_url())
- `base` - a base changeset revision number to bundle against (doesn't require internet access)

serve(*port=8200, address='localhost', open_viewer=True, options=''*)
Start a web server for this repository.

This server is very nice - you can browse all files in the repository, see their changelogs, see who wrote any given line, etc. Very nice.

INPUT:

- `port` - port that the server will listen on
- `address` - (default: 'localhost') address to listen on
- `open_viewer` - boolean (default: True); whether to pop up the web page
- `options` - a string passed directly to hg's serve command.

status()

switch(*name=None*)
Switch to a different branch. You must restart Sage after switching.

Only available for `hg_sage.`

INPUT:

- `name` - name of a Sage branch (default: None)

If the name is not given, this function returns a list of all branches.

unbundle(*bundle, update=True, options=''*)

Apply patches from a hg patch to the repository.

If the bundle is a .patch file, instead call the import_patch method. To see what is in a bundle before applying it, using self.incoming(bundle).

INPUT:

- `bundle` - an hg bundle (created with the bundle command)
- `update` - if True (the default), update the working directory after unbundling.

up(*options=''*)

update or merge working directory

Update the working directory to the specified revision.

If there are no outstanding changes in the working directory and there is a linear relationship between the current version and the requested version, the result is the requested version.

To merge the working directory with another revision, use the merge command.

By default, update will refuse to run if doing so would require merging or discarding local changes.

aliases: up, checkout, co

INPUT:

- `options` - string (default: ''):

```
-C --clean  overwrite locally modified files
-d --date   tipmost revision matching date
-r --rev    revision
```

update(*options=''*)

update or merge working directory

Update the working directory to the specified revision.

If there are no outstanding changes in the working directory and there is a linear relationship between the current version and the requested version, the result is the requested version.

To merge the working directory with another revision, use the merge command.

By default, update will refuse to run if doing so would require merging or discarding local changes.

aliases: up, checkout, co

INPUT:

- `options` - string (default: ''):

```
-C --clean  overwrite locally modified files
-d --date   tipmost revision matching date
-r --rev    revision
```

what(*files='', rev=None*)

Show differences between revisions for the specified files as a unified diff.

By default this command tells you exactly what you have changed in your working repository since you last commited changes.

INPUT:

- `files` - space separated list of files (relative to self.dir())
- `rev` - None or a list of integers.

Differences between files are shown using the unified diff format.

When two revision arguments are given, then changes are shown between those revisions. If only one revision is specified then that revision is compared to the working directory, and, when no revisions are specified, the working directory files are compared to its parent.

get_remote_file(*f, **kwds*)

Wrap the get_remote_file method to move the file if it ends in ?stuff, as happens with funny urls from web servers.

pager()

Return a page program, which is either cat or less at present.

Return cat if embedded in the notebook, and less otherwise.

11.8 Functional notation

These are function so that you can write foo(x) instead of x.foo() in certain common cases.

AUTHORS:

- William Stein: Initial version
- David Joyner (2005-12-20): More Examples

N(*x, prec=None, digits=None*)

Return a numerical approximation of x with at least prec bits of precision.

Note: Both upper case N and lower case n are aliases for `numerical_approx()`.

INPUT:

- `x` - an object that has a numerical_approx method, or can be coerced into a real or complex field
- `prec (optional)` - an integer (bits of precision)
- `digits (optional)` - an integer (digits of precision)

If neither the prec or digits are specified, the default is 53 bits of precision.

EXAMPLES:

```
sage: numerical_approx(pi, 10)
3.1
sage: numerical_approx(pi, digits=10)
3.141592654
sage: numerical_approx(pi^2 + e, digits=20)
12.587886229548403854
sage: n(pi^2 + e)
12.5878862295484
sage: N(pi^2 + e)
12.5878862295484
sage: n(pi^2 + e, digits=50)
12.587886229548403854194778471228813633070946500941
sage: a = CC(-5).n(prec=100)
sage: b = ComplexField(100)(-5)
sage: a == b
True
sage: type(a) == type(b)
True
```

You can also usually use method notation:

```
sage: (pi^2 + e).n()
12.5878862295484
```

TESTS:

```
sage: numerical_approx(I)
1.00000000000000*I
sage: x = QQ['x'].gen()
sage: F.<k> = NumberField(x^2+2, embedding=sqrt(CC(2))*CC.0)
sage: numerical_approx(k)
1.41421356237309*I

sage: type(numerical_approx(CC(1/2)))
<type 'sage.rings.complex_number.ComplexNumber'>
```

acos(*x*)
Return the arc cosine of x.

additive_order(*x*)
Return the additive order of x.

arg(*x*)
Return the argument of a complex number x.

EXAMPLES:

```
sage: z = CC(1,2)
sage: theta = arg(z)
sage: cos(theta)*abs(z)
1.00000000000000
sage: sin(theta)*abs(z)
2.00000000000000
```

asin(*x*)
Return the arc sine of x.

atan(*x*)
Return the arc tangent of x.

base_field(*x*)
Return the base field over which x is defined.

base_ring(*x*)
Return the base ring over which x is defined.

EXAMPLES:

```
sage: R = PolynomialRing(GF(7), 'x')
sage: base_ring(R)
Finite Field of size 7
```

basis(*x*)
Return the fixed basis of x.

EXAMPLES:

```
sage: V = VectorSpace(QQ,3)
sage: S = V.subspace([[1,2,0],[2,2,-1]])
sage: basis(S)
[
(1, 0, -1),
(0, 1, 1/2)
]
```

category(*x*)
Return the category of x.

EXAMPLES:

```
sage: V = VectorSpace(QQ,3)
sage: category(V)
Category of vector spaces over Rational Field
```

ceil(*x*)

characteristic_polynomial(*x*, *var='x'*)

Return the characteristic polynomial of x in the given variable.

EXAMPLES:

```
sage: M = MatrixSpace(QQ,3,3)
sage: A = M([1,2,3,4,5,6,7,8,9])
sage: charpoly(A)
x^3 - 15*x^2 - 18*x
sage: charpoly(A, 't')
t^3 - 15*t^2 - 18*t
```

```
sage: k.<alpha> = GF(7^10); k
Finite Field in alpha of size 7^10
sage: alpha.charpoly('T')
T^10 + T^6 + T^5 + 4*T^4 + T^3 + 2*T^2 + 3*T + 3
sage: characteristic_polynomial(alpha, 'T')
T^10 + T^6 + T^5 + 4*T^4 + T^3 + 2*T^2 + 3*T + 3
```

charpoly(*x*, *var='x'*)

Return the characteristic polynomial of x in the given variable.

EXAMPLES:

```
sage: M = MatrixSpace(QQ,3,3)
sage: A = M([1,2,3,4,5,6,7,8,9])
sage: charpoly(A)
x^3 - 15*x^2 - 18*x
sage: charpoly(A, 't')
t^3 - 15*t^2 - 18*t
```

```
sage: k.<alpha> = GF(7^10); k
Finite Field in alpha of size 7^10
sage: alpha.charpoly('T')
T^10 + T^6 + T^5 + 4*T^4 + T^3 + 2*T^2 + 3*T + 3
sage: characteristic_polynomial(alpha, 'T')
T^10 + T^6 + T^5 + 4*T^4 + T^3 + 2*T^2 + 3*T + 3
```

coerce(*P*, *x*)

cyclotomic_polynomial(*n*, *var='x'*)

EXAMPLES:

```
sage: cyclotomic_polynomial(3)
x^2 + x + 1
sage: cyclotomic_polynomial(4)
x^2 + 1
sage: cyclotomic_polynomial(9)
x^6 + x^3 + 1
sage: cyclotomic_polynomial(10)
x^4 - x^3 + x^2 - x + 1
```

```
sage: cyclotomic_polynomial(11)
x^10 + x^9 + x^8 + x^7 + x^6 + x^5 + x^4 + x^3 + x^2 + x + 1
```

decomposition (*x*)
Return the decomposition of x.

denominator (*x*)
Return the denominator of x.

EXAMPLES:

```
sage: denominator(17/11111)
11111
sage: R.<x> = PolynomialRing(QQ)
sage: F = FractionField(R)
sage: r = (x+1)/(x-1)
sage: denominator(r)
x - 1
```

det (*x*)
Return the determinant of x.

EXAMPLES:

```
sage: M = MatrixSpace(QQ,3,3)
sage: A = M([1,2,3,4,5,6,7,8,9])
sage: det(A)
0
```

dim (*x*)
Return the dimension of x.

EXAMPLES:

```
sage: V = VectorSpace(QQ,3)
sage: S = V.subspace([[1,2,0],[2,2,-1]])
sage: dimension(S)
2
```

dimension (*x*)
Return the dimension of x.

EXAMPLES:

```
sage: V = VectorSpace(QQ,3)
sage: S = V.subspace([[1,2,0],[2,2,-1]])
sage: dimension(S)
2
```

disc (*x*)
EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: S = R.quotient(x^29 - 17*x - 1, 'alpha')
sage: K = S.number_field()
sage: discriminant(K)
-15975100446626038280218213241591829458737190477345113376757479850566957249523
```

discriminant (*x*)
EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: S = R.quotient(x^29 - 17*x - 1, 'alpha')
sage: K = S.number_field()
sage: discriminant(K)
-15975100446626038280218213241591829458737190477345113376757479850566957249523
```

eta (*x*)
Return the value of the eta function at x, which must be in the upper half plane.

The η function is

$$\eta(z) = e^{\pi i z/12} \prod_{n=1}^{\infty} (1 - e^{2\pi i n z})$$

EXAMPLES:

```
sage: eta(1+I)
0.742048775837 + 0.19883137023*I
```

exp (*x*)
Return the value of the exponentation function at x.

factor (*x, *args, **kwds*)
Return the prime factorization of x.

EXAMPLES:

```
sage: factor(factorial(10))
2^8 * 3^4 * 5^2 * 7
sage: n = next_prime(10^6); n
1000003
sage: factor(n)
1000003
```

factorisation (*x, *args, **kwds*)
Return the prime factorization of x.

EXAMPLES:

```
sage: factor(factorial(10))
2^8 * 3^4 * 5^2 * 7
sage: n = next_prime(10^6); n
1000003
sage: factor(n)
1000003
```

factorization (*x, *args, **kwds*)
Return the prime factorization of x.

EXAMPLES:

```
sage: factor(factorial(10))
2^8 * 3^4 * 5^2 * 7
sage: n = next_prime(10^6); n
1000003
sage: factor(n)
1000003
```

fcp (*x, var='x'*)
Return the factorization of the characteristic polynomial of x.

EXAMPLES:

```
sage: M = MatrixSpace(QQ,3,3)
sage: A = M([1,2,3,4,5,6,7,8,9])
sage: fcp(A, 'x')
x * (x^2 - 15*x - 18)
```

gen (*x*)
Return the generator of x.

gens (*x*)
Return the generators of x.

hecke_operator (*x, n*)
Return the n-th Hecke operator T_n acting on x.

EXAMPLES:

```
sage: M = ModularSymbols(1,12)
sage: hecke_operator(M,5)
Hecke operator T_5 on Modular Symbols space of dimension 3 for Gamma_0(1) of weight 12 with sign
```

image (*x*)
Return the image of x.

EXAMPLES:

```
sage: M = MatrixSpace(QQ,3,3)
sage: A = M([1,2,3,4,5,6,7,8,9])
sage: image(A)
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1  0 -1]
[ 0  1  2]
```

integral (*x, *args, **kwds*)
Return an indefinite integral of an object x.

First call x.integrate() and if that fails make an object and integrate it using maxima, maple, etc, as specified by algorithm.

EXAMPLES:

```
sage: f = cyclotomic_polynomial(10)
sage: integral(f)
1/5*x^5 - 1/4*x^4 + 1/3*x^3 - 1/2*x^2 + x
sage: integral(sin(x),x)
-cos(x)
sage: y = var('y')
sage: integral(sin(x),y)
y*sin(x)
sage: integral(sin(x), x, 0, pi/2)
1
sage: sin(x).integral(x, 0,pi/2)
1
```

integral_closure (*x*)

integrate(*x, *args, **kwds*)

Return an indefinite integral of an object x.

First call x.integrate() and if that fails make an object and integrate it using maxima, maple, etc, as specified by algorithm.

EXAMPLES:

```
sage: f = cyclotomic_polynomial(10)
sage: integral(f)
1/5*x^5 - 1/4*x^4 + 1/3*x^3 - 1/2*x^2 + x
sage: integral(sin(x),x)
-cos(x)
sage: y = var('y')
sage: integral(sin(x),y)
y*sin(x)
sage: integral(sin(x), x, 0, pi/2)
1
sage: sin(x).integral(x, 0,pi/2)
1
```

interval(*a, b*)

Integers between a and b *inclusive* (a and b integers).

EXAMPLES:

```
sage: I = interval(1,3)
sage: 2 in I
True
sage: 1 in I
True
sage: 4 in I
False
```

is_commutative(*x*)

EXAMPLES:

```
sage: R = PolynomialRing(QQ, 'x')
sage: is_commutative(R)
True
```

is_even(*x*)

Return whether or not an integer x is even, e.g., divisible by 2.

EXAMPLES:

```
sage: is_even(-1)
False
sage: is_even(4)
True
sage: is_even(-2)
True
```

is_field(*x*)

EXAMPLES:

```
sage: R = PolynomialRing(QQ, 'x')
sage: F = FractionField(R)
sage: is_field(F)
True
```

is_integrally_closed(*x*)

is_noetherian(*x*)

is_odd(*x*)
Return whether or not x is odd. This is by definition the complement of is_even.

EXAMPLES:

```
sage: is_odd(-2)
False
sage: is_odd(-3)
True
sage: is_odd(0)
False
sage: is_odd(1)
True
```

isqrt(*x*)
Return an integer square root, i.e., the floor of a square root.

EXAMPLES:

```
sage: isqrt(10)
3
sage: isqrt(10r)
3
```

kernel(*x*)
Return the left kernel of x.

EXAMPLES:

```
sage: M = MatrixSpace(QQ,3,2)
sage: A = M([1,2,3,4,5,6])
sage: kernel(A)
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2  1]
sage: kernel(A.transpose())
Vector space of degree 2 and dimension 0 over Rational Field
Basis matrix:
[]
```

Here are two corner cases: sage: M=MatrixSpace(QQ,0,3) sage: A=M([]) sage: kernel(A) Vector space of degree 0 and dimension 0 over Rational Field Basis matrix: [] sage: kernel(A.transpose()).basis() [(1, 0, 0), (0, 1, 0), (0, 0, 1)]

krull_dimension(*x*)

lift(*x*)
Lift an object of a quotient ring R/I to R.

EXAMPLES: We lift an integer modulo 3.

```
sage: Mod(2,3).lift()
2
```

We lift an element of a quotient polynomial ring.

```
sage: R.<x> = QQ['x']
sage: S.<xmod> = R.quo(x^2 + 1)
sage: lift(xmod-7)
x - 7
```

log (*x, b=None*)

Return the log of x to the base b. The default base is e.

INPUT:

- x - number
- b - base (default: None, which means natural log)

OUTPUT: number

Note: In Magma, the order of arguments is reversed from in Sage, i.e., the base is given first. We use the opposite ordering, so the base can be viewed as an optional second argument.

minimal_polynomial (*x, var='x'*)

Return the minimal polynomial of x.

EXAMPLES:

```
sage: a = matrix(ZZ, 2, [1..4])
sage: minpoly(a)
x^2 - 5*x - 2
sage: minpoly(a,'t')
t^2 - 5*t - 2
sage: minimal_polynomial(a)
x^2 - 5*x - 2
sage: minimal_polynomial(a,'theta')
theta^2 - 5*theta - 2
```

minpoly (*x, var='x'*)

Return the minimal polynomial of x.

EXAMPLES:

```
sage: a = matrix(ZZ, 2, [1..4])
sage: minpoly(a)
x^2 - 5*x - 2
sage: minpoly(a,'t')
t^2 - 5*t - 2
sage: minimal_polynomial(a)
x^2 - 5*x - 2
sage: minimal_polynomial(a,'theta')
theta^2 - 5*theta - 2
```

multiplicative_order (*x*)

Return the multiplicative order of self, if self is a unit, or raise `ArithmeticError` otherwise.

n (*x, prec=None, digits=None*)

Return a numerical approximation of x with at least prec bits of precision.

Note: Both upper case N and lower case n are aliases for `numerical_approx()`.

INPUT:

- x - an object that has a numerical_approx method, or can be coerced into a real or complex field
- `prec (optional)` - an integer (bits of precision)
- `digits (optional)` - an integer (digits of precision)

If neither the prec or digits are specified, the default is 53 bits of precision.

EXAMPLES:

```
sage: numerical_approx(pi, 10)
3.1
sage: numerical_approx(pi, digits=10)
3.141592654
sage: numerical_approx(pi^2 + e, digits=20)
12.587886229548403854
sage: n(pi^2 + e)
12.5878862295484
sage: N(pi^2 + e)
12.5878862295484
sage: n(pi^2 + e, digits=50)
12.587886229548403854194778471228813633070946500941
sage: a = CC(-5).n(prec=100)
sage: b = ComplexField(100)(-5)
sage: a == b
True
sage: type(a) == type(b)
True
```

You can also usually use method notation:

```
sage: (pi^2 + e).n()
12.5878862295484
```

TESTS:

```
sage: numerical_approx(I)
1.00000000000000*I
sage: x = QQ['x'].gen()
sage: F.<k> = NumberField(x^2+2, embedding=sqrt(CC(2))*CC.0)
sage: numerical_approx(k)
1.41421356237309*I

sage: type(numerical_approx(CC(1/2)))
<type 'sage.rings.complex_number.ComplexNumber'>
```

ngens(*x*)

Return the number of generators of x.

norm(*x*)

Return the norm of x.

EXAMPLES:

```
sage: z = 1+2*I
sage: norm(z)
5
sage: norm(CDF(z))
5.0
sage: norm(CC(z))
5.00000000000000
```

numerator(*x*)

Return the numerator of x.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: F = FractionField(R)
sage: r = (x+1)/(x-1)
sage: numerator(r)
x + 1
sage: numerator(17/11111)
17
```

numerical_approx(*x, prec=None, digits=None*)

Return a numerical approximation of x with at least prec bits of precision.

Note: Both upper case N and lower case n are aliases for `numerical_approx()`.

INPUT:

- `x` - an object that has a numerical_approx method, or can be coerced into a real or complex field
- `prec (optional)` - an integer (bits of precision)
- `digits (optional)` - an integer (digits of precision)

If neither the prec or digits are specified, the default is 53 bits of precision.

EXAMPLES:

```
sage: numerical_approx(pi, 10)
3.1
sage: numerical_approx(pi, digits=10)
3.141592654
sage: numerical_approx(pi^2 + e, digits=20)
12.587886229548403854
sage: n(pi^2 + e)
12.5878862295484
sage: N(pi^2 + e)
12.5878862295484
sage: n(pi^2 + e, digits=50)
12.587886229548403854194778471228813633070946500941
sage: a = CC(-5).n(prec=100)
sage: b = ComplexField(100)(-5)
sage: a == b
True
sage: type(a) == type(b)
True
```

You can also usually use method notation:

```
sage: (pi^2 + e).n()
12.5878862295484
```

TESTS:

```
sage: numerical_approx(I)
1.00000000000000*I
sage: x = QQ['x'].gen()
sage: F.<k> = NumberField(x^2+2, embedding=sqrt(CC(2))*CC.0)
sage: numerical_approx(k)
1.41421356237309*I

sage: type(numerical_approx(CC(1/2)))
<type 'sage.rings.complex_number.ComplexNumber'>
```

objgen(*x*)
EXAMPLES:

```
sage: R, x = objgen(FractionField(QQ['x']))
sage: R
Fraction Field of Univariate Polynomial Ring in x over Rational Field
sage: x
x
```

objgens(*x*)
EXAMPLES:

```
sage: R, x = objgens(PolynomialRing(QQ,3, 'x'))
sage: R
Multivariate Polynomial Ring in x0, x1, x2 over Rational Field
sage: x
(x0, x1, x2)
```

one(*R*)
Return the one element of the ring R.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: one(R)*x == x
True
sage: one(R) in R
True
```

order(*x*)
Return the order of x. If x is a ring or module element, this is the additive order of x.

EXAMPLES:

```
sage: C = CyclicPermutationGroup(10)
sage: order(C)
10
sage: F = GF(7)
sage: order(F)
7
```

parent(*x*)
Return x.parent() if defined, or type(x) if not.

EXAMPLE:

```
sage: Z = parent(int(5))
sage: Z(17)
17
sage: Z
<type 'int'>
```

quo(*x, y, *args, **kwds*)
Return the quotient object x/y, e.g., a quotient of numbers or of a polynomial ring x by the ideal generated by y, etc.

quotient(*x, y, *args, **kwds*)
Return the quotient object x/y, e.g., a quotient of numbers or of a polynomial ring x by the ideal generated by y, etc.

rank(*x*)
Return the rank of x.

EXAMPLES: We compute the rank of a matrix:

```
sage: M = MatrixSpace(QQ,3,3)
sage: A = M([1,2,3,4,5,6,7,8,9])
sage: rank(A)
2
```

We compute the rank of an elliptic curve:

```
sage: E = EllipticCurve([0,0,1,-1,0])
sage: rank(E)
1
```

regulator(*x*)
Return the regulator of x.

round(*x, ndigits=0*)
round(number[, ndigits]) - double-precision real number

Round a number to a given precision in decimal digits (default 0 digits). This always returns a real double field element.

EXAMPLES:

```
sage: round(sqrt(2),2)
1.41
sage: round(sqrt(2),5)
1.41421
sage: round(pi)
3.0
sage: b = 5.4999999999999999
sage: round(b)
5.0
```

Since we use floating-point with a limited range, some roundings can't be performed:

```
sage: round(sqrt(Integer('1'*1000)))
+infinity
```

IMPLEMENTATION: If ndigits is specified, it calls Python's builtin round function, and converts the result to a real double field element. Otherwise, it tries the argument's .round() method, and if that fails, it falls back to the builtin round function.

Note: This is currently slower than the builtin round function, since it does more work - i.e., allocating an RDF element and initializing it. To access the builtin version do `import __builtin__; __builtin__.round`.

show(*x, *args, **kwds*)
Show a graphics object x.

For additional ways to show objects in the notebook, look at the methods on the html object. For example, html.table will produce an HTML table from a nested list.

OPTIONAL INPUT:

- `filename` - (default: None) string

SOME OF THESE MAY APPLY:

- `dpi` - dots per inch

- `figsize` - [width, height] (same for square aspect)
- `axes` - (default: True)
- `fontsize` - positive integer
- `frame` - (default: False) draw a MATLAB-like frame around the image

EXAMPLES:

```
sage: show(graphs(3))
sage: show(list(graphs(3)))
```

sqrt (*x*)

Return a square root of x.

This function (`numerical_sqrt`) is deprecated. Use `sqrt(x, prec=n)` instead.

EXAMPLES:

```
sage: numerical_sqrt(10.1)
doctest:1: DeprecationWarning: numerical_sqrt is deprecated, use sqrt(x, prec=n) instead
3.17804971641414
sage: numerical_sqrt(9)
3
```

squarefree_part (*x*)

Return the square free part of x, i.e., a divisor z such that $x = zy^2$, for a perfect square y^2.

EXAMPLES:

```
sage: squarefree_part(100)
1
sage: squarefree_part(12)
3
sage: squarefree_part(10)
10
```

```
sage: x = QQ['x'].0
sage: S = squarefree_part(-9*x*(x-6)^7*(x-3)^2); S
-9*x^2 + 54*x
sage: S.factor()
(-9) * (x - 6) * x
```

```
sage: f = (x^3 + x + 1)^3*(x-1); f
x^10 - x^9 + 3*x^8 + 3*x^5 - 2*x^4 - x^3 - 2*x - 1
sage: g = squarefree_part(f); g
x^4 - x^3 + x^2 - 1
sage: g.factor()
(x - 1) * (x^3 + x + 1)
```

transpose (*x*)

EXAMPLES:

```
sage: M = MatrixSpace(QQ,3,3)
sage: A = M([1,2,3,4,5,6,7,8,9])
sage: transpose(A)
[1 4 7]
[2 5 8]
[3 6 9]
```

xinterval(*a, b*)
Iterator over the integers between a and b, *inclusive*.

zero(*R*)
Return the zero element of the ring R.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: zero(R) in R
True
sage: zero(R)*x == zero(R)
True
```

11.9 LaTeX printing support

In order to support latex formating, an object should define a special method _latex_(self) that returns a string.

class JSMath()
A simple object for rendering LaTeX input using JSMath.

eval(*x, globals=None, locals=None, mode='display'*)

class JSMathExpr(*y*)
An arbitrary JSMath expression that can be nicely concatenated.

class Latex(*debug=False, slide=False, density=150, pdflatex=None*)
Enter, e.g.,

```
%latex
The equation $y^2 = x^3 + x$ defines an elliptic curve.
We have $2006 = Sage{factor(2006)}$.
```

in an input cell to get a typeset version. Use `%latex_debug` to get debugging output.

Use `latex(...)` to typeset a Sage object.

Use `%slide` instead to typeset slides.

> **Warning:** You must have dvipng (or dvips and convert) installed on your operating system, or this command won't work.

add_macro(*macro*)
Append to the string of extra LaTeX macros, for use with %latex, %html, and %jsmath.

INPUT: `macro` - string

EXAMPLES:: sage: latex.extra_macros() '' sage: latex.add_macro("newcommand{foo}{bar}") sage: latex.extra_macros() 'newcommand{foo}{bar}' sage: latex.extra_macros("") # restore to default

add_to_preamble(*s*)
Append to the string of extra LaTeX macros, for use with %latex. Anything in this string won't be processed by %jsmath.

EXAMPLES:

```
sage: latex.extra_preamble()
''
sage: latex.add_to_preamble("\\DeclareMathOperator{\\Ext}{Ext}")
```

At this point, a notebook cell containing

```
%latex
$\Ext_A^*(\GF{2}, \GF{2}) \Rightarrow \pi_*^s*(S^0)$
```

will be typeset correctly.

```
sage: latex.add_to_preamble("\\usepackage{xypic}")
sage: latex.extra_preamble()
'\\DeclareMathOperator{\\Ext}{Ext}\\usepackage{xypic}'
```

Now one can put various xypic diagrams into a %latex cell, such as

```
%latex
\[ \xymatrix{ \circ \ar `r[d]^{a} `[rr]^{b} `/4pt[rr]^{c} `[rrr]^{d}
`_dl[drrr]^{e} [drrr]^{f} & \circ & \circ & \circ \\ \circ & \circ &
\circ & \circ } \]
```

Reset the preamble to its default, the empty string:

```
sage: latex.extra_preamble('')
sage: latex.extra_preamble()
''
```

blackboard_bold(*t=None*)

Controls whether Sage uses blackboard bold or ordinary bold face for typesetting ZZ, RR, etc.

INPUT:

- t – boolean or None

OUTPUT: if t is None, return the current setting (True or False).

If t == True, use blackboard bold (mathbb); otherwise use boldface (mathbf).

EXAMPLES:

```
sage: latex.blackboard_bold()
False
sage: latex.blackboard_bold(True)
sage: latex.blackboard_bold()
True
sage: latex.blackboard_bold(False)
```

eval(*x, globals, strip=False, filename=None, debug=None, density=None, pdflatex=None, locals={}*)

INPUT: globals – a globals dictionary

- x - string to evaluate.
- strip - ignored
- filename - output filename
- debug - whether to print verbose debugging output
- density - how big output image is.
- pdflatex - whether to use pdflatex.
- locals - extra local variables used when evaluating Sage.. code in x.

> **Warning:** When using latex (the default), you must have 'dvipng' (or 'dvips' and 'convert') installed on your operating system, or this command won't work. When using pdflatex, you must have 'convert' installed.

extra_macros(*macros=None*)

String containing extra LaTeX macros to use with %latex, %html, and %jsmath.

INPUT: macros - string

If macros is None, return the current string. Otherwise, set it to macros. If you want to *append* to the string of macros instead of replacing it, using latex.add_macro.

EXAMPLES:

```
sage: latex.extra_macros("\newcommand{\foo}{bar}")
sage: latex.extra_macros()
'\newcommand{\foo}{bar}'
sage: latex.extra_macros("")
sage: latex.extra_macros()
''
```

extra_preamble(*s=None*)

String containing extra preamble to be used with %latex. Anything in this string won't be processed by %jsmath.

INPUT: `s` - string or `None`

If `s` is None, return the current preamble. Otherwise, set it to `s`. If you want to *append* to the current extra preamble instead of replacing it, using `latex.add_to_preamble`.

EXAMPLES:

```
sage: latex.extra_preamble("\DeclareMathOperator{\Ext}{Ext}")
sage: latex.extra_preamble()
'\DeclareMathOperator{\Ext}{Ext}'
sage: latex.extra_preamble("")
sage: latex.extra_preamble()
''
```

matrix_delimiters(*left=None, right=None*)

Change the left and right delimiters for the LaTeX representation of matrices

INPUT:

- `left`, `right` - strings or None

If both `left` and `right` are `None`, then return the current delimiters. Otherwise, set the left and/or right delimiters, whichever are specified.

Good choices for `left` and `right` are any delimiters which LaTeX understands and knows how to resize; some examples are:

- parentheses: '(', ')'
- brackets: '[', ']'
- braces: '\{', '\}'
- vertical lines: '|'
- angle brackets: '\langle', '\rangle'

Note: Putting aside aesthetics, you may combine these in any way imaginable; for example, you could set `left` to be a right-hand bracket ']' and `right` to be a right-hand brace '\}', and it will be typeset correctly.

EXAMPLES:

```
sage: a = matrix(1, 1, [17])
sage: latex(a)
\left(\begin{array}{r}
17
\end{array}\right)
sage: latex.matrix_delimiters("[", "]")
sage: latex(a)
\left[\begin{array}{r}
17
\end{array}\right]
sage: latex.matrix_delimiters(left="\\{")
sage: latex(a)
\left\{\begin{array}{r}
17
```

```
\end{array}\right]
sage: latex.matrix_delimiters()
['\\{', ']']
```

Restore defaults:

```
sage: latex.matrix_delimiters("(", ")")
```

pdflatex(*t=None*)

Controls whether Sage uses PDFLaTeX or LaTeX when typesetting with `view`, in `%latex` cells, etc.

INPUT:

- `t` – boolean or None

OUTPUT: if t is None, return the current setting (True or False).

If t == True, use PDFLaTeX; otherwise use LaTeX.

EXAMPLES:

```
sage: latex.pdflatex()
False
sage: latex.pdflatex(True)
sage: latex.pdflatex()
True
sage: latex.pdflatex(False)
```

vector_delimiters(*left=None, right=None*)

Change the left and right delimiters for the LaTeX representation of vectors

INPUT:

- `left`, `right` - strings or None

If both `left` and `right` are `None`, then return the current delimiters. Otherwise, set the left and/or right delimiters, whichever are specified.

Good choices for `left` and `right` are any delimiters which LaTeX understands and knows how to resize; some examples are:

- parentheses: '(', ')'
- brackets: '[', ']'
- braces: '\{', '\}'
- vertical lines: '|'
- angle brackets: '\langle', '\rangle'

Note: Putting aside aesthetics, you may combine these in any way imaginable; for example, you could set `left` to be a right-hand bracket ']' and `right` to be a right-hand brace '\}', and it will be typeset correctly.

EXAMPLES:

```
sage: a = vector(QQ, [1,2,3])
sage: latex(a)
\left(1,2,3\right)
sage: latex.vector_delimiters("[", "]")
sage: latex(a)
\left[1,2,3\right]
sage: latex.vector_delimiters(right="\\}")
sage: latex(a)
\left[1,2,3\right\}
sage: latex.vector_delimiters()
['[', '\\}']
```

Restore defaults:

```
sage: latex.vector_delimiters("(", ")")
```

class LatexExpr(*x*)

bool_function(*x*)

Returns the LaTeX code for a tuple x.

INPUT: x - boolean

EXAMPLES:

```
sage: from sage.misc.latex import bool_function
sage: bool_function(2==3)
'\\mbox{\\rm False}'
sage: bool_function(3==(2+1))
'\\mbox{\\rm True}'
```

coeff_repr(*c*)

have_convert()

Return True if this computer has the program convert.

The first time it is run, this function caches its result in the variable `_have_convert`, and any subsequent time, it just checks the value of the variable.

If this computer doesn't have convert installed, you may obtain it (along with the rest of the ImageMagick suite) from http://www.imagemagick.org

EXAMPLES:

```
sage: from sage.misc.latex import have_convert
sage: sage.misc.latex._have_convert is None
True
sage: have_convert() # random
True
sage: sage.misc.latex._have_convert is None
False
sage: sage.misc.latex._have_convert == have_convert()
True
```

have_dvipng()

Return True if this computer has the program dvipng.

The first time it is run, this function caches its result in the variable `_have_dvipng`, and any subsequent time, it just checks the value of the variable.

If this computer doesn't have dvipng installed, you may obtain it from http://sourceforge.net/projects/dvipng/

EXAMPLES:

```
sage: from sage.misc.latex import have_dvipng
sage: sage.misc.latex._have_dvipng is None
True
sage: have_dvipng() # random
True
sage: sage.misc.latex._have_dvipng is None
False
sage: sage.misc.latex._have_dvipng == have_dvipng()
True
```

jsmath(*x, mode='display'*)

Attempt to nicely render an arbitrary SAGE object wih jsmath typesetting. Tries to call ._latex_() on x. If that fails, it will render a string representation of x.

Warning: 2009-04: This function is deprecated; use `html` instead: replace `jsmath('MATH', mode='display')` with `html('$$MATH$$')`, and replace `jsmath('MATH', mode='inline')` with `html('$MATH$')`.

INPUT: x – the object to render mode – 'display' for displaymath or 'inline' for inline math

OUTPUT: A string of html that contains the LaTeX represntation of x. In the notebook this gets embedded into the cell.

EXAMPLES:

```
sage: from sage.misc.latex import jsmath
sage: f = maxima('1/(x^2+1)')
sage: g = f.integrate()
sage: jsmath(f)
... DeprecationWarning: The jsmath function is deprecated.  Use html('$math$') for inline mode c
# -*- coding: utf-8 -*-
<html><font color='black'><div class="math">{{1}\over{x^2+1}}</div></font></html>
sage: jsmath(g, 'inline')
<html><font color='black'><span class="math">\tan^{-1} x</span></font></html>
sage: jsmath('\int' + latex(f) + '\ dx=' + latex(g))
<html><font color='black'><div class="math">\int{{1}\over{x^2+1}}\ dx=\tan^{-1} x</div></font></
```

AUTHORS:

- William Stein (2006-10): general layout (2006-10)
- Bobby Moretti (2006-10): improvements, comments, documentation

latex_extra_preamble()

Return the string containing the user-configured preamble, `sage_latex_macros`, and any user-configured macros. This is used in the `eval` method for the `Latex` class, and in `_latex_file`; it follows either `LATEX_HEADER` or `SLIDE_HEADER` (defined at the top of this file) which is a string containing the documentclass and standard usepackage commands.

EXAMPLES:

```
sage: from sage.misc.latex import latex_extra_preamble
sage: latex_extra_preamble()
'\n\\newcommand{\\ZZ}{\\Bold{Z}}\n\\newcommand{\\RR}{\\Bold{R}}\n\\newcommand{\\CC}{\\Bold{C}}\n
```

latex_variable_name(*x*)

Return latex version of a variable name.

Here are some guiding principles for usage of this function:

1. If the variable is a single letter, that is the latex version.
2. If the variable name is suffixed by a number, we put the number in the subscript.
3. If the variable name contains an '_' we start the subscript at the underscore. Note that #3 trumps rule #2.
4. If a component of the variable is a greek letter, escape it properly.
5. Recurse nicely with subscripts.

Refer to the examples section for how these rules might play out in practice.

EXAMPLES:

```
sage: from sage.misc.latex import latex_variable_name
sage: latex_variable_name('a')
'a'
sage: latex_variable_name('abc')
'\\mbox{abc}'
sage: latex_variable_name('sigma')
'\\sigma'
sage: latex_variable_name('sigma_k')
'\\sigma_{k}'
sage: latex_variable_name('sigma389')
'\\sigma_{389}'
sage: latex_variable_name('beta_00')
'\\beta_{00}'
sage: latex_variable_name('Omega84')
'\\Omega_{84}'
sage: latex_variable_name('sigma_alpha')
'\\sigma_{\\alpha}'
sage: latex_variable_name('nothing1')
'\\mbox{nothing}_{1}'
sage: latex_variable_name('nothing_abc')
'\\mbox{nothing}_{\\mbox{abc}}'
sage: latex_variable_name('alpha_beta_gamma12')
'\\alpha_{\\beta_{\\gamma_{12}}}'
```

AUTHORS:

- Joel B. Mohler: drastic rewrite and many doc-tests

latex_varify(*a*)

list_function(*x*)

Returns the LaTeX code for a list x.

INPUT: x - a list

EXAMPLES:

```
sage: from sage.misc.latex import list_function
sage: list_function([1,2,3])
'\\left[1, \n 2, \n 3\\right]'
sage: latex([1,2,3])  # indirect doctest
\left[1,
2,
3\right]
sage: latex([Matrix(ZZ,3,range(9)), Matrix(ZZ,3,range(9))]) # indirect doctest
\left[\left(\begin{array}{rrr}
0 & 1 & 2 \\
3 & 4 & 5 \\
6 & 7 & 8
\end{array}\right),
\\\left(\begin{array}{rrr}
0 & 1 & 2 \\
3 & 4 & 5 \\
6 & 7 & 8
\end{array}\right)\right]
```

png(*x, filename, density=150, debug=False, do_in_background=True, tiny=False*)

Create a png image representation of x and save to the given filename.

INPUT:

- `x` - object to be displayed
- `filename` - file in which to save the image
- `density` - integer (default: 150)
- `debug` - bool (default: False): print verbose output
- `do_in_background` - bool (default: True): create the file in the background
- `tiny` - bool (default: False): use 'tiny' font

pretty_print (*object*)
Try to pretty print the object in an intelligent way. For many things, this will convert the object to latex inside of html and rely on a latex-aware front end (like jsMath) to render the text

pretty_print_default (*enable=True*)
Enable or disable default pretty printing. Pretty printing means rendering things so that jsMath or some other latex-aware front end can render real math.

print_or_typeset (*object*)
'view' or 'print' the object depending on the situation.

In particular, if in notebook mode with the typeset box checked, view the object. Otherwise, print the object.

INPUT: object: anything

EXAMPLES:

```
sage: sage.misc.latex.print_or_typeset(3)
3
sage: sage.misc.latex.EMBEDDED_MODE=True
sage: sage.misc.latex.print_or_typeset(3)
3
sage: TEMP = sys.displayhook
sage: sys.displayhook = sage.misc.latex.pretty_print
sage: sage.misc.latex.print_or_typeset(3)
<html><span class="math">\newcommand{\Bold}[1]{\mathbf{#1}}3</span></html>
sage: sage.misc.latex.EMBEDDED_MODE=False
sage: sys.displayhook = TEMP
```

repr_lincomb (*symbols, coeffs*)
Compute a latex representation of a linear combination of some formal symbols.

INPUT:

- `symbols` - list of symbols
- `coeffs` - list of coefficients of the symbols

OUTPUT:

- `str` - a string

EXAMPLES:

```
sage: t = PolynomialRing(QQ, 't').0
sage: from sage.misc.latex import repr_lincomb
sage: repr_lincomb(['a', 's', ''], [-t, t - 2, t^12 + 2])
'-t\text{a} + \left(t - 2\right)\text{s} + \left(t^{12} + 2\right)\text{}'
sage: repr_lincomb(['a', 'b'], [1,1])
'\text{a} + \text{b}'
```

Verify that a certain corner case works (see trac 5707 and 5766):

```
sage: repr_lincomb([1,5,-3],[2,8/9,7])
'2\cdot 1 + \frac{8}{9}\cdot 5 + 7\cdot -3'
```

str_function(*x*)

Returns the LaTeX code for a string x.

INPUT: x - a string

EXAMPLES:

```
sage: from sage.misc.latex import str_function
sage: str_function('hello world')
'\\text{hello world}'
```

tuple_function(*x*)

Returns the LaTeX code for a tuple x.

INPUT: x - a tuple

EXAMPLES:

```
sage: from sage.misc.latex import tuple_function
sage: tuple_function((1,2,3))
'\\left(1, \n 2, \n 3\\right)'
```

typeset(*x*)

view(*objects, title='SAGE', debug=False, sep='', tiny=False, pdflatex=None, **kwds*)

Compute a latex representation of each object in objects, compile, and display typeset. If used from the command line, this requires that latex be installed.

INPUT:

- `objects` - list (or object)
- `title` - string (default: 'Sage'): title for the document
- `debug` - bool (default: False): print verbose output
- `sep` - string (default: ''): separator between math objects
- `tiny` - bool (default: False): use tiny font.
- `pdflatex` - bool (default: False): use pdflatex.

OUTPUT: Display typeset objects.

This function behaves differently depending on whether in notebook mode or not.

If not in notebook mode, this opens up a window displaying a dvi (or pdf) file, displaying the following: the title string is printed, centered, at the top. Beneath that, each object in objects is typeset on its own line, with the string sep inserted between these lines.

The value of `sep` is inserted between each element of the list `objects`; you can, for example, add vertical space between objects with `sep='\\vspace{15mm}'`, while `sep='\\hrule'` adds a horizontal line between objects, and `sep='\\newpage'` inserts a page break between objects.

If in notebook mode, this uses jmath to display the output in the notebook. Only the first argument, objects, is relevant; the others are ignored. If objects is a list, the result is typeset as a Python list, e.g. [12, -3.431] - each object in the list is not printed on its own line.

EXAMPLES:

```
sage: sage.misc.latex.EMBEDDED_MODE = True
sage: view(3)
<html><span class="math">\newcommand{\Bold}[1]{\mathbf{#1}}3</span></html>
sage: sage.misc.latex.EMBEDDED_MODE = False
```

11.10 LaTeX macros

AUTHORS:

- John H. Palmieri (2009-03)

The code here sets up LaTeX macro definitions for use in the documentation. To add a macro, modify the list `macros`, near the end of this file, and then run 'sage -b'. The entries in this list are used to produce `sage_latex_macros`, a list of strings of the form '\newcommand...', and `sage_js_macros`, a list of strings of the form 'jsMath.Macro...'. The LaTeX macros are produced using the `_latex_` method for each Sage object listed in `macros`, and the jsMath macros are produced from the LaTeX macros. The list of LaTeX macros is used in the file `SAGE_ROOT/devel/sage/doc/common/conf.py` to add to the preambles of both the LaTeX file used to build the PDF version of the documentation and the LaTeX file used to build the html version. The list of jsMath macros is used in the file `sage/server/notebook/notebook.py` to define jsMath macros for use in the live documentation (and also in the notebook).

Any macro defined here may be used in docstrings or in the tutorial (or other pieces of documentation). In a docstring, for example, "ZZ" in backquotes (demarking math mode) will appear as "ZZ" in interactive help, but will be typeset as "\Bold{Z}" in the reference manual.

More details on the list `macros`: the entries are lists or tuples of the form `[name]` or `[name, arguments]`, where `name` is a string and `arguments` consists of valid arguments for the Sage object named `name`. For example, `["ZZ"]` and `["GF", 2]` produce the LaTeX macros '\newcommand{\ZZ}{\Bold{Z}}' and '\newcommand{\GF}[1]{\Bold{F}_{#1}}', respectively. (For the second of these, `latex(GF(2))` is called and the string '2' gets replaced by '#1', so `["GF", 17]` would have worked just as well. `["GF", p]` would have raised an error, though, because `p` is not defined, and `["GF", 4]` would have raised an error, because to define the field with four elements in Sage, you also need to specify the name of a generator.)

To see evidence of the results of the code here, run `sage -docbuild tutorial latex` (for example), and look at the resulting LaTeX file in `SAGE_ROOT/sage/doc/output/latex/en/tutorial/`. The preamble should contain 'newcommand' lines for each of the entries in `macros`.

convert_latex_macro_to_jsmath(*macro*)

This converts a LaTeX macro definition (newcommand...) to a jsMath macro definition (jsMath.Macro...).

INPUT:

- `macro` - LaTeX macro definition

See the web page http://www.math.union.edu/~dpvc/jsMath/authors/macros.html for a description of the format for jsMath macros.

EXAMPLES:

```
sage: from sage.misc.latex_macros import convert_latex_macro_to_jsmath
sage: convert_latex_macro_to_jsmath('\\newcommand{\\ZZ}{\\Bold{Z}}')
"jsMath.Macro('ZZ','\\\\Bold{Z}')"
sage: convert_latex_macro_to_jsmath('\\newcommand{\\GF}[1]{\\Bold{F}_{#1}}')
"jsMath.Macro('GF','\\\\Bold{F}_{#1}',1)"
```

produce_latex_macro(*name, *sample_args*)

Produce a string defining a LaTeX macro.

INPUT:

- `name` - name of macro to be defined, also name of corresponding Sage object
- `sample_args` - (optional) sample arguments for this Sage object

EXAMPLES:

```
sage: from sage.misc.latex_macros import produce_latex_macro
sage: produce_latex_macro('ZZ')
'\\newcommand{\\ZZ}{\\Bold{Z}}'
```

If the Sage object takes arguments, then the LaTeX macro will accept arguments as well. You must pass valid arguments, which will then be converted to #1, #2, etc. in the macro definition. The following allows the use of "GF{p^n}", for example:

```
sage: produce_latex_macro('GF', 37)
'\\newcommand{\\GF}[1]{\\Bold{F}_{#1}}'
```

If the Sage object is not in the global name space, describe it like so:

```
sage: produce_latex_macro('sage.rings.finite_field.FiniteField', 3)
'\\newcommand{\\FiniteField}[1]{\\Bold{F}_{#1}}'
```

11.11 Lazy attributes

class **lazy_attribute**(*f*)

A lazy attribute for an object is like a usual attribute, except that, instead of being computed when the object is constructed (i.e. in __init__), it is computed on the fly the first time it is accessed.

For constant values attached to an object, lazy attributes provide a shorter syntax and automatic caching (unlike methods), while playing well with inheritance (like methods): a subclass can easily override a given attribute; you don't need to call the super class constructor, etc.

Technically, a lazy_attribute is a non-data descriptor (see Invoking Descriptors in the Python reference manual).

EXAMPLES:

We create a class whose instances have a lazy attribute x:

```
sage: class A(object):
...       def __init__(self):
...           self.a=2 # just to have some data to calculate from
...
...       @lazy_attribute
...       def x(self):
...           print "calculating x in A"
...           return self.a + 1
...
```

For an instance a of A, a.x is calculated the first time it is accessed, and then stored as a usual attribute:

```
sage: a = A()
sage: a.x
calculating x in A
3
sage: a.x
3
```

Implementation details

We redo the same example, but opening the hood to see what happens to the internal dictionary of the object:

```
sage: a = A()
sage: a.__dict__
{'a': 2}
sage: a.x
calculating x in A
3
sage: a.__dict__
{'a': 2, 'x': 3}
sage: a.x
3
sage: timeit('a.x') # random
625 loops, best of 3: 89.6 ns per loop
```

This shows that, after the first calculation, the attribute x becomes a usual attribute; in particular, there is no time penalty to access it.

A lazy attribute may be set as usual, even before its first access, in which case the lazy calculation is completely ignored:

```
sage: a = A()
sage: a.x = 4
sage: a.x
4
sage: a.__dict__
{'a': 2, 'x': 4}
```

Class binding results in the lazy attribute itself:

```
sage: A.x
<sage.misc.lazy_attribute.lazy_attribute object at ...>
```

Conditional definitions

The function calculating the attribute may return NotImplemented to declare that, after all, it is not able to do it. In that case, the attribute lookup proceeds in the super class hierarchy:

```
sage: class B(A):
...       @lazy_attribute
...       def x(self):
...           if hasattr(self, "y"):
...               print "calculating x from y in B"
...               return self.y
...           else:
...               print "y not there; B does not define x"
...               return NotImplemented
...
sage: b = B()
sage: b.x
y not there; B does not define x
calculating x in A
3
sage: b = B()
sage: b.y = 1
sage: b.x
calculating x from y in B
1
```

Attribute existence testing

Testing for the existence of an attribute with hasattr currently always triggers its full calculation, which may not be desirable when the calculation is expensive:

```
sage: a = A()
sage: hasattr(a, "x")
calculating x in A
True
```

It would be great if we could take over the control somehow, if at all possible without a special implementation of hasattr, so as to allow for something like:

```
sage: class A (object):
...       @lazy_attribute
...       def x(self, existence_only=False):
...           if existence_only:
...               print "testing for x existence"
...               return True
...           else:
...               print "calculating x in A"
...               return 3
...
sage: a = A()
sage: hasattr(a, "x") # todo: not implemented
testing for x existence
sage: a.x
calculating x in A
3
sage: a.x
3
```

Here is a full featured example, with both conditional definition and existence testing:

```
sage: class B(A):
...       @lazy_attribute
...       def x(self, existence_only=False):
...           if hasattr(self, "y"):
...               if existence_only:
...                   print "testing for x existence in B"
...                   return True
...               else:
...                   print "calculating x from y in B"
...                   return self.y
...           else:
...               print "y not there; B does not define x"
...               return NotImplemented
...
sage: b = B()
sage: hasattr(b, "x") # todo: not implemented
y not there; B does not define x
testing for x existence
True
sage: b.x
y not there; B does not define x
calculating x in A
3
sage: b = B()
```

```
sage: b.y = 1
sage: hasattr(b, "x") # todo: not implemented
testing for x existence in B
True
sage: b.x
calculating x from y in B
1
```

lazy attributes and introspection

TODO: make the following work nicely:

```
sage:  b.x?                # todo: not implemented
sage:  b.x??               # todo: not implemented
```

Right now, the first one includes the doc of this class, and the second one brings up the code of this class, both being not very useful.

TESTS:

```
.. rubric:: Partial support for old style classes
```

Old style and new style classes play a bit differently with @property and attribute setting:

```
sage: class A:
...       @property
...       def x(self):
...           print "calculating x"
...           return 3
...
sage: a = A()
sage: a.x = 4
sage: a.__dict__
{'x': 4}
sage: a.x
4
sage: a.__dict__['x']=5
sage: a.x
5

sage: class A (object):
...       @property
...       def x(self):
...           print "calculating x"
...           return 3
...
sage: a = A()
sage: a.x = 4
...
AttributeError: can't set attribute
sage: a.__dict__
{}
sage: a.x
calculating x
3
sage: a.__dict__['x']=5
sage: a.x
```

```
calculating x
3
```

In particular, lazy_attributes need to be implemented as non-data descriptors for new style classes, so as to leave access to setattr. We now check that this implementation also works for old style classes (conditional definition does not work yet):

```
sage: class A:
...       def __init__(self):
...           self.a=2 # just to have some data to calculate from
...
...       @lazy_attribute
...       def x(self):
...           print "calculating x"
...           return self.a + 1
...
sage: a = A()
sage: a.__dict__
{'a': 2}
sage: a.x
calculating x
3
sage: a.__dict__
{'a': 2, 'x': 3}
sage: a.x
3
sage: timeit('a.x') # random
625 loops, best of 3: 115 ns per loop

sage: a = A()
sage: a.x = 4
sage: a.x
4
sage: a.__dict__
{'a': 2, 'x': 4}

sage: class B(A):
...       @lazy_attribute
...       def x(self):
...           if hasattr(self, "y"):
...               print "calculating x from y in B"
...               return self.y
...           else:
...               print "y not there; B does not define x"
...               return NotImplemented
...
sage: b = B()
sage: b.x                          # todo: not implemented
y not there; B does not define x
calculating x in A
3
sage: b = B()
sage: b.y = 1
sage: b.x
calculating x from y in B
1
```

lazy_attributes and cpdef functions

This attempts to check that lazy_attributes work with builtin functions like cpdef methods:

```
sage: class A:
...       def __len__(x):
...           return int(5)
...       len = lazy_attribute(len)
...
sage: A().len
5
```

About descriptor specifications

The specifications of descriptors (see 3.4.2.3 Invoking Descriptors in the Python reference manual) are incomplete w.r.t. inheritence, and maybe even ill-implemented. We illustrate this on a simple class hierarchy, with an instrumented descriptor:

```
sage: class descriptor(object):
...       def __get__(self, obj, cls):
...           print cls
...           return 1
...
sage: class A(object):
...       x = descriptor()
...
sage: class B(A):
...       pass
...
```

This is fine:

```
sage: A.x
<class '__main__.A'>
1
```

The behaviour for the following case is not specified (see Instance Binding) when x is not in the dictionary of B but in that of some super category:

```
sage: B().x
<class '__main__.B'>
1
```

It would seem more natural (and practical!) to get A rather than B.

From the specifications for Super Binding, it would be expected to get A and not B as cls parameter:

```
sage: super(B, B()).x
<class '__main__.B'>
1
```

Due to this, the natural implementation runs into an infinite loop in the following example:

```
sage: class A(object):
...       @lazy_attribute
...       def unimplemented_A(self):
...           return NotImplemented
```

```
...       @lazy_attribute
...       def unimplemented_AB(self):
...           return NotImplemented
...       @lazy_attribute
...       def unimplemented_B_implemented_A(self):
...           return 1
...
sage: class B(A):
...       @lazy_attribute
...       def unimplemented_B(self):
...           return NotImplemented
...       @lazy_attribute
...       def unimplemented_AB(self):
...           return NotImplemented
...       @lazy_attribute
...       def unimplemented_B_implemented_A(self):
...           return NotImplemented
...
sage: class C(B):
...       pass
...
```

This is the simplest case where, without workaround, we get an infinite loop:

```
sage: hasattr(B(), "unimplemented_A") # todo: not implemented
False
```

TODO: improve the error message:

```
sage: B().unimplemented_A # todo: not implemented
...
AttributeError: 'super' object has no attribute 'unimplemented_A'
```

We now make some systematic checks:

```
sage: B().unimplemented_A
...
AttributeError: '...' object has no attribute 'unimplemented_A'
sage: B().unimplemented_B
...
AttributeError: '...' object has no attribute 'unimplemented_B'
sage: B().unimplemented_AB
...
AttributeError: '...' object has no attribute 'unimplemented_AB'
sage: B().unimplemented_B_implemented_A
1

sage: C().unimplemented_A()
...
AttributeError: '...' object has no attribute 'unimplemented_A'
sage: C().unimplemented_B()
...
AttributeError: '...' object has no attribute 'unimplemented_B'
sage: C().unimplemented_AB()
...

11.12 Logging of Sage sessions.

TODO: Pressing "control-D" can mess up the I/O sequence because of a known bug.

You can create a log of your Sage session as a web page and/or as a latex document. Just type `log_html()` to create an HTML log, or `log_dvi()` to create a dvi (LaTeX) log. Your complete session so far up until when you type the above command will be logged, along with any future input. Thus you can view the log system as a way to print or view your entire session so far, along with a way to see nicely typeset incremental updates as you work.

If `L=log_dvi()` or `L=log_html()` is a logger, you can type `L.stop()` and `L.start()` to stop and start logging.

The environment variables `BROWSER` and `DVI_VIEWER` determine which web browser or dvi viewer is used to display your running log.

For both log systems you must have a TeX system installed on your computer. For HTML logging, you must have the convert command, which comes with the free ImageMagick tools.

Note: The HTML output is done via LaTeX and png images right now, sort of like how latex2html works. Obviously it would be interesting to do something using MathML in the long run.

AUTHORS:

- William Stein (2006-02): initial version
- William Stein (2006-02-27): changed html generation so log directory is relocatable (no hardcoded paths).
- William Stein (2006-03-04): changed environment variable to BROWSER.
- Didier Deshommes (2006-05-06): added MathML support; refactored code.
- Dan Drake (2008-03-27): fix bit rotting so that optional directories work, dvi logging works, viewer() command works, remove no-longer-working MathML logger; fix off-by-one problems with IPython history; add text logger; improve documentation about viewers.

class Log (*dir=None, debug=False, viewer=None*)

This is the base logger class. The two classes that you actually instantiate are derived from this one.

dir()

Return the directory that contains the log files.

start()

Start the logger. To stop use the stop function.

stop()

Stop the logger. To restart use the start function.

class log_dvi (*dir=None, debug=False, viewer=None*)

Create a running log of your Sage session as a nicely typeset dvi file.

Easy usage: `log_dvi()`

TODO: Pressing "control-D" can mess up the I/O sequence because of a known bug.

Use `L=log_dvi([optional directory])` to create a dvi log. Your complete session so far up until when you type the above command will be logged, along with any future input. Thus you can view the log system as a way to print or view your entire session so far, along with a way to see nicely typeset incremental updates as you work.

If L is a logger, you can type `L.stop()` and `L.start()` to stop and start logging.

The environment variable `DVI_VIEWER` determines which web browser or dvi viewer is used to display your running log. You can also specify a viewer when you start the logger with something like `log_dvi([opt. dir], viewer='xdvi')`.

You must have a LaTeX system installed on your computer and a dvi viewer.

view()

class log_html(*dir=None, debug=False, viewer=None*)
Create a running log of your Sage session as a web page.

Easy usage: `log_html()`

TODO: Pressing "control-D" can mess up the I/O sequence because of a known bug.

Use `L=log_html([optional directory])` to create an HTML log. Your complete session so far up until when you type the above command will be logged, along with any future input. Thus you can view the log system as a way to print or view your entire session so far, along with a way to see nicely typeset incremental updates as you work.

If L is a logger, you can type `L.stop()` and `L.start()` to stop and start logging.

The environment variable `WEB_BROWSER` determines which web browser or dvi viewer is used to display your running log. You can also specify a viewer when you start the logger with something like `log_html([opt. dir], viewer='firefox')`.

You must have a TeX system installed on your computer, and you must have the convert command, which comes with the free ImageMagick tools.

view()

class log_text(*dir=None, debug=False, viewer=None*)
Create a running log of your Sage session as a plain text file.

Easy usage: `log_text()`

TODO: Pressing "control-D" can mess up the I/O sequence because of a known bug.

Use `L=log_text([optional directory])` to create a text log. Your complete session so far up until when you type the above command will be logged, along with any future input. Thus you can view the log system as a way to print or view your entire session so far, along with a way to see incremental updates as you work.

Unlike the html and dvi loggers, this one does not automatically start a viewer unless you specify one; you can do that when you start the logger with something like `log_text([opt. dir], viewer='xterm -e tail -f')`.

If L is a logger, you can type `L.stop()` and `L.start()` to stop and start logging.

view()

update()

11.13 Object persistence

You can load and save most Sage object to disk using the load and save member functions and commands.

Note: It is impossible to save certain Sage objects to disk. For example, if x is a MAGMA object, i.e., a wrapper around an object that is defined in MAGMA, there is no way to save x it to disk, since MAGMA doesn't support saving of individual objects to disk.

- Versions: Loading and saving of objects is guaranteed to work even if the version of Python changes. Saved objects can be loaded in future versions of Python. However, if the data structure that defines the object, e.g., in Sage code, changes drastically (or changes name or disappears), then the object might not load correctly or work correctly.
- Objects are zlib compressed for space efficiency.

db(*name*)
Load object with given name from the Sage database. Use x.db(name) or db_save(x, name) to save objects to the database.

The database directory is `$HOME/.sage/db`.

db_save(*x, name=None*)
Save x to the Sage database.

The database directory is `$HOME/.sage/db`.

load_sage_element(*cls, parent, dic_pic*)

load_sage_object(*cls, dic*)

11.14 Support for persistent functions in .sage files.

Persistent functions are functions whose values are stored on disk so they do not have to be recomputed.

The inputs to the function must be hashable (so lists are not allowed). Though a hash is used, in the incredibly unlikely event that a hash collision occurs, your function will not return an incorrect result because of this (though the cache might not be used either).

This is meant to be used from `.sage` files, not from library `.py` files.

To use this disk caching mechanism, just put `@func_persist` right before your function definition. For example,

```
@func_persist
def bern(n):
    "Return the n-th Bernoulli number, caching the result to disk."
    return bernoulli(n)
```

You can then use the function `bern` as usual, except it will almost instantly return values that have already been computed, even if you quit and restart.

The disk cache files are stored by default in the subdirectory `func_persist` of the current working directory, with one file for each evaluation of the function.

class func_persist(*f, dir='func_persist'*)
Put `@func_persist` right before your function definition to cache values it computes to disk.

11.15 Evaluating a String in Sage

sage_eval(*source, locals=None, cmds='', preparse=True*)
Obtain a Sage object from the input string by evaluating it using Sage. This means calling eval after preparsing and with globals equal to everything included in the scope of `from sage.all import *`.).

INPUT:

- `source` - a string or object with a _sage_ method
- `locals` - evaluate in namespace of sage.all plus the locals dictionary
- `cmds` - string; sequence of commands to be run before source is evaluated.
- `preparse` - (default: True) if True, preparse the string expression.

EXAMPLES: This example illustrates that preparsing is applied.

```
sage: eval('2^3')
1
sage: sage_eval('2^3')
8
```

However, preparsing can be turned off.

```
sage: sage_eval('2^3', preparse=False)
1
```

Note that you can explicitly define variables and pass them as the second option:

```
sage: x = PolynomialRing(RationalField(),"x").gen()
sage: sage_eval('x^2+1', locals={'x':x})
x^2 + 1
```

This example illustrates that evaluation occurs in the context of `from sage.all import *`. Even though bernoulli has been redefined in the local scope, when calling `sage_eval` the default value meaning of bernoulli is used. Likewise for QQ below.

```
sage: bernoulli = lambda x : x^2
sage: bernoulli(6)
36
sage: eval('bernoulli(6)')
36
sage: sage_eval('bernoulli(6)')
1/42
```

```
sage: QQ = lambda x : x^2
sage: QQ(2)
4
sage: sage_eval('QQ(2)')
2
sage: parent(sage_eval('QQ(2)'))
Rational Field
```

This example illustrates setting a variable for use in evaluation.

```
sage: x = 5
sage: eval('4/3 + x', {'x':25})
26
sage: sage_eval('4/3 + x',  locals={'x':25})
79/3
```

You can also specify a sequence of commands to be run before the expression is evaluated:

```
sage: sage_eval('p', cmds='K.<x> = QQ[]\np = x^2 + 1')
x^2 + 1
```

If you give commands to execute and a dictionary of variables, then the dictionary will be modified by assignments in the commands:

```
sage: vars = {}
sage: sage_eval('None', cmds='y = 3', locals=vars)
sage: vars['y'], parent(vars['y'])
(3, Integer Ring)
```

You can also specify the object to evaluate as a tuple. A 2-tuple is assumed to be a pair of a command sequence and an expression; a 3-tuple is assumed to be a triple of a command sequence, an expression, and a dictionary holding local variables. (In this case, the given dictionary will not be modified by assignments in the commands.)

```
sage: sage_eval(('f(x) = x^2', 'f(3)'))
9
sage: vars = {'rt2': sqrt(2.0)}
sage: sage_eval(('rt2 += 1', 'rt2', vars))
2.41421356237309
sage: vars['rt2']
1.41421356237310
```

This example illustrates how `sage_eval` can be useful when evaluating the output of other computer algebra systems.

```
sage: R.<x> = PolynomialRing(RationalField())
sage: gap.eval('R:=PolynomialRing(Rationals,["x"]);')
'PolynomialRing(..., [ x ])'
sage: ff = gap.eval('x:=IndeterminatesOfPolynomialRing(R);; f:=x^2+1;'); ff
'x^2+1'
sage: sage_eval(ff, locals={'x':x})
x^2 + 1
sage: eval(ff)
...
RuntimeError: Use ** for exponentiation, not '^', which means xor
in Python, and has the wrong precedence.
```

Here you can see eval simply will not work but `sage_eval` will.

TESTS:

We get a nice minimal error message for syntax errors, that still points to the location of the error (in the input string):

```
sage: sage_eval('RR(22/7]')
...
 File "<string>", line 1
    RR(Integer(22)/Integer(7)]
                             ^
SyntaxError: unexpected EOF while parsing

sage: sage_eval('None', cmds='$x = $y[3] # Does Perl syntax work?')
...
 File "<string>", line 1
    $x = $y[Integer(3)] # Does Perl syntax work?
    ^
SyntaxError: invalid syntax
```

sageobj(*x, vars=None*)

Return a native Sage object associated to x, if possible and implemented.

If the object has an _sage_ method it is called and the value is returned. Otherwise str is called on the object, and all preparsing is applied and the resulting expression is evaluated in the context of `from sage.all import *`. To evaluate the expression with certain variables set, use the vars argument, which should be a dictionary.

EXAMPLES:

```
sage: type(sageobj(gp('34/56')))
<type 'sage.rings.rational.Rational'>
sage: n = 5/2
sage: sageobj(n) is n
True
sage: k = sageobj('Z(8^3/1)', {'Z':ZZ}); k
512
sage: type(k)
<type 'sage.rings.integer.Integer'>
```

This illustrates interfaces:

```
sage: f = gp('2/3')
sage: type(f)
<class 'sage.interfaces.gp.GpElement'>
sage: f._sage_()
2/3
sage: type(f._sage_())
<type 'sage.rings.rational.Rational'>
sage: a = gap(939393/2433)
sage: a._sage_()
313131/811
sage: type(a._sage_())
<type 'sage.rings.rational.Rational'>
```

11.16 Random testing.

Some Sage modules do random testing in their doctests; that is, they construct test cases using a random number generator. To get the broadest possible test coverage, we want everybody who runs the doctests to use a different random seed; but we also want to be able to reproduce the problems when debugging. This module provides a decorator to help write random testers that meet these goals.

random_testing(*fn*)

This decorator helps create random testers. These can be run as part of the standard Sage test suite; everybody who runs the test will use a different random number seed, so many different random tests will eventually be run.

INPUT:

- `fn` - The function that we are wrapping for random testing.

The resulting function will take two additional arguments, *seed* (default `None`) and *print_seed* (default `False`). The result will set the random number seed to the given seed value (or to a truly random value, if *seed* is not specified), then call the original function. If *print_seed* is true, then the seed will be printed before calling the original function. If the original function raises an exception, then the random seed that was used will be displayed, along with a message entreating the user to submit a bug report. All other arguments will be passed through to the original function.

Here is a set of recommendations for using this wrapper.

The function to be tested should take arguments specifying the difficulty of the test (size of the test cases, number of iterations, etc.), as well as an argument *verbose* (defaulting to false). With *verbose* true, it should print the values being tested. Suppose `test_foo()` takes an argument for number of iterations. Then the doctests could be:

```
test_foo(2, verbose=True, seed=0)
test_foo(10)
test_foo(100) # long time
```

The first doctest, with the specified seed and `verbose=True`, simply verifies that the tests really are reproducible (that `test_foo` is correctly using the `randstate` framework). The next two tests use truly random seeds, and will print out the seed used if the test fails (raises an exception).

If you want a very long-running test using this setup, you should do something like:

```
for _ in xrange(10^10): test_foo(100)
```

instead of:

```
test_foo(10^12)
```

If the test fails after several hours, the latter snippet would make you rerun the test for several hours while reproducing and debugging the problem. With the former snippet, you only need to rerun `test_foo(100)` with a known-failing random seed.

See `sage.misc.random_testing.test_add_commutes()` for a simple example using this decorator, and `sage.rings.tests` for realistic uses.

Setting *print_seed* to true is useless in doctests, because the random seed printed will never match the expected doctest result (and using `# random` means the doctest framework will never report an error even if one happens). However, it is useful if you have a random test that sometimes segfaults. The normal print-the-random-seed-on-exceptions won't work then, so you can run:

```
while True: test_foo(print_seed=True)
```

and look at the last seed that was printed before it crashed.

TESTS:

```
sage: from sage.misc.random_testing import random_testing
sage: def foo(verbose=False):
...       'oh look, a docstring'
...       n = ZZ.random_element(2^50)
...       if verbose:
...           print "Random value: %s" % n
...       assert(n == 49681376900427)
sage: foo = random_testing(foo)
sage: foo(seed=0, verbose=True)
Random value: 49681376900427
sage: foo(seed=15, verbose=True)
Random value: 1049538412064764
Random testing has revealed a problem in foo
Please report this bug!  You may be the first
person in the world to have seen this problem.
Please include this random seed in your bug report:
Random seed: 15
AssertionError()
sage: foo() # random
Random testing has revealed a problem in foo
Please report this bug!  You may be the first
person in the world to have seen this problem.
Please include this random seed in your bug report:
Random seed: 272500700755151445506092479579811710040
AssertionError()
```

```
sage: foo.__doc__
'oh look, a docstring'
sage: foo.__name__
'foo'
sage: def bar(): pass
sage: bar = random_testing(bar)
sage: bar(print_seed=True) # random
Random seed: 26284109189015634692353976554381414605l
```

test_add_commutes(**args, **kwargs*)

This is a simple demonstration of the `random_testing()` decorator and its recommended usage.

We test that addition is commutative over rationals.

EXAMPLES:

```
sage: from sage.misc.random_testing import test_add_commutes
sage: test_add_commutes(2, verbose=True, seed=0)
a == -4, b == 0 ...
Passes!
a == -1/2, b == -1/95 ...
Passes!
sage: test_add_commutes(10)
sage: test_add_commutes(1000) # long time
```

test_add_is_mul(**args, **kwargs*)

This example demonstrates a failing `random_testing()` test, and shows how to reproduce the error.

DO NOT USE THIS AS AN EXAMPLE OF HOW TO USE `random_testing()`! Instead, look at `sage.misc.random_testing.test_add_commutes()`.

We test that `a+b == a*b`, for *a*, *b* rational. This is of course false, so the test will almost always fail.

EXAMPLES:

```
sage: from sage.misc.random_testing import test_add_is_mul
```

We start by testing that we get reproducible results when setting *seed* to 0.

```
sage: test_add_is_mul(2, verbose=True, seed=0)
a == -4, b == 0 ...
Random testing has revealed a problem in test_add_is_mul
Please report this bug!  You may be the first
person in the world to have seen this problem.
Please include this random seed in your bug report:
Random seed: 0
AssertionError()
```

Normally in a `@random_testing` doctest, we would leave off the `verbose=True` and the `# random`. We put it in here so that we can verify that we are seeing the exact same error when we reproduce the error below.

```
sage: test_add_is_mul(10, verbose=True) # random
a == -2/7, b == 1 ...
Random testing has revealed a problem in test_add_is_mul
Please report this bug!  You may be the first
person in the world to have seen this problem.
Please include this random seed in your bug report:
Random seed: 216390410596009428782506007128692114173
AssertionError()
```

OK, now assume that some user has reported a `test_add_is_mul()` failure. We can specify the same *random_seed* that was found in the bug report, and we will get the exact same failure so that we can debug the "problem".

```
sage: test_add_is_mul(10, verbose=True, seed=216390410596009428782506007128692114173)
a == -2/7, b == 1 ...
Random testing has revealed a problem in test_add_is_mul
Please report this bug!  You may be the first
person in the world to have seen this problem.
Please include this random seed in your bug report:
Random seed: 216390410596009428782506007128692114173
AssertionError()
```

11.17 Miscellaneous arithmetic functions

CRT (*a, b, m, n*)

Use the Chinese Remainder Theorem to find some integer x such that x=a (mod m) and x=b (mod n). Note that x is only well-defined modulo m*n.

EXAMPLES:

```
sage: crt(2, 1, 3, 5)
-4
sage: crt(13,20,100,301)
-2087
```

You can also use upper case:

```
sage: c = CRT(2,3, 3, 5); c
8
sage: c % 3 == 2
True
sage: c % 5 == 3
True
```

CRT_basis (*moduli*)

Return a list of integers a[i] such that CRT to the given moduli of numbers x[0],...,x[n-1] is a[0]*x0 + ... + a[n-1]*x[n-1].

INPUT:

- `list` - list of integers

CRT_list (*v, moduli*)

Given a list v of integers and a list of corresponding moduli, find a single integer that reduces to each element of v modulo the corresponding moduli.

EXAMPLES:

```
sage: CRT_list([2,3,2], [3,5,7])
23
```

CRT_vectors (*X, moduli*)

INPUT:

- `X` - list of lists of the same length
- `moduli` - list of len(X) moduli

OUTPUT:

- `list` - application of CRT componentwise.

class Euler_Phi()

Return the value of the Euler phi function on the integer n. We defined this to be the number of positive integers <= n that are relatively prime to n. Thus if n<=0 then `euler_phi(n)` is defined and equals 0.

INPUT:

- `n` - an integer

EXAMPLES:

```
sage: euler_phi(1)
1
sage: euler_phi(2)
1
sage: euler_phi(3)
2
sage: euler_phi(12)
4
sage: euler_phi(37)
36
```

Notice that euler_phi is defined to be 0 on negative numbers and 0.

```
sage: euler_phi(-1)
0
sage: euler_phi(0)
0
sage: type(euler_phi(0))
<type 'sage.rings.integer.Integer'>
```

We verify directly that the phi function is correct for 21.

```
sage: euler_phi(21)
12
sage: [i for i in range(21) if gcd(21,i) == 1]
[1, 2, 4, 5, 8, 10, 11, 13, 16, 17, 19, 20]
```

The length of the list of integers 'i' in range(n) such that the gcd(i,n) == 1 equals euler_phi(n).

```
sage: len([i for i in range(21) if gcd(21,i) == 1]) == euler_phi(21)
True
```

The phi function also has a special plotting method.

```
sage: P = plot(euler_phi, -3, 71)
```

AUTHORS:

- William Stein
- Alex Clemesha (2006-01-10): some examples

plot(*xmin=1, xmax=50, pointsize=30, rgbcolor=(0, 0, 1), join=True, **kwds*)

Plot the Euler phi function.

INPUT:

- `xmin` - default: 1

- `xmax` - default: 50
- `pointsize` - default: 30
- `rgbcolor` - default: (0,0,1)
- `join` - default: True; whether to join the points.
- `**kwds` - passed on

GCD(*a, b=None, **kwargs*)

The greatest common divisor of a and b, or if a is a list and b is omitted the greatest common divisor of all elements of a.

INPUT:

- `a,b` - two elements of a ring with gcd or
- `a` - a list or tuple of elements of a ring with gcd

Additional keyword arguments are passed to the respectively called methods.

EXAMPLES:

```
sage: GCD(97,100)
1
sage: GCD(97*10^15, 19^20*97^2)
97
sage: GCD(2/3, 4/3)
1
sage: GCD([2,4,6,8])
2
sage: GCD(srange(0,10000,10))  # fast  !!
10
```

Note that to take the gcd of n elements for $n \neq 2$ you must put the elements into a list by enclosing them in `[..]`. Before #4988 the following wrongly returned 3 since the third parameter was just ignored:

```
sage: gcd(3,6,2)
...
TypeError: gcd() takes at most 2 arguments (3 given)
sage: gcd([3,6,2])
1
```

Similarly, giving just one element (which is not a list) gives an error:

```
sage: gcd(3)
...
TypeError: 'sage.rings.integer.Integer' object is not iterable
```

By convention, the gcd of the empty list is (the integer) 0:

```
sage: gcd([])
0
sage: type(gcd([]))
<type 'sage.rings.integer.Integer'>
```

LCM(*a, b=None*)

The least common multiple of a and b, or if a is a list and b is omitted the least common multiple of all elements of a.

Note that LCM is an alias for lcm.

INPUT:

- a, b - two elements of a ring with lcm or
- a - a list or tuple of elements of a ring with lcm

EXAMPLES:

```
sage: lcm(97,100)
9700
sage: LCM(97,100)
9700
sage: LCM(0,2)
0
sage: LCM(-3,-5)
15
sage: LCM([1,2,3,4,5])
60
sage: v = LCM(range(1,10000))    # *very* fast!
sage: len(str(v))
4349
```

class Moebius()

Returns the value of the Moebius function of abs(n), where n is an integer.

DEFINITION: $\mu(n)$ is 0 if n is not square free, and otherwise equals $(-1)^r$, where n has r distinct prime factors.

For simplicity, if $n = 0$ we define $\mu(n) = 0$.

IMPLEMENTATION: Factors or - for integers - uses the PARI C library.

INPUT:

- n - anything that can be factored.

OUTPUT: 0, 1, or -1

EXAMPLES:

```
sage: moebius(-5)
-1
sage: moebius(9)
0
sage: moebius(12)
0
sage: moebius(-35)
1
sage: moebius(-1)
1
sage: moebius(7)
-1

sage: moebius(0)    # potentially nonstandard!
0
```

The moebius function even makes sense for non-integer inputs.

```
sage: x = GF(7)['x'].0
sage: moebius(x+2)
-1
```

plot(*xmin=0, xmax=50, pointsize=30, rgbcolor=(0, 0, 1), join=True, **kwds*)

Plot the Moebius function.

INPUT:

- xmin - default: 0
- xmax - default: 50
- pointsize - default: 30
- rgbcolor - default: (0,0,1)
- join - default: True; whether to join the points (very helpful in seeing their order).
- **kwds - passed on

range(*start, stop=None, step=None*)

Return the Moebius function evaluated at the given range of values, i.e., the image of the list range(start, stop, step) under the Mobius function.

This is much faster than directly computing all these values with a list comprehension.

EXAMPLES:

```
sage: v = moebius.range(-10,10); v
[1, 0, 0, -1, 1, -1, 0, -1, -1, 1, 0, 1, -1, -1, 0, -1, 1, -1, 0, 0]
sage: v == [moebius(n) for n in range(-10,10)]
True
sage: v = moebius.range(-1000, 2000, 4)
sage: v == [moebius(n) for n in range(-1000,2000, 4)]
True
```

class Sigma()

Return the sum of the k-th powers of the divisors of n.

INPUT:

- n - integer
- k - integer (default: 1)

OUTPUT: integer

EXAMPLES:

```
sage: sigma(5)
6
sage: sigma(5,2)
26
```

The sigma function also has a special plotting method.

```
sage: P = plot(sigma, 1, 100)
```

This method also works with k-th powers.

```
sage: P = plot(sigma, 1, 100, k=2)
```

AUTHORS:

- William Stein: original implementation
- Craig Citro (2007-06-01): rewrote for huge speedup

TESTS:

```
sage: sigma(100,4)
106811523
sage: sigma(factorial(100),3).mod(144169)
3672
sage: sigma(factorial(150),12).mod(691)
176
```

```
sage: RR(sigma(factorial(133),20))
2.80414775675747e4523
sage: sigma(factorial(100),0)
39001250856960000
sage: sigma(factorial(41),1)
2291995322730299887677338587007329065117587079168 00
```

plot (*xmin=1, xmax=50, k=1, pointsize=30, rgbcolor=(0, 0, 1), join=True, **kwds*)

Plot the sigma (sum of k-th powers of divisors) function.

INPUT:

- `xmin` - default: 1
- `xmax` - default: 50
- `k` - default: 1
- `pointsize` - default: 30
- `rgbcolor` - default: (0,0,1)
- `join` - default: True; whether to join the points.
- `**kwds` - passed on

XGCD (*a, b*)

Returns triple (g,s,t) such that $g = s * a + t * b = gcd(a, b)$.

INPUT:

- `a, b` - integers or univariate polynomials (or any type with an xgcd method).

OUTPUT:

- `g, s, t` - such that g = s*a + t*b

Note: There is no guarantee that the returned cofactors (s and t) are minimal. In the integer case, see Integer._xgcd() for minimal cofactors.

EXAMPLES:

```
sage: xgcd(56, 44)
(4, 4, -5)
sage: 4*56 + (-5)*44
4
sage: g, a, b = xgcd(5/1, 7/1); g, a, b
(1, 3, -2)
sage: a*(5/1) + b*(7/1) == g
True
sage: x = polygen(QQ)
sage: xgcd(x^3 - 1, x^2 - 1)
(x - 1, 1, -x)
sage: K.<g> = NumberField(x^2-3)
sage: R.<a,b> = K[]
sage: S.<y> = R.fraction_field()[]
sage: xgcd(y^2, a*y+b)
(b^2/a^2, 1, ((-1)/a)*y + b/a^2)
sage: xgcd((b+g)*y^2, (a+g)*y+b)
((b^3 + (g)*b^2)/(a^2 + (2*g)*a + 3), 1, ((-b + (-g))/(a + (g)))*y + (b^2 + (g)*b)/(a^2 + (2*g)*
```

algdep (*z, n, known_bits=None, use_bits=None, known_digits=None, use_digits=None*)

Returns a polynomial of degree at most n which is approximately satisfied by the number z. Note that the returned polynomial need not be irreducible, and indeed usually won't be if z is a good approximation to an algebraic number of degree less than n.

You can specify the number of known bits or digits with known_bits=k or known_digits=k; Pari is then told to compute the result using .8*k of these bits/digits. (The Pari documentation recommends using a factor between .6 and .9, but internally defaults to .8.) Or, you can specify the precision to use directly with use_bits=k or use_digits=k. If none of these are specified, then the precision is taken from the input value.

ALGORITHM: Uses the PARI C-library algdep command.

INPUT:

- z - real, complex, or p-adic number
- n - an integer

EXAMPLES:

```
sage: algdep(1.888888888888888, 1)
9*x - 17
sage: algdep(0.12121212121212,1)
33*x - 4
sage: algdep(sqrt(2),2)
x^2 - 2
```

This example involves a complex number.

```
sage: z = (1/2)*(1 + RDF(sqrt(3)) *CC.0); z
0.500000000000000 + 0.866025403784439*I
sage: p = algdep(z, 6); p
x^5 + x^2
sage: p.factor()
(x + 1) * x^2 * (x^2 - x + 1)
sage: z^2 - z + 1
1.11022302462516e-16
```

This example involves a p-adic number.

```
sage: K = Qp(3, print_mode = 'series')
sage: a = K(7/19); a
1 + 2*3 + 3^2 + 3^3 + 2*3^4 + 2*3^5 + 3^8 + 2*3^9 + 3^11 + 3^12 + 2*3^15 + 2*3^16 + 3^17 + 2*3^1
sage: algdep(a, 1)
19*x - 7
```

These examples show the importance of proper precision control. We compute a 200-bit approximation to sqrt(2) which is wrong in the 33'rd bit.

```
sage: z = sqrt(RealField(200)(2)) + (1/2)^33
sage: p = algdep(z, 4); p
177858662573*x^4 + 59566570004*x^3 - 221308611561*x^2 - 84791308378*x - 317384111411
sage: factor(p)
177858662573*x^4 + 59566570004*x^3 - 221308611561*x^2 - 84791308378*x - 317384111411
sage: algdep(z, 4, known_bits=32)
x^2 - 2
sage: algdep(z, 4, known_digits=10)
x^2 - 2
sage: algdep(z, 4, use_bits=25)
x^2 - 2
sage: algdep(z, 4, use_digits=8)
x^2 - 2
```

algebraic_dependency(*z, n, known_bits=None, use_bits=None, known_digits=None, use_digits=None*)

Returns a polynomial of degree at most n which is approximately satisfied by the number z. Note that the

returned polynomial need not be irreducible, and indeed usually won't be if z is a good approximation to an algebraic number of degree less than n.

You can specify the number of known bits or digits with known_bits=k or known_digits=k; Pari is then told to compute the result using .8*k of these bits/digits. (The Pari documentation recommends using a factor between .6 and .9, but internally defaults to .8.) Or, you can specify the precision to use directly with use_bits=k or use_digits=k. If none of these are specified, then the precision is taken from the input value.

ALGORITHM: Uses the PARI C-library algdep command.

INPUT:

- z - real, complex, or p-adic number
- n - an integer

EXAMPLES:

```
sage: algdep(1.888888888888888, 1)
9*x - 17
sage: algdep(0.12121212121212,1)
33*x - 4
sage: algdep(sqrt(2),2)
x^2 - 2
```

This example involves a complex number.

```
sage: z = (1/2)*(1 + RDF(sqrt(3)) *CC.0); z
0.500000000000000 + 0.866025403784439*I
sage: p = algdep(z, 6); p
x^5 + x^2
sage: p.factor()
(x + 1) * x^2 * (x^2 - x + 1)
sage: z^2 - z + 1
1.11022302462516e-16
```

This example involves a p-adic number.

```
sage: K = Qp(3, print_mode = 'series')
sage: a = K(7/19); a
1 + 2*3 + 3^2 + 3^3 + 2*3^4 + 2*3^5 + 3^8 + 2*3^9 + 3^11 + 3^12 + 2*3^15 + 2*3^16 + 3^17 + 2*3^1
sage: algdep(a, 1)
19*x - 7
```

These examples show the importance of proper precision control. We compute a 200-bit approximation to sqrt(2) which is wrong in the 33'rd bit.

```
sage: z = sqrt(RealField(200)(2)) + (1/2)^33
sage: p = algdep(z, 4); p
177858662573*x^4 + 59566570004*x^3 - 221308611561*x^2 - 84791308378*x - 317384111411
sage: factor(p)
177858662573*x^4 + 59566570004*x^3 - 221308611561*x^2 - 84791308378*x - 317384111411
sage: algdep(z, 4, known_bits=32)
x^2 - 2
sage: algdep(z, 4, known_digits=10)
x^2 - 2
sage: algdep(z, 4, use_bits=25)
x^2 - 2
sage: algdep(z, 4, use_digits=8)
x^2 - 2
```

bernoulli(*n, algorithm='default', num_threads=1*)

Return the n-th Bernoulli number, as a rational number.

INPUT:

- `n` - an integer
- `algorithm`:
  - `'default'` - (default) use 'pari' for n <= 30000, and 'bernmm' for n > 30000 (this is just a heuristic, and not guaranteed to be optimal on all hardware)
  - `'pari'` - use the PARI C library
  - `'gap'` - use GAP
  - `'gp'` - use PARI/GP interpreter
  - `'magma'` - use MAGMA (optional)
  - `'bernmm'` - use bernmm package (a multimodular algorithm)
- `num_threads` - positive integer, number of threads to use (only used for bernmm algorithm)

EXAMPLES:

```
sage: bernoulli(12)
-691/2730
sage: bernoulli(50)
495057205241079648212477525/66
```

We demonstrate each of the alternative algorithms:

```
sage: bernoulli(12, algorithm='gap')
-691/2730
sage: bernoulli(12, algorithm='gp')
-691/2730
sage: bernoulli(12, algorithm='magma')           # optional - magma
-691/2730
sage: bernoulli(12, algorithm='pari')
-691/2730
sage: bernoulli(12, algorithm='bernmm')
-691/2730
sage: bernoulli(12, algorithm='bernmm', num_threads=4)
-691/2730
```

TESTS:

```
sage: algs = ['gap','gp','pari','bernmm'] #long time
sage: vals = [[bernoulli(i,algorithm = j) for j in algs] for i in range(2,2255)] #long time
sage: union([len(union(x))==1 for x in vals]) #long time
[True]
sage: algs = ['gp','pari','bernmm'] #long time
sage: vals = [[bernoulli(i,algorithm = j) for j in algs] for i in range(2256,5000)] #long time
sage: union([len(union(x))==1 for x in vals]) #long time
[True]
```

Note: If $n > 50000$ then algorithm = 'gp' is used instead of algorithm = 'pari', since the C-library interface to PARI is limited in memory for individual operations.

AUTHOR:

- David Joyner and William Stein

binomial(*x*, *m*)

Return the binomial coefficient

$$x(x-1)\cdots(x-m+1)/m!$$

which is defined for $m \in \mathbf{Z}$ and any x. We extend this definition to include cases when $x - m$ is an integer but m is not by

binomial(x,m)= binomial(x,x-m)

If $m < 0$ return 0.

INPUT:

- `x, m` - numbers or symbolic expressions. Either m or x-m must be an integer.

OUTPUT: number or symbolic expression (if input is symbolic)

EXAMPLES:

```
sage: binomial(5,2)
10
sage: binomial(2,0)
1
sage: binomial(1/2, 0)
1
sage: binomial(3,-1)
0
sage: binomial(20,10)
184756
sage: binomial(-2, 5)
-6
sage: binomial(RealField()('2.5'), 2)
1.87500000000000
sage: n=var('n'); binomial(n,2)
1/2*(n - 1)*n
sage: n=var('n'); binomial(n,n)
1
sage: n=var('n'); binomial(n,n-1)
n
sage: binomial(2^100, 2^100)
1

sage: k, i = var('k,i',ns=1)
sage: binomial(k,i)
binomial(k,i)
```

TESTS:

We test that certain binomials are very fast (this should be instant) – see trac 3309:

```
sage: a = binomial(RR(1140000.78), 42000000)
```

binomial_coefficients(*n*)

Return a dictionary containing pairs $\{(k_1, k_2) : C_{k,n}\}$ where C_{k_n} are binomial coefficients and $n = k_1 + k_2$.

INPUT:

- `n` - an integer

OUTPUT: dict

EXAMPLES:

```
sage: sorted(binomial_coefficients(3).items())
[((0, 3), 1), ((1, 2), 3), ((2, 1), 3), ((3, 0), 1)]
```

Notice the coefficients above are the same as below:

```
sage: R.<x,y> = QQ[]
sage: (x+y)^3
x^3 + 3*x^2*y + 3*x*y^2 + y^3
```

AUTHORS:

- Fredrik Johansson

continuant(*v, n=None*)

Function returns the continuant of the sequence v (list or tuple).

Definition: see Graham, Knuth and Patashnik: Concrete Mathematics: 6.7 Continuants:

$K_0() = 1$

$K_1(x_1) = x_1$

$K_n(x_1, \cdots, x_n) = K_{n-1}(x_n, \cdots x_{n-1})x_n + K_{n-2}(x_1, \cdots, x_{n-2})$

If $n = None$ or $n > len(v)$ the default $n = len(v)$ is used.

INPUT:

- v - list or tuple of elements of a ring
- n - optional integer

OUTPUT: element of ring (integer, polynomial, etcetera).

EXAMPLES:

```
sage: continuant([1,2,3])
10
sage: p = continuant([2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 1, 1, 10])
sage: q = continuant([1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 1, 1, 10])
sage: p/q
517656/190435
sage: convergent([2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 1, 1, 10],14)
517656/190435
sage: x = PolynomialRing(RationalField(),'x',5).gens()
sage: continuant(x)
x0*x1*x2*x3*x4 + x0*x1*x2 + x0*x1*x4 + x0*x3*x4 + x2*x3*x4 + x0 + x2 + x4
sage: continuant(x, 3)
x0*x1*x2 + x0 + x2
sage: continuant(x,2)
x0*x1 + 1
```

$\binom{K_n(z,z,\cdots,z)=sum_{k=0}^{n} n-k}{kz^{n-2k}}$:

```
sage: z = QQ['z'].0
sage: continuant((z,z,z,z,z,z,z,z,z,z,z,z,z,z,z,z),6)
z^6 + 5*z^4 + 6*z^2 + 1
sage: continuant(9)
...
TypeError: object of type 'sage.rings.integer.Integer' has no len()
```

AUTHORS:

- Jaap Spies (2007-02-06)

continued_fraction_list(*x, partial_convergents=False, bits=None*)

Returns the continued fraction of x as a list.

This may be slow since it's implemented in pure Python for real input. For rational number input the PARI C library is used.

EXAMPLES:

```
sage: continued_fraction_list(45/17)
[2, 1, 1, 1, 5]
sage: continued_fraction_list(e, bits=20)
[2, 1, 2, 1, 1, 4, 1, 1, 6]
sage: continued_fraction_list(e, bits=30)
[2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 1, 1]
sage: continued_fraction_list(sqrt(2))
[1, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 1, 1]
sage: continued_fraction_list(sqrt(4/19))
[0, 2, 5, 1, 1, 2, 1, 16, 1, 2, 1, 1, 5, 4, 5, 1, 1, 2, 1, 15, 2]
sage: continued_fraction_list(RR(pi), partial_convergents=True)
([3, 7, 15, 1, 292, 1, 1, 1, 2, 1, 3, 1, 14, 3],
 [(3, 1),
  (22, 7),
  (333, 106),
  (355, 113),
  (103993, 33102),
  (104348, 33215),
  (208341, 66317),
  (312689, 99532),
  (833719, 265381),
  (1146408, 364913),
  (4272943, 1360120),
  (5419351, 1725033),
  (80143857, 25510582),
  (245850922, 78256779)])
sage: continued_fraction_list(e)
[2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 1, 1, 10, 1, 1, 12, 1, 1, 11]
sage: continued_fraction_list(RR(e))
[2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 1, 1, 10, 1, 1, 12, 1, 1, 11]
sage: print continued_fraction_list(RealField(200)(e))
[2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 1, 1, 10, 1, 1, 12, 1, 1, 14, 1, 1, 16, 1, 1, 18, 1, 1, 20,
```

convergent(*v, n*)

Return the n-th continued fraction convergent of the continued fraction defined by the sequence of integers v. We assume $n \geq 0$.

INPUT:

- `v` - list of integers
- `n` - integer

OUTPUT: a rational number

If the continued fraction integers are

$$v = [a_0, a_1, a_2, \ldots, a_k]$$

then `convergent(v,2)` is the rational number

$$a_0 + 1/a_1$$

and `convergent(v,k)` is the rational number

$$a1 + 1/(a2 + 1/(...)...)$$

represented by the continued fraction.

EXAMPLES:

```
sage: convergent([2, 1, 2, 1, 1, 4, 1, 1], 7)
193/71
```

convergents (*v*)

Return all the partial convergents of a continued fraction defined by the sequence of integers v.

If v is not a list, compute the continued fraction of v and return its convergents (this is potentially much faster than calling continued_fraction first, since continued fractions are implemented using PARI and there is overhead moving the answer back from PARI).

INPUT:

- `v` - list of integers or a rational number

OUTPUT:

- `list` - of partial convergents, as rational numbers

EXAMPLES:

```
sage: convergents([2, 1, 2, 1, 1, 4, 1, 1])
[2, 3, 8/3, 11/4, 19/7, 87/32, 106/39, 193/71]
```

crt (*a, b, m, n*)

Use the Chinese Remainder Theorem to find some integer x such that x=a (mod m) and x=b (mod n). Note that x is only well-defined modulo m*n.

EXAMPLES:

```
sage: crt(2, 1, 3, 5)
-4
sage: crt(13,20,100,301)
-2087
```

You can also use upper case:

```
sage: c = CRT(2,3, 3, 5); c
8
sage: c % 3 == 2
True
sage: c % 5 == 3
True
```

differences (*lis, n=1*)

Returns the n successive differences of the elements in lis.

EXAMPLES:

```
sage: differences(prime_range(50))
[1, 2, 2, 4, 2, 4, 2, 4, 6, 2, 6, 4, 2, 4]
sage: differences([i^2 for i in range(1,11)])
[3, 5, 7, 9, 11, 13, 15, 17, 19]
sage: differences([i^3 + 3*i for i in range(1,21)])
[10, 22, 40, 64, 94, 130, 172, 220, 274, 334, 400, 472, 550, 634, 724, 820, 922, 1030, 1144]
```

```
sage: differences([i^3 - i^2 for i in range(1,21)], 2)
[10, 16, 22, 28, 34, 40, 46, 52, 58, 64, 70, 76, 82, 88, 94, 100, 106, 112]
sage: differences([p - i^2 for i, p in enumerate(prime_range(50))], 3)
[-1, 2, -4, 4, -4, 4, 0, -6, 8, -6, 0, 4]
```

AUTHORS:

- Timothy Clemans (2008-03-09)

divisors(*n*)

Returns a list of all positive integer divisors of the nonzero integer n.

INPUT:

- n - the element

EXAMPLES:

```
sage: divisors(-3)
[1, 3]
sage: divisors(6)
[1, 2, 3, 6]
sage: divisors(28)
[1, 2, 4, 7, 14, 28]
sage: divisors(2^5)
[1, 2, 4, 8, 16, 32]
sage: divisors(100)
[1, 2, 4, 5, 10, 20, 25, 50, 100]
sage: divisors(1)
[1]
sage: divisors(0)
...
ValueError: n must be nonzero
sage: divisors(2^3 * 3^2 * 17)
[1, 2, 3, 4, 6, 8, 9, 12, 17, 18, 24, 34, 36, 51, 68, 72, 102, 136, 153, 204, 306, 408, 612, 122
```

This function works whenever one has unique factorization:

```
sage: K.<a> = QuadraticField(7)
sage: divisors(K.ideal(7))
[Fractional ideal (1), Fractional ideal (-a), Fractional ideal (7)]
sage: divisors(K.ideal(3))
[Fractional ideal (1), Fractional ideal (3), Fractional ideal (a - 2), Fractional ideal (-a - 2)
sage: divisors(K.ideal(35))
[Fractional ideal (1), Fractional ideal (35), Fractional ideal (-5*a), Fractional ideal (5), Fra
```

TESTS:

```
sage: divisors(int(300))
[1, 2, 3, 4, 5, 6, 10, 12, 15, 20, 25, 30, 50, 60, 75, 100, 150, 300]
```

eratosthenes(*n*)

Return a list of the primes $\leq n$.

This is extremely slow and is for educational purposes only.

factor(*n, proof=None, int_=False, algorithm='pari', verbose=0, **kwds*)

Returns the factorization of n. The result depends on the type of n.

If n is an integer, factor returns the factorization of the integer n as an object of type Factorization.

If n is not an integer, `n.factor(proof=proof, **kwds)` gets called. See `n.factor??` for more documentation in this case.

Warning: This means that applying factor to an integer result of a symbolic computation will not factor the integer, because it is considered as an element of a larger symbolic ring.
EXAMPLE:

```
sage: f(n)=n^2
sage: is_prime(f(3))
False
sage: factor(f(3))
9
```

INPUT:

- `n` - an nonzero integer
- `proof` - bool or None (default: None)
- `int_` - bool (default: False) whether to return answers as Python ints
- `algorithm` - string
  - `'pari'` - (default) use the PARI c library
  - `'kash'` - use KASH computer algebra system (requires the optional kash package be installed)
  - `'magma'` - use Magma (requires magma be installed)
- `verbose` - integer (default 0); pari's debug variable is set to this; e.g., set to 4 or 8 to see lots of output during factorization.

OUTPUT: factorization of n

The qsieve and ecm commands give access to highly optimized implementations of algorithms for doing certain integer factorization problems. These implementations are not used by the generic factor command, which currently just calls PARI (note that PARI also implements sieve and ecm algorithms, but they aren't as optimized). Thus you might consider using them instead for certain numbers.

The factorization returned is an element of the class Factorization; see Factorization?? for more details, and examples below for usage. A Factorization contains both the unit factor (+1 or -1) and a sorted list of (prime, exponent) pairs.

The factorization displays in pretty-print format but it is easy to obtain access to the (prime,exponent) pairs and the unit, to recover the number from its factorization, and even to multiply two factorizations. See examples below.

EXAMPLES:

```
sage: factor(500)
2^2 * 5^3
sage: factor(-20)
-1 * 2^2 * 5
sage: f=factor(-20)
sage: list(f)
[(2, 2), (5, 1)]
sage: f.unit()
-1
sage: f.value()
-20
```

```
sage: factor(-500, algorithm='kash')       # optional - kash
-1 * 2^2 * 5^3
```

```
sage: factor(-500, algorithm='magma')      # optional - magma
-1 * 2^2 * 5^3

sage: factor(0)
...
ArithmeticError: Prime factorization of 0 not defined.
sage: factor(1)
1
sage: factor(-1)
-1
sage: factor(2^(2^7)+1)
59649589127497217 * 5704689200685129054721
```

Sage calls PARI's factor, which has proof False by default. Sage has a global proof flag, set to True by default (see sage.structure.proof, or proof.[tab]). To override the default, call this function with proof=False.

```
sage: factor(3^89-1, proof=False)
2 * 179 * 1611479891519807 * 504293943956596049162197

sage: factor(2^197 + 1)       # takes a long time (e.g., 3 seconds!)
3 * 197002597249 * 1348959352853811313 * 251951573867253012259144010843
```

To access the data in a factorization:

```
sage: f = factor(420); f
2^2 * 3 * 5 * 7
sage: [x for x in f]
[(2, 2), (3, 1), (5, 1), (7, 1)]
sage: [p for p,e in f]
[2, 3, 5, 7]
sage: [e for p,e in f]
[2, 1, 1, 1]
sage: [p^e for p,e in f]
[4, 3, 5, 7]
```

factorial(*n, algorithm='gmp'*)

Compute the factorial of n, which is the product $1 \cdot 2 \cdot 3 \cdots (n-1)n$.

INPUT:

- `n` - an integer
- `algorithm` - string (default: 'gmp')
  - `'gmp'` - use the GMP C-library factorial function
  - `'pari'` - use PARI's factorial function

OUTPUT: an integer

EXAMPLES:

```
sage: factorial(0)
1
sage: factorial(4)
24
sage: factorial(10)
3628800
sage: factorial(1) == factorial(0)
True
```

```
sage: factorial(6) == 6*5*4*3*2
True
sage: factorial(1) == factorial(0)
True
sage: factorial(71) == 71* factorial(70)
True
sage: factorial(-32)
...
ValueError: factorial -- must be nonnegative
```

PERFORMANCE: This discussion is valid as of April 2006. All timings below are on a Pentium Core Duo 2Ghz MacBook Pro running Linux with a 2.6.16.1 kernel.

- It takes less than a minute to compute the factorial of 10^7 using the GMP algorithm, and the factorial of 10^6 takes less than 4 seconds.
- The GMP algorithm is faster and more memory efficient than the PARI algorithm. E.g., PARI computes 10^7 factorial in 100 seconds on the core duo 2Ghz.
- For comparison, computation in Magma $\leq$ 2.12-10 of $n!$ is best done using `*[1..n]`. It takes 113 seconds to compute the factorial of 10^7 and 6 seconds to compute the factorial of 10^6. Mathematica V5.2 compute the factorial of 10^7 in 136 seconds and the factorial of 10^6 in 7 seconds. (Mathematica is notably very efficient at memory usage when doing factorial calculations.)

falling_factorial(*x*, *a*)

Returns the falling factorial $(x)_a$.

The notation in the literature is a mess: often $(x)_a$, but there are many other notations: GKP: Concrete Mathematics uses $x^{\underline{a}}$.

Definition: for integer $a \geq 0$ we have $x(x-1)\cdots(x-a+1)$. In all other cases we use the GAMMA-function: $\frac{\Gamma(x+1)}{\Gamma(x-a+1)}$.

INPUT:

- `x` - element of a ring
- `a` - a non-negative integer or

OR

- `x and a` - any numbers

OUTPUT: the falling factorial

EXAMPLES:

```
sage: falling_factorial(10, 3)
720
sage: falling_factorial(10, RR('3.0'))
720.000000000000
sage: falling_factorial(10, RR('3.3'))
1310.11633396601
sage: falling_factorial(10, 10)
3628800
sage: factorial(10)
3628800
sage: a = falling_factorial(1+I, I); a
gamma(I + 2)
sage: CC(a)
0.652965496420167 + 0.343065839816545*I
sage: falling_factorial(1+I, 4)
```

```
4*I + 2
sage: falling_factorial(I, 4)
-10

sage: M = MatrixSpace(ZZ, 4, 4)
sage: A = M([1,0,1,0,1,0,1,0,1,0,10,10,1,0,1,1])
sage: falling_factorial(A, 2) # A(A - I)
[  1   0  10  10]
[  1   0  10  10]
[ 20   0 101 100]
[  2   0  11  10]

sage: x = ZZ['x'].0
sage: falling_factorial(x, 4)
x^4 - 6*x^3 + 11*x^2 - 6*x
```

AUTHORS:

- Jaap Spies (2006-03-05)

farey (*v, lim*)

Return the Farey sequence associated to the floating point number v.

INPUT:

- `v` - float (automatically converted to a float)
- `lim` - maximum denominator.

OUTPUT: Results are (numerator, denominator); (1, 0) is"infinity".

AUTHORS:

- Scott David Daniels: Python Cookbook, 2nd Ed., Recipe 18.13

fundamental_discriminant (*D*)

Return the discriminant of the quadratic extension $K = Q(\sqrt{D})$, i.e. an integer d congruent to either 0 or 1, mod 4, and such that, at most, the only square dividing it is 4.

gaussian_binomial (*n, k, q=None*)

Return the gaussian binomial

$$\binom{n}{k}_q = \frac{(1-q^n)(1-q^{n-1})\cdots(1-q^{n-k+1})}{(1-q)(1-q^2)\cdots(1-q^k)}.$$

EXAMPLES:

```
sage: gaussian_binomial(5,1)
q^4 + q^3 + q^2 + q + 1
sage: gaussian_binomial(5,1).subs(q=2)
31
sage: gaussian_binomial(5,1,2)
31
```

AUTHORS:

- David Joyner and William Stein

gcd(*a, b=None, **kwargs*)

The greatest common divisor of a and b, or if a is a list and b is omitted the greatest common divisor of all elements of a.

INPUT:

- `a, b` - two elements of a ring with gcd or
- `a` - a list or tuple of elements of a ring with gcd

Additional keyword arguments are passed to the respectively called methods.

EXAMPLES:

```
sage: GCD(97,100)
1
sage: GCD(97*10^15, 19^20*97^2)
97
sage: GCD(2/3, 4/3)
1
sage: GCD([2,4,6,8])
2
sage: GCD(srange(0,10000,10))  # fast  !!
10
```

Note that to take the gcd of n elements for $n \neq 2$ you must put the elements into a list by enclosing them in `[..]`. Before #4988 the following wrongly returned 3 since the third parameter was just ignored:

```
sage: gcd(3,6,2)
...
TypeError: gcd() takes at most 2 arguments (3 given)
sage: gcd([3,6,2])
1
```

Similarly, giving just one element (which is not a list) gives an error:

```
sage: gcd(3)
...
TypeError: 'sage.rings.integer.Integer' object is not iterable
```

By convention, the gcd of the empty list is (the integer) 0:

```
sage: gcd([])
0
sage: type(gcd([]))
<type 'sage.rings.integer.Integer'>
```

get_gcd(*order*)

Return the fastest gcd function for integers of size no larger than order.

EXAMPLES:

```
sage: sage.rings.arith.get_gcd(4000)
<built-in method gcd_int of sage.rings.fast_arith.arith_int object at ...>
sage: sage.rings.arith.get_gcd(400000)
<built-in method gcd_longlong of sage.rings.fast_arith.arith_llong object at ...>
sage: sage.rings.arith.get_gcd(4000000000)
<function gcd at ...>
```

get_inverse_mod(*order*)

Return the fastest inverse_mod function for integers of size no larger than order.

EXAMPLES:

```
sage: sage.rings.arith.get_inverse_mod(6000)
<built-in method inverse_mod_int of sage.rings.fast_arith.arith_int object at ...>
sage: sage.rings.arith.get_inverse_mod(600000)
<built-in method inverse_mod_longlong of sage.rings.fast_arith.arith_llong object at ...>
sage: sage.rings.arith.get_inverse_mod(6000000000)
<function inverse_mod at ...>
```

hilbert_conductor(*a, b*)

This is the product of all (finite) primes where the hilbert symbol is -1. What is the same, this is the (reduced) discriminant of the quaternion algebra (a,b) over Q.

INPUT: a, b – integers

OUTPUT: squarefree positive integer

EXAMPLES: sage: hilbert_conductor(-1, -1) 2 sage: hilbert_conductor(-1, -11) 11 sage: hilbert_conductor(-2, -5) 5 sage: hilbert_conductor(-3, -17) 17

AUTHOR: – Gonzalo Tornaria (2009-03-02)

hilbert_conductor_inverse(*d*)

Finds a pair of integers (a,b) such that hilbert_conductor(a,b) == d. The quaternion algebra (a,b) over Q will have (reduced) discriminant d.

INPUT:

- d – square-free positive integer

OUTPUT: pair of integers

EXAMPLES:

```
sage: hilbert_conductor_inverse(2)
(-1, -1)
sage: hilbert_conductor_inverse(3)
(-1, -3)
sage: hilbert_conductor_inverse(6)
(-1, 3)
sage: hilbert_conductor_inverse(30)
(-3, -10)
sage: hilbert_conductor_inverse(4)
...
ValueError: d needs to be squarefree
sage: hilbert_conductor_inverse(-1)
...
ValueError: d needs to be positive
```

AUTHOR:

- Gonzalo Tornaria (2009-03-02)

TESTS:

```
sage: for i in xrange(100):
...       d = ZZ.random_element(2**32).squarefree_part()
...       if hilbert_conductor(*hilbert_conductor_inverse(d)) != d:
...           print "hilbert_conductor_inverse failed for d =", d
```

hilbert_symbol(*a, b, p, algorithm='pari'*)

Returns 1 if $ax^2 + by^2$ p-adically represents a nonzero square, otherwise returns -1. If either a or b is 0, returns 0.

INPUT:

- `a, b` - integers
- `p` - integer; either prime or -1 (which represents the archimedean place)
- `algorithm` - string
  - `'pari'` - (default) use the PARI C library
  - `'direct'` - use a Python implementation
  - `'all'` - use both PARI and direct and check that the results agree, then return the common answer

OUTPUT: integer (0, -1, or 1)

EXAMPLES:

```
sage: hilbert_symbol (-1, -1, -1, algorithm='all')
-1
sage: hilbert_symbol (2,3, 5, algorithm='all')
1
sage: hilbert_symbol (4, 3, 5, algorithm='all')
1
sage: hilbert_symbol (0, 3, 5, algorithm='all')
0
sage: hilbert_symbol (-1, -1, 2, algorithm='all')
-1
sage: hilbert_symbol (1, -1, 2, algorithm='all')
1
sage: hilbert_symbol (3, -1, 2, algorithm='all')
-1

sage: hilbert_symbol(QQ(-1)/QQ(4), -1, 2) == -1
True
sage: hilbert_symbol(QQ(-1)/QQ(4), -1, 3) == 1
True
```

AUTHORS:

- William Stein and David Kohel (2006-01-05)

integer_ceil(*x*)

Return the ceiling of x.

EXAMPLES:

```
sage: integer_ceil(5.4)
6
```

integer_floor(*x*)

Return the largest integer $\leq x$.

INPUT:

- `x` - an object that has a floor method or is coercible to int

OUTPUT: an Integer

EXAMPLES:

```
sage: integer_floor(5.4)
5
sage: integer_floor(float(5.4))
5
sage: integer_floor(-5/2)
-3
sage: integer_floor(RDF(-5/2))
-3
```

inverse_mod(*a*, *m*)

The inverse of the ring element a modulo m.

If no special inverse_mod is defined for the elements, it tries to coerce them into integers and perform the inversion there

```
sage: inverse_mod(7,1)
0
sage: inverse_mod(5,14)
3
sage: inverse_mod(3,-5)
2
```

is_power_of_two(*n*)

This function returns True if and only if n is a power of 2

INPUT:

- `n` - integer

OUTPUT:

- `True` - if n is a power of 2
- `False` - if not

EXAMPLES:

```
sage: is_power_of_two(1024)
True

sage: is_power_of_two(1)
True

sage: is_power_of_two(24)
False

sage: is_power_of_two(0)
False

sage: is_power_of_two(-4)
False
```

AUTHORS:

- Jaap Spies (2006-12-09)

is_prime(*n, flag=0*)

Returns True if x is prime, and False otherwise. The result is proven correct - *this is NOT a pseudo-primality test!*.

INPUT:

- `flag` - int
  - `0` (default) - use a combination of algorithms.
  - `1` - certify primality using the Pocklington-Lehmer Test.
  - `2` - certify primality using the APRCL test.

OUTPUT:

- `bool` - True or False

Note: We do not consider negatives of prime numbers as prime.

EXAMPLES::

```
sage: is_prime(389)
True
sage: is_prime(2000)
False
sage: is_prime(2)
True
sage: is_prime(-1)
False
sage: factor(-6)
-1 * 2 * 3
sage: is_prime(1)
False
sage: is_prime(-2)
False
```

IMPLEMENTATION: Calls the PARI isprime function.

is_prime_power(*n, flag=0*)

Returns True if x is a prime power, and False otherwise. The result is proven correct - *this is NOT a pseudo-primality test!*.

INPUT:

- `n` - an integer
- `flag (for primality testing)` - int
  - `0` (default): use a combination of algorithms.
  - `1`: certify primality using the Pocklington-Lehmer Test.
  - `2`: certify primality using the APRCL test.

EXAMPLES::

```
sage: is_prime_power(389)
True
sage: is_prime_power(2000)
False
sage: is_prime_power(2)
True
sage: is_prime_power(1024)
True
sage: is_prime_power(-1)
```

```
False
sage: is_prime_power(1)
True
sage: is_prime_power(997^100)
True
```

is_pseudoprime(*n, flag=0*)

Returns True if x is a pseudo-prime, and False otherwise. The result is *NOT* proven correct - *this is a pseudo-primality test!*.

INPUT:

- `flag` - int
  - `0` (default): checks whether x is a Baillie-Pomerance- Selfridge-Wagstaff pseudo prime (strong Rabin-Miller pseudo prime for base 2, followed by strong Lucas test for the sequence (P,-1), P smallest positive integer such that $P^2 - 4$ is not a square mod x).
  - `>0`: checks whether x is a strong Miller-Rabin pseudo prime for flag randomly chosen bases (with end-matching to catch square roots of -1).

OUTPUT:

- `bool` - True or False

Note: We do not consider negatives of prime numbers as prime.

EXAMPLES::

```
sage: is_pseudoprime(389)
True
sage: is_pseudoprime(2000)
False
sage: is_pseudoprime(2)
True
sage: is_pseudoprime(-1)
False
sage: factor(-6)
-1 * 2 * 3
sage: is_pseudoprime(1)
False
sage: is_pseudoprime(-2)
False
```

IMPLEMENTATION: Calls the PARI ispseudoprime function.

is_square(*n, root=False*)

Returns whether or not n is square, and if n is a square also returns the square root. If n is not square, also returns None.

INPUT:

- `n` - an integer
- `root` - whether or not to also return a square root (default: False)

OUTPUT:

- `bool` - whether or not a square
- `object` - (optional) an actual square if found, and None otherwise.

EXAMPLES:

```
sage: is_square(2)
False
sage: is_square(4)
True
sage: is_square(2.2)
True
sage: is_square(-2.2)
False
sage: is_square(CDF(-2.2))
True
sage: is_square((x-1)^2)
True

sage: is_square(4, True)
(True, 2)
```

is_squarefree(*n*)
Returns True if and only if n is not divisible by the square of an integer > 1.

kronecker(*x, y*)
Synonym for `kronecker_symbol()`.

kronecker_symbol(*x, y*)
The Kronecker symbol $(x|y)$.

INPUT:

- `x` - integer
- `y` - integer

EXAMPLES:

```
sage: kronecker(3,5)
-1
sage: kronecker(3,15)
0
sage: kronecker(2,15)
1
sage: kronecker(-2,15)
-1
sage: kronecker(2/3,5)
1
```

IMPLEMENTATION: Using GMP.

lcm(*a, b=None*)
The least common multiple of a and b, or if a is a list and b is omitted the least common multiple of all elements of a.

Note that LCM is an alias for lcm.

INPUT:

- `a,b` - two elements of a ring with lcm or
- `a` - a list or tuple of elements of a ring with lcm

EXAMPLES:

```
sage: lcm(97,100)
9700
sage: LCM(97,100)
9700
sage: LCM(0,2)
0
sage: LCM(-3,-5)
15
sage: LCM([1,2,3,4,5])
60
sage: v = LCM(range(1,10000))    # *very* fast!
sage: len(str(v))
4349
```

legendre_symbol(*x, p*)

The Legendre symbol $(x|p)$, for p prime.

Note: The `kronecker_symbol()` command extends the Legendre symbol to composite moduli and $p = 2$.

INPUT:

- `x` - integer
- `p` - an odd prime number

EXAMPLES:

```
sage: legendre_symbol(2,3)
-1
sage: legendre_symbol(1,3)
1
sage: legendre_symbol(1,2)
...
ValueError: p must be odd
sage: legendre_symbol(2,15)
...
ValueError: p must be a prime
sage: kronecker_symbol(2,15)
1
sage: legendre_symbol(2/3,7)
-1
```

mqrr_rational_reconstruction(*u, m, T*)

Maximal Quotient Rational Reconstruction.

FOR research purposes only - this is pure Python, so slow.

INPUT:

- `u, m, T` - integers such that $m > u \geq 0, T > 0$.

OUTPUT:

Either integers n, d such that $d > 0$, $gcd(n, d) = 1$, $n/d = u(modm)$, and $T * d * |n| < m$, or `None`.

Reference: Monagan, Maximal Quotient Rational Reconstruction: An Almost Optimal Algorithm for Rational Reconstruction (page 11)

This algorithm is probabilistic.

multinomial(*ks)

Return the multinomial coefficient

$$\binom{k_1 + \cdots + k_n}{k_1, \cdots, k_n} = \frac{(\sum_{i=1}^n k_i)!}{\prod_{i=1}^n k_i!} = \prod_{i=1}^n \binom{\sum_{j=1}^i k_j}{k_i}$$

EXAMPLES:

```
sage: multinomial(0, 0, 2, 1, 0, 0)
3
sage: multinomial(3, 2)
10
sage: multinomial(2^30, 2, 1)
618970023101454657175683075
```

AUTHORS:

- Gabriel Ebner

multinomial_coefficients(*m, n, _tuple=<type 'tuple'>, _zip=<built-in function zip>*)

Return a dictionary containing pairs $\{(k_1, k_2, ..., k_m) : C_{k,n}\}$ where $C_{k,n}$ are multinomial coefficients such that $n = k_1 + k_2 + ... + k_m$.

INPUT:

- `m` - integer
- `n` - integer
- `_tuple, _zip` - hacks for speed; don't set these as a user.

OUTPUT: dict

EXAMPLES:

```
sage: sorted(multinomial_coefficients(2,5).items())
[((0, 5), 1), ((1, 4), 5), ((2, 3), 10), ((3, 2), 10), ((4, 1), 5), ((5, 0), 1)]
```

Notice that these are the coefficients of $(x + y)^5$:

```
sage: R.<x,y> = QQ[]
sage: (x+y)^5
x^5 + 5*x^4*y + 10*x^3*y^2 + 10*x^2*y^3 + 5*x*y^4 + y^5
```

```
sage: sorted(multinomial_coefficients(3,2).items())
[((0, 0, 2), 1), ((0, 1, 1), 2), ((0, 2, 0), 1), ((1, 0, 1), 2), ((1, 1, 0), 2), ((2, 0, 0), 1)]
```

ALGORITHM: The algorithm we implement for computing the multinomial coefficients is based on the following result:

Consider a polynomial and its n-th exponent:

$$P(x) = \sum_{i=0}^{m} p_i x^k$$

$$P(x)^n = \sum_{k=0}^{mn} a(n,k) x^k$$

We compute the coefficients $a(n,k)$ using the J.C.P. Miller Pure Recurrence [see D.E.Knuth, Seminumerical Algorithms, The art of Computer Programming v.2, Addison Wesley, Reading, 1981].

$$a(n,k) = 1/(kp_0)\sum_{i=1}^{m} p_i((n+1)i-k)a(n,k-i),$$

where $a(n,0) = p_0^n$.

AUTHORS:

- Pearu Peterson

next_prime(*n, proof=None*)

The next prime greater than the integer n. If n is prime, then this function does not return n, but the next prime after n. If the optional argument proof is False, this function only returns a pseudo-prime, as defined by the PARI nextprime function. If it is None, uses the global default (see sage.structure.proof)

INPUT:

- `n` - integer
- `proof` - bool or None (default: None)

EXAMPLES:

```
sage: next_prime(-100)
2
sage: next_prime(1)
2
sage: next_prime(2)
3
sage: next_prime(3)
5
sage: next_prime(4)
5
```

Notice that the next_prime(5) is not 5 but 7.

```
sage: next_prime(5)
7
sage: next_prime(2004)
2011
```

next_prime_power(*n*)

The next prime power greater than the integer n. If n is a prime power, then this function does not return n, but the next prime power after n.

EXAMPLES:

```
sage: next_prime_power(-10)
1
sage: is_prime_power(1)
True
sage: next_prime_power(0)
1
sage: next_prime_power(1)
2
sage: next_prime_power(2)
3
sage: next_prime_power(10)
11
```

```
sage: next_prime_power(7)
8
sage: next_prime_power(99)
101
```

next_probable_prime(*n*)

Returns the next probable prime after self, as determined by PARI.

INPUT:

- n - an integer

EXAMPLES:

```
sage: next_probable_prime(-100)
2
sage: next_probable_prime(19)
23
sage: next_probable_prime(int(999999999))
1000000007
sage: next_probable_prime(2^768)
155251809230070893514897948846250255525688601711669661113905203802605095268637688633087840882864
```

nth_prime(*n*)

EXAMPLES:

```
sage: nth_prime(3)
5
sage: nth_prime(10)
29

sage: nth_prime(0)
...
ValueError: nth prime meaningless for non-positive n (=0)
```

number_of_divisors(*n*)

Return the number of divisors of the integer n.

odd_part(*n*)

The odd part of the integer n. This is $n/2^v$, where $v = \text{valuation}(n, 2)$.

EXAMPLES:

```
sage: odd_part(5)
5
sage: odd_part(4)
1
sage: odd_part(factorial(31))
122529844256906551386796875
```

power_mod(*a, n, m*)

The n-th power of a modulo the integer m.

EXAMPLES:

```
sage: power_mod(0,0,5)
...
ArithmeticError: 0^0 is undefined.
sage: power_mod(2,390,391)
```

```
285
sage: power_mod(2,-1,7)
4
sage: power_mod(11,1,7)
4
sage: R.<x> = ZZ[]
sage: power_mod(3*x, 10, 7)
4*x^10

sage: power_mod(11,1,0)
...
ZeroDivisionError: modulus must be nonzero.
```

previous_prime(*n*)

The largest prime < n. The result is provably correct. If n <= 1, this function raises a ValueError.

EXAMPLES:

```
sage: previous_prime(10)
7
sage: previous_prime(7)
5
sage: previous_prime(8)
7
sage: previous_prime(7)
5
sage: previous_prime(5)
3
sage: previous_prime(3)
2
sage: previous_prime(2)
...
ValueError: no previous prime
sage: previous_prime(1)
...
ValueError: no previous prime
sage: previous_prime(-20)
...
ValueError: no previous prime
```

previous_prime_power(*n*)

The largest prime power $< n$. The result is provably correct. If $n \leq 2$, this function returns $-x$, where x is prime power and $-x < n$ and no larger negative of a prime power has this property.

EXAMPLES:

```
sage: previous_prime_power(2)
1
sage: previous_prime_power(10)
9
sage: previous_prime_power(7)
5
sage: previous_prime_power(127)
125

sage: previous_prime_power(0)
...
ValueError: no previous prime power
```

```
sage: previous_prime_power(1)
...
ValueError: no previous prime power

sage: n = previous_prime_power(2^16 - 1)
sage: while is_prime(n):
...     n = previous_prime_power(n)
sage: factor(n)
251^2
```

prime_divisors(*n*)

The prime divisors of the integer n, sorted in increasing order. If n is negative, we do *not* include -1 among the prime divisors, since -1 is not a prime number.

EXAMPLES:

```
sage: prime_divisors(1)
[]
sage: prime_divisors(100)
[2, 5]
sage: prime_divisors(-100)
[2, 5]
sage: prime_divisors(2004)
[2, 3, 167]
```

prime_factors(*n*)

The prime divisors of the integer n, sorted in increasing order. If n is negative, we do *not* include -1 among the prime divisors, since -1 is not a prime number.

EXAMPLES:

```
sage: prime_divisors(1)
[]
sage: prime_divisors(100)
[2, 5]
sage: prime_divisors(-100)
[2, 5]
sage: prime_divisors(2004)
[2, 3, 167]
```

prime_powers(*start, stop=None*)

List of all positive primes powers between start and stop-1, inclusive. If the second argument is omitted, returns the primes up to the first argument.

EXAMPLES:

```
sage: prime_powers(20)
[1, 2, 3, 4, 5, 7, 8, 9, 11, 13, 16, 17, 19]
sage: len(prime_powers(1000))
194
sage: len(prime_range(1000))
168
sage: a = [z for z in range(95,1234) if is_prime_power(z)]
sage: b = prime_powers(95,1234)
sage: len(b)
194
sage: len(a)
194
```

```
sage: a[:10]
[97, 101, 103, 107, 109, 113, 121, 125, 127, 128]
sage: b[:10]
[97, 101, 103, 107, 109, 113, 121, 125, 127, 128]
sage: a == b
True
```

TESTS:

```
sage: v = prime_powers(10)
sage: type(v[0])      # trac #922
<type 'sage.rings.integer.Integer'>
```

prime_to_m_part(*n, m*)

Returns the prime-to-m part of n, i.e., the largest divisor of n that is coprime to m.

INPUT:

- n - Integer (nonzero)
- m - Integer

OUTPUT: Integer

EXAMPLES:

```
sage: z = 43434
sage: z.prime_to_m_part(20)
21717
```

primes(*start, stop=None*)

Returns an iterator over all primes between start and stop-1, inclusive. This is much slower than prime_range, but potentially uses less memory.

This command is like the xrange command, except it only iterates over primes. In some cases it is better to use primes than prime_range, because primes does not build a list of all primes in the range in memory all at once. However it is potentially much slower since it simply calls the next_prime function repeatedly, and next_prime is slow, partly because it proves correctness.

EXAMPLES:

```
sage: for p in primes(5,10):
...     print p
...
5
7
sage: list(primes(11))
[2, 3, 5, 7]
sage: list(primes(10000000000, 10000000100))
[10000000019, 10000000033, 10000000061, 10000000069, 10000000097]
```

primes_first_n(*n, leave_pari=False*)

Return the first n primes.

INPUT:

- n - a nonnegative integer

OUTPUT:

- a list of the first n prime numbers.

EXAMPLES:

```
sage: primes_first_n(10)
[2, 3, 5, 7, 11, 13, 17, 19, 23, 29]
sage: len(primes_first_n(1000))
1000
sage: primes_first_n(0)
[]
```

primitive_root(*n*)

Return a generator for the multiplicative group of integers modulo n, if one exists.

EXAMPLES:

```
sage: primitive_root(23)
5
sage: print [primitive_root(p) for p in primes(100)]
[1, 2, 2, 3, 2, 2, 3, 2, 5, 2, 3, 2, 6, 3, 5, 2, 2, 2, 2, 7, 5, 3, 2, 3, 5]
```

quadratic_residues(*n*)

Return a sorted list of all squares modulo the integer n in the range $0 \leq x < |n|$.

EXAMPLES:

```
sage: quadratic_residues(11)
[0, 1, 3, 4, 5, 9]
sage: quadratic_residues(1)
[0]
sage: quadratic_residues(2)
[0, 1]
sage: quadratic_residues(8)
[0, 1, 4]
sage: quadratic_residues(-10)
[0, 1, 4, 5, 6, 9]
sage: v = quadratic_residues(1000); len(v);
159
```

random_prime(*n, proof=None*)

Returns a random prime p between 2 and n (i.e. 2 <= p <= n). The returned prime is chosen uniformly at random from the set of prime numbers less than or equal to n.

INPUT:

- `n` - an integer >= 2.
- `proof` - bool or None (default: None) If False, the function uses a pseudo-primality test, which is much faster for really big numbers but does not provide a proof of primality. If None, uses the global default (see sage.structure.proof)

EXAMPLES:

```
sage: random_prime(100000)
88237
sage: random_prime(2)
2
```

TESTS:

```
sage: type(random_prime(2))
<type 'sage.rings.integer.Integer'>
sage: type(random_prime(100))
<type 'sage.rings.integer.Integer'>
```

AUTHORS:

rational_reconstruction(*a, m, algorithm='fast'*)

This function tries to compute x/y, where x/y is a rational number in lowest terms such that the reduction of x/y modulo m is equal to a and the absolute values of x and y are both $\leq \sqrt{m/2}$. If such x/y exists, that pair is unique and this function returns it. If no such pair exists, this function raises ZeroDivisionError.

An efficient algorithm for computing rational reconstruction is very similar to the extended Euclidean algorithm. For more details, see Knuth, Vol 2, 3rd ed, pages 656-657.

INPUT:

- `a` - an integer
- `m` - a modulus
- `algorithm` - (default: 'fast')
  - `'fast'` - a fast compiled implementation
  - `'python'` - a slow pure python implementation

OUTPUT:

Numerator and denominator n, d of the unique rational number $r = n/d$, if it exists, with n and $|d| \leq \sqrt{N/2}$. Return $(0, 0)$ if no such number exists.

The algorithm for rational reconstruction is described (with a complete nontrivial proof) on pages 656-657 of Knuth, Vol 2, 3rd ed. as the solution to exercise 51 on page 379. See in particular the conclusion paragraph right in the middle of page 657, which describes the algorithm thus:

> This discussion proves that the problem can be solved efficiently by applying Algorithm 4.5.2X with $u = m$ and $v = a$, but with the following replacement for step X2: If $v3 \leq \sqrt{m/2}$, the algorithm terminates. The pair $(x, y) = (|v2|, v3 * \text{sign}(v2))$ is then the unique solution, provided that x and y are coprime and $x \leq \sqrt{m/2}$; otherwise there is no solution. (Alg 4.5.2X is the extended Euclidean algorithm.)

Knuth remarks that this algorithm is due to Wang, Kornerup, and Gregory from around 1983.

EXAMPLES:

```
sage: m = 100000
sage: (119*inverse_mod(53,m))%m
11323
sage: rational_reconstruction(11323,m)
119/53
```

```
sage: rational_reconstruction(400,1000)
...
ValueError: Rational reconstruction of 400 (mod 1000) does not exist.
```

```
sage: rational_reconstruction(3,292393, algorithm='python')
3
sage: a = Integers(292393)(45/97); a
204977
sage: rational_reconstruction(a,292393, algorithm='python')
45/97
sage: a = Integers(292393)(45/97); a
204977
sage: rational_reconstruction(a,292393, algorithm='fast')
45/97
sage: rational_reconstruction(293048,292393, algorithm='fast')
...
ValueError: Rational reconstruction of 655 (mod 292393) does not exist.
sage: rational_reconstruction(293048,292393, algorithm='python')
...
ValueError: Rational reconstruction of 655 (mod 292393) does not exist.
```

rising_factorial(*x*, *a*)

Returns the rising factorial $(x)^a$.

The notation in the literature is a mess: often $(x)^a$, but there are many other notations: GKP: Concrete Mathematics uses $x^{\overline{a}}$.

The rising factorial is also known as the Pochhammer symbol, see Maple and Mathematica.

Definition: for integer $a \geq 0$ we have $x(x+1)\cdots(x+a-1)$. In all other cases we use the GAMMA-function: $\frac{\Gamma(x+a)}{\Gamma(x)}$.

INPUT:

- `x` - element of a ring
- `a` - a non-negative integer or
- `x and a` - any numbers

OUTPUT: the rising factorial

EXAMPLES:

```
sage: rising_factorial(10,3)
1320

sage: rising_factorial(10,RR('3.0'))
1320.00000000000

sage: rising_factorial(10,RR('3.3'))
2826.38895824964

sage: a = rising_factorial(1+I, I); a
gamma(2*I + 1)/gamma(I + 1)
sage: CC(a)
0.266816390637832 + 0.122783354006372*I

sage: a = rising_factorial(I, 4); a
-10
```

See falling_factorial(I, 4).

```
sage: x = polygen(ZZ)
sage: rising_factorial(x, 4)
x^4 + 6*x^3 + 11*x^2 + 6*x
```

- Jaap Spies (2006-03-05)

sort_complex_numbers_for_display(*nums*)

Given a list of complex numbers (or a list of tuples, where the first element of each tuple is a complex number), we sort the list in a "pretty" order. First come the real numbers (with zero imaginary part), then the complex numbers sorted according to their real part. If two complex numbers have a real part which is sufficiently close, then they are sorted according to their imaginary part.

This is not a useful function mathematically (not least because there's no principled way to determine whether the real components should be treated as equal or not). It is called by various polynomial root-finders; its purpose is to make doctest printing more reproducible.

We deliberately choose a cumbersome name for this function to discourage use, since it is mathematically meaningless.

EXAMPLES:

```
sage: import sage.rings.arith
sage: sort_c = sort_complex_numbers_for_display
sage: nums = [CDF(i) for i in range(3)]
sage: for i in range(3):
...       nums.append(CDF(i + RDF.random_element(-3e-11, 3e-11),
...                       RDF.random_element()))
...       nums.append(CDF(i + RDF.random_element(-3e-11, 3e-11),
...                       RDF.random_element()))
sage: shuffle(nums)
sage: sort_c(nums)
[0, 1.0, 2.0, -2.862406201e-11 - 0.708874026302*I, 2.2108362707e-11 - 0.436810529675*I, 1.000000
```

squarefree_divisors(*x*)

Iterator over the squarefree divisors (up to units) of the element x.

Depends on the output of the prime_divisors function.

INPUT:

```
x -- an element of any ring for which the prime_divisors
     function works.
```

EXAMPLES:

```
sage: list(squarefree_divisors(7))
[1, 7]
sage: list(squarefree_divisors(6))
[1, 2, 3, 6]
sage: list(squarefree_divisors(12))
[1, 2, 3, 6]
```

subfactorial(*n*)

Subfactorial or rencontres numbers, or derangements: number of permutations of n elements with no fixed points.

INPUT:

- n - non negative integer

OUTPUT:

- integer - function value

EXAMPLES:

```
sage: subfactorial(0)
1
sage: subfactorial(1)
0
sage: subfactorial(8)
14833
```

AUTHORS:

- Jaap Spies (2007-01-23)

trial_division(*n, bound=None*)

Return the smallest prime divisor <= bound of the positive integer n, or n if there is no such prime. If the optional argument bound is omitted, then bound <= n.

INPUT:

- n - a positive integer
- bound - (optional) a positive integer

OUTPUT:

- int - a prime p=bound that divides n, or n if there is no such prime.

EXAMPLES:

```
sage: trial_division(15)
3
sage: trial_division(91)
7
sage: trial_division(11)
11
sage: trial_division(387833, 300)
387833
sage: # 300 is not big enough to split off a
sage: # factor, but 400 is.
sage: trial_division(387833, 400)
389
```

two_squares(*n, algorithm='gap'*)

Write the integer n as a sum of two integer squares if possible; otherwise raise a ValueError.

EXAMPLES:

```
sage: two_squares(389)
(10, 17)
sage: two_squares(7)
...
ValueError: 7 is not a sum of two squares
sage: a,b = two_squares(2009); a,b
(28, 35)
sage: a^2 + b^2
2009
```

TODO: Create an implementation using PARI's continued fraction implementation.

valuation(*m, p*)

The exact power of p that divides m.

m should be an integer or rational (but maybe other types work too.)

This actually just calls the m.valuation() method.

If m is 0, this function returns rings.infinity.

EXAMPLES:

```
sage: valuation(512,2)
9
sage: valuation(1,2)
0
sage: valuation(5/9, 3)
-2
```

Valuation of 0 is defined, but valuation with respect to 0 is not:

```
sage: valuation(0,7)
+Infinity
sage: valuation(3,0)
...
ValueError: You can only compute the valuation with respect to a integer larger than 1.
```

Here are some other examples:

```
sage: valuation(100,10)
2
sage: valuation(200,10)
2
sage: valuation(243,3)
5
sage: valuation(243*10007,3)
5
sage: valuation(243*10007,10007)
1
```

xgcd(*a, b*)

Returns triple (g,s,t) such that $g = s * a + t * b = gcd(a, b)$.

INPUT:

- `a, b` - integers or univariate polynomials (or any type with an xgcd method).

OUTPUT:

- `g, s, t` - such that g = s*a + t*b

Note: There is no guarantee that the returned cofactors (s and t) are minimal. In the integer case, see Integer._xgcd() for minimal cofactors.

EXAMPLES:

```
sage: xgcd(56, 44)
(4, 4, -5)
sage: 4*56 + (-5)*44
4
sage: g, a, b = xgcd(5/1, 7/1); g, a, b
(1, 3, -2)
sage: a*(5/1) + b*(7/1) == g
True
```

```
sage: x = polygen(QQ)
sage: xgcd(x^3 - 1, x^2 - 1)
(x - 1, 1, -x)
sage: K.<g> = NumberField(x^2-3)
sage: R.<a,b> = K[]
sage: S.<y> = R.fraction_field()[]
sage: xgcd(y^2, a*y+b)
(b^2/a^2, 1, ((-1)/a)*y + b/a^2)
sage: xgcd((b+g)*y^2, (a+g)*y+b)
((b^3 + (g)*b^2)/(a^2 + (2*g)*a + 3), 1, ((-b + (-g))/(a + (g)))*y + (b^2 + (g)*b)/(a^2 + (2*g)*
```

xlcm(*m, n*)

Extended lcm function: given two positive integers m,n, returns a triple (l,m1,n1) such that l=lcm(m,n)=m1*n1 where m1|m, n1|n and gcd(m1,n1)=1. All with no factorization.

Used to construct an element of order l from elements of orders m,n in any group: see sage/groups/generic.py for examples.

EXAMPLES:

```
sage: xlcm(120,36)
(360, 40, 9)
```

CHAPTER

TWELVE

DATABASES

There are numerous specific mathematical databases either included in Sage or available as optional packages. Also, Sage includes two powerful general database packages.

Sage includes the ZOPE object oriented database ZODB, which "is a Python object persistence system. It provides transparent object-oriented persistency."

Sage also includes the powerful relational database SQLite, along with a Python interface to SQLite. SQlite is a small C library that implements a self-contained, embeddable, zero-configuration SQL database engine.

- Transactions are atomic, consistent, isolated, and durable (ACID) even after system crashes and power failures.
- Zero-configuration - no setup or administration needed.
- Implements most of SQL92. (Features not supported)
- A complete database is stored in a single disk file.
- Database files can be freely shared between machines with different byte orders.
- Supports databases up to 2 tebibytes (2^41 bytes) in size.
- Strings and BLOBs up to 2 gibibytes (2^31 bytes) in size.
- Small code footprint: less than 250KiB fully configured or less than 150KiB with optional features omitted.
- Faster than popular client/server database engines for most common operations.
- Simple, easy to use API.
- TCL bindings included. Bindings for many other languages available separately.
- Well-commented source code with over 95% test coverage.
- Self-contained: no external dependencies.
- Sources are in the public domain. Use for any purpose.

12.1 Cremona's tables of elliptic curves.

Sage includes John Cremona's tables of elliptic curves in an easy-to-use format. The unique instance of the class CremonaDatabase() gives access to the database.

If the full CremonaDatabase isn't installed, a mini-version is included by default with Sage. It contains Weierstrass equations, rank, and torsion for curves up to conductor 10000.

The large database includes all curves of conductor up to 120,000 (!). It also includes data related to the BSD conjecture and modular degrees for all of these curves, and generators for the Mordell-Weil groups. To install it type the following in Sage: !sage -i database_cremona_ellcurve-2005.11.03

The name of the database may change as it is updated. Type "!sage -optional" to see the latest package names.

CremonaDatabase()

class LargeCremonaDatabase(*read_only=True*)

The Cremona database of elliptic curves.

EXAMPLES:

```
sage: c = CremonaDatabase()
sage: c.allcurves(11)
{'a1': [[0, -1, 1, -10, -20], 0, 5], 'a3': [[0, -1, 1, 0, 0], 0, 5], 'a2': [[0, -1, 1, -7820, -2
```

allbsd(*N*)

Return the allbsd table for conductor N. The entries are:

```
[id, tamagawa_product, Omega_E, L, Reg_E, Sha_an(E)],
```

where id is the isogeny class (letter) followed by a number, e.g., b3, and L is $L^r(E,1)/r!$, where E has rank r.

INPUT:

- N - int, the conductor

OUTPUT: dict

allcurves(*N*)

Returns the allcurves table of curves of conductor N.

INPUT:

- N - int, the conductor

OUTPUT:

- dict - id:[ainvs, rank, tor], ...

allgens(*N*)

Return the allgens table for conductor N.

INPUT:

- N - int, the conductor

OUTPUT:

- dict - id:[points, ...], ...

conductor_range()

Return the range of conductors that are covered by the database.

OUTPUT:

- int - smallest cond
- int - largest conductor plus one

EXAMPLES:

```
sage: CremonaDatabase().conductor_range()      # random -- depends on database installed
(1, 10000)
```

curves(*N*)

Returns the curves table of all *optimal* curves of conductor N.

INPUT:

- N - int, the conductor

OUTPUT:

- dict - id:[ainvs, rank, tor], ...

EXAMPLES:

Optimal curves of conductor 37:

```
sage: CremonaDatabase().curves(37)
{'a1': [[0, 0, 1, -1, 0], 1, 1], 'b1': [[0, 1, 1, -23, -50], 0, 3]}
```

Note the 'h3', which is the unique case in the tables where the optimal curve doesn't have label ending in 1:

```
sage: list(sorted(CremonaDatabase().curves(990).keys()))
['a1', 'b1', 'c1', 'd1', 'e1', 'f1', 'g1', 'h3', 'i1', 'j1', 'k1', 'l1']
```

degphi (*N*)

Return the degphi table for conductor N.

INPUT:

- N - int, the conductor

OUTPUT:

- dict - id:degphi, ...

elliptic_curve (*label*)

Return an elliptic curve with given label with some data about it from the database pre-filled in.

INPUT:

- label - str (Cremona label)

OUTPUT: EllipticCurve

elliptic_curve_from_ainvs (*N, ainvs*)

Returns the elliptic curve in the database of conductor N with minimal ainvs, if it exists, or raises a RuntimeError exception otherwise.

INPUT:

- N - int
- ainvs - list (5-tuple of int's); the minimal Weierstrass model for an elliptic curve of conductor N

OUTPUT: EllipticCurve

isogeny_class (*label*)

Returns the isogeny class of elliptic curves that are isogenous to the curve with given Cremona label.

INPUT:

- label - string

OUTPUT:

- list - list of EllipticCurve objects.

isogeny_classes (*conductor*)

Return the allcurves data (ainvariants, rank and torsion) for the elliptic curves in the database of given conductor as a list of lists, one for each isogeny class. The curve with number 1 is always listed first.

iter (*conductors*)

Returns an iterator through all curves with conductor between Nmin and Nmax-1, inclusive, in the database.

INPUT:

- conductors - list or generator of ints

OUTPUT: generator that iterates over EllipticCurve objects.

iter_optimal(*conductors*)

Returns an iterator through all optimal curves with conductor between Nmin and Nmax-1 in the database.

INPUT:

- `conductors` - list or generator of ints

OUTPUT:

generator that iterates over EllipticCurve objects.

EXAMPLES:

We list optimal curves with conductor up to 20:

```
sage: [e.cremona_label() for e in CremonaDatabase().iter_optimal([11..20])]
['11a1', '14a1', '15a1', '17a1', '19a1', '20a1']
```

Note the unfortunate 990h3 special case:

```
sage: [e.cremona_label() for e in CremonaDatabase().iter_optimal([990])]
['990a1', '990b1', '990c1', '990d1', '990e1', '990f1', '990g1', '990h3', '990i1', '990j1', '
```

largest_conductor()

The largest conductor for which the database is complete.

OUTPUT:

- `int` - largest conductor

EXAMPLES:

```
sage: CremonaDatabase().largest_conductor()    # random -- depends on size of installed datab
9999
```

list(*conductors*)

Returns a list of all curves with conductor between Nmin and Nmax-1, inclusive, in the database.

INPUT:

- `conductors` - list or generator of ints

OUTPUT:

- list of EllipticCurve objects.

list_optimal(*conductors*)

Returns a list of all optimal curves with conductor between Nmin and Nmax-1, inclusive, in the database.

INPUT:

- **`conductors` - list or generator of ints** list of EllipticCurve objects.

OUTPUT:

list of EllipticCurve objects.

EXAMPLES:

```
sage: CremonaDatabase().list_optimal([37])
[Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field,
 Elliptic Curve defined by y^2 + y = x^3 + x^2 - 23*x - 50 over Rational Field]
```

number_of_curves(*N=0, i=0*)

Returns the number of curves stored in the database with conductor N. If N = 0, returns the total number of curves in the database.

If i is nonzero, returns the number of curves in the i-th isogeny class. If i is a Cremona letter code, e.g., 'a' or 'bc', it is converted to the corresponding number.

INPUT:

- `N` - int
- `i` - int or str

OUTPUT: int

EXAMPLES:

```
sage: c = CremonaDatabase()
sage: c.number_of_curves(11)
3
sage: c.number_of_curves(37)
4
sage: c.number_of_curves(990)
42
sage: num = c.number_of_curves()
```

number_of_isogeny_classes(*N=0*)

Returns the number of isogeny classes of curves in the database of conductor N. If N is 0, return the total number of isogeny classes of curves in the database.

INPUT:

- N - int

OUTPUT: int

EXAMPLES:

```
sage: c = CremonaDatabase()
sage: c.number_of_isogeny_classes(11)
1
sage: c.number_of_isogeny_classes(37)
2
sage: num = c.number_of_isogeny_classes()
```

random()

Returns a random curve from the database.

EXAMPLES:

```
sage: CremonaDatabase().random() # random -- depends on database installed
Elliptic Curve defined by y^2 + x*y  = x^3 - x^2 - 224*x + 3072 over Rational Field
```

smallest_conductor()

The smallest conductor for which the database is complete. (Always 1.)

OUTPUT:

- int - smallest conductor

EXAMPLES:

```
sage: CremonaDatabase().smallest_conductor()
1
```

class MiniCremonaDatabase(*read_only=True*)

A mini version of the Cremona database that contains only the Weierstrass equations, rank and torsion of elliptic curves of conductor up to 10000 and nothing else.

class_to_int(*k*)

Converts class id string into an integer. Note that this is the inverse of cremona_letter_code.

EXAMPLES:

```
sage: import sage.databases.cremona as cremona
sage: cremona.class_to_int('ba')
26
sage: cremona.class_to_int('cremona')
821863562
sage: cremona_letter_code(821863562)
'cremona'
```

cmp_code(*key1, key2*)

Comparison function for curve id strings.

Note: Not the same as standard lexicographic order!

EXAMPLES:

```
sage: import sage.databases.cremona as cremona
sage: cremona.cmp_code('ba1','z1')
1
```

By contrast:

```
sage: cmp('ba1','z1')
-1
```

cremona_letter_code(*n*)

Returns the Cremona letter code corresponding to an integer. For example, 0 - a 25 - z 26 - ba 51 - bz 52 - ca 53 - cb etc.

Note: This is just the base 26 representation of n, where a=0, b=1, ..., z=25. This extends the old Cremona notation (counting from 0) for the first 26 classes, and is different for classes above 26.

INPUT:

- n - int

OUTPUT: str

EXAMPLES:

```
sage: cremona_letter_code(0)
'a'
sage: cremona_letter_code(26)
'ba'
sage: cremona_letter_code(27)
'bb'
sage: cremona_letter_code(521)
'ub'
sage: cremona_letter_code(53)
'cb'
sage: cremona_letter_code(2005)
'czd'
```

is_optimal_id(*id*)

Returns true if the Cremona id refers to an optimal curve, and false otherwise. The curve is optimal if the id, which is of the form [letter code][number] has number 1.

Note: 990h3 is the optimal curve in that class, so doesn't obey this rule.

INPUT:

- id - str of form letter code followed by an integer, e.g., a3, bb5, etc.

OUTPUT: bool

EXAMPLES:

```
False
sage: is_optimal_id('b1')
True
sage: is_optimal_id('bb1')
True
```

```
sage: is_optimal_id('c1')
True
sage: is_optimal_id('c2')
False
```

old_cremona_letter_code(*n*)

Returns the *old* Cremona letter code corresponding to an integer. integer.

For example,

:: 1 –> A 26 –> Z 27 –> AA 52 –> ZZ 53 –> AAA etc.

INPUT:

- n - int

OUTPUT: str

EXAMPLES:

```
sage: old_cremona_letter_code(1)
'A'
sage: old_cremona_letter_code(26)
'Z'
sage: old_cremona_letter_code(27)
'AA'
sage: old_cremona_letter_code(521)
'AAAAAAAAAAAAAAAAAAAAA'
sage: old_cremona_letter_code(53)
'AAA'
sage: old_cremona_letter_code(2005)
'CCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCC'
```

parse_cremona_label(*label*)

Given a Cremona label that defines an elliptic curve, e.g., 11A1 or 37B3, parse the label and return the conductor, isogeny class label, and number.

The isogeny number may be omitted, in which case it defaults to 1. If the isogeny number and letter are both omitted, so label is just a string representing a conductor, then the label defaults to 'A' and the number to 1.

INPUT:

- label - str

OUTPUT:

- int - the conductor
- str - the isogeny class label
- int - the number

EXAMPLES:

```
sage: parse_cremona_label('37a2')
(37, 'a', 2)
sage: parse_cremona_label('37b1')
(37, 'b', 1)
sage: parse_cremona_label('10bb2')
(10, 'bb', 2)
```

rebuild(*data_tgz, largest_conductor, decompress=True*)

Rebuild the LargeCremonaDatabase from scratch using the data_tgz tarball.

split_code(*key*)
Splits class+curve id string into its two parts.

EXAMPLES:

```
sage: import sage.databases.cremona as cremona
sage: cremona.split_code('ba2')
('ba', '2')
```

12.2 The Stein-Watkins table of elliptic curves.

Sage gives access to the Stein-Watkins table of elliptic curves, via an optional package that you must install. This is a huge database of elliptic curves. You can download the database as a 2.6GB Sage package from http://modular.ucsd.edu/sagedb/, which you install with the command

```
sage -i stein-watkins-ecdb.spkg
```

You can also download a small version, without having to explicitly download anything from a website, using the command

```
sage -i stein-watkins-ecdb-mini
```

This database covers a wide range of conductors, but unlike CremonaDatabase(), this database need not list all curves of a given conductor. It lists the curves whose coefficients aren't "too large" (see [Stein-Watkins, Ants 5]).

- The command `SteinWatkinsAllData(n)` returns an iterator over the curves in the n^{th} Stein-Watkins table, which contains elliptic curves of conductor between $n10^5$ and $(n+1)10^5$. Here n can be between 0 and 999, inclusive.
- The command `SteinWatkinsPrimeData(n)` returns an iterator over the curves in the n^{th} Stein-Watkins table, which contains prime conductor elliptic curves of conductor between $n10^6$ and $(n+1)10^6$. Here n varies between 0 and 99, inclusive.

EXAMPLES: We obtain the first table of elliptic curves.

```
sage: d = SteinWatkinsAllData(0)
sage: d
Stein-Watkins Database a.0 Iterator
```

We type `d.next()` to get each isogeny class of curves from `d`:

```
sage: C = d.next()                                  # optional - stein_watkins_database
sage: C                                             # optional - stein_watkins_database
Stein-Watkins isogeny class of conductor 11
sage: d.next()                                      # optional - stein_watkins_database
Stein-Watkins isogeny class of conductor 14
sage: d.next()                                      # optional - stein_watkins_database
Stein-Watkins isogeny class of conductor 15
```

An isogeny class has a number of attributes that give data about the isogeny class, such as the rank, equations of curves, conductor, leading coefficient of L-function, etc.

```
sage: C.data                                          # optional - stein_watkins_database
['11', '[11]', '0', '0.253842', '25', '+*1']
sage: C.curves                                        # optional - stein_watkins_database
[[[0, -1, 1, 0, 0], '(1)', '1', '5'],
 [[0, -1, 1, -10, -20], '(5)', '1', '5'],
 [[0, -1, 1, -7820, -263580], '(1)', '1', '1']]
sage: C.conductor                                     # optional - stein_watkins_database
11
sage: C.leading_coefficient                           # optional - stein_watkins_database
'0.253842'
sage: C.modular_degree                                # optional - stein_watkins_database
'+*1'
sage: C.rank                                          # optional - stein_watkins_database
0
sage: C.isogeny_number                                # optional - stein_watkins_database
'25'
```

If we were to continue typing `d.next()` we would iterate over all curves in the Stein-Watkins database up to conductor 10^5. We could also type `for C in d: ...`

To access the data file starting at 10^5 do the following:

```
sage: d = SteinWatkinsAllData(1)                      # optional - stein_watkins_database
sage: C = d.next()                                    # optional - stein_watkins_database
sage: C                                               # optional - stein_watkins_database
Stein-Watkins isogeny class of conductor 100002
sage: C.curves                                        # optional - stein_watkins_database
[[[1, 1, 0, 112, 0], '(8,1,2,1)', 'X', '2'],
 [[1, 1, 0, -448, -560], '[4,2,1,2]', 'X', '2']]
```

Next we access the prime-conductor data:

```
sage: d = SteinWatkinsPrimeData(0)                    # optional - stein_watkins_database
sage: C = d.next()                                    # optional - stein_watkins_database
sage: C                                               # optional - stein_watkins_database
Stein-Watkins isogeny class of conductor 11
```

Each call `d.next()` gives another elliptic curve of prime conductor:

```
sage: C = d.next()                                    # optional - stein_watkins_database
sage: C                                               # optional - stein_watkins_database
Stein-Watkins isogeny class of conductor 17
sage: C.curves                                        # optional - stein_watkins_database
[[[1, -1, 1, -1, 0], '[1]', '1', '4'],
 [[1, -1, 1, -6, -4], '[2]', '1', '2x'],
 [[1, -1, 1, -1, -14], '(4)', '1', '4'],
 [[1, -1, 1, -91, -310], '[1]', '1', '2']]
sage: C = d.next()                                    # optional - stein_watkins_database
sage: C                                               # optional - stein_watkins_database
Stein-Watkins isogeny class of conductor 19
```

class **SteinWatkinsAllData**(*num*)

Class for iterating through one of the Stein-Watkins database files for all conductors.

iter_levels()

Iterate through the curve classes, but grouped into lists by level.

next()

class SteinWatkinsIsogenyClass(*conductor*)

class SteinWatkinsPrimeData(*num*)

ecdb_num_curves(*max_level=200000*)

12.3 John Jones's tables of number fields

In order to use the Jones database, the optional database package must be installed using the Sage command !sage -i database_jones_numfield

This is a table of number fields with bounded ramification and degree ≤ 6. You can query the database for all number fields in Jones's tables with bounded ramification and degree.

EXAMPLES: First load the database:

```
sage: J = JonesDatabase()
sage: J
John Jones's table of number fields with bounded ramification and degree <= 6
```

List the degree and discriminant of all fields in the database that have ramification at most at 2:

```
sage: [(k.degree(), k.disc()) for k in J.unramified_outside([2])]     # optional - jones_database
[(1, 1), (2, 8), (2, -4), (2, -8), (4, 2048), (4, -1024), (4, 512), (4, -2048), (4, 256), (4, 2048),
```

List the discriminants of the fields of degree exactly 2 unramified outside 2:

```
sage: [k.disc() for k in J.unramified_outside([2],2)]                 # optional - jones_database

[8, -4, -8]
```

List the discriminants of cubic field in the database ramified exactly at 3 and 5:

```
sage: [k.disc() for k in J.ramified_at([3,5],3)]                      # optional - jones_database

[-6075, -6075, -675, -135]
sage: factor(6075)
3^5 * 5^2
sage: factor(675)
3^3 * 5^2
sage: factor(135)
3^3 * 5
```

List all fields in the database ramified at 101:

```
sage: J.ramified_at(101)                                              # optional - jones_database
[Number Field in a with defining polynomial x^2 - 101, Number Field in a with defining polynomial x^
```

class JonesDatabase()

get(*S, var='a'*)

ramified_at(*S, d=None, var='a'*)

Return all fields in the database of degree d ramified exactly at the primes in S. INPUT:

- S - list or set of primes

- d - None (default) or an integer

EXAMPLES:

```
sage: J = JonesDatabase()               # requires optional package
sage: J.ramified_at([101,119])          # requires optional package
[]
sage: J.ramified_at([119])              # requires optional package
[]
sage: J.ramified_at(101)                # requires optional package
[Number Field in a with defining polynomial x^2 - 101, Number Field in a with defining polyn
```

unramified_outside (*S, d=None*)

Return iterator over fields in the database of degree d unramified outside S. If d is omitted, return fields of any degree up to 6. INPUT:

- S - list or set of primes
- d - None (default) or an integer

EXAMPLES:

```
sage: J = JonesDatabase()              # requires optional package
sage: J.unramified_outside([101,119]) # requires optional package
[Number Field in a with defining polynomial x - 1, Number Field in a with defining polynomia
```

12.4 Linear codes

Linear codes

parse_bound_html (*text, n, k*)

12.5 Interface to Sloane On-Line Encyclopedia of Integer Sequences

To look up sequence A060843, type one of the following:

```
sage: sloane_sequence(60843)       # optional - internet
Searching Sloane's online database...
[60843, 'Busy Beaver problem: maximal number of steps that an n-state Turing machine can make on an
```

```
sage: sloane_sequence("60843")     # optional - internet
Searching Sloane's online database...
[60843, 'Busy Beaver problem: maximal number of steps that an n-state Turing machine can make on an
```

```
sage: sloane_sequence("060843")    # optional - internet
Searching Sloane's online database...
[60843, 'Busy Beaver problem: maximal number of steps that an n-state Turing machine can make on an
```

Do not prefix an integer with a 0 or it will be interpreted in octal. Results are of the form [number, description, list], and invalid numbers will cause sloane_sequence to raise an ValueError exception:

```
sage: sloane_sequence('sage')     # optional - internet
...
ValueError: sequence 'sage' not found
```

To look up the sequence

```
sage: sloane_find([2,3,5,7], 2)       # optional - internet
Searching Sloane's online database...
[[40, 'The prime numbers.', [2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67,
```

To return no more than 2 results (default is 30), type

```
sage: sloane_find([1,2,3,4,5], 2)      # optional - internet
Searching Sloane's online database...
[[27, 'The natural numbers. Also called the whole numbers, the counting numbers or the positive integ
```

Note that the OEIS (http://www.research.att.com/ njas/sequences/) claims to limit the number of results to 100. Results are lists of the form [[number, description, list]], and invalid input will cause sloane_find to return [].

In some cases, these functions may return [] even though the inputs are legal. These cases correspond to errors from the OEIS server, and calling the functions again may fix the problem.

Alternatively, the SloaneEncyclopedia object provides access to a local copy of the database containing only the sequences. To use this you must install the optional database_sloane_oeis-2005-12 package using `sage -i database_sloane_oeis-2005-12`.

To look up a sequence, type

```
sage: SloaneEncyclopedia[60843]               # optional - sloane_database
[1, 6, 21, 107]
```

To search locally for a particular subsequence, type

```
sage: SloaneEncyclopedia.find([1,2,3,4,5], 1)     # optional - sloane_database
[(15, [1, 2, 3, 4, 5, 7, 7, 8, 9, 11, 11, 13, 13, 16, 16, 16, 17, 19, 19, 23, 23, 23, 23, 25, 25, 27,
```

The default maximum number of results is 30, but to return up to 100, type

```
sage: SloaneEncyclopedia.find([1,2,3,4,5], 100)     # optional - sloane_database
[(15, [1, 2, 3, 4, 5, 7, 7, 8, 9, 11, 11, ...
```

Results in either case are of the form [(number, list)].

TODO:

- When this program gets a sloane sequence from the database it actually downloads a huge amount of information about it, then throws most of it away. Also, it returns the data to the user as a very simple tuple. It would be much better to return an instance of a class:

  ```
  class SloaneSequence: ...
  ```

  and the class should have methods for each of the things that Sloane records about a sequence. Also, when possible, it should be able to compute more terms.

AUTHORS:

- Steven Sivek (2005-12-22): first version
- Steven Sivek (2006-02-07): updated to correctly handle the new search form on the Sloane website, and it's now also smarter about loading the local database in that it doesn't convert a sequence from string form to a list of integers until absolutely necessary. This seems to cut the loading time roughly in half.

class SloaneEncyclopediaClass()

A local copy of the Sloane Online Encyclopedia of Integer Sequences that contains only the sequence numbers and the sequences themselves.

find(*seq, maxresults=30*)

Return a list of all sequences which have seq as a subsequence, up to maxresults results. Sequences are returned in the form (number, list).

INPUT:

- `seq` - list
- `maxresults` - int

OUTPUT: list of 2-tuples (i, v), where v is a sequence with seq as a subsequence.

load()

Load the entire encyclopedia into memory from a file. This is done automatically if the user tries to perform a lookup or a search.

unload()

Remove the database from memory.

parse_sequence(*text*)

sloane_find(*list, nresults=30, verbose=True*)

Searches Sloane's Online Encyclopedia of Integer Sequences for a sequence containing the number provided in `list`.

INPUT:

- `list` - (list) a list of integers to search Sloane's for
- `nresults` - (integer) the maximum number of results to return default: 30
- `verbose` - (boolean) print a string to let the user know that it is working and not hanging. default: True

OUTPUT: A list of matches in Sloane's database. Each match consists of a list of the sequence number, the name of the sequence, and some initial terms of the sequence.

EXAMPLES:

```
sage: sloane_find([1,1,2,3,5,8,13,21], nresults=1) #optional - internet
Searching Sloane's online database...
[[45,
  'Fibonacci numbers: F(n) = F(n-1) + F(n-2), F(0) = 0, F(1) = 1, F(2) = 1, ...',
  [0,
   1,
   1,
   2,
   3,
   5,
   8,
   13,
   21,
   ...
   39088169]]]
```

sloane_sequence(*number*)

Returns a list with the number, name, and values for the sequence `number` in Sloane's online database of integer sequences.

EXAMPLES:

```
sage: sloane_sequence(22) # optional - internet
Searching Sloane's online database...
[22,
 'Number of centered hydrocarbons with n atoms.',
 [0,
  1,
  0,
  1,
  ...
  36201693122]]
```

The input must not be a sequence itself:

```
sage: sloane_sequence(prime_range(100))
...
TypeError: input must be an integer or string that specifies the id of the Sloane sequence to do
```

12.6 Frank Luebeck's tables of Conway polynomials over finite fields.

class ConwayPolynomials (*read_only=True*)

degrees (*p*)

has_polynomial (*p, n*)

polynomial (*p, n*)

primes ()

12.7 Tables of zeros of the Riemann-Zeta function.

zeta_zeros ()

List of the imaginary parts of the first 100,000 nontrivial zeros of the Riemann zeta function. Andrew Odlyzko computed these to precision within $3 \cdot 10^{-9}$.

In order to use `zeta_zeros()`, you will need to install the optional Odlyzko database package: `sage -i database_odlyzko_zeta`. You can see a list of all available optional packages with `sage -optional`.

REFERENCES:

- http://www.dtc.umn.edu/~odlyzko/zeta_tables/

EXAMPLES:

The following example prints the imaginary part of the 13th nontrivial zero of the Riemann zeta function. Note that only the first 9 digits after the decimal come from the database. Subsequent digits are the result of the inherent imprecision of a binary representation of decimal numbers.

```
sage: zz = zeta_zeros() # optional
sage: zz[12]            # optional
59.347044003000001
```

CHAPTER

THIRTEEN

INTERPRETER INTERFACES

Sage provides a unified interface to the best computational software. This is accomplished using both C-libraries (see *C/C++ Library Interfaces*) and interpreter interfaces, which are implemented using pseudo-tty's, system files, etc. This chapter is about these interpreter interfaces.

Note: Each interface requires that the corresponding software is installed on your computer. Sage includes GAP, PARI, Singular, and Maxima, but does not include Octave (very easy to install), MAGMA (non-free), Maple (non-free), or Mathematica (non-free).

There is overhead associated with each call to one of these systems. For example, computing `2+2` thousands of times using the GAP interface will be slower than doing it directly in Sage. In contrast, the C-library interfaces of *C/C++ Library Interfaces* incur less overhead.

In addition to the commands described for each of the interfaces below, you can also type e.g., `%gap`, `%magma`, etc., to directly interact with a given interface in its state. Alternatively, if `X` is an interface object, typing `X.interact()` allows you to interact with it. This is completely different than `X.console()` which starts a complete new copy of whatever program `X` interacts with. Note that the input for `X.interact()` is handled by Sage, so the history buffer is the same as for Sage, tab completion is as for Sage (unfortunately!), and input that spans multiple lines must be indicated using a backslash at the end of each line. You can pull data into an interactive session with `X` using `sage(expression)`.

The console and interact methods of an interface do very different things. For example, using gap as an example:

1. `gap.console()`: You are completely using another program, e.g., gap/magma/gp Here Sage is serving as nothing more than a convenient program launcher, similar to bash.
2. `gap.interact()`: This is a convenient way to interact with a running gap instance that may be "full of" Sage objects. You can import Sage objects into this gap (even from the interactive interface), etc.

The console function is very useful on occasion, since you get the exact actual program available (especially useful for tab completion and testing to make sure nothing funny is going on).

13.1 Common Interface Functionality

See the examples in the other sections for how to use specific interfaces. The interface classes all derive from the generic interface that is described in this section.

AUTHORS:

- William Stein (2005): initial version
- William Stein (2006-03-01): got rid of infinite loop on startup if client system missing

class **AsciiArtString**(*x*)

class **Expect**(*name, prompt, command=None, server=None, server_tmpdir=None, ulimit=None, maxread=100000, script_subdirectory='', restart_on_ctrlc=False, verbose_start=False, init_code=, [], max_startup_time=30, logfile=None, eval_using_file_cutoff=0, do_cleaner=True, remote_cleaner=False, path=None*)

Expect interface object.

call(*function_name, *args, **kwds*)

clear(*var*)

Clear the variable named var.

clear_prompts()

console()

cputime()

CPU time since this process started running.

eval(*code, strip=True, synchronize=False, locals=None, **kwds*)

INPUT:

- `code` - text to evaluate
- `strip` - bool; whether to strip output prompts, etc. (ignored in the base class).
- `locals` - None (ignored); this is used for compatibility with the Sage notebook's generic system interface.
- `**kwds` - All other arguments are passed onto the _eval_line method. An often useful example is reformat=False.

execute(*args, **kwds*)

expect()

function_call(*function, args=None, kwds=None*)

EXAMPLES:

```
sage: maxima.quad_qags(x, x, 0, 1, epsrel=1e-4)
[0.5,5.5511151231257...e-15,21,0]
sage: maxima.function_call('quad_qags', [x, x, 0, 1], {'epsrel':'1e-4'})
[0.5,5.5511151231257...e-15,21,0]
```

get(*var*)

Get the value of the variable var.

get_using_file(*var*)

Return the string representation of the variable var in self, possibly using a file. Use this if var has a huge string representation, since it may be way faster.

Warning: In fact unless a special derived class implements this, it will *not* be any faster. This is the case for this class if you're reading it through introspection and seeing this.

help(*s*)

interact()

This allows you to interactively interact with the child interpreter. Press Ctrl-D or type 'quit' or 'exit' to exit and return to Sage.

Note: This is completely different than the console() member function. The console function opens a new copy of the child interepreter, whereas the interact function gives you interactive access to the interpreter that is being used by Sage. Use sage(xxx) or interpretername(xxx) to pull objects in from sage to the interpreter.

interrupt(*tries=20, timeout=0.29999999999999999, quit_on_fail=True*)

is_local()

is_remote()

is_running()
Return True if self is currently running.

name(*new_name=None*)

new(*code*)

path()

pid()

quit(*verbose=False, timeout=0.25*)
EXAMPLES:

```
sage: a = maxima('y')
sage: maxima.quit()
sage: a._check_valid()
...
ValueError: The maxima session in which this object was defined is no longer running.
```

read(*filename*)
EXAMPLES:

```
sage: filename = tmp_filename()
sage: f = open(filename, 'w')
sage: f.write('x = 2\n')
sage: f.close()
sage: octave.read(filename)  #optional -- requires Octave
sage: octave.get('x')        #optional
' 2'
sage: import os
sage: os.unlink(filename)
```

set(*var, value*)
Set the variable var to the given value.

user_dir()

class ExpectElement(*parent, value, is_name=False, name=None*)
Expect element.

attribute(*attrname*)
If this wraps the object x in the system, this returns the object x.attrname. This is useful for some systems that have object oriented attribute access notation.
EXAMPLES:

```
sage: g = gap('SO(1,4,7)')
sage: k = g.InvariantQuadraticForm()
sage: k.attribute('matrix')
[ [ 0*Z(7), Z(7)^0, 0*Z(7), 0*Z(7) ], [ 0*Z(7), 0*Z(7), 0*Z(7), 0*Z(7) ],
  [ 0*Z(7), 0*Z(7), Z(7), 0*Z(7) ], [ 0*Z(7), 0*Z(7), 0*Z(7), Z(7)^0 ] ]

sage: e = gp('ellinit([0,-1,1,-10,-20])')
sage: e.attribute('j')
-122023936/161051
```

bool()

gen(*n*)

get_using_file()
Return this element's string representation using a file. Use this if self has a huge string representation. It'll be way faster.
EXAMPLES:

```
sage: a = maxima(str(2^1000))
sage: a.get_using_file()
'10715086071862673209484250490600018105614048117055336074437503883703510511249361224931983788
```

hasattr(*attrname*)

Returns whether the given attribute is already defined by this object, and in particular is not dynamically generated.

EXAMPLES:

```
sage: m = maxima('2')
sage: m.hasattr('integral')
True
sage: m.hasattr('gcd')
False
```

name(*new_name=None*)

Returns the name of self. If new_name is passed in, then this function returns a new object identitical to self whose name is new_name.

Note that this can overwrite existing variables in the system.

EXAMPLES:

```
sage: x = r([1,2,3]); x
[1] 1 2 3
sage: x.name()
'sage3'
sage: x = r([1,2,3]).name('x'); x
[1] 1 2 3
sage: x.name()
'x'

sage: s5 = gap.SymmetricGroup(5).name('s5')
sage: s5
SymmetricGroup( [ 1 .. 5 ] )
sage: s5.name()
's5'
```

sage()

Attempt to return a Sage version of this object.

EXAMPLES:

```
sage: gp(1/2).sage()
1/2
sage: _.parent()
Rational Field
```

class **ExpectFunction**(*parent, name*)

Expect function.

class **FunctionElement**(*obj, name*)

Expect function element.

help()

exception **PropTypeError**

console(*cmd*)

class **gc_disabled**()

This is a "with" statement context manager. Garbage collection is disabled within its scope. Nested usage is properly handled.

EXAMPLES:

```
sage: import gc
sage: from sage.interfaces.expect import gc_disabled
sage: gc.isenabled()
True
sage: with gc_disabled():
...       print gc.isenabled()
...       with gc_disabled():
...           print gc.isenabled()
...       print gc.isenabled()
False
False
False
sage: gc.isenabled()
True
```

is_ExpectElement(*x*)

reduce_load(*parent, x*)

tmp_expect_interface_local()

13.2 Interface to Axiom

TODO:

- Evaluation using a file is not done. Any input line with more than a few thousand characters would hang the system, so currently it automatically raises an exception.
- All completions of a given command.
- Interactive help.

Axiom is a free GPL-compatible (modified BSD license) general purpose computer algebra system whose development started in 1973 at IBM. It contains symbolic manipulation algorithms, as well as implementations of special functions, including elliptic functions and generalized hypergeometric functions. Moreover, Axiom has implementations of many functions relating to the invariant theory of the symmetric group S_n. For many links to Axiom documentation see http://wiki.axiom-developer.org.

AUTHORS:

- Bill Page (2006-10): Created this (based on maxima interface)

  Note: Bill Page put a huge amount of effort into the Sage Axiom interface over several days during the Sage Days 2 coding sprint. This is contribution is greatly appreciated.
- William Stein (2006-10): misc touchup.
- Bill Page (2007-08): Minor modifications to support axiom4sage-0.3

Note: The axiom4sage-0.3.spkg is based on an experimental version of the FriCAS fork of the Axiom project by Waldek Hebisch that uses pre-compiled cached Lisp code to build Axiom very quickly with clisp.

If the string "error" (case insensitive) occurs in the output of anything from axiom, a RuntimeError exception is raised.

EXAMPLES: We evaluate a very simple expression in axiom.

```
sage: axiom('3 * 5')                        #optional - axiom
15
sage: a = axiom(3) * axiom(5); a            #optional - axiom
15
```

The type of a is AxiomElement, i.e., an element of the axiom interpreter.

```
sage: type(a)                               #optional - axiom
<class 'sage.interfaces.axiom.AxiomElement'>
sage: parent(a)                             #optional - axiom
Axiom
```

The underlying Axiom type of a is also available, via the type method:

```
sage: a.type()                              #optional - axiom
PositiveInteger
```

We factor $x^5 - y^5$ in Axiom in several different ways. The first way yields a Axiom object.

```
sage: F = axiom.factor('x^5 - y^5'); F      #optional - axiom
           4      3    2 2    3     4
- (y - x)(y  + x y  + x y  + x y + x )
sage: type(F)                               #optional - axiom
<class 'sage.interfaces.axiom.AxiomElement'>
sage: F.type()                              #optional - axiom
Factored Polynomial Integer
```

Note that Axiom objects are normally displayed using "ASCII art".

```
sage: a = axiom(2/3); a          #optional - axiom
  2
  -
  3
sage: a = axiom('x^2 + 3/7'); a      #optional - axiom
   2   3
  x  + -
       7
```

The `axiom.eval` command evaluates an expression in axiom and returns the result as a string. This is exact as if we typed in the given line of code to axiom; the return value is what Axiom would print out.

```
sage: print axiom.eval('factor(x^5 - y^5)')   #optional - axiom
           4      3    2 2    3     4
- (y - x)(y  + x y  + x y  + x y + x )
Type: Factored Polynomial Integer
```

We can create the polynomial f as a Axiom polynomial, then call the factor method on it. Notice that the notation `f.factor()` is consistent with how the rest of Sage works.

```
sage: f = axiom('x^5 - y^5')                  #optional - axiom
sage: f^2                                     #optional - axiom
   10     5 5    10
  y   - 2x y  + x
sage: f.factor()                              #optional - axiom
```

```
           4       3     2 2     3      4
- (y - x)(y  + x y  + x y  + x y + x )
```

Control-C interruption works well with the axiom interface, because of the excellent implementation of axiom. For example, try the following sum but with a much bigger range, and hit control-C.

```
sage:  f = axiom('(x^5 - y^5)^10000')        # not tested
Interrupting Axiom...
...
<type 'exceptions.TypeError'>: Ctrl-c pressed while running Axiom

sage: axiom('1/100 + 1/101')                  #optional - axiom
   201
  -----
  10100
sage: a = axiom('(1 + sqrt(2))^5'); a         #optional - axiom
     +-+
  29\|2  + 41
```

TESTS: We check to make sure the subst method works with keyword arguments.

```
sage: a = axiom(x+2); a  #optional - axiom
x + 2
sage: a.subst(x=3)       #optional - axiom
5
```

We verify that Axiom floating point numbers can be converted to Python floats.

```
sage: float(axiom(2))      #optional - axiom
2.0
```

class **Axiom**(*name='axiom', command='axiom -nox -noclef', script_subdirectory=None, logfile=None, server=None, server_tmpdir=None, init_code=, [')lisp (si::readline-off)']*)

console()

Spawn a new Axiom command-line session.

EXAMPLES:

```
sage: axiom.console() #not tested
                          AXIOM Computer Algebra System
                          Version: Axiom (January 2009)
                 Timestamp: Sunday January 25, 2009 at 07:08:54
------------------------------------------------------------------------------
   Issue )copyright to view copyright notices.
   Issue )summary for a summary of useful system commands.
   Issue )quit to leave AXIOM and return to shell.
------------------------------------------------------------------------------
```

class **AxiomElement**(*parent, value, is_name=False, name=None*)

class **AxiomExpectFunction**(*parent, name*)

class **AxiomFunctionElement**(*object, name*)

class **PanAxiom**(*name='axiom', command='axiom -nox -noclef', script_subdirectory=None, logfile=None, server=None, server_tmpdir=None, init_code=, [')lisp (si::readline-off)']*)

Interface to a PanAxiom interpreter.

get (*var*)

Get the string value of the Axiom variable var.

EXAMPLES:

```
sage: axiom.set('xx', '2')     #optional - axiom
sage: axiom.get('xx')          #optional - axiom
'2'
sage: a = axiom('(1 + sqrt(2))^5') #optional - axiom
sage: axiom.get(a.name())          #optional - axiom
'      +-+\r\r\n  29\\|2  + 41'
```

set (*var, value*)

Set the variable var to the given value.

EXAMPLES:

```
sage: axiom.set('xx', '2')     #optional - axiom
sage: axiom.get('xx')          #optional - axiom
'2'

sage: fricas.set('xx', '2')     #optional - fricas
sage: fricas.get('xx')          #optional - fricas
'2'
```

trait_names (*verbose=True, use_disk_cache=True*)

Returns a list of all the commands defined in Axiom and optionally (per default) store them to disk.

EXAMPLES:

```
sage: c = axiom.trait_names(use_disk_cache=False, verbose=False) #optional - axiom
sage: len(c) > 100  #optional - axiom
True
sage: 'factor' in c  #optional - axiom
True
sage: '**' in c     #optional - axiom
False
sage: 'upperCase?' in c  #optional - axiom
False
sage: 'upperCase_q' in c #optional - axiom
True
sage: 'upperCase_e' in c #optional - axiom
True
```

class **PanAxiomElement** (*parent, value, is_name=False, name=None*)

as_type (*type*)

Returns self as type.

EXAMPLES:

```
sage: a = axiom(1.2); a            #optional - axiom
1.2
sage: a.as_type(axiom.DoubleFloat) #optional - axiom
1.2
sage: _.type()                     #optional - axiom
DoubleFloat

sage: a = fricas(1.2); a            #optional - fricas
1.2
sage: a.as_type(fricas.DoubleFloat) #optional - fricas
1.2
```

```
sage: _.type()                          #optional - fricas
DoubleFloat
```

comma(**args*)

Returns a Axiom tuple from self and args.

EXAMPLES:

```
sage: two = axiom(2)  #optional - axiom
sage: two.comma(3)    #optional - axiom
[2,3]
sage: two.comma(3,4)  #optional - axiom
[2,3,4]
sage: _.type()        #optional - axiom
Tuple PositiveInteger

sage: two = fricas(2)  #optional - fricas
sage: two.comma(3)     #optional - fricas
[2,3]
sage: two.comma(3,4)   #optional - fricas
[2,3,4]
sage: _.type()         #optional - fricas
Tuple PositiveInteger
```

type()

Returns the type of an AxiomElement.

EXAMPLES:

```
sage: axiom(x+2).type()  #optional - axiom
Polynomial Integer
```

unparsed_input_form()

Get the linear string representation of this object, if possible (often it isn't).

EXAMPLES:

```
sage: a = axiom(x^2+1); a     #optional - axiom
   2
  x  + 1
sage: a.unparsed_input_form() #optional - axiom
'x*x+1'

sage: a = fricas(x^2+1)       #optional - fricas
sage: a.unparsed_input_form() #optional - fricas
'x^2+1'
```

class **PanAxiomExpectFunction**(*parent, name*)

class **PanAxiomFunctionElement**(*object, name*)

axiom_console()

Spawn a new Axiom command-line session.

EXAMPLES:

```
sage: axiom_console() #not tested
                        AXIOM Computer Algebra System
                        Version: Axiom (January 2009)
                Timestamp: Sunday January 25, 2009 at 07:08:54
------------------------------------------------------------------------------
   Issue )copyright to view copyright notices.
   Issue )summary for a summary of useful system commands.
```

```
   Issue )quit to leave AXIOM and return to shell.
------------------------------------------------------------------------------
```

is_AxiomElement(*x*)

Returns True of x is of type AxiomElement.

EXAMPLES:

```
sage: from sage.interfaces.axiom import is_AxiomElement
sage: is_AxiomElement(axiom(2)) #optional - axiom
True
sage: is_AxiomElement(2)
False
```

reduce_load_Axiom()

Returns the Axiom interface object defined in sage.interfaces.axiom.

EXAMPLES:

```
sage: from sage.interfaces.axiom import reduce_load_Axiom
sage: reduce_load_Axiom()
Axiom
```

13.3 Interface to GAP

Sage provides an interface to the GAP system. This system provides extensive group theory, combinatorics, etc.

The GAP interface will only work if GAP is installed on your computer; this should be the case, since GAP is included with Sage. The interface offers three pieces of functionality:

1. `gap_console()` - A function that dumps you into an interactive command-line GAP session.
2. `gap(expr)` - Evaluation of arbitrary GAP expressions, with the result returned as a string.
3. `gap.new(expr)` - Creation of a Sage object that wraps a AP object. This provides a Pythonic interface to GAP. For example, if `f=gap.new(10)`, then `f.Factors()` returns the prime factorization of 10 computed using GAP.

13.3.1 First Examples

We factor an integer using GAP:

```
sage: n = gap(20062006); n
20062006
sage: n.parent()
Gap
sage: fac = n.Factors(); fac
[ 2, 17, 59, 73, 137 ]
sage: fac.parent()
Gap
sage: fac[1]
2
```

13.3.2 GAP and Singular

This example illustrates conversion between Singular and GAP via Sage as an intermediate step. First we create and factor a Singular polynomial.

```
sage: singular(389)
389
sage: R1 = singular.ring(0, '(x,y)', 'dp')
sage: f = singular('9*x^16-18*x^13*y^2-9*x^12*y^3+9*x^10*y^4-18*x^11*y^2+36*x^8*y^4+18*x^7*y^5-18*x^5
sage: F = f.factorize()
sage: print F
[1]:
   _[1]=9
   _[2]=x^6-2*x^3*y^2-x^2*y^3+y^4
   _[3]=-x^5+y^2
[2]:
   1,1,2
```

Next we convert the factor $-x^5 + y^2$ to a Sage multivariate polynomial. Note that it is important to let x and y be the generators of a polynomial ring, so the eval command works.

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: s = F[1][3].sage_polystring(); s
'-x**5+y**2'
sage: g = eval(s); g
-x^5 + y^2
```

Next we create a polynomial ring in GAP and obtain its indeterminates:

```
sage: R = gap.PolynomialRing('Rationals', 2); R
PolynomialRing( Rationals, ["x_1", "x_2"] )
sage: I = R.IndeterminatesOfPolynomialRing(); I
[ x_1, x_2 ]
```

In order to eval g in GAP, we need to tell GAP to view the variables `x0` and `x1` as the two generators of R. This is the one tricky part. In the GAP interpreter the object `I` has its own name (which isn't `I`). We can access its name using `I.name()`.

```
sage: _ = gap.eval("x := %s[1];; y := %s[2];;"%(I.name(), I.name()))
```

Now x_0 and x_1 are defined, so we can construct the GAP polynomial f corresponding to g:

```
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: f = gap(str(g)); f
-x_1^5+x_2^2
```

We can call GAP functions on f. For example, we evaluate the GAP `Value` function, which evaluates f at the point $(1, 2)$.

```
sage: f.Value(I, [1,2])
3
sage: g(1,2)          # agrees
3
```

13.3.3 Saving and loading objects

Saving and loading GAP objects (using the dumps method, etc.) is *not* supported, since the output string representation of Gap objects is sometimes not valid input to GAP. Creating classes that wrap GAP objects *is* supported, via simply defining the a _gap_init_ member function that returns a string that when evaluated in GAP constructs the object. See `groups/permutation_group.py` for a nontrivial example of this.

13.3.4 Long Input

The GAP interface reads in even very long input (using files) in a robust manner, as long as you are creating a new object.

Note: Using `gap.eval` for long input is much less robust, and is not recommended.

```
sage: t = '"%s"'%10^10000   # ten thousand character string.
sage: a = gap(t)
```

13.3.5 Changing which GAP is used

Use this code to change which GAP interpreter is run. E.g.,

```
import sage.interfaces.gap
sage.interfaces.gap.gap_cmd = "/usr/local/bin/gap"
```

AUTHORS:

- David Joyner and William Stein: initial version(s)
- William Stein (2006-02-01): modified gap_console command so it uses exactly the same startup command as Gap.__init__.
- William Stein (2006-03-02): added tab completions: gap.[tab], x = gap(...), x.[tab], and docs, e.g., gap.function? and x.function?

class Gap (*max_workspace_size=None, maxread=100000, script_subdirectory=None, use_workspace_cache=True, server=None, server_tmpdir=None, logfile=None*)

Interface to the GAP interpreter.

AUTHORS:

•William Stein and David Joyner

console()

Spawn a new GAP command-line session.

EXAMPLES:

```
sage: gap.console() #not tested
GAP4, Version: 4.4.10 of 02-Oct-2007, x86_64-unknown-linux-gnu-gcc
gap>
```

cputime (*t=None*)

Returns the amount of CPU time that the GAP session has used. If `t` is not None, then it returns the difference between the current CPU time and `t`.

EXAMPLES:

```
sage: t = gap.cputime()
sage: t  #random
0.13600000000000001
sage: gap.Order(gap.SymmetricGroup(5))
120
sage: gap.cputime(t)  #random
0.059999999999999998
```

eval(*x, newlines=False, strip=True, **kwds*)

Send the code in the string s to the GAP interpreter and return the output as a string.

INPUT:

- `s` - string containing GAP code.
- `newlines` - bool (default: True); if False, remove all backslash-newlines inserted by the GAP output formatter.
- `strip` - ignored

EXAMPLES:

```
sage: gap.eval('2+2')
'4'
sage: gap.eval('Print(4); #test\n Print(6);')
'46'
sage: gap.eval('Print("#"); Print(6);')
'#6'
sage: gap.eval('4; \n 6;')
'4\n6'
```

function_call(*function, args=None, kwds=None*)

Calls the GAP function with args and kwds.

EXAMPLES:

```
sage: gap.function_call('SymmetricGroup', [5])
SymmetricGroup( [ 1 .. 5 ] )
```

If the GAP function does not return a value, but prints something to the screen, then a string of the printed output is returned.

```
sage: s = gap.function_call('Display', [gap.SymmetricGroup(5).CharacterTable()])
sage: type(s)
<class 'sage.interfaces.expect.AsciiArtString'>
sage: s.startswith('CT')
True
```

get(*var, use_file=False*)

Get the string representation of the variable var.

EXAMPLES:

```
sage: gap.set('x', '2')
sage: gap.get('x')
'2'
```

help(*s, pager=True*)

Print help on a given topic.

EXAMPLES:

```
sage: print gap.help('SymmetricGroup', pager=False)
Basic Groups ____________________________________________ Group Libraries
...
```

load_package(*pkg, verbose=False*)
Load the Gap package with the given name.
If loading fails, raise a RuntimeError exception.

save_workspace()

set(*var, value*)
Set the variable var to the given value.
EXAMPLES:

```
sage: gap.set('x', '2')
sage: gap.get('x')
'2'
```

trait_names()
EXAMPLES:

```
sage: c = gap.trait_names()
sage: len(c) > 100
True
sage: 'Order' in c
True
```

unbind(*var*)
Clear the variable named var.
EXAMPLES:

```
sage: gap.set('x', '2')
sage: gap.get('x')
'2'
sage: gap.unbind('x')
sage: gap.get('x')
...
RuntimeError: Gap produced error output
Variable: 'x' must have a value
...
```

version()
Returns the version of GAP being used.
EXAMPLES:

```
sage: gap.version()
'4.4.10'
```

class **GapElement**(*parent, value, is_name=False, name=None*)

bool()
EXAMPLES:

```
sage: bool(gap(2))
True
sage: gap(0).bool()
False
sage: gap('false').bool()
False
```

str(*use_file=False*)
EXAMPLES:

```
sage: print gap(2)
2
```

trait_names()
EXAMPLES:

```
sage: s5 = gap.SymmetricGroup(5)
sage: 'Centralizer' in s5.trait_names()
True
```

class GapFunction(*parent, name*)

class GapFunctionElement(*obj, name*)

gap_command(*use_workspace_cache=True, local=True*)

gap_console(*use_workspace_cache=True*)
Spawn a new GAP command-line session.

EXAMPLES:

```
sage: gap.console() #not tested
GAP4, Version: 4.4.10 of 02-Oct-2007, x86_64-unknown-linux-gnu-gcc
gap>
```

gap_reset_workspace(*max_workspace_size=None, verbose=False*)
Call this to completely reset the GAP workspace, which is used by default when Sage first starts GAP.

The first time you start GAP from Sage, it saves the startup state of GAP in the file

```
$HOME/.sage/gap-workspace
```

This is useful, since then subsequent startup of GAP is at least 10 times as fast. Unfortunately, if you install any new code for GAP, it won't be noticed unless you explicitly load it, e.g., with gap.load_package("my_package")

The packages sonata, guava, factint, gapdoc, grape, design, toric, and laguna are loaded in all cases before the workspace is saved, if they are available.

gap_version()
Returns the version of GAP being used.

EXAMPLES:

```
sage: gap_version()
'4.4.10'
```

gfq_gap_to_sage(*x, F*)
INPUT:

- x - gap finite field element
- F - Sage finite field

OUTPUT: element of F

EXAMPLES:

```
sage: x = gap('Z(13)')
sage: F = GF(13, 'a')
sage: F(x)
2
sage: F(gap('0*Z(13)'))
0
sage: F = GF(13^2, 'a')
sage: x = gap('Z(13)')
sage: F(x)
2
```

```
sage: x = gap('Z(13^2)^3')
sage: F(x)
12*a + 11
sage: F.multiplicative_generator()^3
12*a + 11
```

AUTHOR:

- David Joyner and William Stein

is_GapElement(*x*)

Returns True if x is a GapElement.

EXAMPLES:

```
sage: from sage.interfaces.gap import is_GapElement
sage: is_GapElement(gap(2))
True
sage: is_GapElement(2)
False
```

reduce_load()

Returns an invalid GAP element. Note that this is the object returned when a GAP element is unpickled.

EXAMPLES:

```
sage: from sage.interfaces.gap import reduce_load
sage: reduce_load()
(invalid object -- defined in terms of closed session)
sage: loads(dumps(gap(2)))
(invalid object -- defined in terms of closed session)
```

reduce_load_GAP()

Returns the GAP interface object definedin sage.interfaces.gap.

EXAMPLES:

```
sage: from sage.interfaces.gap import reduce_load_GAP
sage: reduce_load_GAP()
Gap
```

13.4 Interface to GP/Pari

Type `gp.[tab]` for a list of all the functions available from your Gp install. Type `gp.[tab]?` for Gp's help about a given function. Type `gp(...)` to create a new Gp object, and `gp.eval(...)` to run a string using Gp (and get the result back as a string).

EXAMPLES: We illustrate objects that wrap GP objects (gp is the PARI interpreter):

```
sage: M = gp('[1,2;3,4]')
sage: M
[1, 2; 3, 4]
sage: M * M
[7, 10; 15, 22]
sage: M + M
[2, 4; 6, 8]
```

```
sage: M.matdet()
-2
```

```
sage: E = gp.ellinit([1,2,3,4,5])
sage: E.ellglobalred()
[10351, [1, -1, 0, -1], 1]
sage: E.ellan(20)
[1, 1, 0, -1, -3, 0, -1, -3, -3, -3, -1, 0, 1, -1, 0, -1, 5, -3, 4, 3]
```

```
sage: primitive_root(7)
3
sage: x = gp("znlog( Mod(2,7), Mod(3,7))")
sage: 3^x % 7
2
```

```
sage: print gp("taylor(sin(x),x)")
x - 1/6*x^3 + 1/120*x^5 - 1/5040*x^7 + 1/362880*x^9 - 1/39916800*x^11 + 1/6227020800*x^13 - 1/130767
```

GP has a powerful very efficient algorithm for numerical computation of integrals.

```
sage: gp("a = intnum(x=0,6,sin(x))")
0.039829713349633979454347702077075594548     # 32-bit
0.039829713349633979454347702077075594548     # 64-bit
sage: gp("a")
0.039829713349633979454347702077075594548     # 32-bit
0.039829713349633979454347702077075594548     # 64-bit
sage: gp.kill("a")
sage: gp("a")
a
```

Note that gp ASCII plots *do* work in Sage, as follows:

```
sage: print gp.eval("plot(x=0,6,sin(x))")
<BLANKLINE>
0.9988963 |''''''''''''_x"...x_''''''''''''''''''''''''''''''''''''''''''''''''''''''''''''''''''''''|
          |           x"         "x                                                                    |
          |         _"             "_                                                                  |
          |        x                 x                                                                 |
          |       "                   "                                                                |
          |      "                     "                                                               |
          |    _"                       "_                                                             |
          |  _                            _                                                            |
          | _                              _                                                           |
          |_                                _                                                          |
          _,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,
          |                                  "                                                        |
          |                                   "                                                       |
          |                                    "                                                      |
          |                                     "                                                    "|
          |                                      "_                                               _"  |
          |                                        _                                           _     |
          |                                         _                                       _        |
          |                                          x                                   x          |
          |                                           "_                               _"           |
          |                                             x_                         _x              |
```

```
-0.998955 |.........................................."x____x".........|
          0                                                          6
```

The GP interface reads in even very long input (using files) in a robust manner, as long as you are creating a new object.

```
sage: t = '"%s"'%10^10000   # ten thousand character string.
sage: a = gp.eval(t)
sage: a = gp(t)
```

In Sage, the PARI large galois groups datafiles should be installed by default:

```
sage: f = gp('x^9 - x - 2')
sage: f.polgalois()
[362880, -1, 34, "S9"]
```

AUTHORS:

- William Stein
- David Joyner: some examples
- William Stein (2006-03-01): added tab completion for methods: gp.[tab] and x = gp(blah); x.[tab]
- William Stein (2006-03-01): updated to work with PARI 2.2.12-beta
- William Stein (2006-05-17): updated to work with PARI 2.2.13-beta

class Gp (*stacksize=10000000, maxread=100000, script_subdirectory=None, logfile=None, server=None, server_tmpdir=None, init_list_length=1024*)

Interface to the PARI gp interpreter.

Type `gp.[tab]` for a list of all the functions available from your Gp install. Type `gp.[tab]?` for Gp's help about a given function. Type `gp(...)` to create a new Gp object, and `gp.eval(...)` to run a string using Gp (and get the result back as a string).

console()

Spawn a new GP command-line session.

EXAMPLES:

```
sage: gp.console() #not tested
GP/PARI CALCULATOR Version 2.3.3 (released)
amd64 running linux (x86-64/GMP-4.2.1 kernel) 64-bit version
compiled: Feb 22 2008, gcc-4.1.3 20070929 (prerelease) (Ubuntu 4.1.2-16ubuntu2)
(readline v5.2 enabled, extended help available)
...
```

cputime (*t=None*)

cputime for pari - cputime since the pari process was started.

INPUT:

- `t` - (default: None); if not None, then returns time since t

> **Warning:** If you call gettime explicitly, e.g., gp.eval('gettime'), you will throw off this clock.

EXAMPLES:

```
sage: gp.cputime()          # random output
0.0080000000000000002
sage: gp.factor('2^157-1')
[852133201, 1; 60726444167, 1; 1654058017289, 1; 2134387368610417, 1]
sage: gp.cputime()          # random output
0.26900000000000002
```

get(*var*)

Get the value of the variable var.

EXAMPLES:

```
sage: gp.set('x', '2')
sage: gp.get('x')
'2'
```

get_precision()

Return the current PARI precision for real number computations.

EXAMPLES:

```
sage: gp.get_precision()
28              # 32-bit
38              # 64-bit
```

get_real_precision()

Return the current PARI precision for real number computations.

EXAMPLES:

```
sage: gp.get_precision()
28              # 32-bit
38              # 64-bit
```

help(*command*)

Returns GP's help for `command`.

EXAMPLES:

```
sage: gp.help('gcd')
'gcd(x,{y}): greatest common divisor of x and y.'
```

kill(*var*)

EXAMPLES:

```
sage: gp.set('xx', '22')
sage: gp.get('xx')
'22'
sage: gp.kill('xx')
sage: gp.get('xx')
'xx'
```

new_with_bits_prec(*s, precision=0*)

Creates a GP object from s with `precision` bits of precision. GP actually automatically increases this precision to the nearest word (i.e. the next multiple of 32 on a 32-bit machine, or the next multiple of 64 on a 64-bit machine).

EXAMPLES:

```
sage: pi_def = gp(pi); pi_def
3.1415926535897932384626433383                  # 32-bit
3.1415926535897932384626433832795028842        # 64-bit
sage: pi_def.precision()
28                                              # 32-bit
```

```
38                                                  # 64-bit
sage: pi_150 = gp.new_with_bits_prec(pi, 150)
sage: new_prec = pi_150.precision(); new_prec
48                                                  # 32-bit
57                                                  # 64-bit
sage: old_prec = gp.get_precision()
sage: gp.set_precision(new_prec)
28                                                  # 32-bit
38                                                  # 64-bit
sage: pi_150
3.14159265358979323846264338327950288419716939937  # 32-bit
3.14159265358979323846264338327950288419716939937510582098  # 64-bit
sage: gp.set_precision(old_prec)
48                                                  # 32-bit
57                                                  # 64-bit
```

quit (*verbose=False, timeout=0.25*)

EXAMPLES:

```
sage: a = gp('10'); a
10
sage: gp.quit()
sage: a
(invalid object -- defined in terms of closed session)
sage: gp(pi)
3.14159265358979323846264338327950288420    # 64-bit
3.14159265358979323846264383                # 32-bit
```

set (*var, value*)

Set the variable var to the given value.

EXAMPLES:

```
sage: gp.set('x', '2')
sage: gp.get('x')
'2'
```

set_precision (*prec=None*)

Sets the current PARI precision (in decimal digits) for real number computations, and returns the old one.

EXAMPLES:

```
sage: old_prec = gp.set_precision(53)
sage: gp.get_precision()
57
sage: gp.set_precision(old_prec)
57
sage: gp.get_precision()
28              # 32-bit
38              # 64-bit
```

set_real_precision (*prec=None*)

Sets the current PARI precision (in decimal digits) for real number computations, and returns the old one.

EXAMPLES:

```
sage: old_prec = gp.set_precision(53)
sage: gp.get_precision()
57
sage: gp.set_precision(old_prec)
57
sage: gp.get_precision()
```

```
28              # 32-bit
38              # 64-bit
```

trait_names()
EXAMPLES:

```
sage: c = gp.trait_names()
sage: len(c) > 100
True
sage: 'gcd' in c
True
```

version()
Returns the version of GP being used.
EXAMPLES:

```
sage: gp.version()
((2, 3, 3), 'GP/PARI CALCULATOR Version 2.3.3 (released)')
```

class GpElement(*parent, value, is_name=False, name=None*)
EXAMPLES: This example illustrates dumping and loading GP elements to compressed strings.

```
sage: a = gp(39393)
sage: loads(a.dumps()) == a
True
```

Since dumping and loading uses the string representation of the object, it need not result in an identical object from the point of view of PARI:

```
sage: E = gp('ellinit([1,2,3,4,5])')
sage: loads(E.dumps()) == E
False
sage: loads(E.dumps())
[1, 2, 3, 4, 5, 9, 11, 29, 35, -183, -3429, -10351, 6128487/10351, [-1.6189099322673713423780009
[1, 2, 3, 4, 5, 9, 11, 29, 35, -183, -3429, -10351, 6128487/10351, [-1.6189099322673713423780009
sage: E
[1, 2, 3, 4, 5, 9, 11, 29, 35, -183, -3429, -10351, 6128487/10351, [-1.6189099322673713423780009
[1, 2, 3, 4, 5, 9, 11, 29, 35, -183, -3429, -10351, 6128487/10351, [-1.6189099322673713423780009
```

The two elliptic curves look the same, but internally the floating point numbers are slightly different.

bool()
EXAMPLES:

```
sage: gp(2).bool()
True
sage: bool(gp(2))
True
sage: bool(gp(0))
False
```

trait_names()
EXAMPLES:

```
sage: 'gcd' in gp(2).trait_names()
True
```

class GpFunction(*parent, name*)

class GpFunctionElement(*obj, name*)

gp_console()
Spawn a new GP command-line session.

EXAMPLES:

```
sage: gp.console() #not tested
GP/PARI CALCULATOR Version 2.3.3 (released)
amd64 running linux (x86-64/GMP-4.2.1 kernel) 64-bit version
compiled: Feb 22 2008, gcc-4.1.3 20070929 (prerelease) (Ubuntu 4.1.2-16ubuntu2)
(readline v5.2 enabled, extended help available)
...
```

gp_version()
EXAMPLES:

```
sage: gp.version()       # random output
((2, 3, 1), 'GP/PARI CALCULATOR Version 2.3.1 (0)')
```

is_GpElement(*x*)
Returns True of x is a GpElement.

EXAMPLES:

```
sage: from sage.interfaces.gp import is_GpElement
sage: is_GpElement(gp(2))
True
sage: is_GpElement(2)
False
```

reduce_load_GP()
Returns the GP interface object defined in sage.interfaces.gp.

EXAMPLES:

```
sage: from sage.interfaces.gp import reduce_load_GP
sage: reduce_load_GP()
GP/PARI interpreter
```

13.5 Interface to the Gnuplot interpreter.

class Gnuplot()
Interface to the Gnuplot interpreter.

console()

gnuplot()

interact(*cmd*)

plot(*cmd, file=None, verbose=True, reset=True*)
Draw the plot described by cmd, and possibly also save to an eps or png file.

INPUT:

- `cmd` - string
- `file` - string (default: None), if specified save plot to given file, which may be either an eps (default) or png file.
- `verbose` - print some info
- `reset` - True: reset gnuplot before making graph

OUTPUT: displays graph

Note: Note that ^ s are replaced by ** s before being passed to gnuplot.

plot3d(*f, xmin=-1, xmax=1, ymin=-1, ymax=1, zmin=-1, zmax=1, title=None, samples=25, isosamples=20, xlabel='x', ylabel='y', interact=True*)

plot3d_parametric(*f='cos(u)*(3 + v*cos(u/2)), sin(u)*(3 + v*cos(u/2)), v*sin(u/2)', range1=', [u=-pi:pi], ', range2=', [v=-0.2:0.2], ', samples=50, title=None, interact=True*)

Draw a parametric 3d surface and rotate it interactively.

INPUT:

- `f` - (string) a function of two variables, e.g., 'cos(u)*(3 + v*cos(u/2)), sin(u)*(3 + v*cos(u/2)), v*sin(u/2)'
- `range1` - (string) range of values for one variable, e.g., '[u=-pi:pi]'
- `range2` - (string) range of values for another variable, e.g., '[v=-0.2:0.2]'
- `samples` - (int) number of sample points to use
- `title` - (string) title of the graph.

EXAMPLES:

```
sage: gnuplot.plot3d_parametric('v^2*sin(u), v*cos(u), v*(1-v)')    # optional -- requires gr
```

gnuplot_console()

13.6 Interface to KASH

Sage provides an interface to the KASH computer algebra system, which is a *free* (as in beer!) but *closed source* program for algebraic number theory that shares much common code with Magma. To use KASH, you must install the appropriate optional Sage package by typing something like "sage -i kash3-linux-2005.11.22" or "sage -i kash3_osx-2005.11.22". For a list of optional packages type "sage -optional". If you type one of the above commands, the (about 16MB) package will be downloaded automatically (you don't have to do that).

It is not enough to just have KASH installed on your computer. Note that the KASH Sage package is currently only available for Linux and OSX. If you need Windows, support contact me (wstein@gmail.com).

The KASH interface offers three pieces of functionality:

1. `kash_console()` - A function that dumps you into an interactive command-line KASH session. Alternatively,

   type `!kash` from the Sage prompt.

2. `kash(expr)` - Creation of a Sage object that wraps a KASH object. This provides a Pythonic interface to KASH. For example, if `f=kash.new(10)`, then `f.Factors()` returns the prime factorization of 10 computed using KASH.

3. `kash.function_name(args ...)` - Call the indicated KASH function with the given arguments are return the result as a KASH object.

4. `kash.eval(expr)` - Evaluation of arbitrary KASH expressions, with the result returned as a string.

13.6.1 Issues

For some reason hitting Control-C to interrupt a calculation doesn't work correctly. (TODO)

13.6.2 Tutorial

The examples in this tutorial require that the optional kash package be installed.

Basics

Basic arithmetic is straightforward. First, we obtain the result as a string.

```
sage: kash.eval('(9 - 7) * (5 + 6)')                # optional -- kash
'22'
```

Next we obtain the result as a new KASH object.

```
sage: a = kash('(9 - 7) * (5 + 6)'); a              # optional -- kash

22
sage: a.parent()                                    # optional -- kash
Kash
```

We can do arithmetic and call functions on KASH objects:

```
sage: a*a                                           # optional -- kash
484
sage: a.Factorial()                                 # optional -- kash
1124000727777607680000
```

Integrated Help

Use the `kash.help(name)` command to get help about a given command. This returns a list of help for each of the definitions of `name`. Use `print kash.help(name)` to nicely print out all signatures.

Arithmetic

Using the `kash.new` command we create Kash objects on which one can do arithmetic.

```
sage: a = kash(12345)                               # optional -- kash
sage: b = kash(25)                                  # optional -- kash
sage: a/b                                           # optional -- kash
2469/5
sage: a**b                                          # optional -- kash
193765903041146393565116739165642262657761441158615231767486923346401992277143215887218713760375976
```

Variable assignment

Variable assignment using `kash` is takes place in Sage.

```
sage: a = kash('32233')                             # optional -- kash
sage: a                                             # optional -- kash
32233
```

In particular, `a` is not defined as part of the KASH session itself.

```
sage: kash.eval('a')                                # optional -- kash
"Error, the variable 'a' must have a value"
```

Use `a.name()` to get the name of the KASH variable:

```
sage: a.name()                                  # somewhat random and optional - kash
'sage0'
sage: kash(a.name())                            # optional -- kash
32233
```

Integers and Rationals

We illustrate arithmetic with integers and rationals in KASH.

```
sage: F = kash.Factorization(4352)              # optional -- kash
sage: F[1]                                      # optional -- kash
<2, 8>
sage: F[2]                                      # optional -- kash
<17, 1>
sage: F                                         # optional -- kash
[ <2, 8>, <17, 1> ], extended by:
  ext1 := 1,
  ext2 := Unassign
```

Note: For some very large numbers KASH's integer factorization seems much faster than PARI's (which is the default in Sage).

```
sage: kash.GCD(15,25)                           # optional -- kash
5
sage: kash.LCM(15,25)                           # optional -- kash
75
sage: kash.Div(25,15)                           # optional -- kash
1
sage: kash(17) % kash(5)                        # optional -- kash
2
sage: kash.IsPrime(10007)                       # optional -- kash
TRUE
sage: kash.IsPrime(2005)                        # optional -- kash
FALSE

sage: kash.NextPrime(10007)                     # optional -- kash
10009
```

Real and Complex Numbers

```
sage: kash.Precision()                          # optional -- kash
30
sage: kash('R')                                 # optional -- kash
Real field of precision 30
sage: kash.Precision(40)                        # optional -- kash
40
sage: kash('R')                                 # optional -- kash
Real field of precision 40
sage: z = kash('1 + 2*I')                       # optional -- kash
sage: z                                         # optional -- kash
1.0000000000000000000000000000000000000000 + 2.0000000000000000000000000000000000000000*I
sage: z*z                                       # optional -- kash
-3.0000000000000000000000000000000000000000 + 4.0000000000000000000000000000000000000000*I
```

```
sage: kash.Cos('1.24')                          # optional -- kash
0.32479628443877623657769341569738039969 92
sage: kash('1.24').Cos()                        # optional -- kash
0.32479628443877623657769341569738039969 92

sage: kash.Log('I')                             # optional -- kash
1.57079632679489661923132169164*I

sage: kash.Sqrt(4)                              # optional -- kash
2.00000000000000000000000000000
sage: kash.Sqrt(2)                              # optional -- kash
1.41421356237309504880168872421

sage: kash.Floor('9/5')                         # optional -- kash
1
sage: kash.Floor('3/5')                         # optional -- kash
0

sage: x_c = kash('3+I')                         # optional -- kash
sage: x_c.Argument()                            # optional -- kash
0.32175055439664219340140461435 9
sage: x_c.Imaginary()                           # optional -- kash
1.00000000000000000000000000000
```

Lists

Note that list appends are completely different in KASH than in Python. Use underscore after the function name for the mutation version.

```
sage: v = kash([1,2,3]); v                      # optional -- kash
[ 1, 2, 3 ]
sage: v[1]                                      # optional -- kash
1
sage: v[3]                                      # optional -- kash
3
sage: v.Append([5])                             # optional -- kash
[ 1, 2, 3, 5 ]
sage: v                                         # optional -- kash
[ 1, 2, 3 ]
sage: v.Append_([5, 6])                         # optional -- kash
SUCCESS
sage: v                                         # optional -- kash
[ 1, 2, 3, 5, 6 ]
sage: v.Add(5)                                  # optional -- kash
[ 1, 2, 3, 5, 6, 5 ]
sage: v                                         # optional -- kash
[ 1, 2, 3, 5, 6 ]
sage: v.Add_(5)                                 # optional -- kash
SUCCESS
```

```
sage: v                                          # optional -- kash
[ 1, 2, 3, 5, 6, 5 ]
```

The `Apply` command applies a function to each element of a list.

:: sage: L = kash([1,2,3,4]) # optional – kash sage: L.Apply('i -> 3*i') # optional – kash [3, 6, 9, 12] sage: L # optional – kash [1, 2, 3, 4] sage: L.Apply('IsEven') # optional – kash [FALSE, TRUE, FALSE, TRUE] sage: L # optional – kash [1, 2, 3, 4]

Ranges

the following are examples of ranges.

```
sage: L = kash('[1..10]')                        # optional -- kash
sage: L                                          # optional -- kash
[ 1 .. 10 ]
sage: L = kash('[2,4..100]')                     # optional -- kash
sage: L                                          # optional -- kash
[ 2, 4 .. 100 ]
```

Sequences

Tuples

Polynomials

```
sage: f = kash('X^3 + X + 1')                    # optional -- kash
sage: f + f                                      # optional -- kash
2*X^3 + 2*X + 2
sage: f * f                                      # optional -- kash
X^6 + 2*X^4 + 2*X^3 + X^2 + 2*X + 1
sage: f.Evaluate(10)                             # optional -- kash
1011
sage: Qx = kash.PolynomialAlgebra('Q')           # optional -- kash
sage: Qx.gen(1)**5 + kash('7/3')    # sage1 below somewhat random; optional -- kash
sage1.1^5 + 7/3
```

Number Fields

We create an equation order.

```
sage: f = kash('X^5 + 4*X^4 - 56*X^2 -16*X + 192')     # optional -- kash
sage: OK = f.EquationOrder()                           # optional -- kash
sage: OK                                               # optional -- kash
Equation Order with defining polynomial X^5 + 4*X^4 - 56*X^2 - 16*X + 192 over Z
```

```
sage: f = kash('X^5 + 4*X^4 - 56*X^2 -16*X + 192')     # optional -- kash
sage: O = f.EquationOrder()                            # optional -- kash
sage: a = O.gen(2)                                     # optional -- kash
sage: a                                                # optional -- kash
[0, 1, 0, 0, 0]
```

```
sage: O.Basis()        # output somewhat random; optional -- kash
[
_NG.1,
_NG.2,
_NG.3,
_NG.4,
_NG.5
]
sage: O.Discriminant()              # optional -- kash
1364202618880
sage: O.MaximalOrder()    # name sage2 below somewhat random; optional -- kash
Maximal Order of sage2

sage: O = kash.MaximalOrder('X^3 - 77')                  # optional -- kash
sage: I = O.Ideal(5,[2, 1, 0])                           # optional -- kash
sage: I                    # name sage14 below random; optional -- kash
Ideal of sage14
Two element generators:
[5, 0, 0]
[2, 1, 0]

sage: F = I.Factorisation()                  # optional -- kash
sage: F                    # name sage14 random; optional -- kash
[
<Prime Ideal of sage14
Two element generators:
[5, 0, 0]
[2, 1, 0], 1>
]
```

Determining whether an ideal is principal.

```
sage: I.IsPrincipal()                      # optional -- kash
FALSE, extended by:
ext1 := Unassign
```

Computation of class groups and unit groups:

```
sage: f = kash('X^5 + 4*X^4 - 56*X^2 -16*X + 192')         # optional -- kash
sage: O = kash.EquationOrder(f)                            # optional -- kash
sage: OK = O.MaximalOrder()                                # optional -- kash
sage: OK.ClassGroup()       # name sage32 below random; optional -- kash
Abelian Group isomorphic to Z/6
  Defined on 1 generator
  Relations:
  6*sage32.1 = 0, extended by:
  ext1 := Mapping from: grp^abl: sage32 to ids/ord^num: _AA

sage: U = OK.UnitGroup()                                  # optional -- kash
sage: U        # name sage34 below random; optional -- kash
Abelian Group isomorphic to Z/2 + Z + Z
  Defined on 3 generators
  Relations:
  2*sage34.1 = 0, extended by:
  ext1 := Mapping from: grp^abl: sage34 to ord^num: sage30
```

```
sage: kash.Apply('x->%s.ext1(x)'%U.name(), U.Generators().List())      # optional -- kash
[ [1, -1, 0, 0, 0], [1, 1, 0, 0, 0], [-1, 0, 0, 0, 0] ]
```

Function Fields

```
sage: k = kash.FiniteField(25)                                         # optional -- kash
sage: kT = k.RationalFunctionField()                                   # optional -- kash
sage: kTy = kT.PolynomialAlgebra()                                     # optional -- kash
sage: T = kT.gen(1)                                                    # optional -- kash
sage: y = kTy.gen(1)                                                   # optional -- kash
sage: f = y**3 + T**4 + 1                                              # optional -- kash
```

13.6.3 Long Input

The KASH interface reads in even very long input (using files) in a robust manner, as long as you are creating a new object.

Note: Using `kash.eval` for long input is much less robust, and is not recommended.

```
sage: a = kash(range(10000))                                           # optional -- kash
```

Note that KASH seems to not support string or integer literals with more than 1024 digits, which is why the above example uses a list unlike for the other interfaces.

class Kash (*max_workspace_size=None, maxread=100000, script_subdirectory=None, restart_on_ctrlc=True, logfile=None, server=None, server_tmpdir=None*)

Interface to the Kash interpreter.

AUTHORS:

- William Stein and David Joyner

console()

eval(*x, newlines=False, strip=True, **kwds*)

Send the code in the string s to the Kash interpreter and return the output as a string.

INPUT:

- `s` - string containing Kash code.
- `newlines` - bool (default: True); if False, remove all backslash-newlines inserted by the Kash output formatter.
- `strip` - ignored

get(*var*)

Get the value of the variable var.

help(*name=None*)

Return help on KASH commands.

Returns help on all commands with a given name. If name is None, return the location of the installed Kash html documentation.

EXAMPLES:

```
sage: X = kash.help('IntegerRing')    # optional -- kash
```

There is one entry in X for each item found in the documentation for this function: If you type `print X[0]` you will get help on about the first one, printed nicely to the screen.

13.7 Interface to Magma

Note: You must have `magma` installed on your computer for this interface to work. Magma is not free, so it is not included with Sage, but you can obtain it from http://magma.maths.usyd.edu.au/.

Type `magma.[tab]` for a list of all the functions available from your Magma install. Type `magma.[tab]?` for Magma's help about a given function. Type `magma(...)` to create a new Magma object, and `magma.eval(...)` to run a string using Magma (and get the result back as a string).

Sage provides an interface to the Magma computational algebra system. This system provides extensive functionality for number theory, group theory, combinatorics and algebra.

The Magma interface offers three pieces of functionality:

1. `magma_console()` - A function that dumps you into an interactive command-line Magma session.
2. `magma(expr)` - Evaluation of arbitrary Magma expressions, with the result returned as a string.
3. `magma.new(expr)` - Creation of a Sage object that wraps a Magma object. This provides a Pythonic interface to Magma. For example, if `f=magma.new(10)`, then `f.Factors()` returns the prime factorization of 10 computed using Magma.

13.7.1 Parameters

Some Magma functions have optional "parameters", which are arguments that in Magma go after a colon. In Sage, you pass these using named function arguments. For example,

```
sage: E = magma('EllipticCurve([0,1,1,-1,0])')                    # optional - magma
sage: E.Rank(Bound = 5)                                           # optional - magma
0
```

13.7.2 Multiple Return Values

Some Magma functions return more than one value. You can control how many you get using the `nvals` named parameter to a function call:

```
sage: n = magma(100)                                                    # optional - magma
sage: n.IsSquare(nvals = 1)                                             # optional - magma
true
sage: n.IsSquare(nvals = 2)                                             # optional - magma
(true, 10)
sage: n = magma(-2006)                                                  # optional - magma
sage: n.Factorization()                                                 # optional - magma
[ <2, 1>, <17, 1>, <59, 1> ]
sage: n.Factorization(nvals=2)                                          # optional - magma
([ <2, 1>, <17, 1>, <59, 1> ], -1)
```

We verify that an obviously principal ideal is principal:

```
sage: _ = magma.eval('R<x> := PolynomialRing(RationalField())')     # optional - magma
sage: O = magma.NumberField('x^2+23').MaximalOrder()                # optional - magma
sage: I = magma('ideal<%s|%s.1>'%(O.name(),O.name()))               # optional - magma
sage: I.IsPrincipal(nvals=2)                                        # optional - magma
(true, [1, 0])
```

13.7.3 Long Input

The Magma interface reads in even very long input (using files) in a robust manner.

```
sage: t = '"%s"'%10^10000   # ten thousand character string.        # optional - magma
sage: a = magma.eval(t)                                             # optional - magma
sage: a = magma(t)                                                  # optional - magma
```

13.7.4 Other Examples

We compute a space of modular forms with character.

```
sage: N = 20
sage: D = 20
sage: eps_top = fundamental_discriminant(D)
sage: eps = magma.KroneckerCharacter(eps_top, RationalField())          # optional - magma
sage: M2 = magma.ModularForms(eps)                                      # optional - magma
sage: print M2                                                          # optional - magma
Space of modular forms on Gamma_1(5) ...
sage: print M2.Basis()                                                  # optional - magma
[
1 + 10*q^2 + 20*q^3 + 20*q^5 + 60*q^7 + ...
q + q^2 + 2*q^3 + 3*q^4 + 5*q^5 + 2*q^6 + ...
]
```

In Sage/Python (and sort of C++) coercion of an element x into a structure S is denoted by S(x). This also works for the Magma interface:

```
sage: G = magma.DirichletGroup(20)                                      # optional - magma
sage: G.AssignNames(['a', 'b'])                                         # optional - magma
sage: (G.1).Modulus()                                                   # optional - magma
20
sage: e = magma.DirichletGroup(40)(G.1)                                 # optional - magma
sage: print e                                                           # optional - magma
```

```
$.1
sage: print e.Modulus()                                                    # optional - magma
40
```

We coerce some polynomial rings into Magma:

```
sage: R.<y> = PolynomialRing(QQ)
sage: S = magma(R)                                                         # optional - magma
sage: print S                                                              # optional - magma
Univariate Polynomial Ring in y over Rational Field
sage: S.1                                                                  # optional - magma
y
```

This example illustrates that Sage doesn't magically extend how Magma implicit coercion (what there is, at least) works. The errors below are the result of Magma having a rather limited automatic coercion system compared to Sage's:

```
sage: R.<x> = ZZ[]
sage: x * 5
5*x
sage: x * 1.0
1.00000000000000*x
sage: x * (2/3)
2/3*x
sage: y = magma(x)                                                         # optional - magma
sage: y * 5                                                                # optional - magma
5*x
sage: y * 1.0                                                              # optional - magma
...
TypeError: unsupported operand parent(s) for '*': 'Magma' and 'Real Field with 53 bits of precision'
sage: y * (2/3)                                                            # optional - magma
...
TypeError: unsupported operand parent(s) for '*': 'Magma' and 'Rational Field'
```

AUTHORS:

- William Stein (2005): initial version
- William Stein (2006-02-28): added extensive tab completion and interactive IPython documentation support.
- William Stein (2006-03-09): added nvals argument for magma.functions...

class Magma (*maxread=10000, script_subdirectory=None, logfile=None, server=None, server_tmpdir=None, user_config=False*)

Interface to the Magma interpreter.

Type `magma.[tab]` for a list of all the functions available from your Magma install. Type `magma.[tab]?` for Magma's help about a given function. Type `magma(...)` to create a new Magma object, and `magma.eval(...)` to run a string using Magma (and get the result back as a string).

Note: If you do not own a local copy of Magma, try using the `magma_free` command instead, which uses the free demo web interface to Magma.

EXAMPLES:

You must use nvals = 0 to call a function that doesn't return anything, otherwise you'll get an error. (nvals is the number of return values.)

```
sage: magma.SetDefaultRealFieldPrecision(200, nvals=0)  # magma >= v2.12; optional - magma
sage: magma.eval('1.1')   # optional - magma
'1.1000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000
sage: magma.SetDefaultRealFieldPrecision(30, nvals=0)  # optional - magma
```

Attach (*filename*)

Attach the given file to the running instance of Magma.

Attaching a file in Magma makes all intrinsics defined in the file available to the shell. Moreover, if the file doesn't start with the `freeze;` command, then the file is reloaded whenever it is changed. Note that functions and procedures defined in the file are *not* available. For only those, use `magma.load(filename)`.

INPUT:

- `filename` - a string

EXAMPLES: Attaching a file that exists is fine:

```
sage: magma.attach('%s/data/extcode/magma/sage/basic.m'%Sage_ROOT)    # optional - magma
```

Attaching a file that doesn't exist raises an exception:

```
sage: magma.attach('%s/data/extcode/magma/sage/basic2.m'%Sage_ROOT)     # optional - magma
...
RuntimeError: Error evaluating Magma code...
```

AttachSpec (*filename*)

Attach the given spec file to the running instance of Magma.

This can attach numerous other files to the running Magma (see the Magma documentation for more details).

INPUT:

- `filename` - a string

EXAMPLES:

```
sage: magma.attach_spec('%s/data/extcode/magma/spec'%SAGE_ROOT)    # optional - magma
sage: magma.attach_spec('%s/data/extcode/magma/spec2'%SAGE_ROOT)   # optional - magma
...
RuntimeError: Can't open package spec file .../data/extcode/magma/spec2 for reading (No such
```

GetVerbose (*type*)

Get the verbosity level of a given algorithm class etc. in Magma.

INPUT:

- `type` - string (e.g. 'Groebner'), see Magma documentation

Note: This method is provided to be consistent with the Magma naming convention.

EXAMPLES:

```
sage: magma.SetVerbose("Groebner", 2)       # optional - magma
sage: magma.GetVerbose("Groebner")          # optional - magma
2
```

SetVerbose (*type, level*)

Set the verbosity level for a given algorithm class etc. in Magma.

INPUT:

- `type` - string (e.g. 'Groebner'), see Magma documentation
- `level` - integer = 0

Note: This method is provided to be consistent with the Magma naming convention.

```
sage: magma.SetVerbose("Groebner", 2)       # optional - magma
sage: magma.GetVerbose("Groebner")          # optional - magma
2
```

attach (*filename*)

Attach the given file to the running instance of Magma.

Attaching a file in Magma makes all intrinsics defined in the file available to the shell. Moreover, if the file doesn't start with the `freeze;` command, then the file is reloaded whenever it is changed. Note that functions and procedures defined in the file are *not* available. For only those, use `magma.load(filename)`.

INPUT:

- `filename` - a string

EXAMPLES: Attaching a file that exists is fine:

```
sage: magma.attach('%s/data/extcode/magma/sage/basic.m'%Sage_ROOT)     # optional - magma
```

Attaching a file that doesn't exist raises an exception:

```
sage: magma.attach('%s/data/extcode/magma/sage/basic2.m'%Sage_ROOT)      # opticnal - magma
...
RuntimeError: Error evaluating Magma code...
```

attach_spec (*filename*)

Attach the given spec file to the running instance of Magma.

This can attach numerous other files to the running Magma (see the Magma documentation for more details).

INPUT:

- `filename` - a string

EXAMPLES:

```
sage: magma.attach_spec('%s/data/extcode/magma/spec'%SAGE_ROOT)     # optional - magma
sage: magma.attach_spec('%s/data/extcode/magma/spec2'%SAGE_ROOT)    # optional - magma
...
RuntimeError: Can't open package spec file .../data/extcode/magma/spec2 for reading (No such
```

bar_call (*left, name, gens, nvals=1*)

This is a wrapper around the Magma constructor

nameleft gens

returning nvals.

INPUT:

- `left` - something coerceable to a magma object
- `name` - name of the constructor, e.g., sub, quo, ideal, etc.
- `gens` - if a list/tuple, each item is coerced to magma; otherwise gens itself is converted to magma
- `nvals` - positive integer; number of return values

OUTPUT: a single magma object if nvals == 1; otherwise a tuple of nvals magma objects.

EXAMPLES: The bar_call function is used by the sub, quo, and ideal methods of Magma elements. Here we illustrate directly using bar_call to create quotients:

```
sage: V = magma.RModule(ZZ,3)     # optional - magma
sage: V                           # optional - magma
RModule(IntegerRing(), 3)
sage: magma.bar_call(V, 'quo', [[1,2,3]], nvals=1)  # optional - magma
RModule(IntegerRing(), 2)
sage: magma.bar_call(V, 'quo', [[1,2,3]], nvals=2)  # optional - magma
(RModule(IntegerRing(), 2),
```

```
 Mapping from: RModule(IntegerRing(), 3) to RModule(IntegerRing(), 2))
sage: magma.bar_call(V, 'quo', V, nvals=2)          # optional - magma
(RModule(IntegerRing(), 0),
 Mapping from: RModule(IntegerRing(), 3) to RModule(IntegerRing(), 0))
```

chdir(*dir*)

Change to the given directory.

INPUT:

- `dir` - string; name of a directory

EXAMPLES:

```
sage: magma.chdir('/')                  # optional - magma
sage: magma.eval('System("pwd")')       # optional - magma
'/'
```

clear(*var*)

Clear the variable named var and make it available to be used again.

INPUT:

- `var` - a string

EXAMPLES:

```
sage: magma = Magma()       # optional - magma
sage: magma.clear('foo')    # sets foo to 0 in magma; optional - magma
sage: magma.eval('foo')     # optional - magma
'0'
```

Because we cleared foo, it is set to be used as a variable name in the future:

```
sage: a = magma('10')       # optional - magma
sage: a.name()              # optional - magma
'foo'
```

The following tests that the whole variable clearing and freeing system is working correctly.

```
sage: magma = Magma()       # optional - magma
sage: a = magma('100')      # optional - magma
sage: a.name()              # optional - magma
'_sage_[1]'
sage: del a                 # optional - magma
sage: b = magma('257')      # optional - magma
sage: b.name()              # optional - magma
'_sage_[1]'
sage: del b                 # optional - magma
sage: magma('_sage_[1]')    # optional - magma
0
```

console()

Run a command line Magma session. This session is completely separate from this Magma interface.

EXAMPLES:

```
sage: magma.console()             # not tested
Magma V2.14-9     Sat Oct 11 2008 06:36:41 on one      [Seed = 1157408761]
Type ? for help.  Type <Ctrl>-D to quit.
>
Total time: 2.820 seconds, Total memory usage: 3.95MB
```

cputime(*t=None*)

Return the CPU time in seconds that has elapsed since this Magma session started. This is a floating point number, computed by Magma.

If t is given, then instead return the floating point time from when t seconds had elapsed. This is useful for computing elapsed times between two points in a running program.

INPUT:

- `t` - float (default: None); if not None, return cputime since t

OUTPUT:

- `float` - seconds

EXAMPLES:

```
sage: type(magma.cputime())          # optional - magma
<type 'float'>
sage: magma.cputime()                 # random, optional - magma
1.9399999999999999
sage: t = magma.cputime()             # optional - magma
sage: magma.cputime(t)                # random, optional - magma
0.02
```

eval(*x, strip=True, **kwds*)

Evaluate the given block x of code in Magma and return the output as a string.

INPUT:

- `x` - string of code
- `strip` - ignored

OUTPUT: string

EXAMPLES: We evaluate a string that involves assigning to a variable and printing.

```
sage: magma.eval("a := 10;print 2+a;")      # optional - magma
'12'
```

We evaluate a large input line (note that no weird output appears and that this works quickly).

```
sage: magma.eval("a := %s;"%(10^10000))    # optional - magma
"
```

function_call(*function, args=, [], params={}, nvals=1*)

Return result of evaluating a Magma function with given input, parameters, and asking for nvals as output.

INPUT:

- `function` - string, a Magma function name
- `args` - list of objects coercible into this magma interface
- `params` - Magma parameters, passed in aftera colon
- `nvals` - number of return values from the function to ask Magma for

OUTPUT: MagmaElement or tuple of nvals MagmaElement's

EXAMPLES:

```
sage: magma.function_call('Factorization', 100)    # optional - magma
[ <2, 2>, <5, 2> ]
sage: magma.function_call('NextPrime', 100, {'Proof':False})    # optional - magma
101
sage: magma.function_call('PolynomialRing', [QQ,2])      # optional - magma
Polynomial ring of rank 2 over Rational Field
Lexicographical Order
Variables: $.1, $.2
```

Next, we illustrate multiple return values:

```
sage: magma.function_call('IsSquare', 100)          # optional - magma
true
sage: magma.function_call('IsSquare', 100, nvals=2)     # optional - magma
```

```
(true, 10)
sage: magma.function_call('IsSquare', 100, nvals=3)      # optional - magma
...
RuntimeError: Error evaluating Magma code...
Runtime error in :=: Expected to assign 3 value(s) but only computed 2 value(s)
```

get(*var*)

Get the value of the variable var.

INPUT:

- `var` - string; name of a variable defined in the Magma session

OUTPUT:

- `string` - string representation of the value of the variable.

EXAMPLES:

```
sage: magma.set('abc', '2 + 3/5')      # optional - magma
sage: magma.get('abc')                 # optional - magma
'13/5'
```

get_verbose(*type*)

Get the verbosity level of a given algorithm class etc. in Magma.

INPUT:

- `type` - string (e.g. 'Groebner'), see Magma documentation

EXAMPLES:

```
sage: magma.set_verbose("Groebner", 2)         # optional - magma
sage: magma.get_verbose("Groebner")            # optional - magma
2
```

help(*s*)

Return Magma help on string s.

This returns what typing ?s would return in Magma.

INPUT:

- `s` - string

OUTPUT: string

EXAMPLES:

```
sage: magma.help("NextPrime")        # optional - magma
================================================================================
PATH: /magma/ring-field-algebra/integer/prime/next-previous/NextPrime
KIND: Intrinsic
================================================================================
NextPrime(n) : RngIntElt -> RngIntElt
NextPrime(n: parameter) : RngIntElt -> RngIntElt
...
```

ideal(*L*)

Return the Magma ideal defined by L.

INPUT:

- `L` - a list of elements of a Sage multivariate polynomial ring.

OUTPUT: The magma ideal generated by the elements of L.

EXAMPLES:

```
sage: R.<x,y> = QQ[]
sage: magma.ideal([x^2, y^3*x])          # optional - magma
Ideal of Polynomial ring of rank 2 over Rational Field
Graded Reverse Lexicographical Order
Variables: x, y
Basis:
[
x^2,
x*y^3
]
```

load (*filename*)

Load the file with given filename using the 'load' command in the Magma shell.

Loading a file in Magma makes all the functions and procedures in the file available. The file should not contain any intrinsics (or you'll get errors). It also runs code in the file, which can produce output.

INPUT:

- `filename` - string

OUTPUT: output printed when loading the file

EXAMPLES:

```
sage: open(SAGE_TMP + 'a.m','w').write('function f(n) return n^2; end function;\nprint "hi";
sage: print magma.load(SAGE_TMP + 'a.m')       # optional - magma
Loading ".../.sage//temp/.../a.m"
hi
sage: magma('f(12)')        # optional - magma
144
```

objgens (*value, gens*)

Create a new object with given value and gens.

INPUT:

- `value` - something coercible to an element of this Magma interface
- `gens` - string; command separated list of variable names

OUTPUT: new Magma element that is equal to value with given gens

EXAMPLES:

```
sage: R = magma.objgens('PolynomialRing(Rationals(),2)', 'alpha,beta')     # optional - magma
sage: R.gens()          # optional - magma
[alpha, beta]
```

Because of how Magma works you can use this to change the variable names of the generators of an object:

```
sage: S = magma.objgens(R, 'X,Y')          # optional - magma
sage: R                                    # optional - magma
Polynomial ring of rank 2 over Rational Field
Lexicographical Order
Variables: X, Y
sage: S                                    # optional - magma
Polynomial ring of rank 2 over Rational Field
Lexicographical Order
Variables: X, Y
```

set (*var, value*)

Set the variable var to the given value in the Magma interpreter.

INPUT:

- `var` - string; a variable name
- `value` - string; what to set var equal to

EXAMPLES:

```
sage: magma.set('abc', '2 + 3/5')        # optional - magma
sage: magma('abc')                       # optional - magma
13/5
```

set_verbose(*type, level*)

Set the verbosity level for a given algorithm, class, etc. in Magma.

INPUT:

- `type` - string (e.g. 'Groebner')
- `level` - integer = 0

EXAMPLES:

```
sage: magma.set_verbose("Groebner", 2)       # optional - magma
sage: magma.get_verbose("Groebner")          # optional - magma
2
```

trait_names(*verbose=True, use_disk_cache=True*)

Return a list of all Magma commands.

This is used as a hook to enable custom command completion.

Magma doesn't provide any fast way to make a list of all commands, which is why caching is done by default. Note that an adverse impact of caching is that *new* commands are not picked up, e.g., user defined variables or functions.

INPUT:

- `verbose` - bool (default: True); whether to verbosely output status info the first time the command list is built
- `use_disk_cache` - bool (default: True); use cached command list, which is saved to disk.

OUTPUT: list of strings

EXAMPLES:

```
sage: len(magma.trait_names(verbose=False))     # random, optional - magma
7261
```

version()

Return the version of Magma that you have in your PATH on your computer.

OUTPUT:

- `numbers` - 3-tuple: major, minor, etc.
- `string` - version as a string

EXAMPLES:

```
sage: magma.version()        # random, optional - magma
((2, 14, 9), 'V2.14-9')
```

class **MagmaElement**(*parent, value, is_name=False, name=None*)

AssignNames(*names*)

EXAMPLES:

```
sage: G = magma.DirichletGroup(20)    # optional - magma
sage: G.AssignNames(['a','b'])        # optional - magma
sage: G.1                             # optional - magma
a
```

```
sage: G.Elements()                    # optional - magma
[
1,
a,
b,
a*b
]
```

assign_names(*names*)

EXAMPLES:

```
sage: G = magma.DirichletGroup(20)    # optional - magma
sage: G.AssignNames(['a','b'])        # optional - magma
sage: G.1                             # optional - magma
a

sage: G.Elements()                    # optional - magma
[
1,
a,
b,
a*b
]
```

eval(**args*)

Evalute self at the inputs.

INPUT:

- `*args` - import arguments

OUTPUT: self(*args)

EXAMPLES:

```
sage: f = magma('Factorization')            # optional - magma
sage: f.evaluate(15)                        # optional - magma
[ <3, 1>, <5, 1> ]
sage: f(15)                                 # optional - magma
[ <3, 1>, <5, 1> ]
sage: f = magma('GCD')                      # optional - magma
sage: f.evaluate(15,20)                     # optional - magma
5
```

evaluate(**args*)

Evalute self at the inputs.

INPUT:

- `*args` - import arguments

OUTPUT: self(*args)

EXAMPLES:

```
sage: f = magma('Factorization')            # optional - magma
sage: f.evaluate(15)                        # optional - magma
[ <3, 1>, <5, 1> ]
sage: f(15)                                 # optional - magma
[ <3, 1>, <5, 1> ]
sage: f = magma('GCD')                      # optional - magma
sage: f.evaluate(15,20)                     # optional - magma
5
```

gen(*n*)

Return the n-th generator of this Magma element. Note that generators are 1-based in Magma rather than 0 based!

INPUT:

- n - a *positive* integer

OUTPUT: MagmaElement

EXAMPLES:

```
sage: k.<a> = GF(9)
sage: magma(k).gen(1)          # optional -- magma
a
sage: R.<s,t,w> = k[]
sage: m = magma(R)             # optional -- magma
sage: m.gen(1)                 # optional -- magma
s
sage: m.gen(2)                 # optional -- magma
t
sage: m.gen(3)                 # optional -- magma
w
sage: m.gen(0)                 # optional -- magma
...
IndexError: index must be positive since Magma indexes are 1-based
sage: m.gen(4)                 # optional -- magma
...
IndexError: list index out of range
```

gen_names()

Return list of Magma variable names of the generators of self.

Note: As illustrated below, these are not the print names of the the generators of the Magma object, but special variable names in the Magma session that reference the generators.

EXAMPLES:

```
sage: R.<x,zw> = QQ[]
sage: S = magma(R)                # optional - magma
sage: S.gen_names()               # optional - magma
('_sage_[...]', '_sage_[...]')
sage: magma(S.gen_names()[1])     # optional - magma
zw
```

gens()

Return generators for self.

If self is named X is Magma, this function evaluates X.1, X.2, etc., in Magma until an error occurs. It then returns a Sage list of the resulting X.i. Note - I don't think there is a Magma command that returns the list of valid X.i. There are numerous ad hoc functions for various classes but nothing systematic. This function gets around that problem. Again, this is something that should probably be reported to the Magma group and fixed there.

AUTHORS:

- William Stein (2006-07-02)

EXAMPLES:

```
sage: magma("VectorSpace(RationalField(),3)").gens()          # optional - magma
[(1 0 0), (0 1 0), (0 0 1)]
sage: magma("AbelianGroup(EllipticCurve([1..5]))").gens()     # optional - magma
[$.1]
```

get_magma_attribute(*attrname*)

Return value of a given Magma attribute. This is like selfattrname in Magma.

OUTPUT: MagmaElement

EXAMPLES:

```
sage: V = magma("VectorSpace(RationalField(),10)")    # optional - magma
sage: V.set_magma_attribute('M','"hello"')            # optional - magma
sage: V.get_magma_attribute('M')                      # optional - magma
hello
sage: V.M                                             # optional - magma
hello
```

ideal (*gens*)

Return the ideal of self with given list of generators.

INPUT:

- gens - object or list/tuple of generators

OUTPUT:

- magma element - a Magma ideal

EXAMPLES:

```
sage: R = magma('PolynomialRing(RationalField())')        # optional - magma
sage: R.assign_names(['x'])                               # optional - magma
sage: x = R.1                                             # optional - magma
sage: R.ideal([x^2 - 1, x^3 - 1])                         # optional - magma
Ideal of Univariate Polynomial Ring in x over Rational Field generated by x - 1
```

list_attributes ()

Return the attributes of self, obtained by calling the ListAttributes function in Magma.

OUTPUT: list of strings

EXAMPLES: We observe that vector spaces in Magma have numerous funny and mysterious attributes.

```
sage: V = magma("VectorSpace(RationalField(),2)")        # optional - magma
sage: V.list_attributes()                                # optional - magma
['Coroots', 'Roots', 'decomp', 'ssbasis', 'M', 'StrLocalData', 'eisen', 'weights', 'RootDatu
```

methods (*any=False*)

Return signatures of all Magma intrinsics that can take self as the first argument, as strings.

INPUT:

- any - (bool: default is False) if True, also include signatures with Any as first argument.

OUTPUT: list of strings

EXAMPLES:

```
sage: v = magma('2/3').methods()          # optional - magma
sage: v[0]                                # optional - magma
"'*'..."
```

quo (*gens*)

Return the quotient of self by the given object or list of generators.

INPUT:

- gens - object or list/tuple of generators

OUTPUT:

- magma element - the quotient object
- magma element - mapping from self to the quotient object

EXAMPLES:

```
sage: V = magma('VectorSpace(RationalField(),3)')       # optional - magma
sage: V.quo([[1,2,3], [1,1,2]])                         # optional - magma
(Full Vector space of degree 1 over Rational Field, Mapping from: Full Vector space of degre
```

We illustrate quotienting out by an object instead of a list of generators:

```
sage: W = V.sub([ [1,2,3], [1,1,2] ])                   # optional - magma
sage: V.quo(W)                                          # optional - magma
(Full Vector space of degree 1 over Rational Field, Mapping from: Full Vector space of degre
```

We quotient a ZZ module out by a submodule.

```
sage: V = magma.RModule(ZZ,3); V # optional - magma
RModule(IntegerRing(), 3)
sage: W, phi = V.quo([[1,2,3]])  # optional - magma
sage: W                          # optional - magma
RModule(IntegerRing(), 2)
sage: phi                        # optional - magma
Mapping from: RModule(IntegerRing(), 3) to RModule(IntegerRing(), 2)
```

set_magma_attribute(*attrname, value*)

INPUTS: attrname - string value - something coercible to a MagmaElement

EXAMPLES:

```
sage: V = magma("VectorSpace(RationalField(),2)")   # optional - magma
sage: V.set_magma_attribute('M',10)                 # optional - magma
sage: V.get_magma_attribute('M')                    # optional - magma
10
sage: V.M                                           # optional - magma
10
```

sub(*gens*)

Return the sub-object of self with given gens.

INPUT:

- `gens` - object or list/tuple of generators

EXAMPLES:

```
sage: V = magma('VectorSpace(RationalField(),3)')       # optional - magma
sage: W = V.sub([ [1,2,3], [1,1,2] ]); W                # optional - magma
Vector space of degree 3, dimension 2 over Rational Field
Generators:
(1 2 3)
(1 1 2)
Echelonized basis:
(1 0 1)
(0 1 1)
```

trait_names()

Return all Magma functions that have this Magma element as first input. This is used for tab completion.

Note: This function can unfortunately be slow if there are a very large number of functions, e.g., when self is an integer. (This could be fixed by the addition of an appropriate function to the Magma kernel, which is something that can only be done by the Magma developers.)

OUTPUT:

- `list` - sorted list of distinct strings

EXAMPLES:

```
sage: v = magma('2/3').trait_names()        # optional - magma
sage: type(v[0])                            # optional - magma
<type 'str'>
```

class MagmaFunction(*parent, name*)

class MagmaFunctionElement(*obj, name*)

extcode_dir()

Return directory that contains all the Magma extcode. This is put in a writable directory owned by the user, since when attached, Magma has to write sig and lck files.

EXAMPLES: sage: sage.interfaces.magma.extcode_dir() '...dir_.../data/'

is_MagmaElement(*x*)

Return True if x is of type MagmaElement, and False otherwise.

INPUT:

- x - any object

OUTPUT: bool

EXAMPLES:

```
sage: from sage.interfaces.magma import is_MagmaElement
sage: is_MagmaElement(2)
False
sage: is_MagmaElement(magma(2))                    # optional - magma
True
```

magma_console()

Run a command line Magma session.

EXAMPLES:

```
sage: magma_console()             # not tested
Magma V2.14-9     Sat Oct 11 2008 06:36:41 on one      [Seed = 1157408761]
Type ? for help.  Type <Ctrl>-D to quit.
>
Total time: 2.820 seconds, Total memory usage: 3.95MB
```

magma_version()

Return the version of Magma that you have in your PATH on your computer.

OUTPUT:

- numbers - 3-tuple: major, minor, etc.
- string - version as a string

EXAMPLES:

```
sage: magma_version()       # random, optional - magma
((2, 14, 9), 'V2.14-9')
```

reduce_load_Magma()

Used in unpickling a Magma interface.

This functions just returns the global default Magma interface.

EXAMPLES:

```
sage: sage.interfaces.magma.reduce_load_Magma()
Magma
```

13.8 Interface to Maple

AUTHORS:

- William Stein (2005): maple interface
- Gregg Musiker (2006-02-02): tutorial
- William Stein (2006-03-05): added tab completion, e.g., maple.[tab], and help, e.g, maple.sin?.

You must have the optional commercial Maple interpreter installed and available as the command `maple` in your PATH in order to use this interface. You do not have to install any optional Sage packages.

Type `maple.[tab]` for a list of all the functions available from your Maple install. Type `maple.[tab]?` for Maple's help about a given function. Type `maple(...)` to create a new Maple object, and `maple.eval(...)` to run a string using Maple (and get the result back as a string).

EXAMPLES:

```
sage: maple('3 * 5')                                  # optional - maple
15
sage: maple.eval('ifactor(2005)')                     # optional - maple
'"(5)*"(401)'
sage: maple.ifactor(2005)                             # optional - maple
"(5)*"(401)
sage: maple.fsolve('x^2=cos(x)+4', 'x=0..5')          # optional - maple
1.914020619
sage: maple.factor('x^5 - y^5')                       # optional - maple
(x-y)*(x^4+x^3*y+x^2*y^2+x*y^3+y^4)
```

If the string "error" (case insensitive) occurs in the output of anything from Maple, a RuntimeError exception is raised.

13.8.1 Tutorial

AUTHORS:

- Gregg Musiker (2006-02-02): initial version.

This tutorial is based on the Maple Tutorial for number theory from http://www.math.mun.ca/~drideout/m3370/numtheory.html.

There are several ways to use the Maple Interface in Sage. We will discuss two of those ways in this tutorial.

1. If you have a maple expression such as

   ```
   factor( (x^5-1));
   ```

   We can write that in sage as

```
sage: maple('factor(x^5-1)')                    # optional - maple
(x-1)*(x^4+x^3+x^2+x+1)
```

Notice, there is no need to use a semicolon.

2. Since Sage is written in Python, we can also import maple commands and write our scripts in a pythonic way. For example, `factor()` is a maple command, so we can also factor in Sage using

```
sage: maple('(x^5-1)').factor()                 # optional - maple
(x-1)*(x^4+x^3+x^2+x+1)
```

where `expression.command()` means the same thing as `command(expression)` in Maple. We will use this second type of syntax whenever possible, resorting to the first when needed.

```
sage: maple('(x^12-1)/(x-1)').simplify()      # optional - maple
x^11+x^10+x^9+x^8+x^7+x^6+x^5+x^4+x^3+x^2+x+1
```

The normal command will always reduce a rational function to the lowest terms. The factor command will factor a polynomial with rational coefficients into irreducible factors over the ring of integers. So for example,

```
sage: maple('(x^12-1)').factor( )             # optional - maple
(x-1)*(x+1)*(x^2+x+1)*(x^2-x+1)*(x^2+1)*(x^4-x^2+1)
```

```
sage: maple('(x^28-1)').factor( )             # optional - maple
(x-1)*(x^6+x^5+x^4+x^3+x^2+x+1)*(x+1)*(1-x+x^2-x^3+x^4-x^5+x^6)*(x^2+1)*(x^12-x^10+x^8-x^6+x^4-x^2+1)
```

Another important feature of maple is its online help. We can access this through sage as well. After reading the description of the command, you can press q to immediately get back to your original prompt.

Incidentally you can always get into a maple console by the command

```
sage:  maple.console()           # not tested
sage:  !maple                    # not tested
```

Note that the above two commands are slightly different, and the first is preferred.

For example, for help on the maple command fibonacci, we type

```
sage: maple.help('fibonacci')   # not tested, since it uses a pager
```

We see there are two choices. Type

```
sage: maple.help('combinat, fibonacci')    # not tested, since it uses a pager
```

We now see how the Maple command fibonacci works under the combinatorics package. Try typing in

```
sage: maple.fibonacci(10)                 # optional - maple
fibonacci(10)
```

You will get fibonacci(10) as output since Maple has not loaded the combinatorics package yet. To rectify this type

```
sage: maple('combinat[fibonacci]')(10)      # optional - maple
55
```

instead.

If you want to load the combinatorics package for future calculations, in Sage this can be done as

```
sage: maple.with_package('combinat')        # optional - maple
```

or

```
sage: maple.load('combinat')                # optional - maple
```

Now if we type `maple.fibonacci(10)`, we get the correct output:

```
sage: maple.fibonacci(10)                   # optional - maple
55
```

Some common maple packages include `combinat`, `linalg`, and `numtheory`. To produce the first 19 Fibonacci numbers, use the sequence command.

```
sage: maple('seq(fibonacci(i),i=1..19)')      # optional - maple
1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987, 1597, 2584,
4181
```

Two other useful Maple commands are ifactor and isprime. For example

```
sage: maple.isprime(maple.fibonacci(27))      # optional - maple
false
sage: maple.ifactor(maple.fibonacci(27))      # optional - maple
"(2)*"(17)*"(53)*"(109)
```

Note that the isprime function that is included with Sage (which uses PARI) is better than the Maple one (it is faster and gives a provably correct answer, whereas Maple is sometimes wrong).

```
sage: alpha = maple('(1+sqrt(5))/2')          # optional - maple
sage: beta = maple('(1-sqrt(5))/2')           # optional - maple
sage: f19  = alpha^19 - beta^19/maple('sqrt(5)')      # optional - maple
sage: f19                                             # optional - maple
(1/2+1/2*5^(1/2))^19-1/5*(1/2-1/2*5^(1/2))^19*5^(1/2)
sage: f19.simplify()                 # somewhat randomly ordered output; optional - maple
6765+5778/5*5^(1/2)
```

Let's say we want to write a maple program now that squares a number if it is positive and cubes it if it is negative. In maple, that would look like

```
mysqcu := proc(x)
if x > 0 then x^2;
else x^3; fi;
end;
```

In Sage, we write

```
sage: mysqcu = maple('proc(x) if x > 0 then x^2 else x^3 fi end')     # optional - maple
sage: mysqcu(5)                                                       # optional - maple
25
sage: mysqcu(-5)                                                      # optional - maple
-125
```

More complicated programs should be put in a separate file and loaded.

class Maple (*maxread=100, script_subdirectory='', server=None, server_tmpdir=None, logfile=None*)
Interface to the Maple interpreter.

Type `maple.[tab]` for a list of all the functions available from your Maple install. Type `maple.[tab]?` for Maple's help about a given function. Type `maple(...)` to create a new Maple object, and `maple.eval(...)` to run a string using Maple (and get the result back as a string).

clear (*var*)
Clear the variable named var.

Unfortunately, Maple does not have a clear command. The next best thing is to set equal to the constant 0, so that memory will be freed.

EXAMPLES:

```
sage: maple.set('xx', '2')  # optional - maple
sage: maple.get('xx')       # optional - maple
'2'
sage: maple.clear('xx')     # optional - maple
sage: maple.get('xx')       # optional - maple
'0'
```

completions (*s*)
Return all commands that complete the command starting with the string s. This is like typing s[Ctrl-T] in the maple interpreter.

EXAMPLES:

```
sage: c = maple.completions('di')  # optional - maple
sage: 'divide' in c                # optional - maple
True
```

console ()
Spawn a new Maple command-line session.

EXAMPLES:

```
sage: maple.console() # not tested
    |^/|     Maple 11 (IBM INTEL LINUX)
._|\|   |/|_. Copyright (c) Maplesoft, a division of Waterloo Maple Inc. 2007
 \  MAPLE  /  All rights reserved. Maple is a trademark of
 <____ ____>  Waterloo Maple Inc.
      |       Type ? for help.
>
```

cputime (*t=None*)
Returns the amount of CPU time that the Maple session has used. If `t` is not None, then it returns the difference between the current CPU time and `t`.

EXAMPLES:

```
sage: t = maple.cputime() # optional - maple
sage: t                   # random; optional - maple
0.02
sage: x = maple('x')      # optional - maple
sage: maple.diff(x^2, x)  # optional - maple
2*x
sage: maple.cputime(t)    # random; optional - maple
0.0
```

expect ()
Returns the pexpect object for this Maple session.

EXAMPLES:

```
sage: m = Maple()
sage: m.expect() is None
True
sage: m._start()           # optional - maple
sage: m.expect()           # optional - maple
<pexpect.spawn instance at 0x...>
sage: m.quit()             # optional - maple
```

get(*var*)

Get the value of the variable var.

EXAMPLES:

```
sage: maple.set('xx', '2') # optional - maple
sage: maple.get('xx')      # optional - maple
'2'
```

help(*str*)

Display Maple help about str. This is the same as typing "?str" in the Maple console.

INPUT:

- `str` - a string to search for in the maple help system

EXAMPLES:

```
sage: maple.help('digamma') #not tested
Psi - the Digamma and Polygamma functions
...
```

load(*package*)

Make a package of Maple procedures available in the interpreter.

INPUT:

- `package` - string

EXAMPLES: Some functions are unknown to Maple until you use with to include the appropriate package.

```
sage: maple.quit()    # optional -- to reset maple.
sage: maple('partition(10)')              # optional -- requires maple
partition(10)
sage: maple('bell(10)')                   # optional -- requires maple
bell(10)
sage: maple.with_package('combinat')      # optional -- requires maple
sage: maple('partition(10)')              # optional -- requires maple
[[1, 1, 1, 1, 1, 1, 1, 1, 1, 1], [1, 1, 1, 1, 1, 1, 1, 1, 2], [1, 1, 1, 1, 1, 1, 2, 2], [1,
sage: maple('bell(10)')                   # optional -- requires maple
115975
sage: maple('fibonacci(10)')              # optional -- requires maple
55
```

set(*var, value*)

Set the variable var to the given value.

EXAMPLES:

```
sage: maple.set('xx', '2') # optional - maple
sage: maple.get('xx')      # optional - maple
'2'
```

source(*s*)

Display the Maple source (if possible) about s. This is the same as returning the output produced by the following Maple commands:

interface(verboseproc=2): print(s)

INPUT:

- s - a string representing the function whose source code you want

EXAMPLES:

```
sage: maple.source('curry')  #not tested
p -> subs('_X' = args[2 .. nargs], () -> p(_X, args))
```

trait_names(*verbose=True, use_disk_cache=True*)

Returns a list of all the commands defined in Maple and optionally (per default) store them to disk.

EXAMPLES:

```
sage: c = maple.trait_names(use_disk_cache=False, verbose=False) # optional - maple
sage: len(c) > 100  # optional - maple
True
sage: 'dilog' in c  # optional - maple
True
```

with_package(*package*)

Make a package of Maple procedures available in the interpreter.

INPUT:

- package - string

EXAMPLES: Some functions are unknown to Maple until you use with to include the appropriate package.

```
sage: maple.quit()   # optional -- to reset maple.
sage: maple('partition(10)')              # optional -- requires maple
partition(10)
sage: maple('bell(10)')                   # optional -- requires maple
bell(10)
sage: maple.with_package('combinat')      # optional -- requires maple
sage: maple('partition(10)')              # optional -- requires maple
[[1, 1, 1, 1, 1, 1, 1, 1, 1, 1], [1, 1, 1, 1, 1, 1, 1, 1, 2], [1, 1, 1, 1, 1, 1, 2, 2], [1,
sage: maple('bell(10)')                   # optional -- requires maple
115975
sage: maple('fibonacci(10)')              # optional -- requires maple
55
```

class MapleElement(*parent, value, is_name=False, name=None*)

trait_names()

EXAMPLES:

```
sage: a = maple(2) # optional - maple
sage: 'sin' in a.trait_names() # optional - maple
True
```

class MapleFunction(*parent, name*)

class MapleFunctionElement(*obj, name*)

maple_console()

Spawn a new Maple command-line session.

EXAMPLES:

```
sage: maple_console() #not tested
    |^/|     Maple 11 (IBM INTEL LINUX)
._|\|   |/|_. Copyright (c) Maplesoft, a division of Waterloo Maple Inc. 2007
 \  MAPLE  /  All rights reserved. Maple is a trademark of
 <____ ____>  Waterloo Maple Inc.
      |       Type ? for help.
>
```

reduce_load_Maple()
Returns the maple object created in sage.interfaces.maple.

EXAMPLES:

```
sage: from sage.interfaces.maple import reduce_load_Maple
sage: reduce_load_Maple()
Maple
```

13.9 Interface to MATLAB

According to their website, MATLAB is "a high-level language and interactive environment that enables you to perform computationally intensive tasks faster than with traditional programming languages such as C, C++, and Fortran."

The commands in this section only work if you have the "matlab" interpreter installed and available in your PATH. It's not necessary to install any special Sage packages.

EXAMPLES:

```
sage: matlab.eval('2+2')                    # optional
'\nans =\n\n     4\n'

sage: a = matlab(10)                        # optional
sage: a**10                                 # optional
   1.0000e+10
```

AUTHORS:

- William Stein (2006-10-11)

13.9.1 Tutorial

EXAMPLES:

```
sage: matlab('4+10')                        # optional
14
sage: matlab('date')                       # optional; random output
18-Oct-2006
sage: matlab('5*10 + 6')                    # optional
56
sage: matlab('(6+6)/3')                     # optional
4
sage: matlab('9')^2                         # optional
81
sage: a = matlab(10); b = matlab(20); c = matlab(30)     # optional
sage: avg = (a+b+c)/3                       # optional
sage: avg                                   # optional
20
sage: parent(avg)                           # optional
Matlab
```

```
sage: my_scalar = matlab('3.1415')        # optional
sage: my_scalar                           # optional
3.1415
sage: my_vector1 = matlab('[1,5,7]')      # optional
sage: my_vector1                          # optional
1     5     7
sage: my_vector2 = matlab('[1;5;7]')      # optional
sage: my_vector2                          # optional
1
5
7
sage: my_vector1 * my_vector2             # optional
75

sage: row_vector1 = matlab('[1 2 3]')              # optional
sage: row_vector2 = matlab('[3 2 1]')              # optional
sage: matrix_from_row_vec = matlab('[%s; %s]'%(row_vector1.name(), row_vector2.name()))     # optiona
sage: matrix_from_row_vec                          # optional
1     2     3
3     2     1

sage: column_vector1 = matlab('[1;3]')             # optional
sage: column_vector2 = matlab('[2;8]')             # optional
sage: matrix_from_col_vec = matlab('[%s %s]'%(column_vector1.name(), column_vector2.name()))
sage: matrix_from_col_vec                          # optional
1     2
3     8

sage: my_matrix = matlab('[8, 12, 19; 7, 3, 2; 12, 4, 23; 8, 1, 1]')     # optional
sage: my_matrix                                    # optional
     8    12    19
     7     3     2
    12     4    23
     8     1     1

sage: combined_matrix = matlab('[%s, %s]'%(my_matrix.name(), my_matrix.name()))
sage: combined_matrix                             # optional
 8    12    19     8    12    19
 7     3     2     7     3     2
12     4    23    12     4    23
 8     1     1     8     1     1

sage: tm = matlab('0.5:2:10')                     # optional
sage: tm                                          # optional
0.5000    2.5000    4.5000    6.5000    8.5000

sage: my_vector1 = matlab('[1,5,7]')              # optional
sage: my_vector1(1)                               # optional
1
sage: my_vector1(2)                               # optional
5
sage: my_vector1(3)                               # optional
7
```

Matrix indexing works as follows:

```
sage: my_matrix = matlab('[8, 12, 19; 7, 3, 2; 12, 4, 23; 8, 1, 1]')      # optional
sage: my_matrix(3,2)                                  # optional
4
```

Setting using paranthesis cannot work (because of how the Python language works). Use square brackets or the set function:

```
sage: my_matrix = matlab('[8, 12, 19; 7, 3, 2; 12, 4, 23; 8, 1, 1]')     # optional
sage: my_matrix.set(2,3, 1999)                            # optional
sage: my_matrix                                           # optional
           8          12          19
           7           3        1999
          12           4          23
           8           1           1
```

class Matlab(*maxread=100, script_subdirectory='', logfile=None, server=None, server_tmpdir=None*)

Interface to the Matlab interpreter.

EXAMPLES:

```
sage: a = matlab('[ 1, 1, 2; 3, 5, 8; 13, 21, 33 ]')     # optional
sage: b = matlab('[ 1; 3; 13]')                           # optional
sage: c = a * b                                           # optional
sage: print c                                             # optional
    30
   122
   505
```

console()

get(*var*)

Get the value of the variable var.

sage2matlab_matrix_string(*A*)

Return an matlab matrix from a Sage matrix.

INPUT: A Sage matrix with entries in the rationals or reals.

OUTPUT: A string that evaluates to an Matlab matrix.

EXAMPLES:

```
sage: M33 = MatrixSpace(QQ,3,3)
sage: A = M33([1,2,3,4,5,6,7,8,0])
sage: matlab.sage2matlab_matrix_string(A)    # requires optional matlab
'[1, 2, 3; 4, 5, 6; 7, 8, 0]'
```

AUTHOR:

- David Joyner and William Stein

set(*var, value*)

Set the variable var to the given value.

version()

whos()

class MatlabElement(*parent, value, is_name=False, name=None*)

set(*i, j, x*)

matlab_console()
This requires that the optional matlab program be installed and in your PATH, but no optional Sage packages need be installed.

EXAMPLES:

```
sage: matlab_console()                                  # optional and not tested
                                  < M A T L A B >
                    Copyright 1984-2006 The MathWorks, Inc.
...
>> 2+3

ans =

5

quit
```

Typing quit exits the matlab console and returns you to Sage. matlab, like Sage, remembers its history from one session to another.

matlab_version()
Return the version of Matlab installed.

EXAMPLES:

```
sage: matlab_version()    # optional matlab package
'7.2.0.283 (R2006a)'
```

reduce_load_Matlab()

13.10 Interface to Maxima

Maxima is a free GPL'd general purpose computer algebra system whose development started in 1968 at MIT. It contains symbolic manipulation algorithms, as well as implementations of special functions, including elliptic functions and generalized hypergeometric functions. Moreover, Maxima has implementations of many functions relating to the invariant theory of the symmetric group S_n. (However, the commands for group invariants, and the corresponding Maxima documenation, are in French.) For many links to Maxima documentation see http://maxima.sourceforge.net/docs.shtml/.

AUTHORS:

- William Stein (2005-12): Initial version
- David Joyner: Improved documentation
- William Stein (2006-01-08): Fixed bug in parsing
- William Stein (2006-02-22): comparisons (following suggestion of David Joyner)
- William Stein (2006-02-24): *greatly* improved robustness by adding sequence numbers to IO bracketing in _eval_line

If the string "error" (case insensitive) occurs in the output of anything from maxima, a RuntimeError exception is raised.

EXAMPLES: We evaluate a very simple expression in maxima.

```
sage: maxima('3 * 5')
15
```

We factor $x^5 - y^5$ in Maxima in several different ways. The first way yields a Maxima object.

```
sage: F = maxima.factor('x^5 - y^5')
sage: F
-(y-x)*(y^4+x*y^3+x^2*y^2+x^3*y+x^4)
sage: type(F)
<class 'sage.interfaces.maxima.MaximaElement'>
```

Note that Maxima objects can also be displayed using "ASCII art"; to see a normal linear representation of any Maxima object x. Just use the print command: use `str(x)`.

```
sage: print F
                              4       3    2  2    3       4
                    - (y - x) (y  + x y  + x  y  + x  y + x )
```

You can always use `repr(x)` to obtain the linear representation of an object. This can be useful for moving maxima data to other systems.

```
sage: repr(F)
'-(y-x)*(y^4+x*y^3+x^2*y^2+x^3*y+x^4)'
sage: F.str()
'-(y-x)*(y^4+x*y^3+x^2*y^2+x^3*y+x^4)'
```

The `maxima.eval` command evaluates an expression in maxima and returns the result as a *string* not a maxima object.

```
sage: print maxima.eval('factor(x^5 - y^5)')
-(y-x)*(y^4+x*y^3+x^2*y^2+x^3*y+x^4)
```

We can create the polynomial f as a Maxima polynomial, then call the factor method on it. Notice that the notation `f.factor()` is consistent with how the rest of Sage works.

```
sage: f = maxima('x^5 - y^5')
sage: f^2
(x^5-y^5)^2
sage: f.factor()
-(y-x)*(y^4+x*y^3+x^2*y^2+x^3*y+x^4)
```

Control-C interruption works well with the maxima interface, because of the excellent implementation of maxima. For example, try the following sum but with a much bigger range, and hit control-C.

```
sage: maxima('sum(1/x^2, x, 1, 10)')
1968329/1270080
```

13.10.1 Tutorial

We follow the tutorial at http://maxima.sourceforge.net/docs/intromax/.

```
sage: maxima('1/100 + 1/101')
201/10100
```

```
sage: a = maxima('(1 + sqrt(2))^5'); a
(sqrt(2)+1)^5
sage: a.expand()
29*sqrt(2)+41
```

```
sage: a = maxima('(1 + sqrt(2))^5')
sage: float(a)
82.012193308819747
sage: a.numer()
82.01219330881975
```

```
sage: maxima.eval('fpprec : 100')
'100'
sage: a.bfloat()
8.2012193308819756415248973002081244278520484385931494122123712401731241875401104126661238495501605
```

```
sage: maxima('100!')
933262154439441526816992388562667004907159682643816214685929638952175999932299156089414639761565182
```

```
sage: f = maxima('(x + 3*y + x^2*y)^3')
sage: f.expand()
x^6*y^3+9*x^4*y^3+27*x^2*y^3+27*y^3+3*x^5*y^2+18*x^3*y^2+27*x*y^2+3*x^4*y+9*x^2*y+x^3
sage: f.subst('x=5/z')
(5/z+25*y/z^2+3*y)^3
sage: g = f.subst('x=5/z')
sage: h = g.ratsimp(); h
(27*y^3*z^6+135*y^2*z^5+(675*y^3+225*y)*z^4+(2250*y^2+125)*z^3+(5625*y^3+1875*y)*z^2+9375*y^2*z+1562
sage: h.factor()
(3*y*z^2+5*z+25*y)^3/z^6
```

```
sage: eqn = maxima(['a+b*c=1', 'b-a*c=0', 'a+b=5'])
sage: s = eqn.solve('[a,b,c]'); s
[[a=(25*sqrt(79)*%i+25)/(6*sqrt(79)*%i-34),b=(5*sqrt(79)*%i+5)/(sqrt(79)*%i+11),c=(sqrt(79)*%i+1)/10]
```

Here is an example of solving an algebraic equation:

```
sage: maxima('x^2+y^2=1').solve('y')
[y=-sqrt(1-x^2),y=sqrt(1-x^2)]
sage: maxima('x^2 + y^2 = (x^2 - y^2)/sqrt(x^2 + y^2)').solve('y')
[y=-sqrt((-y^2-x^2)*sqrt(y^2+x^2)+x^2),y=sqrt((-y^2-x^2)*sqrt(y^2+x^2)+x^2)]
```

You can even nicely typeset the solution in latex:

```
sage: latex(s)
\left[ \left[ a={{25\,\sqrt{79}\,i+25}\over{6\,\sqrt{79}\,i-34}} ,   b={{5\,\sqrt{79}\,i+5}\over{\sqr
```

To have the above appear onscreen via `xdvi`, type `view(s)`. (TODO: For OS X should create pdf output and use preview instead?)

```
sage: e = maxima('sin(u + v) * cos(u)^3'); e
cos(u)^3*sin(v+u)
sage: f = e.trigexpand(); f
cos(u)^3*(cos(u)*sin(v)+sin(u)*cos(v))
```

```
sage: f.trigreduce()
(sin(v+4*u)+sin(v-2*u))/8+(3*sin(v+2*u)+3*sin(v))/8
sage: w = maxima('3 + k*%i')
sage: f = w^2 + maxima('%e')^w
sage: f.realpart()
%e^3*cos(k)-k^2+9

sage: f = maxima('x^3 * %e^(k*x) * sin(w*x)'); f
x^3*%e^(k*x)*sin(w*x)
sage: f.diff('x')
k*x^3*%e^(k*x)*sin(w*x)+3*x^2*%e^(k*x)*sin(w*x)+w*x^3*%e^(k*x)*cos(w*x)
sage: f.integrate('x')
(((k*w^6+3*k^3*w^4+3*k^5*w^2+k^7)*x^3+(3*w^6+3*k^2*w^4-3*k^4*w^2-3*k^6)*x^2+(-18*k*w^4-12*k^3*w^2+6*k

sage: f = maxima('1/x^2')
sage: f.integrate('x', 1, 'inf')
1
sage: g = maxima('f/sinh(k*x)^4')
sage: g.taylor('x', 0, 3)
f/(k^4*x^4)-2*f/(3*k^2*x^2)+11*f/45-62*k^2*f*x^2/945

sage: maxima.taylor('asin(x)','x',0, 10)
x+x^3/6+3*x^5/40+5*x^7/112+35*x^9/1152
```

13.10.2 Examples involving matrices

We illustrate computing with the matrix whose i, j entry is i/j, for $i, j = 1, \ldots, 4$.

```
sage: f = maxima.eval('f[i,j] := i/j')
sage: A = maxima('genmatrix(f,4,4)'); A
matrix([1,1/2,1/3,1/4],[2,1,2/3,1/2],[3,3/2,1,3/4],[4,2,4/3,1])
sage: A.determinant()
0
sage: A.echelon()
matrix([1,1/2,1/3,1/4],[0,0,0,0],[0,0,0,0],[0,0,0,0])
sage: A.eigenvalues()
[[0,4],[3,1]]
sage: A.eigenvectors()
[[[0,4],[3,1]],[1,0,0,-4],[0,1,0,-2],[0,0,1,-4/3],[1,2,3,4]]
```

We can also compute the echelon form in Sage:

```
sage: B = matrix(QQ, A)
sage: B.echelon_form()
[  1 1/2 1/3 1/4]
[  0   0   0   0]
[  0   0   0   0]
[  0   0   0   0]
sage: B.charpoly('x').factor()
(x - 4) * x^3
```

13.10.3 Laplace Transforms

We illustrate Laplace transforms:

```
sage: _ = maxima.eval("f(t) := t*sin(t)")
sage: maxima("laplace(f(t),t,s)")
2*s/(s^2+1)^2

sage: maxima("laplace(delta(t-3),t,s)") #Dirac delta function
%e^-(3*s)

sage: _ = maxima.eval("f(t) := exp(t)*sin(t)")
sage: maxima("laplace(f(t),t,s)")
1/(s^2-2*s+2)

sage: _ = maxima.eval("f(t) := t^5*exp(t)*sin(t)")
sage: maxima("laplace(f(t),t,s)")
360*(2*s-2)/(s^2-2*s+2)^4-480*(2*s-2)^3/(s^2-2*s+2)^5+120*(2*s-2)^5/(s^2-2*s+2)^6
sage: print maxima("laplace(f(t),t,s)")
                                      3                   5
           360 (2 s - 2)     480 (2 s - 2)      120 (2 s - 2)
          --------------- - --------------- + ---------------
            2            4     2            5     2            6
          (s  - 2 s + 2)     (s  - 2 s + 2)     (s  - 2 s + 2)

sage: maxima("laplace(diff(x(t),t),t,s)")
s*?%laplace(x(t),t,s)-x(0)

sage: maxima("laplace(diff(x(t),t,2),t,s)")
-?%at('diff(x(t),t,1),t=0)+s^2*?%laplace(x(t),t,s)-x(0)*s
```

It is difficult to read some of these without the 2d representation:

```
sage: print maxima("laplace(diff(x(t),t,2),t,s)")
                     !
           d         !          2
         - -- (x(t))!       + s  laplace(x(t), t, s) - x(0) s
           dt        !
                     !t = 0
```

Even better, use `view(maxima("laplace(diff(x(t),t,2),t,s)"))` to see a typeset version.

13.10.4 Continued Fractions

A continued fraction $a + 1/(b + 1/(c + \cdots))$ is represented in maxima by the list $[a, b, c, \ldots]$.

```
sage: maxima("cf((1 + sqrt(5))/2)")
[1,1,1,1,2]
sage: maxima("cf ((1 + sqrt(341))/2)")
[9,1,2,1,2,1,17,1,2,1,2,1,17,1,2,1,2,1,17,2]
```

13.10.5 Special examples

In this section we illustrate calculations that would be awkward to do (as far as I know) in non-symbolic computer algebra systems like MAGMA or GAP.

We compute the gcd of $2x^{n+4} - x^{n+2}$ and $4x^{n+1} + 3x^n$ for arbitrary n.

```
sage: f = maxima('2*x^(n+4) - x^(n+2)')
sage: g = maxima('4*x^(n+1) + 3*x^n')
sage: f.gcd(g)
x^n
```

You can plot 3d graphs (via gnuplot):

```
sage: maxima('plot3d(x^2-y^2, [x,-2,2], [y,-2,2], [grid,12,12])')  # not tested
[displays a 3 dimensional graph]
```

You can formally evaluate sums (note the `nusum` command):

```
sage: S = maxima('nusum(exp(1+2*i/n),i,1,n)')
sage: print S
                        2/n + 3                     2/n + 1
                      %e                          %e
                ---------------------- - ----------------------
                   1/n          1/n            1/n          1/n
                (%e    - 1) (%e    + 1)    (%e    - 1) (%e    + 1)
```

We formally compute the limit as $n \to \infty$ of $2S/n$ as follows:

```
sage: T = S*maxima('2/n')
sage: T.tlimit('n','inf')
%e^3-%e
```

13.10.6 Miscellaneous

Obtaining digits of π:

```
sage: maxima.eval('fpprec : 100')
'100'
sage: maxima(pi).bfloat()
3.14159265358979323846264338327950288419716939937510582097494459230781640628620899862803482534211706
```

Defining functions in maxima:

```
sage: maxima.eval('fun[a] := a^2')
'fun[a]:=a^2'
sage: maxima('fun[10]')
100
```

13.10.7 Interactivity

Unfortunately maxima doesn't seem to have a non-interactive mode, which is needed for the Sage interface. If any Sage call leads to maxima interactively answering questions, then the questions can't be answered and the maxima

session may hang. See the discussion at http://www.ma.utexas.edu/pipermail/maxima/2005/011061.html for some ideas about how to fix this problem. An example that illustrates this problem is `maxima.eval('integrate (exp(a*x), x, 0, inf)')`.

13.10.8 Latex Output

To tex a maxima object do this:

```
sage: latex(maxima('sin(u) + sinh(v^2)'))
\sinh v^2+\sin u
```

Here's another example:

```
sage: g = maxima('exp(3*%i*x)/(6*%i) + exp(%i*x)/(2*%i) + c')
sage: latex(g)
-{{i\,e^{3\,i\,x}}\over{6}}-{{i\,e^{i\,x}}\over{2}}+c
```

13.10.9 Long Input

The MAXIMA interface reads in even very long input (using files) in a robust manner, as long as you are creating a new object.

Note: Using `maxima.eval` for long input is much less robust, and is not recommended.

```
sage: t = '"%s"'%10^10000   # ten thousand character string.
sage: a = maxima(t)
```

TESTS: This working tests that a subtle bug has been fixed:

```
sage: f = maxima.function('x','gamma(x)')
sage: g = f(1/7)
sage: g
gamma(1/7)
sage: del f
sage: maxima(sin(x))
sin(x)
```

This tests to make sure we handle the case where Maxima asks if an expression is positive or zero.

```
sage: var('Ax,Bx,By')
(Ax, Bx, By)
sage: t = -Ax*sin(sqrt(Ax^2)/2)/(sqrt(Ax^2)*sqrt(By^2 + Bx^2))
sage: t.limit(Ax=0,dir='above')
...
TypeError: Computation failed since Maxima requested additional constraints (try the command 'assume
Is By^2+Bx^2  positive or zero?
```

A long complicated input expression:

```
sage: maxima._eval_line('((((((((((0) + ((1) / ((n0) ^ (0)))) + ((1) / ((n1) ^ (1)))) + ((1) / ((n2)
'1/n9^9+1/n8^8+1/n7^7+1/n6^6+1/n5^5+1/n4^4+1/n3^3+1/n2^2+1/n1+1'
```

class **Maxima** (*script_subdirectory=None, logfile=None, server=None, init_code=None*)
Interface to the Maxima interpreter.

chdir(*dir*)

Change Maxima's current working directory.

EXAMPLES:

```
sage: maxima.chdir('/')
```

clear(*var*)

Clear the variable named var.

EXAMPLES:

```
sage: maxima.set('xxxxx', '2')
sage: maxima.get('xxxxx')
'2'
sage: maxima.clear('xxxxx')
sage: maxima.get('xxxxx')
'xxxxx'
```

completions(*s, verbose=True*)

Return all commands that complete the command starting with the string s. This is like typing s[tab] in the Maxima interpreter.

EXAMPLES:

```
sage: sorted(maxima.completions('gc', verbose=False))
['gc', 'gcd', 'gcdex', 'gcfactor', 'gcprint', 'gctime']
```

console()

Start the interactive Maxima console. This is a completely separate maxima session from this interface. To interact with this session, you should instead use `maxima.interact()`.

EXAMPLES:

```
sage: maxima.console()              # not tested (since we can't)
Maxima 5.13.0 http://maxima.sourceforge.net
Using Lisp CLISP 2.41 (2006-10-13)
Distributed under the GNU Public License. See the file COPYING.
Dedicated to the memory of William Schelter.
This is a development version of Maxima. The function bug_report()
provides bug reporting information.
(%i1)

sage: maxima.interact()     # this is not tested either
  --> Switching to Maxima <--
maxima: 2+2
4
maxima:
  --> Exiting back to Sage <--
```

cputime(*t=None*)

Returns the amount of CPU time that this Maxima session has used. If var{t} is not None, then it returns the difference between the current CPU time and var{t}.

EXAMPLES: sage: t = maxima.cputime() sage: _ = maxima.de_solve('diff(y,x,2) + 3*x = y', ['x','y'], [1,1,1]) sage: maxima.cputime(t) # output random 0.568913

de_solve(*maxima, de, vars, ics=None*)

Solves a 1st or 2nd order ordinary differential equation (ODE) in two variables, possibly with initial conditions.

INPUT:

- `de` - a string representing the ODE
- `vars` - a list of strings representing the two variables.

- ics - a triple of numbers [a,b1,b2] representing y(a)=b1, y'(a)=b2

EXAMPLES:

```
sage: maxima.de_solve('diff(y,x,2) + 3*x = y', ['x','y'], [1,1,1])
y=3*x-2*%e^(x-1)
sage: maxima.de_solve('diff(y,x,2) + 3*x = y', ['x','y'])
y=%k1*%e^x+%k2*%e^-x+3*x
sage: maxima.de_solve('diff(y,x) + 3*x = y', ['x','y'])
y=(%c-3*(-x-1)*%e^-x)*%e^x
sage: maxima.de_solve('diff(y,x) + 3*x = y', ['x','y'],[1,1])
y=-%e^-1*(5*%e^x-3*%e*x-3*%e)
```

de_solve_laplace(*de, vars, ics=None*)

Solves an ordinary differential equation (ODE) using Laplace transforms.

INPUT:

- de - a string representing the ODE (e.g., de = "diff(f(x),x,2)=diff(f(x),x)+sin(x)")
- vars - a list of strings representing the variables (e.g., vars = ["x","f"])
- ics - a list of numbers representing initial conditions, with symbols allowed which are represented by strings (eg, f(0)=1, f'(0)=2 is ics = [0,1,2])

EXAMPLES:

```
sage: maxima.clear('x'); maxima.clear('f')
sage: maxima.de_solve_laplace("diff(f(x),x,2) = 2*diff(f(x),x)-f(x)", ["x","f"], [0,1,2])
f(x)=x*%e^x+%e^x

sage: maxima.clear('x'); maxima.clear('f')
sage: f = maxima.de_solve_laplace("diff(f(x),x,2) = 2*diff(f(x),x)-f(x)", ["x","f"])
sage: f
f(x)=x*%e^x*('at('diff(f(x),x,1),x=0))-f(0)*x*%e^x+f(0)*%e^x
sage: print f
                                    !
                        x  d        !                    x          x
            f(x) = x %e  (-- (f(x))!     ) - f(0) x %e  + f(0) %e
                         dx         !
                                    !x = 0
```

Note: The second equation sets the values of $f(0)$ and $f'(0)$ in Maxima, so subsequent ODEs involving these variables will have these initial conditions automatically imposed.

demo(*s*)

EXAMPLES:

```
sage: maxima.demo('array') # not tested
batching /opt/sage/local/share/maxima/5.16.3/demo/array.dem
```

At the _ prompt, type ';' followed by enter to get next demo subscrmap : true _

describe(*s*)

EXAMPLES:

```
sage: maxima.help('gcd')
-- Function: gcd (<p_1>, <p_2>, <x_1>, ...)
...
```

example(*s*)

EXAMPLES:

```
sage: maxima.example('arrays')
a[n]:=n*a[n-1]
                                  a  := n a
```

```
                                        n        n - 1
a[0]:1
a[5]
                                      120
a[n]:=n
a[6]
                                       6
a[4]
                                      24
                                     done
```

function(*args, defn, rep=None, latex=None*)

Return the Maxima function with given arguments and definition.

INPUT:

- `args` - a string with variable names separated by commas
- `defn` - a string (or Maxima expression) that defines a function of the arguments in Maxima.
- `rep` - an optional string; if given, this is how the function will print.

EXAMPLES:

```
sage: f = maxima.function('x', 'sin(x)')
sage: f(3.2)
-.05837414342758009
sage: f = maxima.function('x,y', 'sin(x)+cos(y)')
sage: f(2,3.5)
sin(2)-.9364566872907963
sage: f
sin(x)+cos(y)

sage: g = f.integrate('z')
sage: g
(cos(y)+sin(x))*z
sage: g(1,2,3)
3*(cos(2)+sin(1))
```

The function definition can be a maxima object:

```
sage: an_expr = maxima('sin(x)*gamma(x)')
sage: t = maxima.function('x', an_expr)
sage: t
gamma(x)*sin(x)
sage: t(2)
 sin(2)
sage: float(t(2))
0.90929742682568171
sage: loads(t.dumps())
gamma(x)*sin(x)
```

get(*var*)

Get the string value of the variable var.

EXAMPLES:

```
sage: maxima.set('xxxxx', '2')
sage: maxima.get('xxxxx')
'2'
```

help(*s*)

EXAMPLES:

```
sage: maxima.help('gcd')
-- Function: gcd (<p_1>, <p_2>, <x_1>, ...)
...
```

lisp(*cmd*)

Send a lisp command to maxima.

Note: The output of this command is very raw - not pretty.

EXAMPLES:

```
sage: maxima.lisp("(+ 2 17)")    # random formated output
 :lisp (+ 2 17)
19
(
```

plot2d(**args*)

Plot a 2d graph using Maxima / gnuplot.

maxima.plot2d(f, '[var, min, max]', options)

INPUT:

- `f` - a string representing a function (such as f="sin(x)") [var, xmin, xmax]
- `options` - an optional string representing plot2d options in gnuplot format

EXAMPLES:

```
sage: maxima.plot2d('sin(x)','[x,-5,5]')    # not tested
sage: opts = '[gnuplot_term, ps], [gnuplot_out_file, "sin-plot.eps"]'
sage: maxima.plot2d('sin(x)','[x,-5,5]',opts)    # not tested
```

The eps file is saved in the current directory.

plot2d_parametric(*r, var, trange, nticks=50, options=None*)

Plots r = [x(t), y(t)] for t = tmin...tmax using gnuplot with options

INPUT:

- `r` - a string representing a function (such as r="[x(t),y(t)]")
- `var` - a string representing the variable (such as var = "t")
- `trange` - [tmin, tmax] are numbers with tmintmax
- `nticks` - int (default: 50)
- `options` - an optional string representing plot2d options in gnuplot format

EXAMPLES:

```
sage: maxima.plot2d_parametric(["sin(t)","cos(t)"], "t",[-3.1,3.1])    # not tested

sage: opts = '[gnuplot_preamble, "set nokey"], [gnuplot_term, ps], [gnuplot_out_file, "circl
sage: maxima.plot2d_parametric(["sin(t)","cos(t)"], "t", [-3.1,3.1], options=opts)    # not t
```

The eps file is saved to the current working directory.

Here is another fun plot:

```
sage: maxima.plot2d_parametric(["sin(5*t)","cos(11*t)"], "t", [0,2*pi()], nticks=400)    # r
```

plot3d(**args*)

Plot a 3d graph using Maxima / gnuplot.

maxima.plot3d(f, '[x, xmin, xmax]', '[y, ymin, ymax]', '[grid, nx, ny]', options)

INPUT:

- `f` - a string representing a function (such as f="sin(x)") [var, min, max]

EXAMPLES:

```
sage: maxima.plot3d('1 + x^3 - y^2', '[x,-2,2]', '[y,-2,2]', '[grid,12,12]')     # not tested
sage: maxima.plot3d('sin(x)*cos(y)', '[x,-2,2]', '[y,-2,2]', '[grid,30,30]')    # not tested
sage: opts = '[gnuplot_term, ps], [gnuplot_out_file, "sin-plot.eps"]'
sage: maxima.plot3d('sin(x+y)', '[x,-5,5]', '[y,-1,1]', opts)     # not tested
```

The eps file is saved in the current working directory.

plot3d_parametric(*r, vars, urange, vrange, options=None*)

Plot a 3d parametric graph with r=(x,y,z), x = x(u,v), y = y(u,v), z = z(u,v), for u = umin...umax, v = vmin...vmax using gnuplot with options.

INPUT:

- `x, y, z` - a string representing a function (such as `x="u2+v2"`, ...) vars is a list or two strings representing variables (such as vars = ["u","v"])
- `urange` - [umin, umax]
- `vrange` - [vmin, vmax] are lists of numbers with umin umax, vmin vmax
- `options` - optional string representing plot2d options in gnuplot format

OUTPUT: displays a plot on screen or saves to a file

EXAMPLES:

```
sage: maxima.plot3d_parametric(["v*sin(u)","v*cos(u)","v"], ["u","v"],[-3.2,3.2],[0,3])
sage: opts = '[gnuplot_term, ps], [gnuplot_out_file, "sin-cos-plot.eps"]'
sage: maxima.plot3d_parametric(["v*sin(u)","v*cos(u)","v"], ["u","v"],[-3.2,3.2],[0,3],opts)
```

The eps file is saved in the current working directory.

Here is a torus:

```
sage: _ = maxima.eval("expr_1: cos(y)*(10.0+6*cos(x)); expr_2: sin(y)*(10.0+6*cos(x)); expr_
sage: maxima.plot3d_parametric(["expr_1","expr_2","expr_3"], ["x","y"],[0,6],[0,6])    # not
```

Here is a Mobius strip:

```
sage: x = "cos(u)*(3 + v*cos(u/2))"
sage: y = "sin(u)*(3 + v*cos(u/2))"
sage: z = "v*sin(u/2)"
sage: maxima.plot3d_parametric([x,y,z],["u","v"],[-3.1,3.2],[-1/10,1/10])    # not tested
```

plot_list(*ptsx, ptsy, options=None*)

Plots a curve determined by a sequence of points.

INPUT:

- `ptsx` - [x1,...,xn], where the xi and yi are real,
- `ptsy` - [y1,...,yn]
- `options` - a string representing maxima plot2d options.

The points are (x1,y1), (x2,y2), etc.

This function requires maxima 5.9.2 or newer.

Note: More that 150 points can sometimes lead to the program hanging. Why?

EXAMPLES:

```
sage: zeta_ptsx = [ (pari(1/2 + i*I/10).zeta().real()).precision(1) for i in range (70,150)]
sage: zeta_ptsy = [ (pari(1/2 + i*I/10).zeta().imag()).precision(1) for i in range (70,150)]
sage: maxima.plot_list(zeta_ptsx, zeta_ptsy)          # not tested
sage: opts='[gnuplot_preamble, "set nokey"], [gnuplot_term, ps], [gnuplot_out_file, "zeta.ep
sage: maxima.plot_list(zeta_ptsx, zeta_ptsy, opts)       # not tested
```

plot_multilist(*pts_list, options=None*)

Plots a list of list of points pts_list=[pts1,pts2,...,ptsn], where each ptsi is of the form [[x1,y1],...,[xn,yn]] x's must be integers and y's reals options is a string representing maxima plot2d options.

Requires maxima 5.9.2 at least.

Note: More that 150 points can sometimes lead to the program hanging.

EXAMPLES:

```
sage: xx = [ i/10.0 for i in range (-10,10)]
sage: yy = [ i/10.0 for i in range (-10,10)]
sage: x0 = [ 0 for i in range (-10,10)]
sage: y0 = [ 0 for i in range (-10,10)]
sage: zeta_ptsx1 = [ (pari(1/2+i*I/10).zeta().real()).precision(1) for i in range (10)]
sage: zeta_ptsy1 = [ (pari(1/2+i*I/10).zeta().imag()).precision(1) for i in range (10)]
sage: maxima.plot_multilist([[zeta_ptsx1,zeta_ptsy1],[xx,y0],[x0,yy]])       # not tested
sage: zeta_ptsx1 = [ (pari(1/2+i*I/10).zeta().real()).precision(1) for i in range (10,150)]
sage: zeta_ptsy1 = [ (pari(1/2+i*I/10).zeta().imag()).precision(1) for i in range (10,150)]
sage: maxima.plot_multilist([[zeta_ptsx1,zeta_ptsy1],[xx,y0],[x0,yy]])      # not tested
sage: opts='[gnuplot_preamble, "set nokey"]'
sage: maxima.plot_multilist([[zeta_ptsx1,zeta_ptsy1],[xx,y0],[x0,yy]],opts)    # not tested
```

set (*var, value*)

Set the variable var to the given value.

INPUT:

- `var` - string
- `value` - string

EXAMPLES:

```
sage: maxima.set('xxxxx', '2')
sage: maxima.get('xxxxx')
'2'
```

solve_linear (*eqns, vars*)

Wraps maxima's linsolve.

INPUT: eqns is a list of m strings, each rperesenting a linear question in m = n variables vars is a list of n strings, each representing a variable

EXAMPLES:

```
sage: eqns = ["x + z = y","2*a*x - y = 2*a^2","y - 2*z = 2"]
sage: vars = ["x","y","z"]
sage: maxima.solve_linear(eqns, vars)
[x=a+1,y=2*a,z=a-1]
```

trait_names (*verbose=True, use_disk_cache=True*)

Return all Maxima commands, which is useful for tab completion.

EXAMPLES:

```
sage: t = maxima.trait_names(verbose=False)
sage: 'gcd' in t
True
sage: len(t)    # random output
1743
```

unit_quadratic_integer (*n*)

Finds a unit of the ring of integers of the quadratic number field $\mathbf{Q}(\sqrt{n})$, $n > 1$, using the qunit maxima command.

EXAMPLES:

```
sage: u = maxima.unit_quadratic_integer(101); u
a + 10
sage: u.parent()
Number Field in a with defining polynomial x^2 - 101
```

```
sage: u = maxima.unit_quadratic_integer(13)
sage: u
5*a + 18
sage: u.parent()
Number Field in a with defining polynomial x^2 - 13
```

version()

Return the version of Maxima that Sage includes.

EXAMPLES:

```
sage: maxima.version()
'5.16.3'
```

class **MaximaElement**(*parent, value, is_name=False, name=None*)

bool()

EXAMPLES:

```
sage: maxima(0).bool()
False
sage: maxima(1).bool()
True
```

comma(*args*)

Form the expression that would be written 'self, args' in Maxima.

EXAMPLES:

```
sage: maxima('sqrt(2) + I').comma('numer')
I+1.414213562373095
sage: maxima('sqrt(2) + I*a').comma('a=5')
5*I+sqrt(2)
```

derivative(*var='x', n=1*)

Return the n-th derivative of self.

INPUT:

- `var` - variable (default: 'x')
- `n` - integer (default: 1)

OUTPUT: n-th derivative of self with respect to the variable var

EXAMPLES:

```
sage: f = maxima('x^2')
sage: f.diff()
2*x
sage: f.diff('x')
2*x
sage: f.diff('x', 2)
2
sage: maxima('sin(x^2)').diff('x',4)
16*x^4*sin(x^2)-12*sin(x^2)-48*x^2*cos(x^2)

sage: f = maxima('x^2 + 17*y^2')
sage: f.diff('x')
34*y*'diff(y,x,1)+2*x
sage: f.diff('y')
34*y
```

diff(*var='x', n=1*)

Return the n-th derivative of self.

INPUT:

- var - variable (default: 'x')
- n - integer (default: 1)

OUTPUT: n-th derivative of self with respect to the variable var

EXAMPLES:

```
sage: f = maxima('x^2')
sage: f.diff()
2*x
sage: f.diff('x')
2*x
sage: f.diff('x', 2)
2
sage: maxima('sin(x^2)').diff('x',4)
16*x^4*sin(x^2)-12*sin(x^2)-48*x^2*cos(x^2)

sage: f = maxima('x^2 + 17*y^2')
sage: f.diff('x')
34*y*'diff(y,x,1)+2*x
sage: f.diff('y')
34*y
```

display2d(*onscreen=True*)

EXAMPLES:

```
sage: F = maxima('x^5 - y^5').factor()
sage: F.display2d ()
                          4      3    2  2    3      4
            - (y - x) (y  + x y  + x  y  + x  y + x )
```

dot(*other*)

Implements the notation self . other.

EXAMPLES:

```
sage: A = maxima('matrix ([a1],[a2])')
sage: B = maxima('matrix ([b1, b2])')
sage: A.dot(B)
matrix([a1*b1,a1*b2],[a2*b1,a2*b2])
```

imag()

Return the imaginary part of this maxima element.

EXAMPLES:

```
sage: maxima('2 + (2/3)*%i').imag()
2/3
```

integral(*var='x', min=None, max=None*)

Return the integral of self with respect to the variable x.

INPUT:

- var - variable
- min - default: None
- max - default: None

Returns the definite integral if xmin is not None, otherwise returns an indefinite integral.

EXAMPLES:

```
sage: maxima('x^2+1').integral()
x^3/3+x
sage: maxima('x^2+ 1 + y^2').integral('y')
y^3/3+x^2*y+y
sage: maxima('x / (x^2+1)').integral()
log(x^2+1)/2
sage: maxima('1/(x^2+1)').integral()
atan(x)
sage: maxima('1/(x^2+1)').integral('x', 0, infinity)
%pi/2
sage: maxima('x/(x^2+1)').integral('x', -1, 1)
0

sage: f = maxima('exp(x^2)').integral('x',0,1); f
-sqrt(%pi)*%i*erf(%i)/2
sage: f.numer()          # I wonder how to get a real number (~1.463)??
-.8862269254527579*%i*erf(%i)
```

integrate(*var='x', min=None, max=None*)

Return the integral of self with respect to the variable x.

INPUT:

- `var` - variable
- `min` - default: None
- `max` - default: None

Returns the definite integral if xmin is not None, otherwise returns an indefinite integral.

EXAMPLES:

```
sage: maxima('x^2+1').integral()
x^3/3+x
sage: maxima('x^2+ 1 + y^2').integral('y')
y^3/3+x^2*y+y
sage: maxima('x / (x^2+1)').integral()
log(x^2+1)/2
sage: maxima('1/(x^2+1)').integral()
atan(x)
sage: maxima('1/(x^2+1)').integral('x', 0, infinity)
%pi/2
sage: maxima('x/(x^2+1)').integral('x', -1, 1)
0

sage: f = maxima('exp(x^2)').integral('x',0,1); f
-sqrt(%pi)*%i*erf(%i)/2
sage: f.numer()          # I wonder how to get a real number (~1.463)??
-.8862269254527579*%i*erf(%i)
```

nintegral(*var='x', a=0, b=1, desired_relative_error='1e-8', maximum_num_subintervals=200*)

Return a numerical approximation to the integral of self from a to b.

INPUT:

- `var` - variable to integrate with respect to
- `a` - lower endpoint of integration
- `b` - upper endpoint of integration
- `desired_relative_error` - (default: '1e-8') the desired relative error
- `maximum_num_subintervals` - (default: 200) maxima number of subintervals

OUTPUT:

- approximation to the integral

- estimated absolute error of the approximation
- the number of integrand evaluations
- an error code:
  - 0 - no problems were encountered
  - 1 - too many subintervals were done
  - 2 - excessive roundoff error
  - 3 - extremely bad integrand behavior
  - 4 - failed to converge
  - 5 - integral is probably divergent or slowly convergent
  - 6 - the input is invalid

EXAMPLES:

```
sage: maxima('exp(-sqrt(x))').nintegral('x',0,1)
(.5284822353142306, 4.163314137883845e-11, 231, 0)
```

Note that GP also does numerical integration, and can do so to very high precision very quickly:

```
sage: gp('intnum(x=0,1,exp(-sqrt(x)))')
0.52848223531423071361790491935415653021   # 64-bit
sage: _ = gp.set_precision(80)
sage: gp('intnum(x=0,1,exp(-sqrt(x)))')
0.52848223531423071361790491935415653021675547587292866196865279321015401702040079
```

numer()

Return numerical approximation to self as a Maxima object.

EXAMPLES:

```
sage: a = maxima('sqrt(2)').numer(); a
1.414213562373095
sage: type(a)
<class 'sage.interfaces.maxima.MaximaElement'>
```

partial_fraction_decomposition(*var='x'*)

Return the partial fraction decomposition of self with respect to the variable var.

EXAMPLES:

```
sage: f = maxima('1/((1+x)*(x-1))')
sage: f.partial_fraction_decomposition('x')
1/(2*(x-1))-1/(2*(x+1))
sage: print f.partial_fraction_decomposition('x')
                      1           1
                  --------- - ---------
                  2 (x - 1)   2 (x + 1)
```

real()

Return the real part of this maxima element.

EXAMPLES:

```
sage: maxima('2 + (2/3)*%i').real()
2
```

str()

Return string representation of this maxima object.

EXAMPLES:

```
sage: maxima('sqrt(2) + 1/3').str()
'sqrt(2)+1/3'
```

subst(*val*)

Substitute a value or several values into this Maxima object.

EXAMPLES:

```
sage: maxima('a^2 + 3*a + b').subst('b=2')
a^2+3*a+2
sage: maxima('a^2 + 3*a + b').subst('a=17')
b+340
sage: maxima('a^2 + 3*a + b').subst('a=17, b=2')
342
```

trait_names(*verbose=False*)

Return all Maxima commands, which is useful for tab completion.

EXAMPLES:

```
sage: m = maxima(2)
sage: 'gcd' in m.trait_names()
True
```

class **MaximaExpectFunction**(*parent, name*)

class **MaximaFunction**(*parent, name, defn, args, latex*)

arguments(*split=True*)

Returns the arguments of this Maxima function.

EXAMPLES:

```
sage: f = maxima.function('x,y','sin(x+y)')
sage: f.arguments()
['x', 'y']
sage: f.arguments(split=False)
'x,y'
sage: f = maxima.function('', 'sin(x)')
sage: f.arguments()
[]
```

definition()

Returns the definition of this Maxima function as a string.

EXAMPLES:

```
sage: f = maxima.function('x,y','sin(x+y)')
sage: f.definition()
'sin(x+y)'
```

integral(*var*)

Returns the integral of self with respect to the variable var.

Note that integrate is an alias of integral.

EXAMPLES:

```
sage: x,y = var('x,y')
sage: f = maxima.function('x','sin(x)')
sage: f.integral(x)
-cos(x)
sage: f.integral(y)
sin(x)*y
```

integrate(*var*)

Returns the integral of self with respect to the variable var.

Note that integrate is an alias of integral.

EXAMPLES:

```
sage: x,y = var('x,y')
sage: f = maxima.function('x','sin(x)')
sage: f.integral(x)
-cos(x)
sage: f.integral(y)
sin(x)*y
```

class MaximaFunctionElement(*obj, name*)

is_MaximaElement(*x*)

Returns True if x is of type MaximaElement.

EXAMPLES:

```
sage: from sage.interfaces.maxima import is_MaximaElement
sage: m = maxima(1)
sage: is_MaximaElement(m)
True
sage: is_MaximaElement(1)
False
```

maxima_console()

Spawn a new Maxima command-line session.

EXAMPLES:

```
sage: from sage.interfaces.maxima import maxima_console
sage: maxima_console()                    # not tested
Maxima 5.16.3 http://maxima.sourceforge.net
...
```

maxima_version()

EXAMPLES:

```
sage: from sage.interfaces.maxima import maxima_version
sage: maxima_version()
'5.16.3'
```

reduce_load_Maxima()

EXAMPLES:

```
sage: from sage.interfaces.maxima import reduce_load_Maxima
sage: reduce_load_Maxima()
Maxima
```

reduce_load_Maxima_function(*parent, defn, args, latex*)

13.11 Interface to Mathematica

The Mathematica interface will only work if Mathematica is installed on your computer with a command line interface that runs when you give the `math` command. The interface offers three pieces of functionality:

1. `mathematica_console()` - A function that dumps you into an interactive command-line Mathematica session. This is an enhanced version of the usual Mathematica command-line, in that it provides readline editing and history (the usual one doesn't!)

2. `mathematica(expr)` - Creation of a Sage object that wraps a Mathematica object. This provides a Pythonic interface to Mathematica. For example, if `f=mathematica('x2-1')`, then `f.Factor()` returns the factorization of $x^2 - 1$ computed using Mathematica.

3. `mathematica.eval(expr)` - Evaluation of arbitrary Mathematica expressions, with the result returned as a string.

13.11.1 Tutorial

We follow some of the tutorial from http://library.wolfram.com/conferences/devconf99/withoff/Basic1.html/.

For any of this to work you must buy and install the Mathematica program, and it must be available as the command `math` in your PATH.

Syntax

Now make 1 and add it to itself. The result is a Mathematica object.

```
sage: m = mathematica
sage: a = m(1) + m(1); a                # optional - mathematica
2
sage: a.parent()                        # optional - mathematica
Mathematica
sage: m('1+1')                          # optional - mathematica
2
sage: m(3)**m(50)                       # optional - mathematica
717897987691852588770249
```

The following is equivalent to `Plus[2, 3]` in Mathematica:

```
sage: m = mathematica
sage: m(2).Plus(m(3))                   # optional - mathematica
5
```

We can also compute $7(2 + 3)$.

```
sage: m(7).Times(m(2).Plus(m(3)))       # optional - mathematica
35
sage: m('7(2+3)')                       # optional - mathematica
35
```

Some typical input

We solve an equation and a system of two equations:

```
sage: eqn = mathematica('3x + 5 == 14') # optional - mathematica
sage: eqn                               # optional - mathematica
5 + 3*x == 14
sage: eqn.Solve('x')                    # optional - mathematica
{{x -> 3}}
```

```
sage: sys = mathematica('{x^2 - 3y == 3, 2x - y == 1}')  # optional - mathematica
sage: print sys                          # optional - mathematica
          2
        {x  - 3 y == 3, 2 x - y == 1}
sage: sys.Solve('{x, y}')                # optional - mathematica
{{y -> -1, x -> 0}, {y -> 11, x -> 6}}
```

Assignments and definitions

If you assign the mathematica 5 to a variable c in Sage, this does not affect the c in Mathematica.

```
sage: c = m(5)                           # optional - mathematica
sage: print m('b + c x')                 # optional - mathematica
            b + c x
sage: print m('b') + c*m('x')            # optional - mathematica
        b + 5 x
```

The Sage interfaces changes Sage lists into Mathematica lists:

```
sage: m = mathematica
sage: eq1 = m('x^2 - 3y == 3')           # optional - mathematica
sage: eq2 = m('2x - y == 1')             # optional - mathematica
sage: v = m([eq1, eq2]); v               # optional - mathematica
{x^2 - 3*y == 3, 2*x - y == 1}
sage: v.Solve(['x', 'y'])                # optional - mathematica
{{y -> -1, x -> 0}, {y -> 11, x -> 6}}
```

Function definitions

Define mathematica functions by simply sending the definition to the interpreter.

```
sage: m = mathematica
sage: _ = mathematica('f[p_] = p^2');    # optional - mathematica
sage: m('f[9]')                          # optional - mathematica
81
```

Numerical Calculations

We find the x such that $e^x - 3x = 0$.

```
sage: e = mathematica('Exp[x] - 3x == 0') # optional - mathematica
sage: e.FindRoot(['x', 2])               # optional - mathematica
{x -> 1.512134551657842}
```

Note that this agrees with what the PARI interpreter gp produces:

```
sage: gp('solve(x=1,2,exp(x)-3*x)')
1.5121345516578424738967396780720387046    # 64-bit
1.5121345516578424738967396780720387046    # 64-bit
```

Next we find the minimimum of a polynomial using the two different ways of accessing Mathematica:

```
sage: mathematica('FindMinimum[x^3 - 6x^2 + 11x - 5, {x,3}]')  # optional - mathematica
{0.6150998205402516, {x -> 2.5773502699629733}}
sage: f = mathematica('x^3 - 6x^2 + 11x - 5')  # optional - mathematica
sage: f.FindMinimum(['x', 3])                  # optional - mathematica
{0.6150998205402516, {x -> 2.5773502699629733}}
```

Polynomial and Integer Factorization

We factor a polynomial of degree 200 over the integers.

```
sage: R.<x> = PolynomialRing(ZZ)
sage: f = (x**100+17*x+5)*(x**100-5*x+20)
sage: f
x^200 + 12*x^101 + 25*x^100 - 85*x^2 + 315*x + 100
sage: g = mathematica(str(f))            # optional - mathematica
sage: print g                            # optional - mathematica
                          2       100       101    200
        100 + 315 x - 85 x  + 25 x    + 12 x    + x
sage: g                                  # optional - mathematica
100 + 315*x - 85*x^2 + 25*x^100 + 12*x^101 + x^200
sage: print g.Factor()                   # optional - mathematica
                     100               100
        (20 - 5 x + x    ) (5 + 17 x + x    )
```

We can also factor a multivariate polynomial:

```
sage: f = mathematica('x^6 + (-y - 2)*x^5 + (y^3 + 2*y)*x^4 - y^4*x^3')  # optional - mathematica
sage: print f.Factor()                   # optional - mathematica
         3                   2    3
        x  (x - y) (-2 x + x  + y )
```

We factor an integer:

```
sage: n = mathematica(2434500)           # optional - mathematica
sage: n.FactorInteger()                  # optional - mathematica
{{2, 2}, {3, 2}, {5, 3}, {541, 1}}       # optional - mathematica
sage: n = mathematica(2434500)           # optional - mathematica
sage: F = n.FactorInteger(); F           # optional - mathematica
{{2, 2}, {3, 2}, {5, 3}, {541, 1}}
sage: F[1]                               # optional - mathematica
{2, 2}
sage: F[4]                               # optional - mathematica
{541, 1}
```

We can also load the ECM package and factoring using it:

```
sage: _ = mathematica.eval("<<NumberTheory`FactorIntegerECM`");  # optional - mathematica
sage: mathematica.FactorIntegerECM('932901*939321')              # optional - mathematica
8396109
```

13.11.2 Long Input

The Mathematica interface reads in even very long input (using files) in a robust manner.

```
sage: t = '"%s"'%10^10000   # ten thousand character string.
sage: a = mathematica(t)        # optional - mathematica
sage: a = mathematica.eval(t)   # optional - mathematica
```

13.11.3 Loading and saving

Mathematica has an excellent `InputForm` function, which makes saving and loading Mathematica objects possible. The first examples test saving and loading to strings.

```
sage: x = mathematica(pi/2)     # optional - mathematica
sage: print x                   # optional - mathematica
        Pi
        --
        2
sage: loads(dumps(x)) == x      # optional - mathematica
True
sage: n = x.N(50)               # optional - mathematica
sage: print n                   # optional - mathematica
             1.5707963267948966192313216916397514420985846996876
sage: loads(dumps(n)) == n      # optional - mathematica
True
```

OTHER Examples:

```
sage: def math_bessel_K(nu,x):
...       return mathematica(nu).BesselK(x).N(20).sage()
...
sage: math_bessel_K(2,I)                      # optional - mathematica
0.180489972066962*I - 2.592886175491197
```

AUTHORS:

- William Stein (2005): first version
- Doug Cutrell (2006-03-01): Instructions for use under Cygwin/Windows.

class **Mathematica**(*maxread=100, script_subdirectory='', logfile=None, server=None, server_tmpdir=None*)
Interface to the Mathematica interpreter.

chdir(*dir*)
Change Mathematica's current working directory.
EXAMPLES:

```
sage: mathematica.chdir('/')           # optional
sage: mathematica('Directory[]')       # optional
"/"
```

console(*readline=True*)

eval(*code, strip=True, **kwds*)

get(*var, ascii_art=False*)
Get the value of the variable var.
AUTHORS:
•William Stein
•Kiran Kedlaya (2006-02-04): suggested using InputForm

help(*cmd*)

set(*var, value*)
Set the variable var to the given value.

trait_names()

class **MathematicaElement**(*parent, value, is_name=False, name=None*)

show(*filename=None, ImageSize=600*)
Show a mathematica expression or plot in the Sage notebook.
EXAMPLES:

```
sage: P = mathematica('Plot[Sin[x],{x,-2Pi,4Pi}]')    # optional - mathematica
sage: show(P)                                         # optional - mathematica
sage: P.show(ImageSize=800)                           # optional - mathematica
sage: Q = mathematica('Sin[x Cos[y]]/Sqrt[1-x^2]')    # optional - mathematica
sage: show(Q)                                         # optional - mathematica
<html><div class="math">\frac{\sin (x \cos (y))}{\sqrt{1-x^2}}</div></html>
```

str()

class **MathematicaFunction**(*parent, name*)

class **MathematicaFunctionElement**(*obj, name*)

clean_output(*s*)

mathematica_console(*readline=True*)

reduce_load(*X*)

13.12 Interface to mwrank

Mwrank(*options='', server=None, server_tmpdir=None*)
Create and return an mwrank interpreter, with given options.
INPUT:

- `options` - string; passed when starting mwrank. The format is q pprecision vverbosity bhlim_q xnaux chlim_c l t o s d]

class **Mwrank_class**(*options='', server=None, server_tmpdir=None*)
Interface to the Mwrank interpreter.

console()

eval(**args, **kwds*)
Send a line of input to mwrank, then when it finishes return everything that mwrank output.
NOTE: If a RuntimeError exception is raised, then the mwrank interface is restarted and the command is retried once.

EXAMPLES: sage: mwrank.eval('12 3 4 5 6') 'Curve [12,3,4,5,6] :...'

quit(*verbose=False*)
Quit the mwrank process using kill -9 (so exit doesn't dump core, etc.).

INPUT: verbose – ignored

EXAMPLES: sage: m = Mwrank() sage: e = m('1 2 3 4 5') sage: m.quit()

mwrank_console()

13.13 Interface to Octave

Octave is an open source MATLAB-like program with numerical routines for integrating, solving systems of equations, special functions, and solving (numerically) differential equations. Please see http://octave.sourceforge.net for more details.

The commands in this section only work if you have the optional "octave" interpreter installed and available in your PATH. It's not necessary to install any special Sage packages.

EXAMPLES:

```
sage: octave.eval('2+2')     # optional -- requires Octave
'ans = 4'

sage: a = octave(10)         # optional -- requires Octave
sage: a**10                  # optional -- requires Octave
1e+10
```

LOG: - creation (William Stein) - ? (David Joyner, 2005-12-18) - Examples (David Joyner, 2005-01-03)

13.13.1 Computation of Special Functions

Octave implements computation of the following special functions (see the maxima and gp interfaces for even more special functions):

```
airy
    Airy functions of the first and second kind, and their derivatives.
    airy(0,x) = Ai(x), airy(1,x) = Ai'(x), airy(2,x) = Bi(x), airy(3,x) = Bi'(x)
besselj
    Bessel functions of the first kind.
bessely
    Bessel functions of the second kind.
besseli
    Modified Bessel functions of the first kind.
besselk
    Modified Bessel functions of the second kind.
besselh
    Compute Hankel functions of the first (k = 1) or second (k = 2) kind.
beta
    The Beta function,
          beta (a, b) = gamma (a) * gamma (b) / gamma (a + b).
betainc
    The incomplete Beta function,
erf
    The error function,
erfinv
    The inverse of the error function.
gamma
    The Gamma function,
gammainc
    The incomplete gamma function,
```

For example,

```
sage: octave("airy(3,2)")          # optional -- requires Octave
4.10068
```

```
sage: octave("beta(2,2)")          # optional -- requires Octave
0.166667
sage: octave("betainc(0.2,2,2)")   # optional -- requires Octave
0.104
sage: octave("besselh(0,2)")       # optional -- requires Octave
(0.223891,0.510376)
sage: octave("besselh(0,1)")       # optional -- requires Octave
(0.765198,0.088257)
sage: octave("besseli(1,2)")       # optional -- requires Octave
1.59064
sage: octave("besselj(1,2)")       # optional -- requires Octave
0.576725
sage: octave("besselk(1,2)")       # optional -- requires Octave
0.139866
sage: octave("erf(0)")             # optional -- requires Octave
0
sage: octave("erf(1)")             # optional -- requires Octave
0.842701
sage: octave("erfinv(0.842)")      # optional -- requires Octave
0.998315
sage: octave("gamma(1.5)")         # optional -- requires Octave
0.886227
sage: octave("gammainc(1.5,1)")    # optional -- requires Octave
0.77687
```

The Octave interface reads in even very long input (using files) in a robust manner:

```
sage: t = '"%s"'%10^10000   # ten thousand character string.
sage: a = octave.eval(t + ';')     # optional -- requires Octave, < 1/100th of a second
sage: a = octave(t)                # optional -- requires Octave
```

Note that actually reading a back out takes forever. This *must* be fixed ASAP - see http://trac.sagemath.org/sage_trac/ticket/940/.

13.13.2 Tutorial

EXAMPLES:

```
sage: octave('4+10')               # optional -- requires Octave
14
sage: octave('date')               # optional -- requires Octave; random output
18-Oct-2007
sage: octave('5*10 + 6')           # optional -- requires Octave
56
sage: octave('(6+6)/3')            # optional -- requires Octave
4
sage: octave('9')^2                # optional -- requires Octave
81
sage: a = octave(10); b = octave(20); c = octave(30)    # optional -- requires Octave
sage: avg = (a+b+c)/3              # optional -- requires Octave
sage: avg                          # optional -- requires Octave
20
sage: parent(avg)                  # optional -- requires Octave
Octave
```

```
sage: my_scalar = octave('3.1415')        # optional -- requires Octave
sage: my_scalar                           # optional -- requires Octave
3.1415
sage: my_vector1 = octave('[1,5,7]')      # optional -- requires Octave
sage: my_vector1                          # optional -- requires Octave
1     5     7
sage: my_vector2 = octave('[1;5;7]')      # optional -- requires Octave
sage: my_vector2                          # optional -- requires Octave
1
5
7
sage: my_vector1 * my_vector2             # optional -- requires Octave
75
```

class **Octave**(*maxread=100, script_subdirectory='', logfile=None, server=None, server_tmpdir=None*)

Interface to the Octave interpreter.

EXAMPLES:

```
sage: octave.eval("a = [ 1, 1, 2; 3, 5, 8; 13, 21, 33 ]")     # optional -- requires Octave
'a =\n\n 1 1 2\n 3 5 8\n 13 21 33\n\n'
sage: octave.eval("b = [ 1; 3; 13]")                          # optional -- requires Octave
'b =\n\n 1\n 3\n 13\n\n'
sage: octave.eval("c=a \\ b") # solves linear equation: a*c = b  # optional -- requires Octave;
'c =\n\n 1\n 7.21645e-16\n -7.21645e-16\n\n'
sage: octave.eval("c")                                  # optional -- requires Octave; random out
'c =\n\n 1\n 7.21645e-16\n -7.21645e-16\n\n'
```

clear(*var*)

Clear the variable named var.

EXAMPLES:

```
sage: octave.set('x', '2') #optional -- requires Octave
sage: octave.clear('x') #optional -- requires Octave
sage: octave.get('x') #optional -- requires Octave
"error: 'x' undefined near line ... column 1"
```

console()

Spawn a new Octave command-line session.

This requires that the optional octave program be installed and in your PATH, but no optional Sage packages need be installed.

EXAMPLES:

```
sage: octave_console()          # not tested
GNU Octave, version 2.1.73 (i386-apple-darwin8.5.3).
Copyright (C) 2006 John W. Eaton.
...
octave:1> 2+3
ans = 5
octave:2> [ctl-d]
```

Pressing ctrl-d exits the octave console and returns you to Sage. octave, like Sage, remembers its history from one session to another.

de_system_plot(*f, ics, trange*)

Plots (using octave's interface to gnuplot) the solution to a 2×2 system of differential equations.

INPUT:

- `f` - a pair of strings representing the differential equations; The independent variable must be called x and the dependent variable must be called y.

- `ics` - a pair [x0,y0] such that x(t0) = x0, y(t0) = y0
- `trange` - a pair [t0,t1]

OUTPUT: a gnuplot window appears

EXAMPLES:

```
sage: octave.de_system_plot(['x+y','x-y'], [1,-1], [0,2])  # not tested -- does this actuall
```

This should yield the two plots $(t, x(t)), (t, y(t))$ on the same graph (the t-axis is the horizonal axis) of the system of ODEs

$$x' = x + y, x(0) = 1; \qquad y' = x - y, y(0) = -1, \quad \text{for} \quad 0 < t < 2.$$

get (*var*)

Get the value of the variable var.

EXAMPLES:

```
sage: octave.set('x', '2') #optional -- requires Octave
sage: octave.get('x') #optional -- requires Octave
' 2'
```

quit (*verbose=False*)

EXAMPLES:

```
sage: o = Octave()
sage: o._start()    #optional -- requires Octave
sage: o.quit(True)  #optional -- requires Octave
Exiting spawned Octave process.
```

sage2octave_matrix_string (*A*)

Return an octave matrix from a Sage matrix.

INPUT: A Sage matrix with entries in the rationals or reals.

OUTPUT: A string that evaluates to an Octave matrix.

EXAMPLES:

```
sage: M33 = MatrixSpace(QQ,3,3)
sage: A = M33([1,2,3,4,5,6,7,8,0])
sage: octave.sage2octave_matrix_string(A)    # optional -- requires Octave
'[1, 2, 3; 4, 5, 6; 7, 8, 0]'
```

AUTHORS:

- David Joyner and William Stein

set (*var, value*)

Set the variable var to the given value.

EXAMPLES:

```
sage: octave.set('x', '2') #optional -- requires Octave
sage: octave.get('x') #optional -- requires Octave
' 2'
```

solve_linear_system (*A, b*)

Use octave to compute a solution x to A*x = b, as a list.

INPUT:

- `A` - mxn matrix A with entries in QQ or RR
- `b` - m-vector b entries in QQ or RR (resp)

OUTPUT: An list x (if it exists) which solves M*x = b

EXAMPLES:

```
sage: M33 = MatrixSpace(QQ,3,3)
sage: A   = M33([1,2,3,4,5,6,7,8,0])
sage: V3  = VectorSpace(QQ,3)
sage: b   = V3([1,2,3])
sage: octave.solve_linear_system(A,b)     # optional -- requires Octave (and output is slight
[-0.33333299999999999, 0.66666700000000001, -3.5236600000000002e-18]
```

AUTHORS:

- David Joyner and William Stein

version()

Return the version of Octave.

OUTPUT: string

EXAMPLES:

```
sage: octave.version()    # optional -- requires Octave; random output depending on version
'2.1.73'
```

class OctaveElement(*parent, value, is_name=False, name=None*)

octave_console()

Spawn a new Octave command-line session.

This requires that the optional octave program be installed and in your PATH, but no optional Sage packages need be installed.

EXAMPLES:

```
sage: octave_console()          # not tested
GNU Octave, version 2.1.73 (i386-apple-darwin8.5.3).
Copyright (C) 2006 John W. Eaton.
...
octave:1> 2+3
ans = 5
octave:2> [ctl-d]
```

Pressing ctrl-d exits the octave console and returns you to Sage. octave, like Sage, remembers its history from one session to another.

octave_version()

Return the version of Octave installed.

EXAMPLES:

```
sage: octave_version()     # optional -- requires Octave; and output is random
'2.9.12'
```

reduce_load_Octave()

EXAMPLES:

```
sage: from sage.interfaces.octave import reduce_load_Octave
sage: reduce_load_Octave()
Octave
```

13.14 Interface to Sage

This is an expect interface to *another* copy of the Sage interpreter.

class Sage (*logfile=None, preparse=True, python=False, init_code=None, server=None, server_tmpdir=None, remote_cleaner=True, **kwds*)

Expect interface to the Sage interpreter itself.

INPUT:

- `server` - (optional); if specified runs Sage on a remote machine with address. You must have ssh keys setup so you can login to the remote machine by typing "ssh remote_machine" and no password, call _install_hints_ssh() for hints on how to do that.

The version of Sage should be the same as on the local machine, since pickling is used to move data between the two Sage process.

EXAMPLES: We create an interface to a copy of Sage. This copy of Sage runs as an external process with its own memory space, etc.

```
sage: s = Sage()
```

Create the element 2 in our new copy of Sage, and cubeit.

```
sage: a = s(2)
sage: a^3
8
```

Create a vector space of dimension 4, and compute its generators:

```
sage: V = s('QQ^4')
sage: V.gens()
((1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1))
```

Note that V is a not a vector space, it's a wrapper around an object (which happens to be a vector space), in another running instance of Sage.

```
sage: type(V)
<class 'sage.interfaces.sage0.SageElement'>
sage: V.parent()
Sage
sage: g = V.0;  g
(1, 0, 0, 0)
sage: g.parent()
Sage
```

We can still get the actual parent by using the name attribute of g, which is the variable name of the object in the child process.

```
sage: s('%s.parent()'%g.name())
Vector space of dimension 4 over Rational Field
```

Note that the memory space is completely different.

```
sage: x = 10
sage: s('x = 5')
5
sage: x
10
sage: s('x')
5
```

We can have the child interpreter itself make another child Sage process, so now three copies of Sage are running:

```
sage: s3 = s('Sage()')
sage: a = s3(10)
sage: a
10
```

This $a = 10$ is in a subprocess of a subprocesses of your original Sage.

```
sage: _ = s.eval('%s.eval("x=8")'%s3.name())
sage: s3('"x"')
8
sage: s('x')
5
sage: x
10
```

The double quotes are needed because the call to s3 first evaluates its arguments using the s interpeter, so the call to s3 is passed `s('"x"')`, which is the string `"x"` in the s interpreter.

clear(*var*)

Clear the variable named var.

EXAMPLES:

```
sage: sage0.set('x', '2')
sage: sage0.get('x')
'2'
sage: sage0.clear('x')
sage: sage0.get('x')
"...NameError: name 'x' is not defined"
```

console()

Spawn a new Sage command-line session.

EXAMPLES:

```
sage: sage0.console() #not tested
--------------------------------------------------------------------------
| Sage Version ..., Release Date: ...                                    |
| Type notebook() for the GUI, and license() for information.            |
--------------------------------------------------------------------------
...
```

cputime(*t=None*)

Return cputime since this Sage subprocess was started.

EXAMPLES:

```
sage: sage0.cputime()      # random output
1.3530439999999999
sage: sage0('factor(2^157-1)')
852133201 * 60726444167 * 1654058017289 * 2134387368610417
sage: sage0.cputime()      # random output
1.6462939999999999
```

eval(*line, strip=True, **kwds*)

Send the code x to a second instance of the Sage interpreter and return the output as a string.

This allows you to run two completely independent copies of Sage at the same time in a unified way.

INPUT:

- `line` - input line of code
- `strip` - ignored

EXAMPLES:

```
sage: sage0.eval('2+2')
'4'
```

get(*var*)
Get the value of the variable var.
EXAMPLES:

```
sage: sage0.set('x', '2')
sage: sage0.get('x')
'2'
```

new(*x*)
EXAMPLES:

```
sage: sage0.new(2)
2
sage: _.parent()
Sage
```

preparse(*x*)
Returns the preparsed version of the string s.
EXAMPLES:

```
sage: sage0.preparse('2+2')
'Integer(2)+Integer(2)'
```

quit(*verbose=False*)
EXAMPLES:

```
sage: s = Sage()
sage: s.eval('2+2')
'4'
sage: s.quit()
```

set(*var, value*)
Set the variable var to the given value.
EXAMPLES:

```
sage: sage0.set('x', '2')
sage: sage0.get('x')
'2'
```

trait_names()
EXAMPLES:

```
sage: t = sage0.trait_names()
sage: len(t) > 100
True
sage: 'gcd' in t
True
```

version()
EXAMPLES:

```
sage: sage0.version()
'Sage Version ..., Release Date: ...'
sage: sage0.version() == version()
True
```

class SageElement(*parent, value, is_name=False, name=None*)

class SageFunction(*obj*, *name*)

reduce_load_Sage()
EXAMPLES:

```
sage: from sage.interfaces.sage0 import reduce_load_Sage
sage: reduce_load_Sage()
Sage
```

reduce_load_element(*s*)
EXAMPLES:

```
sage: from sage.interfaces.sage0 import reduce_load_element
sage: s = dumps(1/2)
sage: half = reduce_load_element(s); half
1/2
sage: half.parent()
Sage
```

sage0_console()
Spawn a new Sage command-line session.

EXAMPLES:

```
sage: sage0_console() #not tested
--------------------------------------------------------------------------
| Sage Version ..., Release Date: ...                                    |
| Type notebook() for the GUI, and license() for information.            |
--------------------------------------------------------------------------
...
```

sage0_version()
EXAMPLES:

```
sage: from sage.interfaces.sage0 import sage0_version
sage: sage0_version() == version()
True
```

13.15 Interface to Singular

AUTHORS:

- David Joyner and William Stein (2005): first version
- Martin Albrecht (2006-03-05): code so singular.[tab] and x = singular(...), x.[tab] includes all singular commands.
- Martin Albrecht (2006-03-06): This patch adds the equality symbol to singular. Also fix problem in which" " as prompt means comparison will break all further communication with Singular.
- Martin Albrecht (2006-03-13): added current_ring() and current_ring_name()
- William Stein (2006-04-10): Fixed problems with ideal constructor
- Martin Albrecht (2006-05-18): added sage_poly.

13.15.1 Introduction

This interface is extremely flexible, since it's exactly like typing into the Singular interpreter, and anything that works there should work here.

The Singular interface will only work if Singular is installed on your computer; this should be the case, since Singular is included with Sage. The interface offers three pieces of functionality:

1. `singular_console()` - A function that dumps you into an interactive command-line Singular session.
2. `singular(expr, type='def')` - Creation of a Singular object. This provides a Pythonic interface to Singular. For example, if `f=singular(10)`, then `f.factorize()` returns the factorization of 10 computed using Singular.
3. `singular.eval(expr)` - Evaluation of arbitrary Singular expressions, with the result returned as a string.

13.15.2 Tutorial

EXAMPLES: First we illustrate multivariate polynomial factorization:

```
sage: R1 = singular.ring(0, '(x,y)', 'dp')
sage: R1
//   characteristic : 0
//   number of vars : 2
//        block   1 : ordering dp
//                  : names    x y
//        block   2 : ordering C
sage: f = singular('9x16 - 18x13y2 - 9x12y3 + 9x10y4 - 18x11y2 + 36x8y4 + 18x7y5 - 18x5y6 + 9x6y4 - 1
sage: f
9*x^16-18*x^13*y^2-9*x^12*y^3+9*x^10*y^4-18*x^11*y^2+36*x^8*y^4+18*x^7*y^5-18*x^5*y^6+9*x^6*y^4-18*x
sage: f.parent()
Singular

sage: F = f.factorize(); F
[1]:
   _[1]=9
   _[2]=x^6-2*x^3*y^2-x^2*y^3+y^4
   _[3]=-x^5+y^2
[2]:
   1,1,2

sage: F[1]
9,
x^6-2*x^3*y^2-x^2*y^3+y^4,
-x^5+y^2
sage: F[1][2]
x^6-2*x^3*y^2-x^2*y^3+y^4
```

We can convert f and each exponent back to Sage objects as well.

```
sage: R.<x, y> = PolynomialRing(QQ,2)
sage: g = eval(f.sage_polystring()); g
9*x^16 - 18*x^13*y^2 - 9*x^12*y^3 + 9*x^10*y^4 - 18*x^11*y^2 + 36*x^8*y^4 + 18*x^7*y^5 - 18*x^5*y^6 -
sage: eval(F[1][2].sage_polystring())
x^6 - 2*x^3*y^2 - x^2*y^3 + y^4
```

This example illustrates polynomial GCD's:

```
sage: R2 = singular.ring(0, '(x,y,z)', 'lp')
sage: a = singular.new('3x2*(x+y)')
sage: b = singular.new('9x*(y2-x2)')
sage: g = a.gcd(b)
sage: g
x^2+x*y
```

This example illustrates computation of a Groebner basis:

```
sage: R3 = singular.ring(0, '(a,b,c,d)', 'lp')
sage: I = singular.ideal(['a + b + c + d', 'a*b + a*d + b*c + c*d', 'a*b*c + a*b*d + a*c*d + b*c*d',
sage: I2 = I.groebner()
sage: I2
c^2*d^6-c^2*d^2-d^4+1,
c^3*d^2+c^2*d^3-c-d,
b*d^4-b+d^5-d,
b*c-b*d^5+c^2*d^4+c*d-d^6-d^2,
b^2+2*b*d+d^2,
a+b+c+d
```

The following example is the same as the one in the Singular - Gap interface documentation:

```
sage: R  = singular.ring(0, '(x0,x1,x2)', 'lp')
sage: I1 = singular.ideal(['x0*x1*x2 -x0^2*x2', 'x0^2*x1*x2-x0*x1^2*x2-x0*x1*x2^2', 'x0*x1-x0*x2-x1*x
sage: I2 = I1.groebner()
sage: I2
x1^2*x2^2,
x0*x2^3-x1^2*x2^2+x1*x2^3,
x0*x1-x0*x2-x1*x2,
x0^2*x2-x0*x1*x2
```

This example illustrates moving a polynomial from one ring to another. It also illustrates calling a method of an object with an argument.

```
sage: R = singular.ring(0, '(x,y,z)', 'dp')
sage: f = singular('x3+y3+(x-y)*x2y2+z2')
sage: f
x^3*y^2-x^2*y^3+x^3+y^3+z^2
sage: R1 = singular.ring(0, '(x,y,z)', 'ds')
sage: f = R.fetch(f)
sage: f
z^2+x^3+y^3+x^3*y^2-x^2*y^3
```

We can calculate the Milnor number of f:

```
sage: _=singular.LIB('sing.lib')      # assign to _ to suppress printing
sage: f.milnor()
4
```

The Jacobian applied twice yields the Hessian matrix of f, with which we can compute.

```
sage: H = f.jacob().jacob()
sage: H
6*x+6*x*y^2-2*y^3,6*x^2*y-6*x*y^2,  0,
6*x^2*y-6*x*y^2,  6*y+2*x^3-6*x^2*y,0,
```

```
0,                0,                2
sage: H.det()
72*x*y+24*x^4-72*x^3*y+72*x*y^3-24*y^4-48*x^4*y^2+64*x^3*y^3-48*x^2*y^4
```

The 1x1 and 2x2 minors:

```
sage: H.minor(1)
2,
6*y+2*x^3-6*x^2*y,
6*x^2*y-6*x*y^2,
6*x^2*y-6*x*y^2,
6*x+6*x*y^2-2*y^3
sage: H.minor(2)
12*y+4*x^3-12*x^2*y,
12*x^2*y-12*x*y^2,
12*x^2*y-12*x*y^2,
12*x+12*x*y^2-4*y^3,
-36*x*y-12*x^4+36*x^3*y-36*x*y^3+12*y^4+24*x^4*y^2-32*x^3*y^3+24*x^2*y^4
```

```
sage: _=singular.eval('option(redSB)')
sage: H.minor(1).groebner()
1
```

13.15.3 Computing the Genus

We compute the projective genus of ideals that define curves over $\mathbf{Q}$. It is *very important* to load the `normal.lib` library before calling the `genus` command, or you'll get an error message.

EXAMPLE:

```
sage: singular.lib('normal.lib')
sage: R = singular.ring(0,'(x,y)','dp')
sage: i2 = singular.ideal('y9 - x2*(x-1)^9 + x')
sage: i2.genus()
40
```

Note that the genus can be much smaller than the degree:

```
sage: i = singular.ideal('y9 - x2*(x-1)^9')
sage: i.genus()
0
```

13.15.4 An Important Concept

AUTHORS:

- Neal Harris

The following illustrates an important concept: how Sage interacts with the data being used and returned by Singular. Let's compute a Groebner basis for some ideal, using Singular through Sage.

```
sage: singular.lib('poly.lib')
sage: singular.ring(32003, '(a,b,c,d,e,f)', 'lp')
        //   characteristic : 32003
        //   number of vars : 6
        //        block   1 : ordering lp
        //                  : names    a b c d e f
        //        block   2 : ordering C
sage: I = singular.ideal('cyclic(6)')
sage: g = singular('groebner(I)')
...
TypeError: Singular error:
...
```

We restart everything and try again, but correctly.

```
sage: singular.quit()
sage: singular.lib('poly.lib'); R = singular.ring(32003, '(a,b,c,d,e,f)', 'lp')
sage: I = singular.ideal('cyclic(6)')
sage: I.groebner()
f^48-2554*f^42-15674*f^36+12326*f^30-12326*f^18+15674*f^12+2554*f^6-1,
...
```

It's important to understand why the first attempt at computing a basis failed. The line where we gave singular the input 'groebner(I)' was useless because Singular has no idea what 'I' is! Although 'I' is an object that we computed with calls to Singular functions, it actually lives in Sage. As a consequence, the name 'I' means nothing to Singular. When we called `I.groebner()`, Sage was able to call the groebner function on'I' in Singular, since 'I' actually means something to Sage.

13.15.5 Long Input

The Singular interface reads in even very long input (using files) in a robust manner, as long as you are creating a new object.

```
sage: t = '"%s"'%10^15000   # 15 thousand character string (note that normal Singular input must be a
sage: a = singular.eval(t)
sage: a = singular(t)
```

TESTS: We test an automatic coercion:

```
sage: a = 3*singular('2'); a
6
sage: type(a)
<class 'sage.interfaces.singular.SingularElement'>
sage: a = singular('2')*3; a
6
sage: type(a)
<class 'sage.interfaces.singular.SingularElement'>
```

class **Singular**(*maxread=1000, script_subdirectory=None, logfile=None, server=None, server_tmpdir=None*)

Interface to the Singular interpreter.

EXAMPLES: A Groebner basis example.

```
sage: R = singular.ring(0, '(x0,x1,x2)', 'lp')
sage: I = singular.ideal([ 'x0*x1*x2 -x0^2*x2', 'x0^2*x1*x2-x0*x1^2*x2-x0*x1*x2^2', 'x0*x1-x0*x2
```

```
sage: I.groebner()
x1^2*x2^2,
x0*x2^3-x1^2*x2^2+x1*x2^3,
x0*x1-x0*x2-x1*x2,
x0^2*x2-x0*x1*x2
```

AUTHORS:

- David Joyner and William Stein

LIB(*lib, reload=False*)

Load the Singular library named lib.

Note that if the library was already loaded during this session it is not reloaded unless the optional reload argument is True (the default is False).

EXAMPLES:

```
sage: singular.lib('sing.lib')
sage: singular.lib('sing.lib', reload=True)
```

clear(*var*)

Clear the variable named var.

EXAMPLES:

```
sage: singular.set('int', 'x', '2')
sage: singular.get('x')
'2'
sage: singular.clear('x')
sage: singular.get('x')
''x''
```

console()

EXAMPLES:

```
sage: singular_console() #not tested
                     SINGULAR                                /  Development
 A Computer Algebra System for Polynomial Computations     /   version 3-0-4
                                                         0<
     by: G.-M. Greuel, G. Pfister, H. Schoenemann          \   Nov 2007
FB Mathematik der Universitaet, D-67653 Kaiserslautern
```

cputime(*t=None*)

Returns the amount of CPU time that the Singular session has used. If `t` is not None, then it returns the difference between the current CPU time and `t`.

EXAMPLES:

```
sage: t = singular.cputime()
sage: R = singular.ring(0, '(x0,x1,x2)', 'lp')
sage: I = singular.ideal([ 'x0*x1*x2 -x0^2*x2', 'x0^2*x1*x2-x0*x1^2*x2-x0*x1*x2^2', 'x0*x1-x
sage: gb = I.groebner()
sage: singular.cputime(t) #random
0.02
```

current_ring()

Returns the current ring of the runnging Singular session.

EXAMPLES:

```
sage: r = PolynomialRing(GF(127),3,'xyz', order='invlex')
sage: r._singular_()
//   characteristic : 127
```

```
//   number of vars : 3
//        block   1 : ordering rp
//                  : names    x y z
//        block   2 : ordering C
sage: singular.current_ring()
//   characteristic : 127
//   number of vars : 3
//        block   1 : ordering rp
//                  : names    x y z
//        block   2 : ordering C
```

current_ring_name()

Returns the Singular name of the currently active ring in Singular.

OUTPUT: currently active ring's name

EXAMPLES:

```
sage: r = PolynomialRing(GF(127),3,'xyz')
sage: r._singular_().name() == singular.current_ring_name()
True
```

eval(*x, allow_semicolon=True, strip=True, **kwds*)

Send the code x to the Singular interpreter and return the output as a string.

INPUT:

- x - string (of code)
- allow_semicolon - default: False; if False then raise a TypeError if the input line contains a semicolon.
- strip - ignored

EXAMPLES:

```
sage: singular.eval('2 > 1')
'1'
sage: singular.eval('2 + 2')
'4'
```

if the verbosity level is > 1 comments are also printed and not only returned.

```
sage: r = singular.ring(0,'(x,y,z)','dp')
sage: i = singular.ideal(['x^2','y^2','z^2'])
sage: s = i.std()
sage: singular.eval('hilb(%s)'%(s.name()))
'// 1 t^0\n// -3 t^2\n// 3 t^4\n// -1 t^6\n\n// 1 t^0\n//
3 t^1\n// 3 t^2\n// 1 t^3\n// dimension (affine) = 0\n//
degree (affine) = 8'

sage: set_verbose(1)
sage: o = singular.eval('hilb(%s)'%(s.name()))
//         1 t^0
//        -3 t^2
//         3 t^4
//        -1 t^6
//         1 t^0
//         3 t^1
//         3 t^2
//         1 t^3
// dimension (affine) = 0
// degree (affine)  = 8
```

This is mainly useful if this method is called implicitly. Because then intermediate results, debugging outputs and printed statements are printed

```
sage: o = s.hilb()
//         1 t^0
//        -3 t^2
//         3 t^4
//        -1 t^6
//         1 t^0
//         3 t^1
//         3 t^2
//         1 t^3
// dimension (affine) = 0
// degree (affine)  = 8
// ** right side is not a datum, assignment ignored
```

rather than ignored

```
sage: set_verbose(0)
sage: o = s.hilb()
```

get(*var*)

Get string representation of variable named var.

EXAMPLES:

```
sage: singular.set('int', 'x', '2')
sage: singular.get('x')
'2'
```

ideal(**gens*)

Return the ideal generated by gens.

INPUT:

- gens - list or tuple of Singular objects (or objects that can be made into Singular objects via evaluation)

OUTPUT: the Singular ideal generated by the given list of gens

EXAMPLES: A Groebner basis example done in a different way.

```
sage: _ = singular.eval("ring R=0,(x0,x1,x2),lp")
sage: i1 = singular.ideal([ 'x0*x1*x2 -x0^2*x2', 'x0^2*x1*x2-x0*x1^2*x2-x0*x1*x2^2', 'x0*x1-
sage: i1
-x0^2*x2+x0*x1*x2,
x0^2*x1*x2-x0*x1^2*x2-x0*x1*x2^2,
x0*x1-x0*x2-x1*x2

sage: i2 = singular.ideal('groebner(%s);'%i1.name())
sage: i2
x1^2*x2^2,
x0*x2^3-x1^2*x2^2+x1*x2^3,
x0*x1-x0*x2-x1*x2,
x0^2*x2-x0*x1*x2
```

lib(*lib, reload=False*)

Load the Singular library named lib.

Note that if the library was already loaded during this session it is not reloaded unless the optional reload argument is True (the default is False).

EXAMPLES:

```
sage: singular.lib('sing.lib')
sage: singular.lib('sing.lib', reload=True)
```

list(*x*)

Creates a list in Singular from a Sage list x.

EXAMPLES:

```
sage: singular.list([1,2])
[1]:
   1
[2]:
   2
```

load(*lib, reload=False*)

Load the Singular library named lib.

Note that if the library was already loaded during this session it is not reloaded unless the optional reload argument is True (the default is False).

EXAMPLES:

```
sage: singular.lib('sing.lib')
sage: singular.lib('sing.lib', reload=True)
```

matrix(*nrows, ncols, entries=None*)

EXAMPLES:

```
sage: singular.lib("matrix")
sage: R = singular.ring(0, '(x,y,z)', 'dp')
sage: A = singular.matrix(3,2,'1,2,3,4,5,6')
sage: A
1,2,
3,4,
5,6
sage: A.gauss_col()
2,-1,
1,0,
0,1
```

AUTHORS:

- Martin Albrecht (2006-01-14)

option(*cmd=None, val=None*)

Access to Singular's options as follows:

Syntax: option() Returns a string of all defined options.

Syntax: option('option_name') Sets an option. Note to disable an option, use the prefix no.

Syntax: option('get') Returns an intvec of the state of all options.

Syntax: option('set', intvec_expression) Restores the state of all options from an intvec (produced by option('get')).

EXAMPLES:

```
sage: singular.option()
//options: redefine loadLib usage prompt
sage: singular.option('get')
0,
10321
sage: old_options = _
sage: singular.option('noredefine')
sage: singular.option()
//options: loadLib usage prompt
sage: singular.option('set', old_options)
sage: singular.option('get')
0,
10321
```

ring(*char=0, vars='(x)', order='lp', check=True*)

Create a Singular ring and makes it the current ring.

INPUT:

- `char` - characteristic of the base ring (see examples below), which must be either 0, prime (!), or one of several special codes (see examples below).
- `vars` - a tuple or string that defines the variable names
- `order` - string - the monomial order (default: 'lp')
- `check` - if True, check primality of the characteristic if it is an integer.

OUTPUT: a Singular ring

Note: This function is *not* identical to calling the Singular `ring` function. In particular, it also attempts to "kill" the variable names, so they can actually be used without getting errors, and it sets printing of elements for this range to short (i.e., with *'s and carets).

EXAMPLES: We first declare $\mathbf{Q}[x, y, z]$ with degree reverse lexicographic ordering.

```
sage: R = singular.ring(0, '(x,y,z)', 'dp')
sage: R
//   characteristic : 0
//   number of vars : 3
//        block   1 : ordering dp
//                  : names    x y z
//        block   2 : ordering C

sage: R1 = singular.ring(32003, '(x,y,z)', 'dp')
sage: R2 = singular.ring(32003, '(a,b,c,d)', 'lp')
```

This is a ring in variables named x(1) through x(10) over the finite field of order 7:

```
sage: R3 = singular.ring(7, '(x(1..10))', 'ds')
```

This is a polynomial ring over the transcendental extension $\mathbf{Q}(a)$ of $\mathbf{Q}$:

```
sage: R4 = singular.ring('(0,a)', '(mu,nu)', 'lp')
```

This is a ring over the field of single-precision floats:

```
sage: R5 = singular.ring('real', '(a,b)', 'lp')
```

This is over 50-digit floats:

```
sage: R6 = singular.ring('(real,50)', '(a,b)', 'lp')
sage: R7 = singular.ring('(complex,50,i)', '(a,b)', 'lp')
```

To use a ring that you've defined, use the set_ring() method on the ring. This sets the ring to be the "current ring". For example,

```
sage: R = singular.ring(7, '(a,b)', 'ds')
sage: S = singular.ring('real', '(a,b)', 'lp')
sage: singular.new('10*a')
1.000e+01*a
sage: R.set_ring()
sage: singular.new('10*a')
3*a
```

set (*type, name, value*)

Set the variable with given name to the given value.

EXAMPLES:

```
sage: singular.set('int', 'x', '2')
sage: singular.get('x')
'2'
```

set_ring (*R*)

Sets the current Singular ring to R.

EXAMPLES:

```
sage: R = singular.ring(7, '(a,b)', 'ds')
sage: S = singular.ring('real', '(a,b)', 'lp')
sage: singular.current_ring()
//   characteristic : 0 (real)
//   number of vars : 2
//        block   1 : ordering lp
//                  : names    a b
//        block   2 : ordering C
sage: singular.set_ring(R)
sage: singular.current_ring()
//   characteristic : 7
//   number of vars : 2
//        block   1 : ordering ds
//                  : names    a b
//        block   2 : ordering C
```

setring(*R*)

Sets the current Singular ring to R.

EXAMPLES:

```
sage: R = singular.ring(7, '(a,b)', 'ds')
sage: S = singular.ring('real', '(a,b)', 'lp')
sage: singular.current_ring()
//   characteristic : 0 (real)
//   number of vars : 2
//        block   1 : ordering lp
//                  : names    a b
//        block   2 : ordering C
sage: singular.set_ring(R)
sage: singular.current_ring()
//   characteristic : 7
//   number of vars : 2
//        block   1 : ordering ds
//                  : names    a b
//        block   2 : ordering C
```

string(*x*)

Creates a Singular string from a Sage string. Note that the Sage string has to be "double-quoted".

EXAMPLES:

```
sage: singular.string('"Sage"')
Sage
```

trait_names()

Return a list of all Singular commands.

EXAMPLES:

```
sage: singular.trait_names()
['headStand',
 ...
 'stdfglm']
```

version()

EXAMPLES:

class SingularElement(*parent, type, value, is_name=False*)

attrib(*name, value=None*)

Get and set attributs for self.

INPUT:

- `name` - string to choose the attribute
- `value` - boolean value or None for reading, (default:None)

VALUES: isSB - the standard basis property is set by all commands computing a standard basis like groebner, std, stdhilb etc.; used by lift, dim, degree, mult, hilb, vdim, kbase isHomog - the weight vector for homogeneous or quasihomogeneous ideals/modules isCI - complete intersection property isCM - Cohen-Macaulay property rank - set the rank of a module (see nrows) withSB - value of type ideal, resp. module, is std withHilb - value of type intvec is hilb(_,1) (see hilb) withRes - value of type list is a free resolution withDim - value of type int is the dimension (see dim) withMult - value of type int is the multiplicity (see mult)

EXAMPLE:

```
sage: P.<x,y,z> = PolynomialRing(QQ)
sage: I = Ideal([z^2, y*z, y^2, x*z, x*y, x^2])
sage: Ibar = I._singular_()
sage: Ibar.attrib('isSB')
0
sage: singular.eval('vdim(%s)'%Ibar.name()) # sage7 name is random
// ** sage7 is no standard basis
4
sage: Ibar.attrib('isSB',1)
sage: singular.eval('vdim(%s)'%Ibar.name())
'4'
```

sage_flattened_str_list()

EXAMPLES:

```
sage: R=singular.ring(0,'(x,y)','dp')
sage: RL = R.ringlist()
sage: RL.sage_flattened_str_list()
['0', 'x', 'y', 'dp', '1,1', 'C', '0', '_[1]=0']
```

sage_matrix(*R, sparse=True*)

Returns Sage matrix for self

EXAMPLES:

```
sage: R = singular.ring(0, '(x,y,z)', 'dp')
sage: A = singular.matrix(2,2)
sage: A.sage_matrix(ZZ)
[0 0]
[0 0]
sage: A.sage_matrix(RDF)
[0.0 0.0]
[0.0 0.0]
```

sage_poly(*R, kcache=None*)

Returns a Sage polynomial in the ring r matching the provided poly which is a singular polynomial.

INPUT:

- `R` - PolynomialRing: you *must* take care it matches the current singular ring as, e.g., returned by singular.current_ring()
- `kcache` - (default: None); an optional dictionary for faster finite field lookups, this is mainly useful for finite extension fields

OUTPUT: MPolynomial

EXAMPLES:

```
sage: R = PolynomialRing(GF(2^8,'a'),2,'xy')
sage: f=R('a^20*x^2*y+a^10+x')
sage: f._singular_().sage_poly(R)==f
True
sage: R = PolynomialRing(GF(2^8,'a'),1,'x')
sage: f=R('a^20*x^3+x^2+a^10')
sage: f._singular_().sage_poly(R)==f
True

sage: P.<x,y> = PolynomialRing(QQ, 2)
sage: f = x*y**3 - 1/9 * x + 1; f
x*y^3 - 1/9*x + 1
sage: singular(f)
x*y^3-1/9*x+1
sage: P(singular(f))
x*y^3 - 1/9*x + 1
```

AUTHOR:

•Martin Albrecht (2006-05-18)

Note: For very simple polynomials `eval(SingularElement.sage_polystring())` is faster than SingularElement.sage_poly(R), maybe we should detect the crossover point (in dependence of the string length) and choose an appropriate conversion strategy

sage_polystring()

If this Singular element is a polynomial, return a string representation of this polynomial that is suitable for evaluation in Python. Thus * is used for multiplication and ** for exponentiation. This function is primarily used internally.

The short=0 option *must* be set for the parent ring or this function will not work as expected. This option is set by default for rings created using `singular.ring` or set using `ring_name.set_ring()`.

EXAMPLES:

```
sage: R = singular.ring(0,'(x,y)')
sage: f = singular('x^3 + 3*y^11 + 5')
sage: f
x^3+3*y^11+5
sage: f.sage_polystring()
'x**3+3*y**11+5'
```

sage_structured_str_list()

If self is a Singular list of lists of Singular elements, returns corresponding Sage list of lists of strings.

EXAMPLES:

```
sage: R=singular.ring(0,'(x,y)','dp')
sage: RL=R.ringlist()
sage: RL
[1]:
   0
[2]:
   [1]:
      x
   [2]:
      y
[3]:
   [1]:
      [1]:
         dp
      [2]:
         1,1
```

```
      [2]:
         [1]:
            C
         [2]:
            0
   [4]:
      _[1]=0
   sage: RL.sage_structured_str_list()
   ['0', ['x', 'y'], [['dp', '1,\n1 '], ['C', '0 ']], '0']
```

set_ring()

Sets the current ring in Singular to be self.

EXAMPLES:

```
sage: R = singular.ring(7, '(a,b)', 'ds')
sage: S = singular.ring('real', '(a,b)', 'lp')
sage: singular.current_ring()
//   characteristic : 0 (real)
//   number of vars : 2
//        block   1 : ordering lp
//                  : names    a b
//        block   2 : ordering C
sage: R.set_ring()
sage: singular.current_ring()
//   characteristic : 7
//   number of vars : 2
//        block   1 : ordering ds
//                  : names    a b
//        block   2 : ordering C
```

trait_names()

Returns the possible tab-completions for self. In this case, we just return all the tab completions for the Singular object.

EXAMPLES:

```
sage: R = singular.ring(0,'(x,y)','dp')
sage: R.trait_names()
['headStand',
 ...
 'stdfglm']
```

type()

Returns the internal type of this element.

EXAMPLES:

```
sage: R = PolynomialRing(GF(2^8,'a'),2,'x')
sage: R._singular_().type()
'ring'
sage: fs = singular('x0^2','poly')
sage: fs.type()
'poly'
```

class SingularFunction(*parent, name*)

class SingularFunctionElement(*obj, name*)

is_SingularElement(*x*)

Returns True is x is of type `SingularElement`.

EXAMPLES:

```
sage: from sage.interfaces.singular import is_SingularElement
sage: is_SingularElement(singular(2))
True
sage: is_SingularElement(2)
False
```

reduce_load()

Note that this returns an invalid Singular object!

EXAMPLES:

```
sage: from sage.interfaces.singular import reduce_load
sage: reduce_load()
(invalid object -- defined in terms of closed session)
```

reduce_load_Singular()

EXAMPLES:

```
sage: from sage.interfaces.singular import reduce_load_Singular
sage: reduce_load_Singular()
Singular
```

singular_console()

Spawn a new Singular command-line session.

EXAMPLES:

```
sage: singular_console() #not tested
                     SINGULAR                                /  Development
 A Computer Algebra System for Polynomial Computations     /   version 3-0-4
                                                         0<
     by: G.-M. Greuel, G. Pfister, H. Schoenemann          \   Nov 2007
FB Mathematik der Universitaet, D-67653 Kaiserslautern
```

singular_version()

Returns the version of Singular being used.

EXAMPLES:

13.16 The Tachyon Ray Tracer

AUTHOR:

- John E. Stone

class TachyonRT()

The Tachyon Ray Tracer

tachyon_rt(model, outfile='sage.png', verbose=1, block=True, extra_opts='')

INPUT:

- `model` - a string that describes a 3d model in the Tachyon modeling format. Type tachyon_rt.help() for a description of this format.
- `outfile` - (default: 'sage.png') output filename; the extension of the filename determines the type. Supported types include:

- –tga - 24-bit (uncompressed)
- –bmp - 24-bit Windows BMP (uncompressed)
- –ppm - 24-bit PPM (uncompressed)
- –rgb - 24-bit SGI RGB (uncompressed)
- –png - 24-bit PNG (compressed, lossless)

•verbose - integer; (default: 1)

- –0 - silent
- –1 - some output
- –2 - very verbose output

•block - bool (default: True); if False, run the rendering command in the background.

•extra_opts - passed directly to tachyon command line. Use tachyon_rt.usage() to see some of the possibilities.

OUTPUT:

•Some text may be displayed onscreen.

•The file outfile is created.

EXAMPLES:

•John E. Stone

help()

usage()

CHAPTER

FOURTEEN

C/C++ LIBRARY INTERFACES

An underlying philosophy in the development of Sage is that it should provide unified library-level access to the some of the best GPL'd C/C++ libraries. Currently Sage provides some access to MWRANK, NTL, PARI, and Hanke, each of which are included with Sage.

The interfaces are implemented via shared libraries and data is moved between systems purely in memory. In particular, there is no interprocess interpreter parsing (e.g., `expect`), since everything is linked together and run as a single process. This is much more robust and efficient than using `expect`.

Each of these interfaces is used by other parts of Sage. For example, mwrank is used by the elliptic curves module to compute ranks of elliptic curves, and PARI is used for computation of class groups. It is thus probably not necessary for a casual user of Sage to be aware of the modules described in this chapter.

14.1 PARI C-library interface

AUTHORS:

- William Stein (2006-03-01): updated to work with PARI 2.2.12-beta (this involved changing almost every doc string, among other things; the precision behavior of PARI seems to change from any version to the next...).
- William Stein (2006-03-06): added newtonpoly
- Justin Walker: contributed some of the function definitions
- Gonzalo Tornaria: improvements to conversions; much better error handling.

EXAMPLES:

```
sage: pari('5! + 10/x')
(120*x + 10)/x
sage: pari('intnum(x=0,13,sin(x)+sin(x^2) + x)')
85.1885681951527
sage: f = pari('x^3-1')
sage: v = f.factor(); v
[x - 1, 1; x^2 + x + 1, 1]
sage: v[0]   # indexing is 0-based unlike in GP.
[x - 1, x^2 + x + 1]~
sage: v[1]
[1, 1]~
```

Arithmetic obeys the usual coercion rules.

```
sage: type(pari(1) + 1)
<type 'sage.libs.pari.gen.gen'>
sage: type(1 + pari(1))
<type 'sage.libs.pari.gen.gen'>
```

GUIDE TO REAL PRECISION AND THE PARI LIBRARY

The default real precision in communicating with the Pari library is the same as the default Sage real precision, which is 53 bits. Inexact Pari objects are therefore printed by default to 15 decimal digits (even if they are actually more precise).

Default precision example (53 bits, 15 significant decimals):

```
sage: a = pari(1.23); a
1.23000000000000
sage: a.sin()
0.942488801931698
```

Example with custom precision of 200 bits (60 significant decimals):

```
sage: R = RealField(200)
sage: a = pari(R(1.23)); a   # only 15 significant digits printed
1.23000000000000
sage: R(a)          # but the number is known to precision of 200 bits
1.2300000000000000000000000000000000000000000000000000000000000000000000000000
sage: a.sin()       # only 15 significant digits printed
0.942488801931698
sage: R(a.sin())    # but the number is known to precision of 200 bits
0.94248880193169751002382356538924454146128740562765030213504
```

It is possible to change the number of printed decimals:

```
sage: R = RealField(200)     # 200 bits of precision in computations
sage: old_prec = pari.set_real_precision(60)  # 60 decimals printed
sage: a = pari(R(1.23)); a
1.23000000000000000000000000000000000000000000000000000000000000000000000000000
sage: a.sin()
0.94248880193169751002382356538924454146128740562765030213503 8
sage: pari.set_real_precision(old_prec)  # restore the default printing behavior
60
```

Unless otherwise indicated in the docstring, most Pari functions that return inexact objects use the precision of their arguments to decide the precision of the computation. However, if some of these arguments happen to be exact numbers (integers, rationals, etc.), an optional parameter indicates the precision (in bits) to which these arguments should be converted before the computation. If this precision parameter is missing, the default precision of 53 bits is used. The following first converts 2 into a real with 53-bit precision:

```
sage: R = RealField()
sage: R(pari(2).sin())
0.909297426825682
```

We can ask for a better precision using the optional parameter:

```
sage: R = RealField(150)
sage: R(pari(2).sin(precision=150))
0.90929742682568169539601986591174484270225497
```

Warning regarding conversions Sage - Pari - Sage: Some care must be taken when juggling inexact types back and forth between Sage and Pari. In theory, calling p=pari(s) creates a Pari object p with the same precision as s; in practice, the Pari library's precision is word-based, so it will go up to the next word. For example, a default 53-bit Sage real s will be bumped up to 64 bits by adding bogus 11 bits. The function p.python() returns a Sage object with exactly the same precision as the Pari object p. So pari(s).python() is definitely not equal to s, since it has 64 bits of precision, including the bogus 11 bits. The correct way of avoiding this is to coerce pari(s).python() back into a domain with the right precision. This has to be done by the user (or by Sage functions that use Pari library functions in gen.pyx). For instance, if we want to use the Pari library to compute sqrt(pi) with a precision of 100 bits:

```
sage: R = RealField(100)
sage: s = R(pi); s
3.1415926535897932384626433833
sage: p = pari(s).sqrt()
sage: x = p.python(); x  # wow, more digits than I expected!
1.7724538509055160272981674833410973484
sage: x.prec()           # has precision 'improved' from 100 to 128?
128
sage: x == RealField(128)(pi).sqrt()  # sadly, no!
False
sage: R(x)               # x should be brought back to precision 100
1.7724538509055160272981674833
sage: R(x) == s.sqrt()
True
```

Elliptic curves and precision: If you are working with elliptic curves and want to compute with a precision other than the default 53 bits, you should use the precision parameter of ellinit():

```
sage: R = RealField(150)
sage: e = pari([0,0,0,-82,0]).ellinit(precision=150)
sage: eta1 = e.elleta()[0]
sage: R(eta1)
3.6054636014326520863839536934492002728802618
```

Number fields and precision: TODO

exception PariError

errmessage

class PariInstance()

allocatemem()
Double the *PARI* stack.

complex()
Create a new complex number, initialized from re and im.

default()

double_to_gen()

euler()
Return Euler's constant to the requested real precision (in bits).
EXAMPLES:

```
sage: pari.euler()
0.577215664901533
sage: pari.euler(precision=100).python()
0.57721566490153286060651209008 2...
```

factorial()
Return the factorial of the integer n as a PARI gen.

EXAMPLES:

```
sage: pari.factorial(0)
1
sage: pari.factorial(1)
1
sage: pari.factorial(5)
120
sage: pari.factorial(25)
15511210043330985984000000
```

get_debug_level()
Set the debug PARI C library variable.

get_real_precision()
Returns the current PARI default real precision.

This is used both for creation of new objects from strings and for printing. It is the number of digits *IN DECIMAL* in which real numbers are printed. It also determines the precision of objects created by parsing strings (e.g. pari('1.2')), which is *not* the normal way of creating new pari objects in Sage. It has *no* effect on the precision of computations within the pari library.

get_series_precision()

getrand()
Returns Pari's current random number seed.

EXAMPLES:

```
sage: pari.setrand(50)
sage: pari.getrand()
50
sage: pari.pari_rand31()
621715893
sage: pari.getrand()
621715893
```

init_primes()
Recompute the primes table including at least all primes up to M (but possibly more).

EXAMPLES:

```
sage: pari.init_primes(200000)
```

listcreate()
listcreate(n): return an empty pari list of maximal length n.

EXAMPLES:

```
sage: pari.listcreate(20)
List([])
```

matrix()
matrix(long m, long n, entries=None): Create and return the m x n PARI matrix with given list of entries.

new_with_bits_prec()
pari.new_with_bits_prec(self, s, precision) creates s as a PARI gen with (at most) precision *bits* of precision.

nth_prime()

pari_rand31()
Returns a random number from Pari's random number generator.

Warning: You probably don't want to use this; it's a very poor random number generator. Sage exposes it only as a way to test `getrand()` and `setrand()`.

pari_version()

pi()

Return the value of the constant pi to the requested real precision (in bits).

EXAMPLES:

```
sage: pari.pi()
3.14159265358979
sage: pari.pi(precision=100).python()
3.1415926535897932384626433832...
```

polcyclo()

polcyclo(n, v=x): cyclotomic polynomial of degree n, in variable v.

EXAMPLES:

```
sage: pari.polcyclo(8)
x^4 + 1
sage: pari.polcyclo(7, 'z')
z^6 + z^5 + z^4 + z^3 + z^2 + z + 1
sage: pari.polcyclo(1)
x - 1
```

pollegendre()

pollegendre(n, v=x): Legendre polynomial of degree n (n C-integer), in variable v.

EXAMPLES:

```
sage: pari.pollegendre(7)
429/16*x^7 - 693/16*x^5 + 315/16*x^3 - 35/16*x
sage: pari.pollegendre(7, 'z')
429/16*z^7 - 693/16*z^5 + 315/16*z^3 - 35/16*z
sage: pari.pollegendre(0)
1
```

polsubcyclo()

polsubcyclo(n, d, v=x): return the pari list of polynomial(s) defining the sub-abelian extensions of degree d of the cyclotomic field $\mathbf{Q}(\zeta_n)$, where d divides $\phi(n)$.

EXAMPLES:

```
sage: pari.polsubcyclo(8, 4)
[x^4 + 1]
sage: pari.polsubcyclo(8, 2, 'z')
[z^2 - 2, z^2 + 1, z^2 + 2]
sage: pari.polsubcyclo(8, 1)
[x - 1]
sage: pari.polsubcyclo(8, 3)
[]
```

poltchebi()

poltchebi(n, v=x): Chebyshev polynomial of the first kind of degree n, in variable v.

EXAMPLES:

```
sage: pari.poltchebi(7)
64*x^7 - 112*x^5 + 56*x^3 - 7*x
sage: pari.poltchebi(7, 'z')
64*z^7 - 112*z^5 + 56*z^3 - 7*z
sage: pari.poltchebi(0)
1
```

polzagier()

prime_list()

prime_list(n): returns list of the first n primes

To extend the table of primes use pari.init_primes(M).

INPUT:

- n - C long

OUTPUT:

- gen - PARI list of first n primes

EXAMPLES:

```
sage: pari.prime_list(0)
[]
sage: pari.prime_list(-1)
[]
sage: pari.prime_list(3)
[2, 3, 5]
sage: pari.prime_list(10)
[2, 3, 5, 7, 11, 13, 17, 19, 23, 29]
sage: pari.prime_list(20)
[2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71]
sage: len(pari.prime_list(1000))
1000
```

primes_up_to_n()

Return the primes = n as a pari list.

EXAMPLES:

```
sage: pari.primes_up_to_n(1)
[]
sage: pari.primes_up_to_n(20)
[2, 3, 5, 7, 11, 13, 17, 19]
```

read()

Read a script from the named filename into the interpreter, where s is a string. The functions defined in the script are then available for use from Sage/PARI.

EXAMPLE:

If foo.gp is a script that contains

```
{foo(n) =
    n^2
}
```

and you type `read("foo.gp")`, then the command `pari("foo(12)")` will create the Python/PARI gen which is the integer 144.

CONSTRAINTS: The PARI script must *not* contain the following function calls:

print, default, ??? (please report any others that cause trouble)

set_debug_level()

Set the debug PARI C library variable.

set_real_precision()

Sets the PARI default real precision.

This is used both for creation of new objects from strings and for printing. It is the number of digits *IN DECIMAL* in which real numbers are printed. It also determines the precision of objects created by parsing strings (e.g. pari('1.2')), which is *not* the normal way of creating new pari objects in Sage. It has *no* effect on the precision of computations within the pari library.

Returns the previous PARI real precision.

set_series_precision()

setrand()

Sets Pari's current random number seed.

This should not be called directly; instead, use Sage's global random number seed handling in `sage.misc.randstate` and call `current_randstate().set_seed_pari()`.

EXAMPLES:

```
sage: pari.setrand(12345)
sage: pari.getrand()
12345
```

vector()

vector(long n, entries=None): Create and return the length n PARI vector with given list of entries.

EXAMPLES:

```
sage: pari.vector(5, [1, 2, 5, 4, 3])
[1, 2, 5, 4, 3]
sage: pari.vector(2, [x, 1])
[x, 1]
sage: pari.vector(2, [x, 1, 5])
...
IndexError: length of entries (=3) must equal n (=2)
```

class gen()

Python extension class that models the PARI GEN type.

Col()

Col(x): Transforms the object x into a column vector.

The vector will have only one component, except in the following cases:

- When x is a vector or a quadratic form, the resulting vector is the initial object considered as a column vector.
- When x is a matrix, the resulting vector is the column of row vectors comprising the matrix.
- When x is a character string, the result is a column of individual characters.
- When x is a polynomial, the coefficients of the vector start with the leading coefficient of the polynomial.
- When x is a power series, only the significant coefficients are taken into account, but this time by increasing order of degree.

INPUT:

- x - gen

OUTPUT: gen

EXAMPLES:

```
sage: pari(1.5).Col()
[1.50000000000000]~
sage: pari([1,2,3,4]).Col()
[1, 2, 3, 4]~
sage: pari('[1,2; 3,4]').Col()
[[1, 2], [3, 4]]~
sage: pari('"Sage"').Col()
["S", "a", "g", "e"]~
sage: pari('3*x^3 + x').Col()
[3, 0, 1, 0]~
sage: pari('x + 3*x^3 + O(x^5)').Col()
[1, 0, 3, 0]~
```

List()

List(x): transforms the PARI vector or list x into a list.

EXAMPLES:

```
sage: v = pari([1,2,3])
sage: v
[1, 2, 3]
sage: v.type()
't_VEC'
sage: w = v.List()
sage: w
List([1, 2, 3])
sage: w.type()
't_LIST'
```

Mat()

Mat(x): Returns the matrix defined by x.

- If x is already a matrix, a copy of x is created and returned.
- If x is not a vector or a matrix, this function returns a 1x1 matrix.
- If x is a row (resp. column) vector, this functions returns a 1-row (resp. 1-column) matrix, *unless* all elements are column (resp. row) vectors of the same length, in which case the vectors are concatenated sideways and the associated big matrix is returned.

INPUT:

- x - gen

OUTPUT:

- gen - a PARI matrix

EXAMPLES:

```
sage: x = pari(5)
sage: x.type()
't_INT'
sage: y = x.Mat()
sage: y
Mat(5)
sage: y.type()
't_MAT'
sage: x = pari('[1,2;3,4]')
sage: x.type()
't_MAT'
sage: x = pari('[1,2,3,4]')
sage: x.type()
't_VEC'
sage: y = x.Mat()
sage: y
Mat([1, 2, 3, 4])
sage: y.type()
't_MAT'

sage: v = pari('[1,2;3,4]').Vec(); v
[[1, 3]~, [2, 4]~]
sage: v.Mat()
[1, 2; 3, 4]
sage: v = pari('[1,2;3,4]').Col(); v
[[1, 2], [3, 4]]~
sage: v.Mat()
[1, 2; 3, 4]
```

Mod()

Mod(x, y): Returns the object x modulo y, denoted Mod(x, y).

The input y must be a an integer or a polynomial:

- If y is an INTEGER, x must also be an integer, a rational number, or a p-adic number compatible with the modulus y.
- If y is a POLYNOMIAL, x must be a scalar (which is not a polmod), a polynomial, a rational function, or a power series.

Warning: This function is not the same as `x % y` which is an integer or a polynomial.

INPUT:

- `x` - gen
- `y` - integer or polynomial

OUTPUT:

- `gen` - intmod or polmod

EXAMPLES:

```
sage: z = pari(3)
sage: x = z.Mod(pari(7))
sage: x
Mod(3, 7)
sage: x^2
Mod(2, 7)
sage: x^100
Mod(4, 7)
sage: x.type()
't_INTMOD'

sage: f = pari("x^2 + x + 1")
sage: g = pari("x")
sage: a = g.Mod(f)
sage: a
Mod(x, x^2 + x + 1)
sage: a*a
Mod(-x - 1, x^2 + x + 1)
sage: a.type()
't_POLMOD'
```

Pol()

Pol(x, v): convert x into a polynomial with main variable v and return the result.

- If x is a scalar, returns a constant polynomial.
- If x is a power series, the effect is identical to `truncate`, i.e. it chops off the $O(X^k)$.
- If x is a vector, this function creates the polynomial whose coefficients are given in x, with x[0] being the leading coefficient (which can be zero).

Warning: This is *not* a substitution function. It will not transform an object containing variables of higher priority than v:

```
sage: pari('x+y').Pol('y')
...
PariError:  (8)
```

INPUT:

- x - gen
- v - (optional) which variable, defaults to 'x'

OUTPUT:

- gen - a polynomial

EXAMPLES:

```
sage: v = pari("[1,2,3,4]")
sage: f = v.Pol()
sage: f
x^3 + 2*x^2 + 3*x + 4
sage: f*f
x^6 + 4*x^5 + 10*x^4 + 20*x^3 + 25*x^2 + 24*x + 16

sage: v = pari("[1,2;3,4]")
sage: v.Pol()
[1, 3]~*x + [2, 4]~
```

Polrev()

Polrev(x, v): Convert x into a polynomial with main variable v and return the result. This is the reverse of Pol if x is a vector, otherwise it is identical to Pol. By "reverse" we mean that the coefficients are reversed.

INPUT:

- x - gen

OUTPUT:

- gen - a polynomial

EXAMPLES:

```
sage: v = pari("[1,2,3,4]")
sage: f = v.Polrev()
sage: f
4*x^3 + 3*x^2 + 2*x + 1
sage: v.Pol()
x^3 + 2*x^2 + 3*x + 4
sage: v.Polrev('y')
4*y^3 + 3*y^2 + 2*y + 1
```

Note that Polrev does *not* reverse the coefficients of a polynomial!

```
sage: f
4*x^3 + 3*x^2 + 2*x + 1
sage: f.Polrev()
4*x^3 + 3*x^2 + 2*x + 1
sage: v = pari("[1,2;3,4]")
sage: v.Polrev()
[2, 4]~*x + [1, 3]~
```

Qfb()

Qfb(a,b,c,D=0.): Returns the binary quadratic form

$$ax^2 + bxy + cy^2.$$

The optional D is 0 by default and initializes Shanks's distance if $b^2 - 4ac > 0$.

Note: Negative definite forms are not implemented, so use their positive definite counterparts instead. (I.e., if f is a negative definite quadratic form, then -f is positive definite.)

INPUT:

- a - gen
- b - gen

- c - gen
- D - gen (optional, defaults to 0)

OUTPUT:

- gen - binary quadratic form

EXAMPLES:

```
sage: pari(3).Qfb(7, 2)
Qfb(3, 7, 2, 0.E-19)
```

Ser()

Ser(x,v=x): Create a power series from x with main variable v and return the result.

- If x is a scalar, this gives a constant power series with precision given by the default series precision, as returned by get_series_precision().
- If x is a polynomial, the precision is the greatest of get_series_precision() and the degree of the polynomial.
- If x is a vector, the precision is similarly given, and the coefficients of the vector are understood to be the coefficients of the power series starting from the constant term (i.e. the reverse of the function Pol).

Warning: This is *not* a substitution function. It will not transform an object containing variables of higher priority than v.

INPUT:

- x - gen
- v - PARI variable (default: x)

OUTPUT:

- gen - PARI object of PARI type t_SER

EXAMPLES:

```
sage: pari(2).Ser()
2 + O(x^16)
sage: x = pari([1,2,3,4,5])
sage: x.Ser()
1 + 2*x + 3*x^2 + 4*x^3 + 5*x^4 + O(x^5)
sage: f = x.Ser('v'); print f
1 + 2*v + 3*v^2 + 4*v^3 + 5*v^4 + O(v^5)
sage: pari(1)/f
1 - 2*v + v^2 + O(v^5)
sage: pari(1).Ser()
1 + O(x^16)
```

Set()

Set(x): convert x into a set, i.e. a row vector of strings in increasing lexicographic order.

INPUT:

- x - gen

OUTPUT:

- gen - a vector of strings in increasing lexicographic order.

EXAMPLES:

```
sage: pari([1,5,2]).Set()
["1", "2", "5"]
sage: pari([]).Set()      # the empty set
```

```
[]
sage: pari([1,1,-1,-1,3,3]).Set()
["-1", "1", "3"]
sage: pari(1).Set()
["1"]
sage: pari('1/(x*y)').Set()
["1/(y*x)"]
sage: pari('["bc","ab","bc"]').Set()
["ab", "bc"]
```

Str()

Str(self): Return the print representation of self as a PARI object.

INPUT:

- `self` - gen

OUTPUT:

- `gen` - a PARI gen of type t_STR, i.e., a PARI string

EXAMPLES:

```
sage: pari([1,2,['abc',1]]).Str()
[1, 2, [abc, 1]]
sage: pari([1,1, 1.54]).Str()
[1, 1, 1.540000000000000]
sage: pari(1).Str()        # 1 is automatically converted to string rep
1
sage: x = pari('x')        # PARI variable "x"
sage: x.Str()              # is converted to string rep.
x
sage: x.Str().type()
't_STR'
```

Strchr()

Strchr(x): converts x to a string, translating each integer into a character (in ASCII).

Note: `Vecsmall()` is (essentially) the inverse to `Strchr()`.

INPUT:

- `x` - PARI vector of integers

OUTPUT:

- `gen` - a PARI string

EXAMPLES:

```
sage: pari([65,66,123]).Strchr()
AB{
sage: pari('"Sage"').Vecsmall()    # pari('"Sage"') --> PARI t_STR
Vecsmall([83, 97, 103, 101])
sage: _.Strchr()
Sage
sage: pari([83, 97, 103, 101]).Strchr()
Sage
```

Strexpand()

Strexpand(x): Concatenate the entries of the vector x into a single string, performing tilde expansion.

Note: I have no clue what the point of this function is. - William

Strtex()

Strtex(x): Translates the vector x of PARI gens to TeX format and returns the resulting concatenated strings as a PARI t_STR.

INPUT:

- x - gen

OUTPUT:

- gen - PARI t_STR (string)

EXAMPLES:

```
sage: v=pari('x^2')
sage: v.Strtex()
x^2
sage: v=pari(['1/x^2','x'])
sage: v.Strtex()
\frac{1}{x^2}x
sage: v=pari(['1 + 1/x + 1/(y+1)','x-1'])
sage: v.Strtex()
\frac{ \left(y
 + 2\right)  x
 + \left(y
 + 1\right) }{ \left(y
 + 1\right)  x}x
 - 1
```

Vec()

Vec(x): Transforms the object x into a vector.

INPUT:

- x - gen

OUTPUT:

- gen - of PARI type t_VEC

EXAMPLES:

```
sage: pari(1).Vec()
[1]
sage: pari('x^3').Vec()
[1, 0, 0, 0]
sage: pari('x^3 + 3*x - 2').Vec()
[1, 0, 3, -2]
sage: pari([1,2,3]).Vec()
[1, 2, 3]
sage: pari('ab').Vec()
[1, 0]
```

Vecrev()

Vecrev(x): Transforms the object x into a vector. Identical to Vec(x) except when x is - a polynomial, this is the reverse of Vec. - a power series, this includes low-order zero coefficients. - a Laurent series, raises an exception

INPUT:

- x - gen

OUTPUT:

- gen - of PARI type t_VEC

EXAMPLES:

```
sage: pari(1).Vecrev()
[1]
sage: pari('x^3').Vecrev()
[0, 0, 0, 1]
sage: pari('x^3 + 3*x - 2').Vecrev()
```

```
[-2, 3, 0, 1]
sage: pari([1, 2, 3]).Vecrev()
[1, 2, 3]
sage: pari('Col([1, 2, 3])').Vecrev()
[1, 2, 3]
sage: pari('[1, 2; 3, 4]').Vecrev()
[[1, 3]~, [2, 4]~]
sage: pari('ab').Vecrev()
[0, 1]
sage: pari('x^2 + 3*x^3 + O(x^5)').Vecrev()
[0, 0, 1, 3, 0]
sage: pari('x^-2 + 3*x^3 + O(x^5)').Vecrev()
...
ValueError: Vecrev() is not defined for Laurent series
```

Vecsmall()

Vecsmall(x): transforms the object x into a t_VECSMALL.

INPUT:

- x - gen

OUTPUT:

- gen - PARI t_VECSMALL

EXAMPLES:

```
sage: pari([1,2,3]).Vecsmall()
Vecsmall([1, 2, 3])
sage: pari('"Sage"').Vecsmall()
Vecsmall([83, 97, 103, 101])
sage: pari(1234).Vecsmall()
Vecsmall([1234])
```

abs()

Returns the absolute value of x (its modulus, if x is complex). Rational functions are not allowed. Contrary to most transcendental functions, an exact argument is not converted to a real number before applying abs and an exact result is returned if possible.

EXAMPLES:

```
sage: x = pari("-27.1")
sage: x.abs()
27.1000000000000
```

If x is a polynomial, returns -x if the leading coefficient is real and negative else returns x. For a power series, the constant coefficient is considered instead.

EXAMPLES:

```
sage: pari('x-1.2*x^2').abs()
1.20000000000000*x^2 - x
```

acos()

The principal branch of $\cos^{-1}(x)$, so that $\mathbf{R}e(\mathrm{acos}(x))$ belongs to $[0, Pi]$. If x is real and $|x| > 1$, then $\mathrm{acos}(x)$ is complex.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(0.5).acos()
1.04719755119660
sage: pari(1/2).acos()
1.04719755119660
sage: pari(1.1).acos()
-0.443568254385115*I
sage: C.<i> = ComplexField()
sage: pari(1.1+i).acos()
0.849343054245252 - 1.09770986682533*I
```

acosh()

The principal branch of $\cosh^{-1}(x)$, so that $\Im(\text{acosh}(x))$ belongs to $[0, Pi]$. If x is real and $x < 1$, then $\text{acosh}(x)$ is complex.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(2).acosh()
1.31695789692482
sage: pari(0).acosh()
1.57079632679490*I
sage: C.<i> = ComplexField()
sage: pari(i).acosh()
0.881373587019543 + 1.57079632679490*I
```

agm()

The arithmetic-geometric mean of x and y. In the case of complex or negative numbers, the principal square root is always chosen. p-adic or power series arguments are also allowed. Note that a p-adic AGM exists only if x/y is congruent to 1 modulo p (modulo 16 for p=2). x and y cannot both be vectors or matrices.

If any of x or y is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If the arguments are inexact (e.g. real), the smallest of their two precisions is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(2).agm(2)
2.00000000000000
sage: pari(0).agm(1)
0
sage: pari(1).agm(2)
1.45679103104691
sage: C.<i> = ComplexField()
sage: pari(1+i).agm(-3)
-0.964731722290876 + 1.15700282952632*I
```

algdep()

EXAMPLES:

```
sage: n = pari.set_real_precision (200)
sage: w1 = pari('z1=2-sqrt(26); (z1+I)/(z1-I)')
sage: f = w1.algdep(12); f
545*x^11 - 297*x^10 - 281*x^9 + 48*x^8 - 168*x^7 + 690*x^6 - 168*x^5 + 48*x^4 - 281*x^3 - 29
sage: f(w1)
7.75513996 E-200 + 5.70672991 E-200*I     # 32-bit
3.780069700150794274 E-209 - 9.362977321012524836 E-211*I   # 64-bit
sage: f.factor()
[x, 1; x + 1, 2; x^2 + 1, 1; x^2 + x + 1, 1; 545*x^4 - 1932*x^3 + 2790*x^2 - 1932*x + 545, 1
```

```
sage: pari.set_real_precision(n)
200
```

arg()

arg(x): argument of x,such that $-\pi < \arg(x) \leq \pi$.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: C.<i> = ComplexField()
sage: pari(2+i).arg()
0.463647609000806
```

asin()

The principal branch of $\sin^{-1}(x)$, so that $\mathbf{R}e(\mathrm{asin}(x))$ belongs to $[-\pi/2, \pi/2]$. If x is real and $|x| > 1$ then $\mathrm{asin}(x)$ is complex.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(pari(0.5).sin()).asin()
0.500000000000000
sage: pari(2).asin()
1.57079632679490 + 1.31695789692482*I
```

asinh()

The principal branch of $\sinh^{-1}(x)$, so that $\Im(\mathrm{asinh}(x))$ belongs to $[-\pi/2, \pi/2]$.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(2).asinh()
1.44363547517881
sage: C.<i> = ComplexField()
sage: pari(2+i).asinh()
1.52857091948100 + 0.427078586392476*I
```

atan()

The principal branch of $\tan^{-1}(x)$, so that $\mathbf{R}e(\mathrm{atan}(x))$ belongs to $]-\pi/2, \pi/2[$.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(1).atan()
0.785398163397448
sage: C.<i> = ComplexField()
sage: pari(1.5+i).atan()
1.10714871779409 + 0.255412811882995*I
```

atanh()

The principal branch of $\tanh^{-1}(x)$, so that $\Im(\mathrm{atanh}(x))$ belongs to $]-\pi/2, \pi/2]$. If x is real and $|x| > 1$ then $\mathrm{atanh}(x)$ is complex.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(0).atanh()
0.E-19
sage: pari(2).atanh()
0.549306144334055 + 1.57079632679490*I
```

bernfrac()

The Bernoulli number B_x, where $B_0 = 1$, $B_1 = -1/2$, $B_2 = 1/6, \ldots$, expressed as a rational number. The argument x should be of type integer.

EXAMPLES:

```
sage: pari(18).bernfrac()
43867/798
sage: [pari(n).bernfrac() for n in range(10)]
[1, -1/2, 1/6, 0, -1/30, 0, 1/42, 0, -1/30, 0]
```

bernreal()

The Bernoulli number B_x, as for the function bernfrac, but B_x is returned as a real number (with the current precision).

EXAMPLES:

```
sage: pari(18).bernreal()
54.9711779448622
```

bernvec()

Creates a vector containing, as rational numbers, the Bernoulli numbers $B_0, B_2, \ldots, B_{2x}$. This routine is obsolete. Use bernfrac instead each time you need a Bernoulli number in exact form.

Note: this routine is implemented using repeated independent calls to bernfrac, which is faster than the standard recursion in exact arithmetic.

EXAMPLES:

```
sage: pari(8).bernvec()
[1, 1/6, -1/30, 1/42, -1/30, 5/66, -691/2730, 7/6, -3617/510]
sage: [pari(2*n).bernfrac() for n in range(9)]
[1, 1/6, -1/30, 1/42, -1/30, 5/66, -691/2730, 7/6, -3617/510]
```

besselh1()

The H^1-Bessel function of index ν and argument x.

If nu or x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If the arguments are inexact (e.g. real), the smallest of their precisions is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(2).besselh1(3)
0.486091260585891 - 0.160400393484924*I
```

besselh2()

The H^2-Bessel function of index ν and argument x.

If nu or x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If the arguments are inexact (e.g. real), the smallest of their precisions is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(2).besselh2(3)
0.486091260585891 + 0.160400393484924*I
```

besseli()

Bessel I function (Bessel function of the second kind), with index ν and argument x. If x converts to a power series, the initial factor $(x/2)^\nu/\Gamma(\nu+1)$ is omitted (since it cannot be represented in PARI when ν is not integral).

If nu or x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If the arguments are inexact (e.g. real), the smallest of their precisions is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(2).besseli(3)
2.24521244092995
sage: C.<i> = ComplexField()
sage: pari(2).besseli(3+i)
1.12539407613913 + 2.08313822670661*I
```

besselj()

Bessel J function (Bessel function of the first kind), with index ν and argument x. If x converts to a power series, the initial factor $(x/2)^\nu/\Gamma(\nu+1)$ is omitted (since it cannot be represented in PARI when ν is not integral).

If nu or x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If the arguments are inexact (e.g. real), the smallest of their precisions is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(2).besselj(3)
0.486091260585891
```

besseljh()

J-Bessel function of half integral index (Speherical Bessel function of the first kind). More precisely, besseljh(n,x) computes $J_{n+1/2}(x)$ where n must an integer, and x is any complex value. In the current implementation (PARI, version 2.2.11), this function is not very accurate when x is small.

If nu or x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If the arguments are inexact (e.g. real), the smallest of their precisions is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(2).besseljh(3)
0.4127100324          # 32-bit
0.412710032209716     # 64-bit
```

besselk()

nu.besselk(x, flag=0): K-Bessel function (modified Bessel function of the second kind) of index nu, which can be complex, and argument x.

If nu or x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If the arguments are inexact (e.g. real), the smallest of their precisions is used in the computation, and the parameter precision is ignored.

INPUT:

- `nu` - a complex number
- `x` - real number (positive or negative)
- `flag` - default: 0 or 1: use hyperu (hyperu is much slower for small x, and doesn't work for negative x).

EXAMPLES:

```
sage: C.<i> = ComplexField()
sage: pari(2+i).besselk(3)
0.0455907718407551 + 0.0289192946582081*I

sage: pari(2+i).besselk(-3)
-4.34870874986752 - 5.38744882697109*I

sage: pari(2+i).besselk(300, flag=1)
3.74224603319728 E-132 + 2.49071062641525 E-134*I
```

besseln()

nu.besseln(x): Bessel N function (Spherical Bessel function of the second kind) of index nu and argument x.

If nu or x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If the arguments are inexact (e.g. real), the smallest of their precisions is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: C.<i> = ComplexField()
sage: pari(2+i).besseln(3)
-0.280775566958244 - 0.486708533223726*I
```

bezout()

binary()

binary(x): gives the vector formed by the binary digits of abs(x), where x is of type t_INT.

INPUT:

- x - gen of type t_INT

OUTPUT:

- gen - of type t_VEC

EXAMPLES:

```
sage: pari(0).binary()
[0]
sage: pari(-5).binary()
[1, 0, 1]
sage: pari(5).binary()
[1, 0, 1]
sage: pari(2005).binary()
[1, 1, 1, 1, 1, 0, 1, 0, 1, 0, 1]

sage: pari('"2"').binary()
...
TypeError: x (=2) must be of type t_INT, but is of type t_STR.
```

binomial()

binomial(x, k): return the binomial coefficient "x choose k".

INPUT:

- x - any PARI object (gen)
- k - integer

EXAMPLES:

```
sage: pari(6).binomial(2)
15
sage: pari('x+1').binomial(3)
1/6*x^3 - 1/6*x
```

```
sage: pari('2+x+O(x^2)').binomial(3)
1/3*x + O(x^2)
```

bitand()

bitand(x,y): Bitwise and of two integers x and y. Negative numbers behave as if modulo some large power of 2.

INPUT:

- x - gen (of type t_INT)
- y - coercible to gen (of type t_INT)

OUTPUT:

- gen - of type type t_INT

EXAMPLES:

```
sage: pari(8).bitand(4)
0
sage: pari(8).bitand(8)
8
sage: pari(6).binary()
[1, 1, 0]
sage: pari(7).binary()
[1, 1, 1]
sage: pari(6).bitand(7)
6
sage: pari(19).bitand(-1)
19
sage: pari(-1).bitand(-1)
-1
```

bitneg()

bitneg(x,n=-1): Bitwise negation of the integer x truncated to n bits. n=-1 (the default) represents an infinite sequence of the bit 1. Negative numbers behave as if modulo some large power of 2.

With n=-1, this function returns -n-1. With n = 0, it returns a number a such that $a \cong -n-1 \pmod{2^n}$.

INPUT:

- x - gen (t_INT)
- n - long, default = -1

OUTPUT:

- gen - t_INT

EXAMPLES:

```
sage: pari(10).bitneg()
-11
sage: pari(1).bitneg()
-2
sage: pari(-2).bitneg()
1
sage: pari(-1).bitneg()
0
sage: pari(569).bitneg()
-570
sage: pari(569).bitneg(10)
454
sage: 454 % 2^10
454
sage: -570 % 2^10
454
```

bitnegimply()

bitnegimply(x,y): Bitwise negated imply of two integers x and y, in other words, x BITAND BITNEG(y). Negative numbers behave as if modulo big power of 2.

INPUT:

- x - gen (of type t_INT)
- y - coercible to gen (of type t_INT)

OUTPUT:

- gen - of type type t_INT

EXAMPLES:

```
sage: pari(14).bitnegimply(0)
14
sage: pari(8).bitnegimply(8)
0
sage: pari(8+4).bitnegimply(8)
4
```

bitor()

bitor(x,y): Bitwise or of two integers x and y. Negative numbers behave as if modulo big power of 2.

INPUT:

- x - gen (of type t_INT)
- y - coercible to gen (of type t_INT)

OUTPUT:

- gen - of type type t_INT

EXAMPLES:

```
sage: pari(14).bitor(0)
14
sage: pari(8).bitor(4)
12
sage: pari(12).bitor(1)
13
sage: pari(13).bitor(1)
13
```

bittest()

bittest(x, long n): Returns bit number n (coefficient of 2^n in binary) of the integer x. Negative numbers behave as if modulo a big power of 2.

INPUT:

- x - gen (pari integer)

OUTPUT:

- bool - a Python bool

EXAMPLES:

```
sage: x = pari(6)
sage: x.bittest(0)
False
sage: x.bittest(1)
True
sage: x.bittest(2)
True
sage: x.bittest(3)
False
```

```
sage: pari(-3).bittest(0)
True
sage: pari(-3).bittest(1)
False
sage: [pari(-3).bittest(n) for n in range(10)]
[True, False, True, True, True, True, True, True, True, True]
```

bitxor()

bitxor(x,y): Bitwise exclusive or of two integers x and y. Negative numbers behave as if modulo big power of 2.

INPUT:

- x - gen (of type t_INT)
- y - coercible to gen (of type t_INT)

OUTPUT:

- gen - of type type t_INT

EXAMPLES:

```
sage: pari(6).bitxor(4)
2
sage: pari(0).bitxor(4)
4
sage: pari(6).bitxor(0)
6
```

bnfcertify()

bnf being as output by bnfinit, checks whether the result is correct, i.e. whether the calculation of the contents of self are correct without assuming the Generalized Riemann Hypothesis. If it is correct, the answer is 1. If not, the program may output some error message, but more probably will loop indefinitely. In *no* occasion can the program give a wrong answer (barring bugs of course): if the program answers 1, the answer is certified.

> **Warning:** By default, most of the bnf routines depend on the correctness of a heuristic assumption which is stronger than GRH. In order to obtain a provably-correct result you *must* specify $c = c_2 = 12$ for the technical optional parameters to the function. There are known counterexamples for smaller c (which is the default).

bnfinit()

bnfisintnorm()

bnfisprincipal()

bnfisunit()

bnfnarrow()

bnfunit()

ceil()

For real x: return the smallest integer = x. For rational functions: the quotient of numerator by denominator. For lists: apply componentwise.

INPUT:

- x - gen

OUTPUT:

- gen - depends on type of x

EXAMPLES:

```
sage: pari(1.4).ceil()
2
sage: pari(-1.4).ceil()
-1
sage: pari(3/4).ceil()
1
sage: pari(x).ceil()
x
sage: pari((x^2+x+1)/x).ceil()
x + 1
```

This may be unexpected: but it is correct, treating the argument as a rational function in RR(x).

```
sage: pari(x^2+5*x+2.5).ceil()
x^2 + 5*x + 2.50000000000000
```

centerlift()

centerlift(x,v): Centered lift of x. This function returns exactly the same thing as lift, except if x is an integer mod.

INPUT:

- x - gen
- v - var (default: x)

OUTPUT: gen

EXAMPLES:

```
sage: x = pari(-2).Mod(5)
sage: x.centerlift()
-2
sage: x.lift()
3
sage: f = pari('x-1').Mod('x^2 + 1')
sage: f.centerlift()
x - 1
sage: f.lift()
x - 1
sage: f = pari('x-y').Mod('x^2+1')
sage: f
Mod(x - y, x^2 + 1)
sage: f.centerlift('x')
x - y
sage: f.centerlift('y')
Mod(x - y, x^2 + 1)
```

changevar()

changevar(gen x, y): change variables of x according to the vector y.

Warning: This doesn't seem to work right at all in Sage (!). Use with caution. *STRANGE*

INPUT:

- x - gen
- y - gen (or coercible to gen)

OUTPUT: gen

EXAMPLES:

```
sage: pari('x^3+1').changevar(pari(['y']))
y^3 + 1
```

charpoly()
charpoly(A,v=x,flag=0): det(v*Id-A) = characteristic polynomial of A using the comatrix. flag is optional and may be set to 1 (use Lagrange interpolation) or 2 (use Hessenberg form), 0 being the default.

chinese()

component()
component(x, long n): Return n'th component of the internal representation of x. This function is 1-based instead of 0-based.

Note: For vectors or matrices, it is simpler to use x[n-1]. For list objects such as is output by nfinit, it is easier to use member functions.

INPUT:

- x - gen
- n - C long (coercible to)

OUTPUT: gen

EXAMPLES:

```
sage: pari([0,1,2,3,4]).component(1)
0
sage: pari([0,1,2,3,4]).component(2)
1
sage: pari([0,1,2,3,4]).component(4)
3
sage: pari('x^3 + 2').component(1)
2
sage: pari('x^3 + 2').component(2)
0
sage: pari('x^3 + 2').component(4)
1

sage: pari('x').component(0)
...
PariError:  (8)
```

concat()

conj()
conj(x): Return the algebraic conjugate of x.

INPUT:

- x - gen

OUTPUT: gen

EXAMPLES:

```
sage: pari('x+1').conj()
x + 1
sage: pari('x+I').conj()
x - I
sage: pari('1/(2*x+3*I)').conj()
1/(2*x - 3*I)
sage: pari([1,2,'2-I','Mod(x,x^2+1)', 'Mod(x,x^2-2)']).conj()
[1, 2, 2 + I, Mod(-x, x^2 + 1), Mod(-x, x^2 - 2)]
sage: pari('Mod(x,x^2-2)').conj()
Mod(-x, x^2 - 2)
sage: pari('Mod(x,x^3-3)').conj()
...
PariError: incorrect type (20)
```

conjvec()

conjvec(x): Returns the vector of all conjugates of the algebraic number x. An algebraic number is a polynomial over Q modulo an irreducible polynomial.

INPUT:

- x - gen

OUTPUT: gen

EXAMPLES:

```
sage: pari('Mod(1+x,x^2-2)').conjvec()
[-0.414213562373095, 2.414213562373710]~
sage: pari('Mod(x,x^3-3)').conjvec()
[1.44224957030741, -0.721124785153704 + 1.24902476648341*I, -0.721124785153704 - 1.249024766
```

contfrac()

contfrac(x,b,lmax): continued fraction expansion of x (x rational, real or rational function). b and lmax are both optional, where b is the vector of numerators of the continued fraction, and lmax is a bound for the number of terms in the continued fraction expansion.

contfracpnqn()

contfracpnqn(x): [p_n,p_n-1; q_n,q_n-1] corresponding to the continued fraction x.

copy()

cos()

The cosine function.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(1.5).cos()
0.0707372016677029
sage: C.<i> = ComplexField()
sage: pari(1+i).cos()
0.833730025131149 - 0.988897705762865*I
sage: pari('x+O(x^8)').cos()
1 - 1/2*x^2 + 1/24*x^4 - 1/720*x^6 + 1/40320*x^8 + O(x^9)
```

cosh()

The hyperbolic cosine function.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(1.5).cosh()
2.35240961524325
sage: C.<i> = ComplexField()
sage: pari(1+i).cosh()
0.833730025131149 + 0.988897705762865*I
sage: pari('x+O(x^8)').cosh()
1 + 1/2*x^2 + 1/24*x^4 + 1/720*x^6 + O(x^8)
```

cotan()

The cotangent of x.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(5).cotan()
-0.295812915532746
```

Computing the cotangent of π doesn't raise an error, but instead just returns a very large (positive or negative) number.

```
sage: x = RR(pi)
sage: pari(x).cotan()          # random
-8.17674825 E15
```

denominator()

denominator(x): Return the denominator of x. When x is a vector, this is the least common multiple of the denominators of the components of x.

what about poly? INPUT:

- x - gen

OUTPUT: gen

EXAMPLES:

```
sage: pari('5/9').denominator()
9
sage: pari('(x+1)/(x-2)').denominator()
x - 2
sage: pari('2/3 + 5/8*x + 7/3*x^2 + 1/5*y').denominator()
1
sage: pari('2/3*x').denominator()
1
sage: pari('[2/3, 5/8, 7/3, 1/5]').denominator()
120
```

deriv()

dilog()

The principal branch of the dilogarithm of x, i.e. the analytic continuation of the power series $\log_2(x) = \sum_{n>=1} x^n/n^2$.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(1).dilog()
1.64493406684823
sage: C.<i> = ComplexField()
sage: pari(1+i).dilog()
0.616850275068085 + 1.46036211675312*I
```

dirzetak()

disc()

e.disc(): return the discriminant of the elliptic curve e.

EXAMPLES:

```
sage: e = pari([0, -1, 1, -10, -20]).ellinit()
sage: e.disc()
-161051
sage: _.factor()
[-1, 1; 11, 5]
```

divrem()

divrem(x, y, v): Euclidean division of x by y giving as a 2-dimensional column vector the quotient and the remainder, with respect to v (to main variable if v is omitted).

eint1()

x.eint1(n): exponential integral E1(x):

$$\int_x^\infty \frac{e^{-t}}{t} dt$$

If n is present, output the vector [eint1(x), eint1(2*x), ..., eint1(n*x)]. This is faster than repeatedly calling eint1(i*x).

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

REFERENCE:

•See page 262, Prop 5.6.12, of Cohen's book "A Course in Computational Algebraic Number Theory".

EXAMPLES:

elementval()

elladd()

e.elladd(z0, z1): return the sum of the points z0 and z1 on this elliptic curve.

INPUT:

•e - elliptic curve E

•z0 - point on E

•z1 - point on E

OUTPUT: point on E

EXAMPLES: First we create an elliptic curve:

```
sage: e = pari([0, 1, 1, -2, 0]).ellinit()
sage: str(e)[:65]   # first part of output
'[0, 1, 1, -2, 0, 4, -4, 1, -3, 112, -856, 389, 1404928/389, [0.90'
```

Next we add two points on the elliptic curve. Notice that the Python lists are automatically converted to PARI objects so you don't have to do that explicitly in your code.

```
sage: e.elladd([1,0], [-1,1])
[-3/4, -15/8]
```

ellak()

e.ellak(n): Returns the coefficient a_n of the L-function of the elliptic curve e, i.e. the n-th Fourier coefficient of the weight 2 newform associated to e (according to Shimura-Taniyama).

> The curve e *must* be a medium or long vector of the type given by ellinit. For this function to work for every n and not just those prime to the conductor, e must be a minimal Weierstrass equation. If this is not the case, use the function ellminimalmodel first before using ellak (or you will get INCORRECT RESULTS!)

INPUT:

•e - a PARI elliptic curve.

•n - integer.

EXAMPLES:

```
sage: e = pari([0, -1, 1, -10, -20]).ellinit()
sage: e.ellak(6)
2
sage: e.ellak(2005)
2
sage: e.ellak(-1)
0
sage: e.ellak(0)
0
```

ellan()

Return the first n Fourier coefficients of the modular form attached to this elliptic curve. See ellak for more details.

INPUT:

- n - a long integer
- python_ints - bool (default is False); if True, return a list of Python ints instead of a PARI gen wrapper.

EXAMPLES:

```
sage: e = pari([0, -1, 1, -10, -20]).ellinit()
sage: e.ellan(3)
[1, -2, -1]
sage: e.ellan(20)
[1, -2, -1, 2, 1, 2, -2, 0, -2, -2, 1, -2, 4, 4, -1, -4, -2, 4, 0, 2]
sage: e.ellan(-1)
[]
sage: v = e.ellan(10, python_ints=True); v
[1, -2, -1, 2, 1, 2, -2, 0, -2, -2]
sage: type(v)
<type 'list'>
sage: type(v[0])
<type 'int'>
```

ellap()

e.ellap(p): Returns the prime-indexed coefficient a_p of the L-function of the elliptic curve e, i.e. the p-th Fourier coefficient of the newform attached to e.

The computation uses the baby-step giant-step method and a trick due to Mestre, and requires $O(p^{1/4})$ time and $O(p^{1/4})$ storage.

If p is not prime, this function will return an incorrect answer.
The curve e must be a medium or long vector of the type given by ellinit. For this function to work for every n and not just those prime to the conductor, e must be a minimal Weierstrass equation. If this is not the case, use the function ellminimalmodel first before using ellap (or you will get INCORRECT RESULTS!)

INPUT:

- e - a PARI elliptic curve.
- p - prime integer

EXAMPLES:

```
sage: e = pari([0, -1, 1, -10, -20]).ellinit()
sage: e.ellap(2)
-2
sage: e.ellap(2003)
4
sage: e.ellak(-1)
0
```

ellaplist()

e.ellaplist(n): Returns a PARI list of all the prime-indexed coefficients a_p (up to n) of the L-function of the elliptic curve e, i.e. the Fourier coefficients of the newform attached to e.

INPUT:

- n - a long integer
- python_ints - bool (default is False); if True, return a list of Python ints instead of a PARI gen wrapper.

The curve e must be a medium or long vector of the type given by ellinit. For this function to work for every n and not just those prime to the conductor, e must be a minimal Weierstrass equation. If this is not the case, use the function ellminimalmodel first before using ellaplist (or you will get INCORRECT RESULTS!)

INPUT:

- e - a PARI elliptic curve.
- n - an integer

EXAMPLES:

```
sage: e = pari([0, -1, 1, -10, -20]).ellinit()
sage: v = e.ellaplist(10); v
[-2, -1, 1, -2]
sage: type(v)
<type 'sage.libs.pari.gen.gen'>
sage: v.type()
't_VEC'
sage: e.ellan(10)
[1, -2, -1, 2, 1, 2, -2, 0, -2, -2]
sage: v = e.ellaplist(10, python_ints=True); v
[-2, -1, 1, -2]
sage: type(v)
<type 'list'>
sage: type(v[0])
<type 'int'>
```

ellbil()

e.ellbil(z0, z1): return the value of the canonical bilinear form on z0 and z1.

INPUT:

- e - elliptic curve (assumed integral given by a minimal model, as returned by ellminimalmodel)
- z0, z1 - rational points on e

EXAMPLES:

```
sage: e = pari([0,1,1,-2,0]).ellinit().ellminimalmodel()[0]
sage: e.ellbil([1, 0], [-1, 1])
0.418188984498861
```

ellchangecurve()

e.ellchangecurve(ch): return the new model (equation) for the elliptic curve e given by the change of coordinates ch.

The change of coordinates is specified by a vector ch=[u,r,s,t]; if x' and y' are the new coordinates, then $x = u^2x' + r$ and $y = u^3y' + su^2x' + t$.

INPUT:

- e - elliptic curve
- ch - change of coordinates vector with 4 entries

EXAMPLES:

```
sage: e = pari([1,2,3,4,5]).ellinit()
sage: e.ellglobalred()
[10351, [1, -1, 0, -1], 1]
sage: f = e.ellchangecurve([1,-1,0,-1])
sage: f[:5]
[1, -1, 0, 4, 3]
```

ellchangepoint()

self.ellchangepoint(y): change data on point or vector of points self on an elliptic curve according to y=[u,r,s,t]

EXAMPLES:

```
sage: e = pari([0,1,1,-2,0]).ellinit()
sage: x = pari([1,0])
sage: e.ellisoncurve([1,4])
False
sage: e.ellisoncurve(x)
True
sage: f = e.ellchangecurve([1,2,3,-1])
sage: f[:5]   # show only first five entries
[6, -2, -1, 17, 8]
sage: x.ellchangepoint([1,2,3,-1])
[-1, 4]
sage: f.ellisoncurve([-1,4])
True
```

elleisnum()

om.elleisnum(k, flag=0): om=[om1,om2] being a 2-component vector giving a basis of a lattice L and k an even positive integer, computes the numerical value of the Eisenstein series of weight k. When flag is non-zero and k=4 or 6, this gives g2 or g3 with the correct normalization.

INPUT:

- `om` - gen, 2-component vector giving a basis of a lattice L
- `k` - int (even positive)
- `flag` - int (default 0)

OUTPUT:

- `gen` - numerical value of E_k

EXAMPLES:

```
sage: e = pari([0,1,1,-2,0]).ellinit()
sage: om = e.omega()
sage: om
[2.49021256085506, 1.97173770155165*I]
sage: om.elleisnum(2)
-5.28864933965426
sage: om.elleisnum(4)
112.000000000000
sage: om.elleisnum(100)
2.15314248576078 E50
```

elleta()

e.elleta(): return the vector [eta1,eta2] of quasi-periods associated with the period lattice e.omega() of the elliptic curve e.

EXAMPLES:

```
sage: e = pari([0,0,0,-82,0]).ellinit()
sage: e.elleta()
[3.60546360143265, 10.8163908042980*I]
```

ellglobalred()

e.ellglobalred(): return information related to the global minimal model of the elliptic curve e.

INPUT:

- `e` - elliptic curve (returned by ellinit)

OUTPUT:

- `gen` - the (arithmetic) conductor of e
- `gen` - a vector giving the coordinate change over Q from e to its minimal integral model (see also ellminimalmodel)

- gen - the product of the local Tamagawa numbers of e

EXAMPLES:

```
sage: e = pari([0, 5, 2, -1, 1]).ellinit()
sage: e.ellglobalred()
[20144, [1, -2, 0, -1], 1]
sage: e = pari(EllipticCurve('17a').a_invariants()).ellinit()
sage: e.ellglobalred()
[17, [1, 0, 0, 0], 4]
```

ellheight()

e.ellheight(a, flag=2): return the global Neron-Tate height of the point a on the elliptic curve e.

INPUT:

- e - elliptic curve over $\mathbf{Q}$, assumed to be in a standard minimal integral model (as given by ellminimalmodel)
- a - rational point on e
- flag (optional) - specifies which algorithm to be used for computing the archimedean local height:
  - **0 - uses sigma- and theta-functions and a trick** due to J. Silverman
  - 1 - uses Tate's 4^n algorithm
  - 2 - uses Mestre's AGM algorithm (this is the default, being faster than the other two)
- precision (optional) - the precision of the result, in bits.

Note that in order to achieve the desired precision, the elliptic curve must have been created using ellinit with the desired precision.

EXAMPLES:

```
sage: e = pari([0,1,1,-2,0]).ellinit().ellminimalmodel()[0]
sage: e.ellheight([1,0])
0.476711659343740
sage: e.ellheight([1,0], flag=0)
0.476711659343740
sage: e.ellheight([1,0], flag=1)
0.476711659343740
```

ellheightmatrix()

e.ellheightmatrix(x): return the height matrix for the vector x of points on the elliptic curve e.

In other words, it returns the Gram matrix of x with respect to the height bilinear form on e (see ellbil).

INPUT:

- e - elliptic curve over $\mathbf{Q}$, assumed to be in a standard minimal integral model (as given by ellminimalmodel)
- x - vector of rational points on e

EXAMPLES:

```
sage: e = pari([0,1,1,-2,0]).ellinit().ellminimalmodel()[0]
sage: e.ellheightmatrix([[1,0], [-1,1]])
[0.476711659343740, 0.418188984498861; 0.418188984498861, 0.686667083305587]
```

ellinit()

Return the Pari elliptic curve object with Weierstrass coefficients given by self, a list with 5 elements.

INPUT:

- self - a list of 5 coefficients
- flag (optional, default: 0) - if 0, ask for a Pari ell structure with 19 components; if 1, ask for a Pari sell structure with only the first 13 components

- precision (optional, default: 0) - the real precision to be used in the computation of the components of the Pari (s)ell structure; if 0, use the default 53 bits.
  Note: the parameter precision in ellinit() controls not only the real precision of the resulting (s)ell structure, but also the precision of most subsequent computations with this elliptic curve. You should therefore set it from the start to the value you require.

OUTPUT:

- gen - either a Pari ell structure with 19 components (if flag=0), or a Pari sell structure with 13 components (if flag=1)

EXAMPLES: An elliptic curve with integer coefficients:

```
sage: e = pari([0,1,0,1,0]).ellinit(); e
[0, 1, 0, 1, 0, 4, 2, 0, -1, -32, 224, -48, 2048/3, [0.E-28, -0.500000000000000 - 0.8660254(
[0, 1, 0, 1, 0, 4, 2, 0, -1, -32, 224, -48, 2048/3, [0.E-38, -0.500000000000000 - 0.8660254(
```

Its inexact components have the default precision of 53 bits:

```
sage: RR(e[14])
3.37150070962519
```

We can compute this to higher precision:

```
sage: R = RealField(150)
sage: e = pari([0,1,0,1,0]).ellinit(precision=150)
sage: R(e[14])
3.3715007096251920857424073155981539790016018
```

Using flag=1 returns a short elliptic curve Pari object:

```
sage: pari([0,1,0,1,0]).ellinit(flag=1)
[0, 1, 0, 1, 0, 4, 2, 0, -1, -32, 224, -48, 2048/3]
```

The coefficients can be any ring elements that convert to Pari:

```
sage: pari([0,1/2,0,-3/4,0]).ellinit(flag=1)
[0, 1/2, 0, -3/4, 0, 2, -3/2, 0, -9/16, 40, -116, 117/4, 256000/117]
sage: pari([0,0.5,0,-0.75,0]).ellinit(flag=1)
[0, 0.500000000000000, 0, -0.750000000000000, 0, 2.00000000000000, -1.50000000000000, 0, -0.
sage: pari([0,I,0,1,0]).ellinit(flag=1)
[0, I, 0, 1, 0, 4*I, 2, 0, -1, -64, 352*I, -80, 16384/5]
sage: pari([0,x,0,2*x,1]).ellinit(flag=1)
[0, x, 0, 2*x, 1, 4*x, 4*x, 4, -4*x^2 + 4*x, 16*x^2 - 96*x, -64*x^3 + 576*x^2 - 864, 64*x^4
```

ellisoncurve()

e.ellisoncurve(x): return True if the point x is on the elliptic curve e, False otherwise.

If the point or the curve have inexact coefficients, an attempt is made to take this into account.

EXAMPLES:

```
sage: e = pari([0,1,1,-2,0]).ellinit()
sage: e.ellisoncurve([1,0])
True
sage: e.ellisoncurve([1,1])
False
sage: e.ellisoncurve([1,0.00000000000000001])
False
sage: e.ellisoncurve([1,0.000000000000000001])
True
sage: e.ellisoncurve([0])
True
```

ellj()

elllocalred()

e.elllocalred(p): computes the data of local reduction at the prime p on the elliptic curve e

For more details on local reduction and Kodaira types, see IV.8 and IV.9 in J. Silverman's book "Advanced topics in the arithmetic of elliptic curves".

INPUT:

- `e` - elliptic curve with coefficients in **Z**
- `p` - prime number

OUTPUT:

- `gen` - the exponent of p in the arithmetic conductor of e
- `gen` - the Kodaira type of e at p, encoded as an integer:
- `1` - type I_0: good reduction, nonsingular curve of genus 1
- `2` - type II: rational curve with a cusp
- `3` - type III: two nonsingular rational cuves intersecting tangentially at one point
- `4` - type IV: three nonsingular rational curves intersecting at one point
- `5` - type I_1: rational curve with a node
- `6 or larger` - think of it as $4 + v$, then it is type I_v: v nonsingular rational curves arranged as a v-gon
- `-1` - type I_0^*: nonsingular rational curve of multiplicity two with four nonsingular rational curves of multiplicity one attached
- `-2` - type II^*: nine nonsingular rational curves in a special configuration
- `-3` - type III^*: eight nonsingular rational curves in a special configuration
- `-4` - type IV^*: seven nonsingular rational curves in a special configuration
- `-5 or smaller` - think of it as $-4 - v$, then it is type I_v^*: chain of $v + 1$ nonsingular rational curves of multiplicity two, with two nonsingular rational curves of multiplicity one attached at either end
- `gen` - a vector with 4 components, giving the coordinate changes done during the local reduction; if the first component is 1, then the equation for e was already minimal at p
- `gen` - the local Tamagawa number c_p

EXAMPLES:

Type I_0:

```
sage: e = pari([0,0,0,0,1]).ellinit()
sage: e.elllocalred(7)
[0, 1, [1, 0, 0, 0], 1]
```

Type II:

```
sage: e = pari(EllipticCurve('27a3').a_invariants()).ellinit()
sage: e.elllocalred(3)
[3, 2, [1, -1, 0, 1], 1]
```

Type III:

```
sage: e = pari(EllipticCurve('24a4').a_invariants()).ellinit()
sage: e.elllocalred(2)
[3, 3, [1, 1, 0, 1], 2]
```

Type IV:

```
sage: e = pari(EllipticCurve('20a2').a_invariants()).ellinit()
sage: e.elllocalred(2)
[2, 4, [1, 1, 0, 1], 3]
```

Type I_1:

```
sage: e = pari(EllipticCurve('11a2').a_invariants()).ellinit()
sage: e.elllocalred(11)
[1, 5, [1, 0, 0, 0], 1]
```

Type I_2:

```
sage: e = pari(EllipticCurve('14a4').a_invariants()).ellinit()
sage: e.elllocalred(2)
[1, 6, [1, 0, 0, 0], 2]
```

Type I_6:

```
sage: e = pari(EllipticCurve('14a1').a_invariants()).ellinit()
sage: e.elllocalred(2)
[1, 10, [1, 0, 0, 0], 2]
```

Type I_0^*:

```
sage: e = pari(EllipticCurve('32a3').a_invariants()).ellinit()
sage: e.elllocalred(2)
[5, -1, [1, 1, 1, 0], 1]
```

Type II^*:

```
sage: e = pari(EllipticCurve('24a5').a_invariants()).ellinit()
sage: e.elllocalred(2)
[3, -2, [1, 2, 1, 4], 1]
```

Type III^*:

```
sage: e = pari(EllipticCurve('24a2').a_invariants()).ellinit()
sage: e.elllocalred(2)
[3, -3, [1, 2, 1, 4], 2]
```

Type IV^*:

```
sage: e = pari(EllipticCurve('20a1').a_invariants()).ellinit()
sage: e.elllocalred(2)
[2, -4, [1, 0, 1, 2], 3]
```

Type I_1^*:

```
sage: e = pari(EllipticCurve('24a1').a_invariants()).ellinit()
sage: e.elllocalred(2)
[3, -5, [1, 0, 1, 2], 4]
```

Type I_6^*:

```
sage: e = pari(EllipticCurve('90c2').a_invariants()).ellinit()
sage: e.elllocalred(3)
[2, -10, [1, 96, 1, 316], 4]
```

elllseries()

e.elllseries(s, A=1): return the value of the L-series of the elliptic curve e at the complex number s.

This uses an $O(N^{1/2})$ algorithm in the conductor N of e, so it is impractical for large conductors (say greater than 10^{12}).

INPUT:

- e - elliptic curve defined over $\mathbf{Q}$
- s - complex number
- A (optional) - cutoff point for the integral, which must be chosen close to 1 for best speed.

EXAMPLES:

```
sage: e = pari([0,1,1,-2,0]).ellinit()
sage: e.elllseries(2.1)
0.402838047956645
sage: e.elllseries(1)    # random, close to 0
1.822829333527862 E-19
sage: e.elllseries(-2)
0
```

The following example differs for the last digit on 32 vs. 64 bit systems

```
sage: e.elllseries(2.1, A=1.1)
0.402838047956645
```

ellminimalmodel()

ellminimalmodel(e): return the standard minimal integral model of the rational elliptic curve e and the corresponding change of variables. INPUT:

- e - gen (that defines an elliptic curve)

OUTPUT:

- gen - minimal model
- gen - change of coordinates

EXAMPLES:

```
sage: e = pari([1,2,3,4,5]).ellinit()
sage: F, ch = e.ellminimalmodel()
sage: F[:5]
[1, -1, 0, 4, 3]
sage: ch
[1, -1, 0, -1]
sage: e.ellchangecurve(ch)[:5]
[1, -1, 0, 4, 3]
```

ellorder()

e.ellorder(x): return the order of the point x on the elliptic curve e (return 0 if x is not a torsion point)

INPUT:

- e - elliptic curve defined over $\mathbf{Q}$
- x - point on e

EXAMPLES:

```
sage: e = pari(EllipticCurve('65a1').a_invariants()).ellinit()
```

A point of order two:

```
sage: e.ellorder([0,0])
2
```

And a point of infinite order:

```
sage: e.ellorder([1,0])
0
```

ellordinate()

e.ellordinate(x): return the y-coordinates of the points on the elliptic curve e having x as x-coordinate.

INPUT:

- e - elliptic curve
- x - x-coordinate (can be a complex or p-adic number, or a more complicated object like a power series)

EXAMPLES:

```
sage: e = pari([0,1,1,-2,0]).ellinit()
sage: e.ellordinate(0)
[0, -1]
sage: C.<i> = ComplexField()
sage: e.ellordinate(i)
[0.582203589721741 - 1.38606082464177*I, -1.58220358972174 + 1.38606082464177*I]
sage: e.ellordinate(1+3*5^1+O(5^3))
[4*5 + 5^2 + O(5^3), 4 + 3*5^2 + O(5^3)]
sage: e.ellordinate('z+2*z^2+O(z^4)')
[-2*z - 7*z^2 - 23*z^3 + O(z^4), -1 + 2*z + 7*z^2 + 23*z^3 + O(z^4)]
```

ellpointtoz()

e.ellpointtoz(P): return the complex number (in the fundamental parallelogram) corresponding to the point P on the elliptic curve e, under the complex uniformization of e given by the Weierstrass p-function.

The complex number z returned by this function lies in the parallelogram formed by the real and complex periods of e, as given by e.omega().

EXAMPLES:

```
sage: e = pari([0,0,0,1,0]).ellinit()
sage: e.ellpointtoz([0,0])
1.85407467730137
```

The point at infinity is sent to the complex number 0:

```
sage: e.ellpointtoz([0])
0
```

ellpow()

e.ellpow(z, n): return n times the point z on the elliptic curve e.

INPUT:

- e - elliptic curve
- z - point on e
- n - integer, or a complex quadratic integer of complex multiplication for e (CM case is currently broken in pari)

EXAMPLES: We consider a CM curve:

```
sage: e = pari([0,0,0,1,0]).ellinit()
```

Multiplication by two:

```
sage: e.ellpow([0,0], 2)
[0]
```

Complex multiplication (this is broken at the moment):

```
sage: e.ellpow([0,0], I+1) # optional
```

ellrootno()

e.ellrootno(p): return the (local or global) root number of the L-series of the elliptic curve e

If p is a prime number, the local root number at p is returned. If p is 1, the global root number is returned. Note that the global root number is the sign of the functional equation of the L-series, and therefore conjecturally equal to the parity of the rank of e.

INPUT:

- e - elliptic curve over $\mathbf{Q}$
- p (default = 1) - 1 or a prime number

OUTPUT: 1 or -1

EXAMPLES: Here is a curve of rank 3:

```
sage: e = pari([0,0,0,-82,0]).ellinit()
sage: e.ellrootno()
-1
sage: e.ellrootno(2)
1
sage: e.ellrootno(1009)
1
```

ellsigma()

e.ellsigma(z, flag=0): return the value at the complex point z of the Weierstrass σ function associated to the elliptic curve e.

EXAMPLES:

```
sage: e = pari([0,0,0,1,0]).ellinit()
sage: C.<i> = ComplexField()
sage: e.ellsigma(2+i)
1.43490215804166 + 1.80307856719256*I
```

ellsub()

e.ellsub(z0, z1): return z0-z1 on this elliptic curve.

INPUT:

- e - elliptic curve E
- z0 - point on E
- z1 - point on E

OUTPUT: point on E

EXAMPLES:

```
sage: e = pari([0, 1, 1, -2, 0]).ellinit()
sage: e.ellsub([1,0], [-1,1])
[0, 0]
```

elltaniyama()

elltors()

e.elltors(flag = 0): return information about the torsion subgroup of the elliptic curve e

INPUT:

- e - elliptic curve over $\mathbf{Q}$
- flag (optional) - specify which algorithm to use:
- 0 (default) - use Doud's algorithm: bound torsion by computing the cardinality of e(GF(p)) for small primes of good reduction, then look for torsion points using Weierstrass parametrization and Mazur's classification
- 1 - use algorithm given by the Nagell-Lutz theorem (this is much slower)

OUTPUT:

- gen - the order of the torsion subgroup, a.k.a. the number of points of finite order
- gen - vector giving the structure of the torsion subgroup as a product of cyclic groups, sorted in non-increasing order
- gen - vector giving points on e generating these cyclic groups

EXAMPLES:

```
sage: e = pari([1,0,1,-19,26]).ellinit()
sage: e.elltors()
[12, [6, 2], [[-2, 8], [3, -2]]]
```

ellwp()

ellwp(E, z,flag=0): Return the complex value of the Weierstrass P-function at z on the lattice defined by e.

INPUT:

- E - list OR elliptic curve
- list - [om1, om2], which are Z-generators for a lattice
- elliptic curve - created using ellinit
- z - (optional) complex number OR string (default = "z")
- complex number - any number in the complex plane
- string (or PARI variable) - name of a variable.
- n - int (optional: default 20) if z is a variable, compute up to at least $o(z^n)$.
- flag - int: 0 (default): compute only P(z) 1 compute [P(z),P'(z)] 2 consider om or E as an elliptic curve and use P-function to compute the point on E (with the Weierstrass equation for E) P(z) for that curve (identical to ellztopoint in this case).

OUTPUT:

- gen - complex number or list of two complex numbers

EXAMPLES:

We first define the elliptic curve X_0(11):

```
sage: E = pari([0,-1,1,-10,-20]).ellinit()
```

Compute P(1).

```
sage: E.ellwp(1)
13.9658695257485 + 1.140149682... E-18*I
```

Compute P(1+i), where i = sqrt(-1).

```
sage: C.<i> = ComplexField()
sage: E.ellwp(pari(1+i))
-1.11510682565555 + 2.33419052307470*I
sage: E.ellwp(1+i)
-1.11510682565555 + 2.33419052307470*I
```

The series expansion, to the default 20 precision:

```
sage: E.ellwp()
z^-2 + 31/15*z^2 + 2501/756*z^4 + 961/675*z^6 + 77531/41580*z^8 + 1202285717/928746000*z^10
```

Compute the series for wp to lower precision:

```
sage: E.ellwp(n=4)
z^-2 + 31/15*z^2 + O(z^4)
```

Next we use the version where the input is generators for a lattice:

```
sage: pari([1.2692, 0.63 + 1.45*i]).ellwp(1)
13.9656146936689 + 0.000644829272810537*I
```

With flag 1 compute the pair P(z) and P'(z):

```
sage: E.ellwp(1, flag=1)
[13.9658695257485 + 1.140149682 E-18*I, 50.5619300880073 + 1.040834085 E-17*I] # 32-bit
[13.9658695257485 + 1.14014968292839 E-18*I, 50.5619300880073 + 6.93889390390723 E-18*I] # 6
```

With flag=2, the computed pair is (x,y) on the curve instead of [P(z),P'(z)]:

```
sage: E.ellwp(1, flag=2)
[14.2992028590818 + 1.140149682 E-18*I, 50.0619300880073 + 1.040834085 E-17*I] # 32-bit
[14.2992028590818 + 1.14014968292839 E-18*I, 50.0619300880073 + 6.93889390390723 E-18*I] # 6
```

ellzeta()

e.ellzeta(z): return the value at the complex point z of the Weierstrass ζ function associated with the elliptic curve e.

Note: This function has infinitely many poles (one of which is at z=0); attempting to evaluate it too close to one of the poles will result in a PariError.

INPUT:

- e - elliptic curve
- z - complex number

EXAMPLES:

```
sage: e = pari([0,0,0,1,0]).ellinit()
sage: e.ellzeta(1)
1.06479841295883 + 0.E-19*I                 # 32-bit
1.06479841295883 - 5.42101086242752 E-20*I # 64-bit
sage: C.<i> = ComplexField()
sage: e.ellzeta(i-1)
-0.350122658523049 - 0.350122658523049*I
```

ellztopoint()

e.ellztopoint(z): return the point on the elliptic curve e corresponding to the complex number z, under the usual complex uniformization of e by the Weierstrass p-function.

INPUT:

- e - elliptic curve
- z - complex number

OUTPUT point on e

EXAMPLES:

```
sage: e = pari([0,0,0,1,0]).ellinit()
sage: C.<i> = ComplexField()
sage: e.ellztopoint(1+i)
[0.E-19 - 1.02152286795670*I, -0.149072813701096 - 0.149072813701096*I] # 32-bit
[8.67655312026478 E-20 - 1.02152286795670*I, -0.149072813701096 - 0.149072813701096*I] # 64-
```

Complex numbers belonging to the period lattice of e are of course sent to the point at infinity on e:

```
sage: e.ellztopoint(0)
[0]
```

erfc()

Return the complementary error function:

$$(2/\sqrt{\pi})\int_x^\infty e^{-t^2}dt.$$

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(1).erfc()
0.157299207050285
```

eta()

x.eta(flag=0): if flag=0, η function without the $q^{1/24}$; otherwise η of the complex number x in the upper half plane intelligently computed using $\mathrm{SL}(2,\mathbf{Z})$ transformations.

DETAILS: This functions computes the following. If the input x is a complex number with positive imaginary part, the result is $\prod_{n=1}^{\infty}(q-1^n)$, where $q=e^{2i\pi x}$. If x is a power series (or can be converted to a power series) with positive valuation, the result is $\prod_{n=1}^{\infty}(1-x^n)$.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: C.<i> = ComplexField()
sage: pari(i).eta()
0.998129069925959 + 0.E-21*I
```

eval()

exp()

x.exp(): exponential of x.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(0).exp()
1.00000000000000
sage: pari(1).exp()
2.71828182845905
sage: pari('x+O(x^8)').exp()
1 + x + 1/2*x^2 + 1/6*x^3 + 1/24*x^4 + 1/120*x^5 + 1/720*x^6 + 1/5040*x^7 + O(x^8)
```

factor()

Return the factorization of x.

INPUT:

- `limit` - (default: -1) is optional and can be set whenever x is of (possibly recursive) rational type. If limit is set return partial factorization, using primes up to limit (up to primelimit if limit=0).

proof - (default: True) optional. If False (not the default), returned factors $< 10^{15}$ may only be pseudo-primes.

Note: In the standard PARI/GP interpreter and C-library the factor command *always* has proof=False, so beware!

EXAMPLES:

```
sage: pari('x^10-1').factor()
[x - 1, 1; x + 1, 1; x^4 - x^3 + x^2 - x + 1, 1; x^4 + x^3 + x^2 + x + 1, 1]
sage: pari(2^100-1).factor()
[3, 1; 5, 3; 11, 1; 31, 1; 41, 1; 101, 1; 251, 1; 601, 1; 1801, 1; 4051, 1; 8101, 1; 268501,
sage: pari(2^100-1).factor(proof=False)
[3, 1; 5, 3; 11, 1; 31, 1; 41, 1; 101, 1; 251, 1; 601, 1; 1801, 1; 4051, 1; 8101, 1; 268501,
```

We illustrate setting a limit:

```
sage: pari(next_prime(10^50)*next_prime(10^60)*next_prime(10^4)).factor(10^5)
[10007, 1; 10000000000000000000000000000000000000000000000015100000000070000000000000000000
```

PARI doesn't have an algorithm for factoring multivariate polynomials:

```
sage: pari('x^3 - y^3').factor()
...
PariError: sorry, (15)
```

factormod()

x.factormod(p,flag=0): factorization mod p of the polynomial x using Berlekamp. flag is optional, and can be 0: default or 1: simple factormod, same except that only the degrees of the irreducible factors are given.

factorpadic()

self.factorpadic(p,r=20,flag=0): p-adic factorization of the polynomial x to precision r. flag is optional and may be set to 0 (use round 4) or 1 (use Buchmann-Lenstra)

fibonacci()

Return the Fibonacci number of index x.

EXAMPLES:

```
sage: pari(18).fibonacci()
2584
sage: [pari(n).fibonacci() for n in range(10)]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34]
```

floor()

For real x: return the largest integer = x. For rational functions: the quotient of numerator by denominator. For lists: apply componentwise.

INPUT:

- x - gen

OUTPUT: gen

EXAMPLES:

```
sage: pari(5/9).floor()
0
sage: pari(11/9).floor()
1
sage: pari(1.17).floor()
1
sage: pari([1.5,2.3,4.99]).floor()
[1, 2, 4]
sage: pari([[1.1,2.2],[3.3,4.4]]).floor()
[[1, 2], [3, 4]]
sage: pari(x).floor()
x
sage: pari((x^2+x+1)/x).floor()
x + 1
sage: pari(x^2+5*x+2.5).floor()
x^2 + 5*x + 2.50000000000000

sage: pari('"hello world"').floor()
...
PariError: incorrect type (20)
```

frac()

frac(x): Return the fractional part of x, which is x - floor(x).

INPUT:

- x - gen

OUTPUT: gen

EXAMPLES:

```
sage: pari(1.75).frac()
0.750000000000000
sage: pari(sqrt(2)).frac()
0.414213562373095
sage: pari('sqrt(-2)').frac()
...
PariError: incorrect type (20)
```

galoisapply()

galoisconj()

galoisfixedfield()

galoisinit()

galoisinit(K{,den}): calculate Galois group of number field K; see PARI manual for meaning of den

galoispermtopol()

gamma()

s.gamma(precision): Gamma function at s.

If s is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If s is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(2).gamma()
1.00000000000000
sage: pari(5).gamma()
24.0000000000000
sage: C.<i> = ComplexField()
sage: pari(1+i).gamma()
0.498015668118356 - 0.154949828301811*I
```

gammah()

s.gammah(): Gamma function evaluated at the argument x+1/2.

If s is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If s is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(2).gammah()
1.32934038817914
sage: pari(5).gammah()
52.3427777845535
sage: C.<i> = ComplexField()
sage: pari(1+i).gammah()
0.575315188063452 + 0.0882106775440939*I
```

gcd()

gcd(x,y,flag=0): greatest common divisor of x and y. flag is optional, and can be 0: default, 1: use the modular gcd algorithm (x and y must be polynomials), 2 use the subresultant algorithm (x and y must be polynomials)

getattr()

hilbert()

hyperu()

a.hyperu(b,x): U-confluent hypergeometric function.

If a, b, or x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If the arguments are inexact (e.g. real), the smallest of their precisions is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(1).hyperu(2,3)
0.333333333333333
```

idealadd()

idealappr()

idealcoprime()

Given two integral ideals x and y of a pari number field self, return an element a of the field (expressed in the integral basis of self) such that a*x is an integral ideal coprime to y.

EXAMPLES:

```
sage: F = NumberField(x^3-2, 'alpha')
sage: nf = F._pari_()
sage: x = pari('[1, -1, 2]~')
sage: y = pari('[1, -1, 3]~')
sage: nf.idealcoprime(x, y)
[1, 0, 0]~

sage: y = pari('[2, -2, 4]~')
sage: nf.idealcoprime(x, y)
[5/43, 9/43, -1/43]~
```

idealdiv()

idealfactor()

idealhnf()

ideallog()

Return the discrete logarithm of the unit x in (ring of integers)/bid.

INPUT:

- `self` - a pari number field
- `bid` - a big ideal structure (corresponding to an ideal I of self) output by idealstar
- `x` - an element of self with valuation zero at all primes dividing I

OUTPUT:

- the discrete logarithm of x on the generators given in bid[2]

EXAMPLE:

```
sage: F = NumberField(x^3-2, 'alpha')
sage: nf = F._pari_()
sage: I = pari('[1, -1, 2]~')
sage: bid = nf.idealstar(I)
sage: x = pari('5')
sage: nf.ideallog(x, bid)
[25]~
```

idealmul()

idealnorm()

idealred()

idealstar()

Return the big ideal (bid) structure of modulus I.

INPUT:

- `self` - a pari number field
- `I` – an ideal of self, or a row vector whose first component is an ideal and whose second component is a row vector of r_1 0 or 1.
- `flag` - determines the amount of computation and the shape of the output:
  - `1` (default): return a bid structure without generators
  - `2`: return a bid structure with generators (slower)
  - `0` (deprecated): only outputs units of (ring of integers/I) as an abelian group, i.e as a 3-component vector [h,d,g]: h is the order, d is the vector of SNF cyclic components and g the corresponding generators. This flag is deprecated: it is in fact slightly faster to compute a true bid structure, which contains much more information.

EXAMPLE:

```
sage: F = NumberField(x^3-2, 'alpha')
sage: nf = F._pari_()
sage: I = pari('[1, -1, 2]~')
sage: nf.idealstar(I)
[[[43, 9, 5; 0, 1, 0; 0, 0, 1], [0]], [42, [42]], Mat([[43, [9, 1, 0]~, 1, 1, [-5, -9, 1]~],
```

idealtwoelt()

idealval()

imag()

imag(x): Return the imaginary part of x. This function also works component-wise.

INPUT:

- x - gen

OUTPUT: gen

EXAMPLES:

```
sage: pari('1+2*I').imag()
2
sage: pari(sqrt(-2)).imag()
1.41421356237310
sage: pari('x+I').imag()
1
sage: pari('x+2*I').imag()
2
sage: pari('(1+I)*x^2+2*I').imag()
x^2 + 2
sage: pari('[1,2,3] + [4*I,5,6]').imag()
[4, 0, 0]
```

incgam()

s.incgam(x, y, precision): incomplete gamma function. y is optional and is the precomputed value of gamma(s).

If s is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If s is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: C.<i> = ComplexField()
sage: pari(1+i).incgam(3-i)
-0.0458297859919946 + 0.0433696818726677*I
```

incgamc()

s.incgamc(x): complementary incomplete gamma function.

The arguments x and s are complex numbers such that s is not a pole of Γ and $|x|/(|s|+1)$ is not much larger than 1 (otherwise, the convergence is very slow). The function returns the value of the integral $\int_0^x e^{-t}t^{s-1}dt$.

If s or x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If the arguments are inexact (e.g. real), the smallest of their precisions is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(1).incgamc(2)
0.864664716763387
```

int_unsafe()

Returns int form of self, but raises an exception if int does not fit into a long integer.

This is about 5 times faster than the usual int conversion.

intformal()
x.intformal(y): formal integration of x with respect to the main variable of y, or to the main variable of x if y is omitted

intvec_unsafe()
Returns Python int list form of entries of self, but raises an exception if int does not fit into a long integer. Here self must be a vector.

EXAMPLES:

```
sage: pari('[3,4,5]').type()
't_VEC'
sage: pari('[3,4,5]').intvec_unsafe()
[3, 4, 5]
sage: type(pari('[3,4,5]').intvec_unsafe()[0])
<type 'int'>
```

TESTS:

```
sage: pari(3).intvec_unsafe()
...
TypeError: gen must be of PARI type t_VEC
sage: pari('[2^150,1]').intvec_unsafe()
...
PariError: impossible assignment I-->S (23)
```

ispower()
Determine whether or not self is a perfect k-th power. If k is not specified, find the largest k so that self is a k-th power.

INPUT:

- k - int (optional)

OUTPUT:

- power - int, what power it is
- g - what it is a power of

EXAMPLES:

```
sage: pari(9).ispower()
(2, 3)
sage: pari(17).ispower()
(1, 17)
sage: pari(17).ispower(2)
(False, None)
sage: pari(17).ispower(1)
(1, 17)
sage: pari(2).ispower()
(1, 2)
```

isprime()
isprime(x, flag=0): Returns True if x is a PROVEN prime number, and False otherwise.

INPUT:

- flag - int 0 (default): use a combination of algorithms. 1: certify primality using the Pocklington-Lehmer Test. 2: certify primality using the APRCL test.

OUTPUT:

- bool - True or False

EXAMPLES:

```
sage: pari(9).isprime()
False
sage: pari(17).isprime()
True
sage: n = pari(561)     # smallest Carmichael number
sage: n.isprime()       # not just a pseudo-primality test!
False
sage: n.isprime(1)
False
sage: n.isprime(2)
False
```

ispseudoprime()

ispseudoprime(x, flag=0): Returns True if x is a pseudo-prime number, and False otherwise.

INPUT:

- `flag` - int 0 (default): checks whether x is a Baillie-Pomerance-Selfridge-Wagstaff pseudo prime (strong Rabin-Miller pseudo prime for base 2, followed by strong Lucas test for the sequence (P,-1), P smallest positive integer such that $P^2 - 4$ is not a square mod x). 0: checks whether x is a strong Miller-Rabin pseudo prime for flag randomly chosen bases (with end-matching to catch square roots of -1).

OUTPUT:

- `bool` - True or False

EXAMPLES:

```
sage: pari(9).ispseudoprime()
False
sage: pari(17).ispseudoprime()
True
sage: n = pari(561)      # smallest Carmichael number
sage: n.ispseudoprime() # not just any old pseudo-primality test!
False
sage: n.ispseudoprime(2)
False
```

issquare()

issquare(x,n): true(1) if x is a square, false(0) if not. If find_root is given, also returns the exact square root if it was computed.

issquarefree()

EXAMPLES:

```
sage: pari(10).issquarefree()
True
sage: pari(20).issquarefree()
False
```

j()

e.j(): return the j-invariant of the elliptic curve e.

EXAMPLES:

```
sage: e = pari([0, -1, 1, -10, -20]).ellinit()
sage: e.j()
-122023936/161051
sage: _.factor()
[-1, 1; 2, 12; 11, -5; 31, 3]
```

kronecker()

lcm()
Return the least common multiple of x and y. EXAMPLES:

```
sage: pari(10).lcm(15)
30
```

length()

lex()
lex(x,y): Compare x and y lexicographically (1 if xy, 0 if x==y, -1 if xy)

lift()
lift(x,v): Returns the lift of an element of Z/nZ to Z or R[x]/(P) to R[x] for a type R if v is omitted. If v is given, lift only polymods with main variable v. If v does not occur in x, lift only intmods.

INPUT:

- x - gen
- v - (optional) variable

OUTPUT: gen

EXAMPLES:

```
sage: x = pari("x")
sage: a = x.Mod('x^3 + 17*x + 3')
sage: a
Mod(x, x^3 + 17*x + 3)
sage: b = a^4; b
Mod(-17*x^2 - 3*x, x^3 + 17*x + 3)
sage: b.lift()
-17*x^2 - 3*x
```

??? more examples

lindep()

list()

list_str()
Return str that might correctly evaluate to a Python-list.

listinsert()

listput()

lllgram()

lllgramint()

lngamma()
x.lngamma(): logarithm of the gamma function of x.

This function returns the principal branch of the logarithm of the gamma function of x. The function $\log(\Gamma(x))$ is analytic on the complex plane with non-positive integers removed. This function can have much larger inputs than Γ itself.

The p-adic analogue of this function is unfortunately not implemented.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(100).lngamma()
359.134205369575
```

log()
x.log(): natural logarithm of x.

This function returns the principal branch of the natural logarithm of x, i.e., the branch such that $\Im(\log(x)) \in]-\pi, \pi]$. The result is complex (with imaginary part equal to π) if $x \in \mathbf{R}$ and $x < 0$. In general, the algorithm uses the formula

$$\log(x) \simeq \frac{\pi}{2\mathrm{agm}(1, 4/s)} - m\log(2),$$

if $s = x2^m$ is large enough. (The result is exact to B bits provided that $s > 2^{B/2}$.) At low accuracies, this function computes $\log$ using the series expansion near 1.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

Note that p-adic arguments can also be given as input, with the convention that $\log(p) = 0$. Hence, in particular, $\exp(\log(x))/x$ is not in general equal to 1 but instead to a $(p-1)$-st root of unity (or ± 1 if $p = 2$) times a power of p.

EXAMPLES:

```
sage: pari(5).log()
1.60943791243410
sage: C.<i> = ComplexField()
sage: pari(i).log()
0.E-19 + 1.57079632679490*I
```

matadjoint()

matadjoint(x): adjoint matrix of x.

EXAMPLES:

```
sage: pari('[1,2,3; 4,5,6;  7,8,9]').matadjoint()
[-3, 6, -3; 6, -12, 6; -3, 6, -3]
sage: pari('[a,b,c; d,e,f; g,h,i]').matadjoint()
[(i*e - h*f), (-i*b + h*c), (f*b - e*c); (-i*d + g*f), i*a - g*c, -f*a + d*c; (h*d - g*e), -
```

matdet()

Return the determinant of this matrix.

INPUT:

- `flag` - (optional) flag 0: using Gauss-Bareiss. 1: use classical gaussian elimination (slightly better for integer entries)

EXAMPLES:

```
sage: pari('[1,2; 3,4]').matdet(0)
-2
sage: pari('[1,2; 3,4]').matdet(1)
-2
```

matfrobenius()

M.matfrobenius(flag=0): Return the Frobenius form of the square matrix M. If flag is 1, return only the elementary divisors (a list of polynomials). If flag is 2, return a two-components vector [F,B] where F is the Frobenius form and B is the basis change so that $M = B^{-1}FB$.

EXAMPLES:

```
sage: a = pari('[1,2;3,4]')
sage: a.matfrobenius()
[0, 2; 1, 5]
sage: a.matfrobenius(flag=1)
[x^2 - 5*x - 2]
sage: a.matfrobenius(2)
[[0, 2; 1, 5], [1, -1/3; 0, 1/3]]
```

```
sage: v = a.matfrobenius(2)
sage: v[0]
[0, 2; 1, 5]
sage: v[1]^(-1)*v[0]*v[1]
[1, 2; 3, 4]
```

We let t be the matrix of T_2 acting on modular symbols of level 43, which was computed using `ModularSymbols(43,sign=1).T(2).matrix()`:

```
sage: t = pari('[3, -2, 0, 0; 0, -2, 0, 1; 0, -1, -2, 2; 0, -2, 0, 2]')
sage: t.matfrobenius()
[0, 0, 0, -12; 1, 0, 0, -2; 0, 1, 0, 8; 0, 0, 1, 1]
sage: t.charpoly('x')
x^4 - x^3 - 8*x^2 + 2*x + 12
sage: t.matfrobenius(1)
[x^4 - x^3 - 8*x^2 + 2*x + 12]
```

AUTHORS:

- Martin Albrect (2006-04-02)

mathnf()

A.mathnf(flag=0): (upper triangular) Hermite normal form of A, basis for the lattice formed by the columns of A.

INPUT:

- `flag` - optional, value range from 0 to 4 (0 if omitted), meaning : 0: naive algorithm
- `1: Use Batut's algorithm` - output 2-component vector [H,U] such that H is the HNF of A, and U is a unimodular matrix such that xU=H. 3: Use Batut's algorithm. Output [H,U,P] where P is a permutation matrix such that P A U = H. 4: As 1, using a heuristic variant of LLL reduction along the way.

EXAMPLES:

```
sage: pari('[1,2,3; 4,5,6;  7,8,9]').mathnf()
[6, 1; 3, 1; 0, 1]
```

mathnfmod()

Returns the Hermite normal form if d is a multiple of the determinant

Beware that PARI's concept of a hermite normal form is an upper triangular matrix with the same column space as the input matrix.

INPUT:

- `d` - multiple of the determinant of self

EXAMPLES:

```
       sage: M=matrix([[1,2,3],[4,5,6],[7,8,11]])
sage: d=M.det()
sage: pari(M).mathnfmod(d)
       [6, 4, 3; 0, 1, 0; 0, 0, 1]
```

Note that d really needs to be a multiple of the discriminant, not just of the exponent of the cokernel:

```
       sage: M=matrix([[1,0,0],[0,2,0],[0,0,6]])
sage: pari(M).mathnfmod(6)
[1, 0, 0; 0, 1, 0; 0, 0, 6]
sage: pari(M).mathnfmod(12)
[1, 0, 0; 0, 2, 0; 0, 0, 6]
```

mathnfmodid()

Returns the Hermite Normal Form of M concatenated with d*Identity

Beware that PARI's concept of a Hermite normal form is a maximal rank upper triangular matrix with the same column space as the input matrix.

INPUT:

- d - Determines

EXAMPLES:

```
       sage: M=matrix([[1,0,0],[0,2,0],[0,0,6]])
sage: pari(M).mathnfmodid(6)
       [1, 0, 0; 0, 2, 0; 0, 0, 6]
```

This routine is not completely equivalent to mathnfmod:

```
sage: pari(M).mathnfmod(6)
[1, 0, 0; 0, 1, 0; 0, 0, 6]
```

matker()

Return a basis of the kernel of this matrix.

INPUT:

- flag - optional; may be set to 0: default; non-zero: x is known to have integral entries.

EXAMPLES:

```
sage: pari('[1,2,3;4,5,6;7,8,9]').matker()
[1; -2; 1]
```

With algorithm 1, even if the matrix has integer entries the kernel need nto be saturated (which is weird):

```
sage: pari('[1,2,3;4,5,6;7,8,9]').matker(1)
[3; -6; 3]
sage: pari('matrix(3,3,i,j,i)').matker()
[-1, -1; 1, 0; 0, 1]
sage: pari('[1,2,3;4,5,6;7,8,9]*Mod(1,2)').matker()
[Mod(1, 2); Mod(0, 2); 1]
```

matkerint()

Return the integer kernel of a matrix.

This is the LLL-reduced Z-basis of the kernel of the matrix x with integral entries.

INPUT:

- flag - optional, and may be set to 0: default, uses a modified LLL, 1: uses matrixqz.

EXAMPLES:

```
sage: pari('[2,1;2,1]').matker()
[-1/2; 1]
sage: pari('[2,1;2,1]').matkerint()
[-1; 2]
```

This is worrisome (so be careful!):

```
sage: pari('[2,1;2,1]').matkerint(1)
Mat(1)
```

matsnf()

x.matsnf(flag=0): Smith normal form (i.e. elementary divisors) of the matrix x, expressed as a vector d. Binary digits of flag mean 1: returns [u,v,d] where d=u*x*v, otherwise only the diagonal d is returned, 2: allow polynomial entries, otherwise assume x is integral, 4: removes all information corresponding to entries equal to 1 in d.

EXAMPLES:

```
sage: pari('[1,2,3; 4,5,6;  7,8,9]').matsnf()
[0, 3, 1]
```

matsolve()

matsolve(B): Solve the linear system Mx=B for an invertible matrix M

matsolve(B) uses gaussian elimination to solve Mx=B, where M is invertible and B is a column vector.

The corresponding pari library routine is gauss. The gp-interface name matsolve has been given preference here.

INPUT:

- B - a column vector of the same dimension as the square matrix self

EXAMPLES:

```
sage: pari('[1,1;1,-1]').matsolve(pari('[1;0]'))
[1/2; 1/2]
```

mattranspose()

Transpose of the matrix self.

EXAMPLES:

```
sage: pari('[1,2,3; 4,5,6;  7,8,9]').mattranspose()
[1, 4, 7; 2, 5, 8; 3, 6, 9]
```

max()

max(x,y): Return the maximum of x and y.

min()

min(x,y): Return the minumum of x and y.

modreverse()

modreverse(x): reverse polymod of the polymod x, if it exists.

EXAMPLES:

moebius()

moebius(x): Moebius function of x.

ncols()

Return the number of columns of self.

EXAMPLES:

```
sage: pari('matrix(19,8)').ncols()
8
```

newtonpoly()

x.newtonpoly(p): Newton polygon of polynomial x with respect to the prime p.

EXAMPLES:

```
sage: x = pari('y^8+6*y^6-27*y^5+1/9*y^2-y+1')
sage: x.newtonpoly(3)
[1, 1, -1/3, -1/3, -1/3, -1/3, -1/3, -1/3]
```

nextprime()

nextprime(x): smallest pseudoprime = x

EXAMPLES:

```
sage: pari(1).nextprime()
2
sage: pari(2^100).nextprime()
1267650600228229401496703205653
```

nfbasis()

nfbasis_d()

nfbasis_d(x): Return a basis of the number field defined over QQ by x and its discriminant.

EXAMPLES:

```
sage: F = NumberField(x^3-2,'alpha')
sage: F._pari_()[0].nfbasis_d()
([1, x, x^2], -108)

sage: G = NumberField(x^5-11,'beta')
sage: G._pari_()[0].nfbasis_d()
([1, x, x^2, x^3, x^4], 45753125)

sage: pari([-2,0,0,1]).Polrev().nfbasis_d()
([1, x, x^2], -108)
```

nfdisc()

nfdisc(x): Return the discriminant of the number field defined over QQ by x.

EXAMPLES:

```
sage: F = NumberField(x^3-2,'alpha')
sage: F._pari_()[0].nfdisc()
-108

sage: G = NumberField(x^5-11,'beta')
sage: G._pari_()[0].nfdisc()
45753125

sage: f = x^3-2
sage: f._pari_()
x^3 - 2
sage: f._pari_().nfdisc()
-108
```

nfeltreduce()

Given an ideal I in Hermite normal form and an element x of the pari number field self, finds an element r in self such that x-r belongs to the ideal and r is small.

EXAMPLES:

```
sage: k.<a> = NumberField(x^2 + 5)
sage: I = k.ideal(a)
sage: kp = pari(k)
sage: kp.nfeltreduce(12, I.pari_hnf())
[2, 0]~
sage: 12 - k(kp.nfeltreduce(12, I.pari_hnf())) in I
True
```

nffactor()

nfgaloisconj()

Edited from the pari documentation:

nfgaloisconj(nf): list of conjugates of a root of the polynomial x=nf.pol in the same number field.

Uses a combination of Allombert's algorithm and nfroots.

EXAMPLES:

```
sage: x = QQ['x'].0; nf = pari(x^2 + 2).nfinit()
sage: nf.nfgaloisconj()
[-x, x]~
sage: nf = pari(x^3 + 2).nfinit()
sage: nf.nfgaloisconj()
```

```
[x]~
sage: nf = pari(x^4 + 2).nfinit()
sage: nf.nfgaloisconj()
[-x, x]~
```

nfgenerator()

nfinit()

nfisisom()

nfisisom(x, y): Determine if the number fields defined by x and y are isomorphic. According to the PARI documentation, this is much faster if at least one of x or y is a number field. If they are isomorphic, it returns an embedding for the generators. If not, returns 0.

EXAMPLES:

```
sage: F = NumberField(x^3-2,'alpha')
sage: G = NumberField(x^3-2,'beta')
sage: F._pari_().nfisisom(G._pari_())
[x]

sage: GG = NumberField(x^3-4,'gamma')
sage: F._pari_().nfisisom(GG._pari_())
[1/2*x^2]

sage: F._pari_().nfisisom(GG.pari_nf())
[1/2*x^2]

sage: F.pari_nf().nfisisom(GG._pari_()[0])
[x^2]

sage: H = NumberField(x^2-2,'alpha')
sage: F._pari_().nfisisom(H._pari_())
0
```

nfroots()

Return the roots of *poly* in the number field self without multiplicity.

EXAMPLES:

```
sage: y = QQ['yy'].0; _ = pari(y) # pari has variable ordering rules
sage: x = QQ['zz'].0; nf = pari(x^2 + 2).nfinit()
sage: nf.nfroots(y^2 + 2)
[-zz, zz]
sage: nf = pari(x^3 + 2).nfinit()
sage: nf.nfroots(y^3 + 2)
[zz]
sage: nf = pari(x^4 + 2).nfinit()
sage: nf.nfroots(y^4 + 2)
[-zz, zz]
```

nfrootsof1()

nf.nfrootsof1()

number of roots of unity and primitive root of unity in the number field nf.

EXAMPLES:

```
sage: nf = pari('x^2 + 1').nfinit()
sage: nf.nfrootsof1()
[4, [0, 1]~]
```

nfsubfields()

Find all subfields of degree d of number field nf (all subfields if d is null or omitted). Result is a vector of

subfields, each being given by [g,h], where g is an absolute equation and h expresses one of the roots of g in terms of the root x of the polynomial defining nf.

INPUT:

- `self` - nf number field
- `d` - integer

norm()

nrows()

Return the number of rows of self.

EXAMPLES:

```
sage: pari('matrix(19,8)').nrows()
19
```

numbpart()

numbpart(x): returns the number of partitions of x.

EXAMPLES:

```
sage: pari(20).numbpart()
627
sage: pari(100).numbpart()
190569292
```

numdiv()

Return the number of divisors of the integer n.

EXAMPLES:

```
sage: pari(10).numdiv()
4
```

numerator()

numerator(x): Returns the numerator of x.

INPUT:

- `x` - gen

OUTPUT: gen

EXAMPLES:

numtoperm()

numtoperm(k, n): Return the permutation number k (mod n!) of n letters, where n is an integer.

INPUT:

- `k` - gen, integer
- `n` - int

OUTPUT:

- `gen` - vector (permutation of 1,...,n)

EXAMPLES:

omega()

e.omega(): return basis for the period lattice of the elliptic curve e.

EXAMPLES:

```
sage: e = pari([0, -1, 1, -10, -20]).ellinit()
sage: e.omega()
[1.26920930427955, 0.634604652139777 + 1.45881661693850*I]
```

order()

padicappr()
x.padicappr(a): p-adic roots of the polynomial x congruent to a mod p

padicprec()
padicprec(x,p): Return the absolute p-adic precision of the object x.
INPUT:

- x - gen

OUTPUT: int
EXAMPLES:

parent()

permtonum()
permtonum(x): Return the ordinal (between 1 and n!) of permutation vector x. ??? Huh ??? say more. what is a perm vector. 0 to n-1 or 1-n.
INPUT:

- x - gen (vector of integers)

OUTPUT:

- gen - integer

EXAMPLES:

phi()
Return the Euler phi function of n. EXAMPLES:

```
sage: pari(10).phi()
4
```

polcoeff()
EXAMPLES:

```
sage: f = pari("x^2 + y^3 + x*y")
sage: f
x^2 + y*x + y^3
sage: f.polcoeff(1)
y
sage: f.polcoeff(3)
0
sage: f.polcoeff(3, "y")
1
sage: f.polcoeff(1, "y")
x
```

polcompositum()

poldegree()
f.poldegree(var=x): Return the degree of this polynomial.

poldisc()
f.poldist(var=x): Return the discriminant of this polynomial.

poldiscreduced()

polgalois()
f.polgalois(): Galois group of the polynomial f

polhensellift()
self.polhensellift(y, p, e): lift the factorization y of self modulo p to a factorization modulo p^e using Hensel lift. The factors in y must be pairwise relatively prime modulo p.

polinterpolate()
self.polinterpolate(ya,x,e): polynomial interpolation at x according to data vectors self, ya (i.e. return P such that P(self[i]) = ya[i] for all i). Also return an error estimate on the returned value.

polisirreducible()
f.polisirreducible(): Returns True if f is an irreducible non-constant polynomial, or False if f is reducible or constant.

pollead()
self.pollead(v): leading coefficient of polynomial or series self, or self itself if self is a scalar. Error otherwise. With respect to the main variable of self if v is omitted, with respect to the variable v otherwise

polrecip()

polred()

polredabs()

polresultant()

polroots()
polroots(x,flag=0): complex roots of the polynomial x. flag is optional, and can be 0: default, uses Schonhage's method modified by Gourdon, or 1: uses a modified Newton method.

polrootsmod()

polrootspadic()

polrootspadicfast()

polsturm()

polsturm_full()

polsylvestermatrix()

polsym()

polylog()
x.polylog(m,flag=0): m-th polylogarithm of x. flag is optional, and can be 0: default, 1: D_m -modified m-th polylog of x, 2: D_m-modified m-th polylog of x, 3: P_m-modified m-th polylog of x.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

TODO: Add more explanation, copied from the PARI manual.

EXAMPLES:

```
sage: pari(10).polylog(3)
5.64181141475134 - 8.32820207698027*I
sage: pari(10).polylog(3,0)
5.64181141475134 - 8.32820207698027*I
sage: pari(10).polylog(3,1)
0.523778453502411
sage: pari(10).polylog(3,2)
-0.400459056163451
```

precision()
precision(x,n): Change the precision of x to be n, where n is a C-integer). If n is omitted, output the real precision of x.

INPUT:

- x - gen
- n - (optional) int

OUTPUT: nothing or gen if n is omitted

EXAMPLES:

primepi()
Return the number of primes less than or equal to self.

EXAMPLES:

```
sage: pari(7).primepi()
4
sage: pari(100).primepi()
25
sage: pari(1000).primepi()
168
sage: pari(100000).primepi()
9592
sage: pari(0).primepi()
0
sage: pari(-15).primepi()
0
sage: pari(500509).primepi()
41581
```

printtex()

psi()

x.psi(): psi-function at x.

Return the ψ-function of x, i.e., the logarithmic derivative $\Gamma'(x)/\Gamma(x)$.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(1).psi()
-0.577215664901533
```

python()

Return Python eval of self.

Note: is self is a real (type t_REAL) the result will be a RealField element of the equivalent precision; if self is a complex (type t_COMPLEX) the result will be a ComplexField element of precision the minimum precision of the real and imaginary parts.

python_list()

Return a Python list of the PARI gens. This object must be of type t_VEC

INPUT: NoneOUTPUT:

- `list` - Python list whose elements are the elements of the input gen.

EXAMPLES:

```
sage: v=pari([1,2,3,10,102,10])
sage: w = v.python_list()
sage: w
[1, 2, 3, 10, 102, 10]
sage: type(w[0])
<type 'sage.libs.pari.gen.gen'>
sage: pari("[1,2,3]").python_list()
[1, 2, 3]
```

python_list_small()

Return a Python list of the PARI gens. This object must be of type t_VECSMALL, and the resulting list contains python 'int's

EXAMPLES:

```
sage: v=pari([1,2,3,10,102,10]).Vecsmall()
sage: w = v.python_list_small()
sage: w
[1, 2, 3, 10, 102, 10]
```

```
sage: type(w[0])
<type 'int'>
```

qfbhclassno()

Computes the Hurwitz-Kronecker class number of n.

If n is large (more than $5 * 10^5$), the result is conditional upon GRH.

EXAMPLES:

```
sage: pari(-10007).qfbhclassno()
77
sage: pari(-3).qfbhclassno()
1/3
```

qflll()

qflll(x,flag=0): LLL reduction of the vectors forming the matrix x (gives the unimodular transformation matrix). The columns of x must be linearly independent, unless specified otherwise below. flag is optional, and can be 0: default, 1: assumes x is integral, columns may be dependent, 2: assumes x is integral, returns a partially reduced basis, 4: assumes x is integral, returns [K,I] where K is the integer kernel of x and I the LLL reduced image, 5: same as 4 but x may have polynomial coefficients, 8: same as 0 but x may have polynomial coefficients.

qflllgram()

qflllgram(x,flag=0): LLL reduction of the lattice whose gram matrix is x (gives the unimodular transformation matrix). flag is optional and can be 0: default,1: lllgramint algorithm for integer matrices, 4: lllgramkerim giving the kernel and the LLL reduced image, 5: lllgramkerimgen same when the matrix has polynomial coefficients, 8: lllgramgen, same as qflllgram when the coefficients are polynomials.

qfminim()

qfminim(x,bound,maxnum,flag=0): number of vectors of square norm = bound, maximum norm and list of vectors for the integral and definite quadratic form x; minimal non-zero vectors if bound=0. flag is optional, and can be 0: default; 1: returns the first minimal vector found (ignore maxnum); 2: as 0 but uses a more robust, slower implementation, valid for non integral quadratic forms.

qfrep()

qfrep(x,B,flag=0): vector of (half) the number of vectors of norms from 1 to B for the integral and definite quadratic form x. Binary digits of flag mean 1: count vectors of even norm from 1 to 2B, 2: return a t_VECSMALL instead of a t_VEC.

random()

`random(N=2^31)`: Return a pseudo-random integer between 0 and $N - 1$.

INPUT:

-`N` - gen, integer

OUTPUT:

- `gen` - integer

EXAMPLES:

real()

real(x): Return the real part of x.

INPUT:

- x - gen

OUTPUT: gen

EXAMPLES:

reverse()

Return the polynomial obtained by reversing the coefficients of this polynomial.

rnfcharpoly()

rnfdisc()

rnfeltabstorel()

rnfeltreltoabs()

rnfequation()

rnfidealabstorel()

rnfidealdown()

rnfidealdown(rnf,x): finds the intersection of the ideal x with the base field.

EXAMPLES: sage: x = ZZ['xx1'].0; pari(x) xx1 sage: y = ZZ['yy1'].0; pari(y) yy1 sage: nf = pari(y^2 - 6*y + 24).nfinit() sage: rnf = nf.rnfinit(x^2 - pari(y))

This is the relative HNF of the inert ideal (2) in rnf:

sage: P = pari('[[[1, 0]~, [0, 0]~; [0, 0]~, [1, 0]~], [[2, 0; 0, 2], [2, 0; 0, 1/2]]]')

And this is the HNF of the inert ideal (2) in nf:

sage: rnf.rnfidealdown(P) [2, 0; 0, 2]

rnfidealhnf()

rnfidealnormrel()

rnfidealreltoabs()

rnfidealtwoelt()

rnfinit()

EXAMPLES: We construct a relative number field.

```
sage: f = pari('y^3+y+1')
sage: K = f.nfinit()
sage: x = pari('x'); y = pari('y')
sage: g = x^5 - x^2 + y
sage: L = K.rnfinit(g)
```

rnfisfree()

round()

round(x,estimate=False): If x is a real number, returns x rounded to the nearest integer (rounding up). If the optional argument estimate is True, also returns the binary exponent e of the difference between the original and the rounded value (the "fractional part") (this is the integer ceiling of log_2(error)).

When x is a general PARI object, this function returns the result of rounding every coefficient at every level of PARI object. Note that this is different than what the truncate function does (see the example below).

One use of round is to get exact results after a long approximate computation, when theory tells you that the coefficients must be integers.

INPUT:

- x - gen
- `estimate` - (optional) bool, False by default

OUTPUT:

- if estimate is False, return a single gen.
- if estimate is True, return rounded verison of x and error estimate in bits, both as gens.

EXAMPLES:

```
sage: pari('1.5').round()
2
sage: pari('1.5').round(True)
(2, -1)
sage: pari('1.5 + 2.1*I').round()
```

```
2 + 2*I
sage: pari('1.0001').round(True)
(1, -14)
sage: pari('(2.4*x^2 - 1.7)/x').round()
(2*x^2 - 2)/x
sage: pari('(2.4*x^2 - 1.7)/x').truncate()
2.40000000000000*x
```

serconvol()

serlaplace()

serreverse()

serreverse(f): reversion of the power series f.

If f(t) is a series in t with valuation 1, find the series g(t) such that g(f(t)) = t.

EXAMPLES:

```
sage: f = pari('x+x^2+x^3+O(x^4)'); f
x + x^2 + x^3 + O(x^4)
sage: g = f.serreverse(); g
x - x^2 + x^3 + O(x^4)
sage: f.subst('x',g)
x + O(x^4)
sage: g.subst('x',f)
x + O(x^4)
```

shift()

shift(x,n): shift x left n bits if n=0, right -n bits if n0.

shiftmul()

shiftmul(x,n): Return the product of x by 2^n.

sign()

sign(x): Return the sign of x, where x is of type integer, real or fraction.

simplify()

simplify(x): Simplify the object x as much as possible, and return the result.

A complex or quadratic number whose imaginary part is an exact 0 (i.e., not an approximate one such as O(3) or 0.E-28) is converted to its real part, and a a polynomial of degree 0 is converted to its constant term. Simplification occurs recursively.

This function is useful before using arithmetic functions, which expect integer arguments:

EXAMPLES:

```
sage: y = pari('y')
sage: x = pari('9') + y - y
sage: x
9
sage: x.type()
't_POL'
sage: x.factor()
matrix(0,2)
sage: pari('9').factor()
Mat([3, 2])
sage: x.simplify()
9
sage: x.simplify().factor()
Mat([3, 2])
sage: x = pari('1.5 + 0*I')
sage: x.type()
't_COMPLEX'
```

```
sage: x.simplify()
1.50000000000000
sage: y = x.simplify()
sage: y.type()
't_REAL'
```

sin()

x.sin(): The sine of x.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(1).sin()
0.841470984807897
sage: C.<i> = ComplexField()
sage: pari(1+i).sin()
1.29845758141598 + 0.634963914784736*I
```

sinh()

The hyperbolic sine function.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(0).sinh()
0.E-19
sage: C.<i> = ComplexField()
sage: pari(1+i).sinh()
0.634963914784736 + 1.29845758141598*I
```

sizebyte()

sizebyte(x): Return the total number of bytes occupied by the complete tree of the object x. Note that this number depends on whether the computer is 32-bit or 64-bit (see examples).

INPUT:

- x - gen

OUTPUT: int (a Python int)

EXAMPLES:

```
sage: pari('1').sizebyte()
12            # 32-bit
24            # 64-bit
sage: pari('10').sizebyte()
12            # 32-bit
24            # 64-bit
sage: pari('10000000000000').sizebyte()
16            # 32-bit
24            # 64-bit
sage: pari('10^100').sizebyte()
52            # 32-bit
64            # 64-bit
sage: pari('x').sizebyte()
36            # 32-bit
72            # 64-bit
sage: pari('x^20').sizebyte()
264           # 32-bit
```

```
528          # 64-bit
sage: pari('[x, 10^100]').sizebyte()
100          # 32-bit
160          # 64-bit
```

sizedigit()

sizedigit(x): Return a quick estimate for the maximal number of decimal digits before the decimal point of any component of x.

INPUT:

- x - gen

OUTPUT:

- int - Python integer

EXAMPLES:

```
sage: x = pari('10^100')
sage: x.Str().length()
101
sage: x.sizedigit()
101
```

Note that digits after the decimal point are ignored.

```
sage: x = pari('1.234')
sage: x
1.23400000000000
sage: x.sizedigit()
1
```

The estimate can be one too big:

```
sage: pari('7234.1').sizedigit()
4
sage: pari('9234.1').sizedigit()
5
```

sqr()

x.sqr(): square of x. Faster than, and most of the time (but not always - see the examples) identical to x*x.

EXAMPLES:

```
sage: pari(2).sqr()
4
```

For 2-adic numbers, x.sqr() may not be identical to x*x (squaring a 2-adic number increases its precision):

```
sage: pari("1+O(2^5)").sqr()
1 + O(2^6)
sage: pari("1+O(2^5)")*pari("1+O(2^5)")
1 + O(2^5)
```

However:

```
sage: x = pari("1+O(2^5)"); x*x
1 + O(2^6)
```

sqrt()

x.sqrt(precision): The square root of x.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(2).sqrt()
1.41421356237310
```

sqrtn()

x.sqrtn(n): return the principal branch of the n-th root of x, i.e., the one such that $\arg(\sqrt(x)) \in]-\pi/n, \pi/n]$. Also returns a second argument which is a suitable root of unity allowing one to recover all the other roots. If it was not possible to find such a number, then this second return value is 0. If the argument is present and no square root exists, return 0 instead of raising an error.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

Note: intmods (modulo a prime) and p-adic numbers are allowed as arguments.

INPUT:

- x - gen
- n - integer

OUTPUT:

- gen - principal n-th root of x
- gen - root of unity z that gives the other roots

EXAMPLES:

```
sage: s, z = pari(2).sqrtn(5)
sage: z
0.309016994374947 + 0.951056516295154*I
sage: s
1.14869835499704
sage: s^5
2.00000000000000
sage: z^5
1.00000000000000 + 5.42101086 E-19*I         # 32-bit
1.00000000000000 + 4.87890977618477 E-19*I   # 64-bit
sage: (s*z)^5
2.00000000000000 + 1.409462824 E-18*I        # 32-bit
2.00000000000000 + 7.58941520739853 E-19*I   # 64-bit
```

subst()

EXAMPLES:

```
sage: x = pari("x"); y = pari("y")
sage: f = pari('x^3 + 17*x + 3')
sage: f.subst(x, y)
y^3 + 17*y + 3
sage: f.subst(x, "z")
z^3 + 17*z + 3
sage: f.subst(x, "z")^2
z^6 + 34*z^4 + 6*z^3 + 289*z^2 + 102*z + 9
sage: f.subst(x, "x+1")
x^3 + 3*x^2 + 20*x + 21
sage: f.subst(x, "xyz")
xyz^3 + 17*xyz + 3
sage: f.subst(x, "xyz")^2
xyz^6 + 34*xyz^4 + 6*xyz^3 + 289*xyz^2 + 102*xyz + 9
```

substpol()

sumdiv()

Return the sum of the divisors of n.

EXAMPLES:

```
sage: pari(10).sumdiv()
18
```

sumdivk()

Return the sum of the k-th powers of the divisors of n.

EXAMPLES:

```
sage: pari(10).sumdivk(2)
130
```

tan()

x.tan() - tangent of x

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(2).tan()
-2.18503986326152
sage: C.<i> = ComplexField()
sage: pari(i).tan()
0.E-19 + 0.761594155955765*I
```

tanh()

x.tanh() - hyperbolic tangent of x

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(1).tanh()
0.761594155955765
sage: C.<i> = ComplexField()
sage: pari(i).tanh()
0.E-19 + 1.55740772465490*I
```

taylor()

teichmuller()

teichmuller(x): teichmuller character of p-adic number x.

This is the unique $(p-1)$-st root of unity congruent to $x/p^{v_p(x)}$ modulo p.

EXAMPLES:

```
sage: pari('2+O(7^5)').teichmuller()
2 + 4*7 + 6*7^2 + 3*7^3 + O(7^5)
```

theta()

q.theta(z): Jacobi sine theta-function.

If q or z is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If the arguments are inexact (e.g. real), the smallest of their precisions is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(0.5).theta(2)
1.63202590295260
```

thetanullk()

q.thetanullk(k): return the k-th derivative at z=0 of theta(q,z).

If q is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If q is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

EXAMPLES:

```
sage: pari(0.5).thetanullk(1)
0.548978532560341
```

thue()

thueinit()

trace()

Return the trace of this PARI object.

EXAMPLES:

```
sage: pari('[1,2; 3,4]').trace()
5
```

truncate()

truncate(x,estimate=False): Return the truncation of x. If estimate is True, also return the number of error bits.

When x is in the real numbers, this means that the part after the decimal point is chopped away, e is the binary exponent of the difference between the original and truncated value (the "fractional part"). If x is a rational function, the result is the integer part (Euclidean quotient of numerator by denominator) and if requested the error estimate is 0.

When truncate is applied to a power series (in X), it transforms it into a polynomial or a rational function with denominator a power of X, by chopping away the $O(X^k)$. Similarly, when applied to a p-adic number, it transforms it into an integer or a rational number by chopping away the $O(p^k)$.

INPUT:

- x - gen
- estimate - (optional) bool, which is False by default

OUTPUT:

- if estimate is False, return a single gen.
- if estimate is True, return rounded version of x and error estimate in bits, both as gens.

EXAMPLES:

```
sage: pari('(x^2+1)/x').round()
(x^2 + 1)/x
sage: pari('(x^2+1)/x').truncate()
x
sage: pari('1.043').truncate()
1
sage: pari('1.043').truncate(True)
(1, -5)
sage: pari('1.6').truncate()
1
sage: pari('1.6').round()
2
sage: pari('1/3 + 2 + 3^2 + O(3^3)').truncate()
34/3
sage: pari('sin(x+O(x^10))').truncate()
1/362880*x^9 - 1/5040*x^7 + 1/120*x^5 - 1/6*x^3 + x
sage: pari('sin(x+O(x^10))').round()    # each coefficient has abs < 1
x + O(x^10)
```

type()

Return the Pari type of self as a string.

Note: In Cython, it is much faster to simply use typ(self.g) for checking Pari types.

EXAMPLES:

```
sage: pari(7).type()
't_INT'
sage: pari('x').type()
't_POL'
```

valuation()

valuation(x,p): Return the valuation of x with respect to p.

The valuation is the highest exponent of p dividing x.

- If p is an integer, x must be an integer, an intmod whose modulus is divisible by p, a rational number, a p-adic number, or a polynomial or power series in which case the valuation is the minimum of the valuations of the coefficients.
- If p is a polynomial, x must be a polynomial or a rational function. If p is a monomial then x may also be a power series.
- If x is a vector, complex or quadratic number, then the valuation is the minimum of the component valuations.
- If x = 0, the result is $2^31 - 1$ on 32-bit machines or $2^63 - 1$ on 64-bit machines if x is an exact object. If x is a p-adic number or power series, the result is the exponent of the zero.

INPUT:

- x - gen
- p - coercible to gen

OUTPUT:

- gen - integer

EXAMPLES:

```
sage: pari(9).valuation(3)
2
sage: pari(9).valuation(9)
1
sage: x = pari(9).Mod(27); x.valuation(3)
2
sage: pari('5/3').valuation(3)
-1
sage: pari('9 + 3*x + 15*x^2').valuation(3)
1
sage: pari([9,3,15]).valuation(3)
1
sage: pari('9 + 3*x + 15*x^2 + O(x^5)').valuation(3)
1

sage: pari('x^2*(x+1)^3').valuation(pari('x+1'))
3
sage: pari('x + O(x^5)').valuation('x')
1
sage: pari('2*x^2 + O(x^5)').valuation('x')
2

sage: pari(0).valuation(3)
2147483647            # 32-bit
9223372036854775807   # 64-bit
```

variable()

variable(x): Return the main variable of the object x, or p if x is a p-adic number.

This function raises a TypeError exception on scalars, i.e., on objects with no variable associated to them.

INPUT:

- x - gen

OUTPUT: gen

EXAMPLES:

```
sage: pari('x^2 + x -2').variable()
x
sage: pari('1+2^3 + O(2^5)').variable()
2
sage: pari('x+y0').variable()
x
sage: pari('y0+z0').variable()
y0
```

vecextract()

self.vecextract(y,z): extraction of the components of the matrix or vector x according to y and z. If z is omitted, y designates columns, otherwise y corresponds to rows and z to columns. y and z can be vectors (of indices), strings (indicating ranges as in"1..10") or masks (integers whose binary representation indicates the indices to extract, from left to right 1, 2, 4, 8, etc.)

Note: This function uses the PARI row and column indexing, so the first row or column is indexed by 1 instead of 0.

vecmax()

vecmax(x): Return the maximum of the elements of the vector/matrix x.

vecmin()

vecmin(x): Return the maximum of the elements of the vector/matrix x.

weber()

x.weber(flag=0): One of Weber's f functions of x. flag is optional, and can be 0: default, function f(x)=exp(-i*Pi/24)*eta((x+1)/2)/eta(x) such that $j = (f^{24} - 16)^3/f^{24}$, 1: function f1(x)=eta(x/2)/eta(x) such that $j = (f1^24 + 16)^3/f2^{24}$, 2: function f2(x)=sqrt(2)*eta(2*x)/eta(x) such that $j = (f2^{24} + 16)^3/f2^{24}$.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

TODO: Add further explanation from PARI manual.

EXAMPLES:

```
sage: C.<i> = ComplexField()
sage: pari(i).weber()
1.18920711500272 + 0.E-19*I
sage: pari(i).weber(1)
1.09050773266526 + 0.E-19*I
sage: pari(i).weber(2)
1.09050773266526 + 0.E-19*I
```

xgcd()

Returns u,v,d such that d=gcd(x,y) and u*x+v*y=d.

EXAMPLES:

```
sage: pari(10).xgcd(15)
(5, -1, 1)
```

zeta()

zeta(s): zeta function at s with s a complex or a p-adic number.

If s is a complex number, this is the Riemann zeta function $\zeta(s) = \sum_{n\geq 1} n^{-s}$, computed either using the Euler-Maclaurin summation formula (if s is not an integer), or using Bernoulli numbers (if s is a negative integer or an even nonnegative integer), or using modular forms (if s is an odd nonnegative integer).

If s is a p-adic number, this is the Kubota-Leopoldt zeta function, i.e. the unique continuous p-adic function on the p-adic integers that interpolates the values of $(1 - p^{-k})\zeta(k)$ at negative integers k such that $k \equiv 1 \pmod{p-1}$ if p is odd, and at odd k if $p = 2$.

If x is an exact argument, it is first converted to a real or complex number using the optional parameter precision (in bits). If x is inexact (e.g. real), its own precision is used in the computation, and the parameter precision is ignored.

INPUT:

- `s` - gen (real, complex, or p-adic number)

OUTPUT:

- `gen` - value of zeta at s.

EXAMPLES:

```
sage: pari(2).zeta()
1.64493406684823
sage: x = RR(pi)^2/6
sage: pari(x)
1.64493406684823
sage: pari(3).zeta()
1.20205690315959
sage: pari('1+5*7+2*7^2+O(7^3)').zeta()
4*7^-2 + 5*7^-1 + O(7^0)
```

znprimroot()

Return a primitive root modulo self, whenever it exists.

This is a generator of the group $(\mathbf{Z}/n\mathbf{Z})^*$, whenever this group is cyclic, i.e. if $n = 4$ or $n = p^k$ or $n = 2p^k$, where p is an odd prime and k is a natural number.

INPUT:

- `self` - positive integer equal to 4, or a power of an odd prime, or twice a power of an odd prime

OUTPUT: gen

EXAMPLES:

```
sage: pari(4).znprimroot()
Mod(3, 4)
sage: pari(10007^3).znprimroot()
Mod(5, 1002101470343)
sage: pari(2*109^10).znprimroot()
Mod(236736367459211723407, 473472734918423446802)
```

init_pari_stack()

Change the PARI scratch stack space to the given size.

The main application of this command is that you've done some individual PARI computation that used a lot of stack space. As a result the PARI stack may have doubled several times and is now quite large. That object you computed is copied off to the heap, but the PARI stack is never automatically shrunk back down. If you call this function you can shrink it back down.

If you set this too small then it will automatically be increased if it is exceeded, which could make some calculations initially slower (since they have to be redone until the stack is big enough).

INPUT:

- `size` - an integer (default: 8000000)

EXAMPLES:

```
sage: get_memory_usage()                          # random output
'122M+'
sage: a = pari('2^100000000')
sage: get_memory_usage()                          # random output
'157M+'
sage: del a
sage: get_memory_usage()                          # random output
'145M+'
```

Hey, I want my memory back!

```
sage: sage.libs.pari.gen.init_pari_stack()
sage: get_memory_usage()                          # random output
'114M+'
```

Ahh, that's better.

max()
max(x,y): Return the maximum of x and y.

min()
min(x,y): Return the minimum of x and y.

pbw()
Convert from precision expressed in bits to pari real precision expressed in words. Note: this rounds up to the nearest word, adjusts for the two codewords of a pari real, and is architecture-dependent.

EXAMPLES:

```
sage: import sage.libs.pari.gen as gen
sage: gen.prec_bits_to_words(70)
5   # 32-bit
4   # 64-bit

sage: [(32*n,gen.prec_bits_to_words(32*n)) for n in range(1,9)]
[(32, 3), (64, 4), (96, 5), (128, 6), (160, 7), (192, 8), (224, 9), (256, 10)] # 32-bit
[(32, 3), (64, 3), (96, 4), (128, 4), (160, 5), (192, 5), (224, 6), (256, 6)] # 64-bit
```

prec_bits_to_dec()
Convert from precision expressed in bits to precision expressed in decimal.

EXAMPLES:

```
sage: import sage.libs.pari.gen as gen
sage: gen.prec_bits_to_dec(53)
15
sage: [(32*n,gen.prec_bits_to_dec(32*n)) for n in range(1,9)]
[(32, 9),
(64, 19),
(96, 28),
(128, 38),
(160, 48),
(192, 57),
(224, 67),
(256, 77)]
```

prec_bits_to_words()
Convert from precision expressed in bits to pari real precision expressed in words. Note: this rounds up to the nearest word, adjusts for the two codewords of a pari real, and is architecture-dependent.

EXAMPLES:

```
sage: import sage.libs.pari.gen as gen
sage: gen.prec_bits_to_words(70)
5   # 32-bit
4   # 64-bit

sage: [(32*n,gen.prec_bits_to_words(32*n)) for n in range(1,9)]
[(32, 3), (64, 4), (96, 5), (128, 6), (160, 7), (192, 8), (224, 9), (256, 10)] # 32-bit
[(32, 3), (64, 3), (96, 4), (128, 4), (160, 5), (192, 5), (224, 6), (256, 6)] # 64-bit
```

prec_dec_to_bits()

Convert from precision expressed in decimal to precision expressed in bits.

EXAMPLES:

```
sage: import sage.libs.pari.gen as gen
sage: gen.prec_dec_to_bits(15)
49
sage: [(n,gen.prec_dec_to_bits(n)) for n in range(10,100,10)]
[(10, 33),
(20, 66),
(30, 99),
(40, 132),
(50, 166),
(60, 199),
(70, 232),
(80, 265),
(90, 298)]
```

prec_dec_to_words()

Convert from precision expressed in decimal to precision expressed in words. Note: this rounds up to the nearest word, adjusts for the two codewords of a pari real, and is architecture-dependent.

EXAMPLES:

```
sage: import sage.libs.pari.gen as gen
sage: gen.prec_dec_to_words(38)
6   # 32-bit
4   # 64-bit
sage: [(n,gen.prec_dec_to_words(n)) for n in range(10,90,10)]
[(10, 4), (20, 5), (30, 6), (40, 7), (50, 8), (60, 9), (70, 10), (80, 11)] # 32-bit
[(10, 3), (20, 4), (30, 4), (40, 5), (50, 5), (60, 6), (70, 6), (80, 7)] # 64-bit
```

prec_words_to_bits()

Convert from pari real precision expressed in words to precision expressed in bits. Note: this adjusts for the two codewords of a pari real, and is architecture-dependent.

EXAMPLES:

```
sage: import sage.libs.pari.gen as gen
sage: gen.prec_words_to_bits(10)
256   # 32-bit
512   # 64-bit
sage: [(n,gen.prec_words_to_bits(n)) for n in range(3,10)]
[(3, 32), (4, 64), (5, 96), (6, 128), (7, 160), (8, 192), (9, 224)]  # 32-bit
[(3, 64), (4, 128), (5, 192), (6, 256), (7, 320), (8, 384), (9, 448)] # 64-bit
```

prec_words_to_dec()
Convert from precision expressed in words to precision expressed in decimal. Note: this adjusts for the two codewords of a pari real, and is architecture-dependent.

EXAMPLES:

```
sage: import sage.libs.pari.gen as gen
sage: gen.prec_words_to_dec(5)
28   # 32-bit
57   # 64-bit
sage: [(n,gen.prec_words_to_dec(n)) for n in range(3,10)]
[(3, 9), (4, 19), (5, 28), (6, 38), (7, 48), (8, 57), (9, 67)] # 32-bit
[(3, 19), (4, 38), (5, 57), (6, 77), (7, 96), (8, 115), (9, 134)] # 64-bit
```

vecsmall_to_intlist()
INPUT:

- v - a gen of type Vecsmall

OUTPUT: a Python list of Python ints

14.2 Victor Shoup's NTL C++ Library

Sage provides an interface to Victor Shoup's C++ library NTL. Features of this library include *incredibly fast* arithmetic with polynomials and assymptotically fast factorization of polynomials.

14.3 Cremona's mwrank C++ library

mwrank_initprimes(*filename, verb=False*)
mwrank_initprimes(filename, verb=False):

INPUT:

- filename - (string) the name of a file of primes
- verb - (bool: default False) verbose or not?

EXAMPLES:

```
sage: file = tmp_filename()
sage: open(file,'w').write(' '.join([str(p) for p in prime_range(10^6)]))
sage: mwrank_initprimes(file, verb=False)
```

CHAPTER

FIFTEEN

NETWORKING AND GRID COMPUTING

Sage includes custom highly-integrated support for coarse grain distributed (or "grid") computing. See the chapter below on `dsage`.

Sage includes the Moin Moin Wiki by default, which "is an advanced, easy to use and extensible WikiEngine with a large community of users. Said in a few words, it is about collaboration on easily editable web pages."

The Twisted, an event-driven networking framework written in Python, is a networking library that is included with Sage. It is robust, mature, fast, and offers a vast range of networking functionality.

The Sage Notebook (see Chapter *The Sage Notebook*) is another networking application included with Sage.

15.1 Wiki Interactive Web Page.

Sage includes the Moin Moin Wiki interactive web page system standard. To start your own math-typesetting-aware wiki server immediately, just type `wiki()` at the command line.

The Moin Moin Wiki "is an advanced, easy to use and extensible WikiEngine with a large community of users. Said in a few words, it is about collaboration on easily editable web pages."

wiki (*directory='sage_wiki', port=9000, address='localhost', threads=10*)
Create (if necessary) and start up a Moin Moin wiki.

The wiki will be served on the given port.

The moin package contains a modified version of moin moin, which comes with jsmath latex typesetting pre-configured; use dollar signs to typeset.

wiki_create_instance (*directory='sage_wiki'*)

wiki_simple_http (*directory='sage_wiki', port=9000, address='localhost'*)
Create (if necessary) and start up a Moin Moin wiki.

The wiki will be served on the given port.

The moin package contains a modified version of moin moin, which comes with jsmath latex typesetting pre-configured; use dollar signs to typeset.

15.2 DSage: Distributed Sage

Distributed Sage `dsage` is a distributed computing framework suitable for coarse distributed compuatations.

class DistributedSage()
Distributed Sage allows you to do distributed computing in Sage.

To get up and running quickly, run dsage.setup() to run the configuration utility.

Note that configuration files will be stored in the directory `$DOT Sage/dsage`.

QUICK-START

1. Launch sage
2. Run:

```
sage: dsage.setup() #not tested
```

For a really quick start, just hit ENTER on all questions. This will create all the necessary supporting files to get **DSage** running. It will create the databases, set up a private/public key for authentication and create a SSL certificate for the server.

3. Launch a server, monitor and get a connection to the server:

```
sage: D = dsage.start_all() #not tested
```

This will start 2 workers by default. You can change it by passing in the "workers=N" argument where "N" is the number of workers you want.

4. To do a computation, use D just like any other Sage interface. For example:

```
sage: j = D('2+2')  #not tested
sage: j.wait()      #not tested
sage: j             #not tested
4
```

kill_all()
Kills the server and worker.

kill_server()

kill_worker()

server(*blocking=True, port=None, log_level=0, ssl=True, db_file='/home/mvngu/.sage/dsage/db/dsage.db', log_file='/home/mvngu/.sage/dsage/server.log', privkey='/home/mvngu/.sage/dsage/cacert.pem', cert='/home/mvngu/.sage/dsage/pubcert.pem', authenticated_logins=False, failure_threshold=3, verbose=True, testing=False, profile=False*)
Run the Distributed Sage server.

Doing `dsage.server()` will spawn a server process which listens by default on port 8081.

setup(*template=None*)
This is the setup utility which helps you configure dsage.

Type `dsage.setup()` to run the configuration for the server, worker and client. Alternatively, if you want to run the configuration for just one parts, you can launch `dsage.setup_server()`, `dsage.setup worker()` or `dsage.setup()`.

setup_client()
This method runs the configuration utility for the client.

setup_server(**args*)
This method runs the configuration utility for the server.

setup_worker()
This method runs the configuration utility for the worker.

start_all(*port=None, workers=2, log_level=0, poll=1.0, authenticate=False, failure_threshold=3, verbose=True, testing=False*)
Start the server and worker and returns a connection to the server.

worker(*server='localhost', port=8081, workers=2, poll=1.0, username='mvngu', blocking=True, ssl=True, log_level=0, authenticate=True, priority=20, privkey='/home/mvngu/.sage/dsage/dsage_key', pubkey='/home/mvngu/.sage/dsage/dsage_key.pub', log_file='/home/mvngu/.sage/dsage/worker.log', verbose=True*)
Run the Distributed Sage worker.

Typing `sage.worker()` will launch a worker which by default connects to localhost on port 8081 to fetch jobs.

spawn(*cmd, verbose=True, stdout=None, stdin=None*)
Spawns a process and registers it with the Sage.

CHAPTER

SIXTEEN

CRYPTOGRAPHY

16.1 Cryptosystems.

class **Cryptosystem**(*plaintext_space, ciphertext_space, key_space, block_length=1, period=None*)

A cryptosystem is a pair of maps

$$E : \mathcal{K} \to \mathrm{Hom}(\mathcal{M}, \mathcal{C})$$

$$D : \mathcal{K} \to \mathrm{Hom}(\mathcal{C}, \mathcal{M})$$

where $\mathcal{K}$ is the keyspace, $\mathcal{M}$ is the plaintext or message space, and $\mathcal{C}$ is the ciphertext space. In many instances $\mathcal{M} = \mathcal{C}$ and the images will lie in $\mathrm{Aut}(\mathcal{M})$. An element of the image of E is called a cipher.

We may assume that E and D are injective, hence identify a key K in $\mathcal{K}$ with its image $E_K := E(K)$ in $\mathrm{Hom}(\mathcal{M}, \mathcal{C})$.

The cryptosystem has the property that for every encryption key K_1 there is a decryption key K_2 such that $D_{K_2} \circ E_{K_1}$. A cryptosystem with the property that $K := K_2 = K_1$, is called a symmetric cryptosystem. Otherwise, if the key $K_2 \neq K_1$, nor is K_2 easily derived from K_1, we call the cryptosystem asymmetric of public key. In that case, K_1 is called the public key and K_2 is called the private key.

block_length()

cipher_codomain()

cipher_domain()

ciphertext_space()

key_space()

period()

plaintext_space()

class **PublicKeyCryptosystem**(*plaintext_space, ciphertext_space, key_space, block_length=1, period=None*)

class **SymmetricKeyCryptosystem**(*plaintext_space, ciphertext_space, key_space, block_length=1, period=None*)

16.2 Ciphers.

class **Cipher**(*parent, key*)

Cipher class

codomain()

domain()

key()

parent()

class PublicKeyCipher(*parent, key, public=True*)
Public key cipher class

class SymmetricKeyCipher(*parent, key*)
Symmetric key cipher class

16.3 Classical Cryptosystems

class HillCryptosystem(*S, m*)
Create a Hill cryptosystem defined by the m x m matrix space over $\mathbf{Z}/N\mathbf{Z}$, where N is the alphabet size of the string monoid `S`.

INPUT:

- `S` - a string monoid over some alphabet
- `m` - integer > 0; the block length of matrices that specify block permutations

OUTPUT:

- A Hill cryptosystem of block length `m` over the alphabet `S`.

EXAMPLES:

```
sage: S = AlphabeticStrings()
sage: E = HillCryptosystem(S,3)
sage: E
Hill cryptosystem on Free alphabetic string monoid on A-Z of block length 3
sage: R = IntegerModRing(26)
sage: M = MatrixSpace(R,3,3)
sage: A = M([[1,0,1],[0,1,1],[2,2,3]])
sage: A
[1 0 1]
[0 1 1]
[2 2 3]
sage: e = E(A)
sage: e
[1 0 1]
[0 1 1]
[2 2 3]
sage: e(S("LAMAISONBLANCHE"))
JYVKSKQPELAYKPV
```

TESTS:

```
sage: S = AlphabeticStrings()
sage: E = HillCryptosystem(S,3)
sage: E == loads(dumps(E))
True
```

block_length()
The row or column dimension of a matrix specifying a block permutation. Encryption and decryption keys of a Hill cipher are square matrices, i.e. the row and column dimensions of an encryption or decryption key are the same. This row/column dimension is referred to as the *block length*.
OUTPUT:

•The block length of an encryption/decryption key.

EXAMPLES:

```
sage: A = AlphabeticStrings()
sage: n = randint(1, A.ngens() - 1)
sage: H = HillCryptosystem(A, n)
sage: H.block_length() == n
True
```

deciphering(*A*, *C*)

Decrypt the ciphertext `C` using the key `A`.

INPUT:

•`A` - a key within the key space of this Hill cipher

•`C` - a string (possibly empty) over the string monoid of this Hill cipher

OUTPUT:

•The plaintext corresponding to the ciphertext `C`.

EXAMPLES:

```
sage: H = HillCryptosystem(AlphabeticStrings(), 3)
sage: K = H.random_key()
sage: M = H.encoding("Good day, mate! How ya going?")
sage: H.deciphering(K, H.enciphering(K, M)) == M
True
```

enciphering(*A*, *M*)

Encrypt the plaintext `M` using the key `A`.

INPUT:

•`A` - a key within the key space of this Hill cipher

•`M` - a string (possibly empty) over the string monoid of this Hill cipher.

OUTPUT:

•The ciphertext corresponding to the plaintext `M`.

EXAMPLES:

```
sage: H = HillCryptosystem(AlphabeticStrings(), 3)
sage: K = H.random_key()
sage: M = H.encoding("Good day, mate! How ya going?")
sage: H.deciphering(K, H.enciphering(K, M)) == M
True
```

encoding(*M*)

The encoding of the string `M` over the string monoid of this Hill cipher. For example, if the string monoid of this Hill cipher is `AlphabeticStringMonoid`, then the encoding of `M` would be its upper-case equivalent stripped of all non-alphabetic characters.

INPUT:

•`M` - a string, possibly empty

OUTPUT:

•The encoding of `M` over the string monoid of this Hill cipher.

EXAMPLES:

```
sage: M = "The matrix cipher by Lester S. Hill."
sage: A = AlphabeticStrings()
sage: H = HillCryptosystem(A, 7)
sage: H.encoding(M) == A.encoding(M)
True
```

inverse_key(*A*)

The inverse key corresponding to the key A.

INPUT:

•A - an invertible matrix of the key space of this Hill cipher

OUTPUT:

•The inverse matrix of A.

EXAMPLES:

```
sage: S = AlphabeticStrings()
sage: E = HillCryptosystem(S,3)
sage: A = E.random_key()
sage: B = E.inverse_key(A)
sage: M = S("LAMAISONBLANCHE")
sage: e = E(A)
sage: c = E(B)
sage: c(e(M))
LAMAISONBLANCHE
```

random_key()

A random key within the key space of this Hill cipher. That is, generate a random m x m matrix to be used as a block permutation, where m is the block length of this Hill cipher. If n is the size of the cryptosystem alphabet, then there are n^{m^2} possible keys. However the number of valid keys, i.e. invertible m x m square matrices, is smaller than n^{m^2}.

OUTPUT:

•A random key within the key space of this Hill cipher.

EXAMPLES:

```
sage: A = AlphabeticStrings()
sage: n = 3
sage: H = HillCryptosystem(A, n)
sage: K = H.random_key()
sage: Ki = H.inverse_key(K)
sage: M = "LAMAISONBLANCHE"
sage: e = H(K)
sage: d = H(Ki)
sage: d(e(A(M))) == A(M)
True
```

class **SubstitutionCryptosystem**(*S*)

Create a substitution cryptosystem.

INPUT:

•S - a string monoid over some alphabet

OUTPUT:

•A substitution cryptosystem over the alphabet S.

EXAMPLES:

```
sage: M = AlphabeticStrings()
sage: E = SubstitutionCryptosystem(M)
sage: E
Substitution cryptosystem on Free alphabetic string monoid on A-Z
sage: K = M([ 25-i for i in range(26) ])
sage: K
```

```
ZYXWVUTSRQPONMLKJIHGFEDCBA
sage: e = E(K)
sage: m = M("THECATINTHEHAT")
sage: e(m)
GSVXZGRMGSVSZG
```

TESTS:

```
sage: M = AlphabeticStrings()
sage: E = SubstitutionCryptosystem(M)
sage: E == loads(dumps(E))
True
```

deciphering(*K*, *C*)

Decrypt the ciphertext `C` using the key `K`.

INPUT:

- `K` - a key belonging to the key space of this substitution cipher
- `C` - a string (possibly empty) over the string monoid of this cryptosystem.

OUTPUT:

- The plaintext corresponding to the ciphertext `C`.

EXAMPLES:

```
sage: S = SubstitutionCryptosystem(AlphabeticStrings())
sage: K = S.random_key()
sage: M = S.encoding("Don't substitute me!")
sage: S.deciphering(K, S.enciphering(K, M)) == M
True
```

enciphering(*K*, *M*)

Encrypt the plaintext `M` using the key `K`.

INPUT:

- `K` - a key belonging to the key space of this substitution cipher
- `M` - a string (possibly empty) over the string monoid of this cryptosystem.

OUTPUT:

- The ciphertext corresponding to the plaintext `M`.

EXAMPLES:

```
sage: S = SubstitutionCryptosystem(AlphabeticStrings())
sage: K = S.random_key()
sage: M = S.encoding("Don't substitute me.")
sage: S.deciphering(K, S.enciphering(K, M)) == M
True
```

encoding(*M*)

The encoding of the string `M` over the string monoid of this substitution cipher. For example, if the string monoid of this cryptosystem is `AlphabeticStringMonoid`, then the encoding of `M` would be its upper-case equivalent stripped of all non-alphabetic characters.

INPUT:

- `M` - a string, possibly empty

OUTPUT:

- The encoding of `M` over the string monoid of this cryptosystem.

EXAMPLES:

```
sage: M = "Peter Pan(ning) for gold."
sage: A = AlphabeticStrings()
sage: S = SubstitutionCryptosystem(A)
sage: S.encoding(M) == A.encoding(M)
True
```

inverse_key(*K*)

The inverse key corresponding to the key K. The specified key is a permutation of the cryptosystem alphabet.

INPUT:

- K - a key belonging to the key space of this cryptosystem

OUTPUT:

- The inverse key of K.

EXAMPLES:

```
sage: S = AlphabeticStrings()
sage: E = SubstitutionCryptosystem(S)
sage: K = E.random_key()
sage: L = E.inverse_key(K)
sage: M = S("THECATINTHEHAT")
sage: e = E(K)
sage: c = E(L)
sage: c(e(M))
THECATINTHEHAT
```

random_key()

Generate a random key within the key space of this substitution cipher. The generated key is a permutation of the cryptosystem alphabet. Let n be the length of the alphabet. Then there are $n!$ possible keys in the key space.

OUTPUT:

- A random key within the key space of this cryptosystem.

EXAMPLES:

```
sage: A = AlphabeticStrings()
sage: S = SubstitutionCryptosystem(A)
sage: K = S.random_key()
sage: Ki = S.inverse_key(K)
sage: M = "THECATINTHEHAT"
sage: e = S(K)
sage: d = S(Ki)
sage: d(e(A(M))) == A(M)
True
```

class **TranspositionCryptosystem**(*S*, *n*)

Create a transposition cryptosystem of block length n.

INPUT:

- S - a string monoid over some alphabet
- n - integer > 0; a block length of a block permutation

OUTPUT:

- A transposition cryptosystem of block length n over the alphabet S.

EXAMPLES:

```
sage: S = AlphabeticStrings()
sage: E = TranspositionCryptosystem(S,14)
sage: E
Transposition cryptosystem on Free alphabetic string monoid on A-Z of block length 14
sage: K = [ 14-i for i in range(14) ]
sage: K
[14, 13, 12, 11, 10, 9, 8, 7, 6, 5, 4, 3, 2, 1]
sage: e = E(K)
sage: e(S("THECATINTHEHAT"))
TAHEHTNITACEHT
```

TESTS:

```
sage: S = AlphabeticStrings()
sage: E = TranspositionCryptosystem(S,14)
sage: E == loads(dumps(E))
True
```

deciphering(*K*, *C*)

Decrypt the ciphertext `C` using the key `K`.

INPUT:

- `K` - a key belonging to the key space of this transposition cipher
- `C` - a string (possibly empty) over the string monoid of this cryptosystem.

OUTPUT:

- The plaintext corresponding to the ciphertext `C`.

EXAMPLES:

```
sage: T = TranspositionCryptosystem(AlphabeticStrings(), 14)
sage: K = T.random_key()
sage: M = T.encoding("The cat in the hat.")
sage: T.deciphering(K, T.enciphering(K, M)) == M
True
```

enciphering(*K*, *M*)

Encrypt the plaintext `M` using the key `K`.

INPUT:

- `K` - a key belonging to the key space of this transposition cipher
- `M` - a string (possibly empty) over the string monoid of this cryptosystem

OUTPUT:

- The ciphertext corresponding to the plaintext `M`.

EXAMPLES:

```
sage: T = TranspositionCryptosystem(AlphabeticStrings(), 14)
sage: K = T.random_key()
sage: M = T.encoding("The cat in the hat.")
sage: T.deciphering(K, T.enciphering(K, M)) == M
True
```

encoding(*M*)

The encoding of the string `M` over the string monoid of this transposition cipher. For example, if the string monoid of this cryptosystem is `AlphabeticStringMonoid`, then the encoding of `M` would be its upper-case equivalent stripped of all non-alphabetic characters.

INPUT:

- `M` - a string, possibly empty

OUTPUT:

•The encoding of M over the string monoid of this cryptosystem.

EXAMPLES:

```
sage: M = "Transposition cipher is not about matrix transpose."
sage: A = AlphabeticStrings()
sage: T = TranspositionCryptosystem(A, 11)
sage: T.encoding(M) == A.encoding(M)
True
```

inverse_key(*K, check=True*)

The inverse key corresponding to the key K.

INPUT:

•K - a key belonging to the key space of this transposition cipher

•check - bool (default: True); check that K belongs to the key space of this cryptosystem.

OUTPUT:

•The inverse key corresponding to K.

EXAMPLES:

```
sage: S = AlphabeticStrings()
sage: E = TranspositionCryptosystem(S, 14)
sage: K = E.random_key()
sage: Ki = E.inverse_key(K)
sage: e = E(K)
sage: d = E(Ki)
sage: M = "THECATINTHEHAT"
sage: C = e(S(M))
sage: d(S(C)) == S(M)
True
```

random_key()

Generate a random key within the key space of this transposition cryptosystem. Let $n > 0$ be the block length of this cryptosystem. Then there are $n!$ possible keys.

OUTPUT:

•A random key within the key space of this cryptosystem.

EXAMPLES:

```
sage: S = AlphabeticStrings()
sage: E = TranspositionCryptosystem(S, 14)
sage: K = E.random_key()
sage: Ki = E.inverse_key(K)
sage: e = E(K)
sage: d = E(Ki)
sage: M = "THECATINTHEHAT"
sage: C = e(S(M))
sage: d(S(C)) == S(M)
True
```

class **VigenereCryptosystem**(*S, n*)

Create a Vigenere cryptosystem of block length n.

INPUT:

•S– a string monoid over some alphabet

•n - integer > 0; block length of an encryption/decryption key

OUTPUT:

•A Vigenere cryptosystem of block length n over the alphabet S.

EXAMPLES:

```
sage: S = AlphabeticStrings()
sage: E = VigenereCryptosystem(S,14)
sage: E
Vigenere cryptosystem on Free alphabetic string monoid on A-Z of period 14
sage: K = S('ABCDEFGHIJKLMN')
sage: K
ABCDEFGHIJKLMN
sage: e = E(K)
sage: e
ABCDEFGHIJKLMN
sage: e(S("THECATINTHEHAT"))
TIGFEYOUBQOSMG
```

TESTS:

```
sage: S = AlphabeticStrings()
sage: E = VigenereCryptosystem(S,14)
sage: E == loads(dumps(E))
True
```

deciphering(*K*, *C*)

Decrypt the ciphertext C using the key K.

INPUT:

•K - a key belonging to the key space of this Vigenere cipher

•C - a string (possibly empty) over the string monoid of this cryptosystem

OUTPUT:

•The plaintext corresponding to the ciphertext C.

EXAMPLES:

```
sage: V = VigenereCryptosystem(AlphabeticStrings(), 24)
sage: K = V.random_key()
sage: M = V.encoding("Jack and Jill went up the hill.")
sage: V.deciphering(K, V.enciphering(K, M)) == M
True
```

enciphering(*K*, *M*)

Encrypt the plaintext M using the key K.

INPUT:

•K - a key belonging to the key space of this Vigenere cipher

•M - a string (possibly empty) over the string monoid of this cryptosystem

OUTPUT:

•The ciphertext corresponding to the plaintext M.

EXAMPLES:

```
sage: V = VigenereCryptosystem(AlphabeticStrings(), 24)
sage: K = V.random_key()
sage: M = V.encoding("Jack and Jill went up the hill.")
sage: V.deciphering(K, V.enciphering(K, M)) == M
True
```

encoding(*M*)

The encoding of the string `M` over the string monoid of this Vigenere cipher. For example, if the string monoid of this cryptosystem is `AlphabeticStringMonoid`, then the encoding of `M` would be its upper-case equivalent stripped of all non-alphabetic characters.

INPUT:

•`M` - a string, possibly empty

OUTPUT:

•The encoding of `M` over the string monoid of this cryptosystem.

EXAMPLES:

```
sage: A = AlphabeticStrings()
sage: V = VigenereCryptosystem(A, 24)
sage: M = "Jack and Jill went up the hill."
sage: V.encoding(M) == A.encoding(M)
True
```

inverse_key(*K*)

The inverse key corresponding to the key `K`.

INPUT:

•`K` - a key within the key space of this Vigenere cryptosystem

OUTPUT:

•The inverse key corresponding to `K`.

EXAMPLES:

```
sage: S = AlphabeticStrings()
sage: E = VigenereCryptosystem(S,14)
sage: K = E.random_key()
sage: L = E.inverse_key(K)
sage: M = S("THECATINTHEHAT")
sage: e = E(K)
sage: c = E(L)
sage: c(e(M))
THECATINTHEHAT
```

random_key()

Generate a random key within the key space of this Vigenere cryptosystem. Let $n > 0$ be the length of the cryptosystem alphabet and let $m > 0$ be the block length of this cryptosystem. Then there are n^m possible keys.

OUTPUT:

•A random key within the key space of this cryptosystem.

EXAMPLES:

```
sage: A = AlphabeticStrings()
sage: V = VigenereCryptosystem(A, 14)
sage: M = "THECATINTHEHAT"
sage: K = V.random_key()
sage: Ki = V.inverse_key(K)
sage: e = V(K)
sage: d = V(Ki)
sage: d(e(A(M))) == A(M)
True
```

16.4 Classical Ciphers.

class **HillCipher**(*parent, key*)
Hill cipher class

inverse()

class **SubstitutionCipher**(*parent, key*)
Substitution cipher class

inverse()

class **TranspositionCipher**(*parent, key*)
Transition cipher class

inverse()

class **VigenereCipher**(*parent, key*)
Vigenere cipher class

inverse()

16.5 Stream Cryptosystems.

class **LFSRCryptosystem**(*field=None*)
Linear feedback shift register cryptosystem class

encoding(*M*)

class **ShrinkingGeneratorCryptosystem**(*field=None*)
Shrinking generator cryptosystem class

encoding(*M*)

16.6 Stream Ciphers

class **LFSRCipher**(*parent, poly, IS*)

connection_polynomial()
The connection polynomial defining the LFSR of the cipher.
EXAMPLE:

```
sage: k = GF(2)
sage: P.<x> = PolynomialRing( k )
sage: LFSR = LFSRCryptosystem( k )
sage: e = LFSR((x^2+x+1,[k(0), k(1)]))
sage: e.connection_polynomial()
x^2 + x + 1
```

initial_state()
The initial state of the LFSR cipher.
EXAMPLE:

```
sage: k = GF(2)
sage: P.<x> = PolynomialRing( k )
sage: LFSR = LFSRCryptosystem( k )
sage: e = LFSR((x^2+x+1,[k(0), k(1)]))
```

```
sage: e.initial_state()
[0, 1]
```

class ShrinkingGeneratorCipher(*parent, e1, e2*)

decimating_cipher()

The LFSR cipher generating the decimating key stream.

EXAMPLE:

```
        sage: FF = FiniteField(2)
        sage: P.<x> = PolynomialRing(FF)
        sage: LFSR = LFSRCryptosystem(FF)
        sage: IS_1 = [ FF(a) for a in [0,1,0,1,0,0,0] ]
        sage: e1 = LFSR((x^7 + x + 1,IS_1))
        sage: IS_2 = [ FF(a) for a in [0,0,1,0,0,0,1,0,1] ]
        sage: e2 = LFSR((x^9 + x^3 + 1,IS_2))
        sage: E = ShrinkingGeneratorCryptosystem()
        sage: e = E((e1,e2))
    sage: e.decimating_cipher()
        (x^9 + x^3 + 1, [0, 0, 1, 0, 0, 0, 1, 0, 1])
```

keystream_cipher()

The LFSR cipher generating the output key stream.

EXAMPLE:

```
        sage: FF = FiniteField(2)
        sage: P.<x> = PolynomialRing(FF)
        sage: LFSR = LFSRCryptosystem(FF)
        sage: IS_1 = [ FF(a) for a in [0,1,0,1,0,0,0] ]
        sage: e1 = LFSR((x^7 + x + 1,IS_1))
        sage: IS_2 = [ FF(a) for a in [0,0,1,0,0,0,1,0,1] ]
        sage: e2 = LFSR((x^9 + x^3 + 1,IS_2))
        sage: E = ShrinkingGeneratorCryptosystem()
        sage: e = E((e1,e2))
    sage: e.keystream_cipher()
        (x^7 + x + 1, [0, 1, 0, 1, 0, 0, 0])
```

16.7 Linear feedback shift register (LFSR) sequence commands.

Stream ciphers have been used for a long time as a source of pseudo-random number generators.

S. Golomb [G] gives a list of three statistical properties a sequence of numbers $\mathbf{a} = \{a_n\}_{n=1}^{\infty}$, $a_n \in \{0, 1\}$, should display to be considered "random". Define the autocorrelation of $\mathbf{a}$ to be

$$C(k) = C(k, \mathbf{a}) = \lim_{N\to\infty} \frac{1}{N} \sum_{n=1}^{N} (-1)^{a_n + a_{n+k}}.$$

In the case where $\mathbf{a}$ is periodic with period P then this reduces to

$$C(k) = \frac{1}{P} \sum_{n=1}^{P} (-1)^{a_n + a_{n+k}}.$$

Assume $\mathbf{a}$ is periodic with period P.

- balance: $|\sum_{n=1}^{P} (-1)^{a_n}| \leq 1$.

- low autocorrelation:

$$C(k) = \begin{cases} 1, & k = 0, \\ \epsilon, & k \neq 0. \end{cases}$$

  (For sequences satisfying these first two properties, it is known that $\epsilon = -1/P$ must hold.)

- proportional runs property: In each period, half the runs have length 1, one-fourth have length 2, etc. Moreover, there are as many runs of 1's as there are of 0's.

A general feedback shift register is a map $f : \mathbf{F}_q^d \to \mathbf{F}_q^d$ of the form

$$f(x_0, ..., x_{n-1}) = (x_1, x_2, ..., x_n),$$
$$x_n = C(x_0, ..., x_{n-1}),$$

where $C : \mathbf{F}_q^d \to \mathbf{F}_q$ is a given function. When C is of the form

$$C(x_0, ..., x_{n-1}) = a_0 x_0 + ... + a_{n-1} x_{n-1},$$

for some given constants $a_i \in \mathbf{F}_q$, the map is called a linear feedback shift register (LFSR).

Example of a LFSR Let

$$f(x) = a_0 + a_1 x + ... + a_n x^n + ...,$$

$$g(x) = b_0 + b_1 x + ... + b_n x^n + ...,$$

be given polynomials in $\mathbf{F}_2[x]$ and let

$$h(x) = \frac{f(x)}{g(x)} = c_0 + c_1 x + ... + c_n x^n + ...$$

We can compute a recursion formula which allows us to rapidly compute the coefficients of $h(x)$ (take $f(x) = 1$):

$$c_n = \sum_{i=1}^{n} \frac{-b_i}{b_0} c_{n-i}.$$

The coefficients of $h(x)$ can, under certain conditions on $f(x)$ and $g(x)$, be considered "random" from certain statistical points of view.

Example: For instance, if

$$f(x) = 1, \quad g(x) = x^4 + x + 1,$$

then

$$h(x) = 1 + x + x^2 + x^3 + x^5 + x^7 + x^8 + ...$$

The coefficients of h are

$$1, 1, 1, 0, 1, 0, 1, 1, 0, 0, 1, 0, 0, 0, 1,$$
$$1, 1, 1, 0, 1, 0, 1, 1, 0, 0, 1, 0, 0, 0, 1, ...$$

The sequence of $0, 1$'s is periodic with period $P = 2^4 - 1 = 15$ and satisfies Golomb's three randomness conditions. However, this sequence of period 15 can be "cracked" (i.e., a procedure to reproduce $g(x)$) by knowing only 8 terms! This is the function of the Berlekamp-Massey algorithm [M], implemented as `berlekamp_massey.py`.

lfsr_autocorrelation(*L, p, k*)

INPUT:

- L - is a periodic sequence of elements of ZZ or GF(2). L must have length = p
- p - the period of L
- k - k is an integer (0 k p)

OUTPUT: autocorrelation sequence of L

EXAMPLES:

```
sage: F = GF(2)
sage: o = F(0)
sage: l = F(1)
sage: key = [l,o,o,l]; fill = [l,l,o,l]; n = 20
sage: s = lfsr_sequence(key,fill,n)
sage: lfsr_autocorrelation(s,15,7)
4/15
sage: lfsr_autocorrelation(s,int(15),7)
4/15
```

AUTHORS:

- Timothy Brock (2006-04-17)

lfsr_connection_polynomial(*s*)

INPUT:

- s - a sequence of elements of a finite field (F) of even length

OUTPUT:

- C(x) - the connection polynomial of the minimal LFSR.

This implements the algorithm in section 3 of J. L. Massey's article [M].

EXAMPLE:

```
        sage: F = GF(2)
sage: F
Finite Field of size 2
sage: o = F(0); l = F(1)
       sage: key = [l,o,o,l]; fill = [l,l,o,l]; n = 20
       sage: s = lfsr_sequence(key,fill,n); s
       [1, 1, 0, 1, 0, 1, 1, 0, 0, 1, 0, 0, 0, 1, 1, 1, 1, 0, 1, 0]
       sage: lfsr_connection_polynomial(s)
       x^4 + x + 1
       sage: berlekamp_massey(s)
       x^4 + x^3 + 1
```

Notice that berlekamp_massey returns the reverse of the connection polynomial (and is potentially must faster than this implementation).

lfsr_sequence (*key, fill, n*)

This function creates an lfsr sequence.

INPUT:

•`key` - a list of finite field elements, [c_0,c_1,...,c_k].

•`fill` - the list of the initial terms of the lfsr sequence, [x_0,x_1,...,x_k].

•`n` - number of terms of the sequence that the function returns.

OUTPUT: The lfsr sequence defined by $x_{n+1} = c_k x_n + ... + c_0 x_{n-k}$, for $n \leq k$.

EXAMPLES:

```
sage: F = GF(2); l = F(1); o = F(0)
sage: F = GF(2); S = LaurentSeriesRing(F,'x'); x = S.gen()
sage: fill = [l,l,o,l]; key = [1,o,o,l]; n = 20
sage: L = lfsr_sequence(key,fill,20); L
[1, 1, 0, 1, 0, 1, 1, 0, 0, 1, 0, 0, 0, 1, 1, 1, 1, 0, 1, 0]
sage: g = berlekamp_massey(L); g
x^4 + x^3 + 1
sage: (1)/(g.reverse()+O(x^20))
1 + x + x^2 + x^3 + x^5 + x^7 + x^8 + x^11 + x^15 + x^16 + x^17 + x^18 + O(x^20)
sage: (1+x^2)/(g.reverse()+O(x^20))
1 + x + x^4 + x^8 + x^9 + x^10 + x^11 + x^13 + x^15 + x^16 + x^19 + O(x^20)
sage: (1+x^2+x^3)/(g.reverse()+O(x^20))
1 + x + x^3 + x^5 + x^6 + x^9 + x^13 + x^14 + x^15 + x^16 + x^18 + O(x^20)
sage: fill = [l,l,o,l]; key = [l,o,o,o]; n = 20
sage: L = lfsr_sequence(key,fill,20); L
[1, 1, 0, 1, 1, 1, 0, 1, 1, 1, 0, 1, 1, 1, 0, 1, 1, 1, 0, 1]
sage: g = berlekamp_massey(L); g
x^4 + 1
sage: (1+x)/(g.reverse()+O(x^20))
1 + x + x^4 + x^5 + x^8 + x^9 + x^12 + x^13 + x^16 + x^17 + O(x^20)
sage: (1+x+x^3)/(g.reverse()+O(x^20))
1 + x + x^3 + x^4 + x^5 + x^7 + x^8 + x^9 + x^11 + x^12 + x^13 + x^15 + x^16 + x^17 + x^19 + O(x
```

16.8 Small Scale Variants of the AES (SR) Polynomial System Generator.

Sage supports polynomial system generation for small scale (and full scale) AES variants over $\mathbf{F}_2$ and $\mathbf{F}_{2^e}$. Also, Sage supports both the specification of SR as given in the papers [CMR05] and [CMR06] and a variant of SR* which is equivalent to AES.

AUTHORS:

- Martin Albrecht (2008,2009-01): usability improvements
- Martin Albrecht (2007-09): initial version

EXAMPLES:

We construct SR(1,1,1,4) and study its properties.

```
sage: sr = mq.SR(1, 1, 1, 4)
```

`n` is the number of rounds, `r` the number of rows in the state array, `c` the number of columns in the state array, and `e` the degree of the underlying field.

```
sage: sr.n, sr.r, sr.c, sr.e
(1, 1, 1, 4)
```

By default variables are ordered reverse to as they appear, e.g.:

```
sage: print sr.R.repr_long()
Polynomial Ring
  Base Ring : Finite Field in a of size 2^4
       Size : 20 Variables
   Block  0 : Ordering : degrevlex
              Names    : k100, k101, k102, k103, x100, x101, x102, x103, w100, w101, w102, w103, s00
```

However, this can be prevented by passing in `reverse_variables=False` to the constructor.

For SR(1, 1, 1, 4) the `ShiftRows` matrix isn't that interesting.:

```
sage: sr.ShiftRows
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

Also, the `MixColumns` matrix is the identity matrix.:

```
sage: sr.MixColumns
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

`Lin`, however, is not the identity matrix.:

```
sage: sr.Lin
[          a^2 + 1                 1         a^3 + a^2           a^2 + 1]
[               a                  a                 1 a^3 + a^2 + a + 1]
[          a^3 + a               a^2               a^2                 1]
[               1               a^3             a + 1             a + 1]
```

`M` and `Mstar` are identical for SR(1, 1, 1, 4):

```
sage: sr.M
[          a^2 + 1                 1         a^3 + a^2           a^2 + 1]
[               a                  a                 1 a^3 + a^2 + a + 1]
[          a^3 + a               a^2               a^2                 1]
[               1               a^3             a + 1             a + 1]
```

```
sage: sr.Mstar
[          a^2 + 1                 1         a^3 + a^2           a^2 + 1]
[                a                 a                 1 a^3 + a^2 + a + 1]
[          a^3 + a               a^2               a^2                 1]
[                1               a^3             a + 1             a + 1]
```

We can compute a Groebner basis for the ideals spanned by SR instances to recover all solutions to the system.:

```
sage: sr = mq.SR(1,1,1,4, gf2=True, polybori=True)
sage: K = sr.base_ring()
sage: a = K.gen()
sage: K = [a]
sage: P = [1]
sage: F,s = sr.polynomial_system(P=P, K=K)
sage: F.groebner_basis()
[k100, k101 + 1, k102, k103 + k003,
 x100 + 1, x101 + k003 + 1, x102 + k003 + 1,
 x103 + k003, w100, w101, w102 + 1, w103 + k003 + 1,
 s000 + 1, s001 + k003, s002 + k003, s003 + k003 + 1,
 k000, k001, k002 + 1]
```

Note that the order of `k000`, `k001`, `k002` and `k003` is little endian. Thus the result `k002 + 1, k001, k000` indicates that the key is either a or $a + 1$. We can verify that both keys encrypt P to the same ciphertext:

```
sage: sr(P,[a])
[0]
sage: sr(P,[a+1])
[0]
```

All solutions can easily be recovered using the variety function for ideals.:

```
sage: I = F.ideal()
sage: for V in I.variety():
...     for k,v in sorted(V.iteritems()):
...         print k,v
...     print
k003 0
k002 1
k001 0
k000 0
s003 1
s002 0
s001 0
s000 1
w103 1
w102 1
w101 0
w100 0
x103 0
x102 1
x101 1
x100 1
k103 0
k102 0
k101 1
k100 0
```

```
<BLANKLINE>
k003 1
k002 1
k001 0
k000 0
s003 0
s002 1
s001 1
s000 1
w103 0
w102 1
w101 0
w100 0
x103 1
x102 0
x101 0
x100 1
k103 1
k102 0
k101 1
k100 0
```

Note that the S-Box object for SR can be constructed with a call to `sr.sbox()`:

```
sage: sr = mq.SR(1,1,1,4, gf2=True, polybori=True)
sage: S = sr.sbox()
```

For example, we can now study the difference distribution matrix of `S`:

```
sage: S.difference_distribution_matrix()
[16  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0]
[ 0  2  2  2  2  0  0  0  2  0  0  0  2  4  0  0]
[ 0  2  0  4  2  2  2  0  0  2  0  0  0  0  0  2]
[ 0  2  4  0  0  2  0  0  2  2  0  2  0  0  2  0]
[ 0  0  2  0  4  2  0  0  0  0  2  0  2  0  2  2]
[ 0  0  0  2  0  0  0  2  4  2  0  0  2  0  2  2]
[ 0  4  0  0  0  2  0  2  0  2  2  0  2  2  0  0]
[ 0  2  0  0  0  0  2  0  0  0  0  2  4  2  2  2]
[ 0  2  2  0  0  0  2  2  2  0  2  0  0  0  0  4]
[ 0  0  2  2  0  0  0  0  0  2  2  4  0  2  0  2]
[ 0  0  2  0  2  0  2  2  0  4  0  2  2  0  0  0]
[ 0  0  0  0  2  0  2  0  2  2  4  0  0  2  2  0]
[ 0  0  0  2  0  4  2  0  2  0  2  2  2  0  0  0]
[ 0  0  0  0  2  2  0  4  2  0  0  2  0  2  0  2]
[ 0  0  2  2  0  2  4  2  0  0  0  0  0  2  2  0]
[ 0  2  0  2  2  0  0  2  0  0  2  2  0  0  4  0]
```

or use `S` to find alternative polynomial representations for the S-Box.:

```
sage: S.polynomials(degree=3)
[x0*x1 + x1*x2 + x0*x3 + x0*y2 + x1 + y0 + y1 + 1,

```

```
sage: S.interpolation_polynomial()
(a^2 + 1)*x^14 + x^13 + (a^3 + a^2)*x^11 + (a^2 + 1)*x^7 + a^2 + a
```

The SR_gf2_2 gives an example how use alternative polynomial representations of the S-Box for construction of polynomial systems.

TESTS:

```
sage: sr == loads(dumps(sr))
True
```

REFERENCES:

class AllowZeroInversionsContext(*sr*)

Temporarily allow zero inversion.

SR(*n=1, r=1, c=1, e=4, star=False, **kwargs*)

Return a small scale variant of the AES polynomial system constructor subject to the following conditions:

INPUT:

- n - the number of rounds (default: 1)
- r - the number of rows in the state array (default: 1)
- c - the number of columns in the state array (default: 1)
- e - the exponent of the finite extension field (default: 4)
- star - determines if SR* or SR should be constructed (default: False)
- aes_mode - as the SR key schedule specification differs slightly from the AES key schedule, this parameter controls which schedule to use (default: True)
- gf2 - generate polynomial systems over $\mathbf{F}_2$ rather than over $\mathbf{F}_{2^e}$ (default: False)
- polybori - use the BooleanPolynomialRing as polynomial representation (default: False, $\mathbf{F}_2$ only)
- order - a string to specify the term ordering of the variables
- postfix - a string which is appended after the variable name (default: '')
- allow_zero_inversions - a boolean to control whether zero inversions raise an exception (default: False)
- correct_only - only include correct inversion polynomials (default: False, $\mathbf{F}_2$ only)
- biaffine_only - only include bilinear and biaffine inversion polynomials (default: True, $\mathbf{F}_2$ only)

EXAMPLES:

```
sage: sr = mq.SR(1, 1, 1, 4)
sage: ShiftRows = sr.shift_rows_matrix()
sage: MixColumns = sr.mix_columns_matrix()
sage: Lin = sr.lin_matrix()
sage: M = MixColumns * ShiftRows * Lin
sage: print sr.hex_str_matrix(M)
 5 1 C 5
 2 2 1 F
 A 4 4 1

```

class **SR_generic**(*n=1, r=1, c=1, e=4, star=False, **kwargs*)

add_round_key(*d, key*)

Perform the `AddRoundKey` operation on `d` using `key`.

INPUT:

- `d` - state array or something coercible to a state array
- `key` - state array or something coercible to a state array

EXAMPLE:

```
sage: sr = mq.SR(10, 4, 4, 4)
sage: D = sr.random_state_array()
sage: K = sr.random_state_array()
sage: sr.add_round_key(D, K) == K + D
True
```

base_ring()

Return the base field of self as determined by `self.e`.

EXAMPLE:

```
sage: sr = mq.SR(10, 2, 2, 4)
sage: sr.base_ring().polynomial()
a^4 + a + 1
```

The Rijndael polynomial:

```
sage: sr = mq.SR(10, 4, 4, 8)
sage: sr.base_ring().polynomial()
a^8 + a^4 + a^3 + a + 1
```

block_order()

Return a block order for self where each round is a block.

EXAMPLE:

```
sage: sr = mq.SR(2, 1, 1, 4)
sage: sr.block_order()
degrevlex(16),degrevlex(16),degrevlex(4) term order

sage: P = sr.ring(order='block')
sage: print P.repr_long()
Polynomial Ring
  Base Ring : Finite Field in a of size 2^4
       Size : 36 Variables
   Block  0 : Ordering : degrevlex
              Names    : k200, k201, k202, k203, x200, x201, x202, x203, w200, w201, w202, w
   Block  1 : Ordering : degrevlex
              Names    : k100, k101, k102, k103, x100, x101, x102, x103, w100, w101, w102, w
   Block  2 : Ordering : degrevlex
              Names    : k000, k001, k002, k003
```

hex_str(*M*, *typ='matrix'*)

Return a hex string for the provided AES state array/matrix.

INPUT:

- `M` - state array
- `typ` - controls what to return, either 'matrix' or 'vector' (default: `'matrix'`)

EXAMPLE:

```
sage: sr = mq.SR(2, 2, 2, 4)
sage: k = sr.base_ring()
sage: A = matrix(k, 2, 2, [1, k.gen(), 0, k.gen()^2])
sage: sr.hex_str(A)
' 1 2 \n 0 4 \n'

sage: sr.hex_str(A, typ='vector')
'1024'
```

hex_str_matrix(*M*)

Return a two-dimensional AES-like representation of the matrix M.

That is, show the finite field elements as hex strings.

INPUT:

- M - an AES state array

EXAMPLE:

```
sage: sr = mq.SR(2, 2, 2, 4)
sage: k = sr.base_ring()
sage: A = matrix(k, 2, 2, [1, k.gen(), 0, k.gen()^2])
sage: sr.hex_str_matrix(A)
' 1 2 \n 0 4 \n'
```

hex_str_vector(*M*)

Return a one-dimensional AES-like representation of the matrix M.

That is, show the finite field elements as hex strings.

INPUT:

- M - an AES state array

EXAMPLE:

```
sage: sr = mq.SR(2, 2, 2, 4)
sage: k = sr.base_ring()
sage: A = matrix(k, 2, 2, [1, k.gen(), 0, k.gen()^2])
sage: sr.hex_str_vector(A)
'1024'
```

is_state_array(*d*)

Return `True` if `d` is a state array, i.e. has the correct dimensions and base field.

EXAMPLE:

```
sage: sr = mq.SR(2, 2, 4, 8)
sage: k = sr.base_ring()
sage: sr.is_state_array( matrix(k, 2, 4) )
True

sage: sr = mq.SR(2, 2, 4, 8)
sage: k = sr.base_ring()
sage: sr.is_state_array( matrix(k, 4, 4) )
False
```

key_schedule(*kj*, *i*)

Return k_i for a given i and k_j with $j = i - 1$.

EXAMPLES:

```
sage: sr = mq.SR(10, 4, 4, 8, star=True, allow_zero_inversions=True)
sage: ki = sr.state_array()
sage: for i in range(10):
...   ki = sr.key_schedule(ki, i+1)
sage: print sr.hex_str_matrix(ki)
B4 3E 23 6F
EF 92 E9 8F
5B E2 51 18
CB 11 CF 8E
```

key_schedule_polynomials(*i*)

Return polynomials for the i-th round of the key schedule.

INPUT:

- i - round ($0 \leq i \leq n$)

EXAMPLE:

```
sage: sr = mq.SR(1, 1, 1, 4, gf2=True)
```

The 0-th subkey is the user provided key, so only conjugacy relations are added.

```
sage: sr.key_schedule_polynomials(0)
(k000^2 + k000, k001^2 + k001, k002^2 + k002, k003^2 + k003)
```

The 1-th subkey is derived from the user provided key according to the key schedule which is non-linear.

```
sage: sr.key_schedule_polynomials(1)
(k100 + s000 + s002 + s003,
 k101 + s000 + s001 + s003 + 1,
 k102 + s000 + s001 + s002 + 1,
 k103 + s001 + s002 + s003 + 1,
 k100^2 + k100, k101^2 + k101, k102^2 + k102, k103^2 + k103,
 s000^2 + s000, s001^2 + s001, s002^2 + s002, s003^2 + s003,
 s000*k000 + s003*k000 + s002*k001 + s001*k002 + s000*k003,
 s000*k000 + s001*k000 + s000*k001 + s003*k001 + s002*k002 + s001*k003,
 s001*k000 + s002*k000 + s000*k001 + s001*k001 + s000*k002 + s003*k002 + s002*k003,
 s000*k000 + s002*k000 + s003*k000 + s000*k001 + s001*k001 + s002*k002 + s000*k003 + k000,
 s001*k000 + s003*k000 + s001*k001 + s002*k001 + s000*k002 + s003*k002 + s001*k003 + k001,
 s000*k000 + s002*k000 + s000*k001 + s002*k001 + s003*k001 + s000*k002 + s001*k002 + s002*k0
 s001*k000 + s002*k000 + s000*k001 + s003*k001 + s001*k002 + s003*k003 + k003,
 s000*k000 + s001*k000 + s003*k000 + s001*k001 + s000*k002 + s002*k002 + s000*k003 + s000,
 s002*k000 + s000*k001 + s001*k001 + s003*k001 + s001*k002 + s000*k003 + s002*k003 + s001,
 s000*k000 + s001*k000 + s002*k000 + s002*k001 + s000*k002 + s001*k002 + s003*k002 + s001*k0
 s001*k000 + s000*k001 + s002*k001 + s000*k002 + s001*k003 + s003*k003 + s003,
 s002*k000 + s001*k001 + s000*k002 + s003*k003 + 1)
```

mix_columns(*d*)

Perform the MixColumns operation on d.

INPUT:

- d - state array or something coercible to a state array

EXAMPLES:

```
sage: sr = mq.SR(10, 4, 4, 4)
sage: E = sr.state_array() + 1; E
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]

sage: sr.mix_columns(E)
[    a a + 1     1     1]
[    1     a a + 1     1]
[    1     1     a a + 1]
[a + 1     1     1     a]
```

new_generator(***kwds*)

Return a new SR instance equal to this instance except for the parameters passed explicitly to this function.

INPUT:

- **kwds - see the SR constructor for accepted parameters

EXAMPLE:

```
sage: sr = mq.SR(2,1,1,4); sr
SR(2,1,1,4)
sage: sr.ring().base_ring()
Finite Field in a of size 2^4
```

```
sage: sr2 = sr.new_generator(gf2=True); sr2
SR(2,1,1,4)
sage: sr2.ring().base_ring()
Finite Field of size 2
sage: sr3 = sr2.new_generator(correct_only=True)
sage: len(sr2.inversion_polynomials_single_sbox())
20
sage: len(sr3.inversion_polynomials_single_sbox())
19
```

polynomial_system(*P=None, K=None, C=None*)

Return a polynomial system for this small scale AES variant for a given plaintext-key pair.

If neither `P`, `K` nor `C` are provided, a random pair (`P`, `K`) will be generated. If `P` and `C` are provided no `K` needs to be provided.

INPUT:

- `P` - vector, list, or tuple (default: `None`)
- `K` - vector, list, or tuple (default: `None`)
- `C` - vector, list, or tuple (default: `None`)

EXAMPLE:

```
sage: sr = mq.SR(1, 1, 1, 4, gf2=True, polybori=True)
sage: P = sr.vector([0, 0, 1, 0])
sage: K = sr.vector([1, 0, 0, 1])
sage: F, s = sr.polynomial_system(P, K)
```

This returns a polynomial system:

```
sage: F
Polynomial System with 36 Polynomials in 20 Variables
```

and a solution:

```
sage: s # random -- maybe we need a better doctest here?
{k000: 1, k001: 0, k003: 1, k002: 0}
```

This solution is not the only solution that we can learn from the Groebner basis of the system.

```
sage: F.groebner_basis()[-3:]
[k000 + 1, k001, k003 + 1]
```

In particular we have two solutions:

```
sage: len(F.ideal().variety())
2
```

In the following example we provide `C` explicitly:

```
sage: C = sr(P,K)
sage: F,s = sr.polynomial_system(P=P, C=C)
sage: F
Polynomial System with 36 Polynomials in 20 Variables
```

Alternatively, we can use symbols for the `P` and `C`. First, we have to create a polynomial ring:

```
sage: sr = mq.SR(1, 1, 1, 4, gf2=True, polybori=True)
sage: R = sr.R
sage: vn = sr.varstrs("P",0,1,4) + R.variable_names() + sr.varstrs("C",0,1,4)
sage: R = BooleanPolynomialRing(len(vn),vn)
sage: sr.R = R
```

Now, we can construct the purely symbolic equation system:

```
sage: C = sr.vars("C",0); C
(C000, C001, C002, C003)
sage: P = sr.vars("P",0)
sage: F,s = sr.polynomial_system(P=P,C=C)
sage: [(k,v) for k,v in sorted(s.iteritems())] # this can be ignored
[(k003, 1), (k002, 1), (k001, 0), (k000, 0)]
sage: F
Polynomial System with 36 Polynomials in 28 Variables
sage: F.round(0)
(P000 + w100 + k000, P001 + w101 + k001, P002 + w102 + k002, P003 + w103 + k003)
sage: F.round(-2)
(k100 + x100 + x102 + x103 + C000, k101 + x100 + x101 + x103 + C001 + 1, ...)
```

random_element(*elem_type='vector'*)

Return a random element for self.

INPUT:

- `elem_type` - either 'vector' or 'state array' (default: `'vector'`)

EXAMPLE:

```
sage: sr = mq.SR()
sage: sr.random_element()
[  a^3 + a + 1]
[      a^3 + 1]
[a^3 + a^2 + 1]
[a^3 + a^2 + a]
sage: sr.random_element('state_array')
[a + 1]
```

random_state_array()

Return a random element in `MatrixSpace(self.base_ring(), self.r, self.c)`.

EXAMPLE:

```
sage: sr = mq.SR(2, 2, 2, 4)
sage: sr.random_state_array()
[a^3 + a + 1       a + 1]
[      a + 1         a^2]
```

random_vector()

Return a random vector as it might appear in the algebraic expression of self.

EXAMPLE:

```
sage: sr = mq.SR(2, 2, 2, 4)
sage: sr.random_vector()
[  a^3 + a + 1]
[      a^3 + 1]
[a^3 + a^2 + 1]
[a^3 + a^2 + a]
[        a + 1]
[      a^2 + 1]
[            a]
[          a^2]
[        a + 1]
[      a^2 + 1]
[            a]
[          a^2]
[          a^2]
[        a + 1]
```

```
[      a^2 + 1]
[            a]
```

Note: ϕ was already applied to the result.

ring(*order=None, reverse_variables=None*)

Construct a ring as a base ring for the polynomial system.

By default, variables are ordered in the reverse of their natural ordering, i.e. the reverse of as they appear.

INPUT:

- `order` - a monomial ordering (default: `None`)
- `reverse_variables` - reverse rounds of variables (default: `True`)

The variable assignment is as follows:

- $k_{i,j,l}$ - subkey round i word j conjugate/bit l
- $s_{i,j,l}$ - subkey inverse round i word j conjugate/bit l
- $w_{i,j,l}$ - inversion input round i word j conjugate/bit l
- $x_{i,j,l}$ - inversion output round i word j conjugate/bit l

Note that the variables are ordered in column major ordering in the state array and that the bits are ordered in little endian ordering.

For example, if $x_{0,1,0}$ is a variable over $\mathbf{F}_2$ for $r = 2$ and $c = 2$ then refers to the *most* significant bit of the entry in the position (1,0) in the state array matrix.

EXAMPLE:

```
sage: sr = mq.SR(2, 1, 1, 4)
sage: P = sr.ring(order='block')
sage: print P.repr_long()
Polynomial Ring
  Base Ring : Finite Field in a of size 2^4
       Size : 36 Variables
   Block  0 : Ordering : degrevlex
              Names    : k200, k201, k202, k203, x200, x201, x202, x203, w200, w201, w202, w
   Block  1 : Ordering : degrevlex
              Names    : k100, k101, k102, k103, x100, x101, x102, x103, w100, w101, w102, w
   Block  2 : Ordering : degrevlex
              Names    : k000, k001, k002, k003
```

round_polynomials(*i, plaintext=None, ciphertext=None*)

Return list of polynomials for a given round i.

If `i == 0` a plaintext must be provided, if `i == n` a ciphertext must be provided.

INPUT:

- `i` - round number
- `plaintext` - optional plaintext (mandatory in first round)
- `ciphertext` - optional ciphertext (mandatory in last round)

OUTPUT: MPolynomialRoundSystem

EXAMPLE:

```
sage: sr = mq.SR(1, 1, 1, 4)
sage: k = sr.base_ring()
sage: p = [k.random_element() for _ in range(sr.r*sr.c)]
sage: sr.round_polynomials(0, plaintext=p)
(w100 + k000 + (a^2 + 1), w101 + k001 + (a), w102 + k002 + (a^2), w103 + k003 + (a + 1))
```

sbox(*inversion_only=False*)

Return an S-Box object for this SR instance.

INPUT:

•`inversion_only` - do not include the $\mathbf{F}_2$ affine map when computing the S-Box (default: `False`)

EXAMPLE:

```
sage: sr = mq.SR(1,2,2,4, allow_zero_inversions=True)
sage: S = sr.sbox(); S
(6, 11, 5, 4, 2, 14, 7, 10, 9, 13, 15, 12, 3, 1, 0, 8)

sage: sr.sub_byte(0)
a^2 + a
sage: sage_eval(str(sr.sub_byte(0)), {'a':2})
6
sage: S(0)
6

sage: sr.sub_byte(1)
a^3 + a + 1
sage: sage_eval(str(sr.sub_byte(1)), {'a':2})
11
sage: S(1)
11

sage: sr = mq.SR(1,2,2,8, allow_zero_inversions=True)
sage: S = sr.sbox(); S
(99, 124, 119, 123, 242, 107, 111, 197, 48, 1, 103, 43,
254, 215, 171, 118, 202, 130, 201, 125, 250, 89, 71, 240,

153, 45, 15, 176, 84, 187, 22)

sage: sr.sub_byte(0)
a^6 + a^5 + a + 1

sage: sage_eval(str(sr.sub_byte(0)), {'a':2})
99
sage: S(0)
99

sage: sr.sub_byte(1)
a^6 + a^5 + a^4 + a^3 + a^2

sage: sage_eval(str(sr.sub_byte(1)), {'a':2})
124
```

```
sage: S(1)
124

sage: sr = mq.SR(1,2,2,4, allow_zero_inversions=True)
sage: S = sr.sbox(inversion_only=True); S
(0, 1, 9, 14, 13, 11, 7, 6, 15, 2, 12, 5, 10, 4, 3, 8)

sage: S(0)
0
sage: S(1)
1

sage: S(sr.k.gen())
a^3 + 1
```

sbox_constant()

Return the S-Box constant which is added after $L(x^{-1})$ was performed. That is `0x63` if `e == 8` or `0x6` if `e == 4`.

EXAMPLE:

```
sage: sr = mq.SR(10, 1, 1, 8)
sage: sr.sbox_constant()
a^6 + a^5 + a + 1
```

shift_rows(*d*)

Perform the `ShiftRows` operation on `d`.

INPUT:

- `d` - state array or something coercible to a state array

EXAMPLES:

```
sage: sr = mq.SR(10, 4, 4, 4)
sage: E = sr.state_array() + 1; E
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]

sage: sr.shift_rows(E)
[1 0 0 0]
[1 0 0 0]
[1 0 0 0]
[1 0 0 0]
```

state_array(*d=None*)

Convert the parameter to a state array.

INPUT:

- `d` - a matrix, a list, or a tuple (default: `None`)

EXAMPLES:

```
sage: sr = mq.SR(2, 2, 2, 4)
sage: k = sr.base_ring()
sage: e1 = [k.fetch_int(e) for e in range(2*2)]; e1
[0, 1, a, a + 1]
sage: e2 = sr.phi( Matrix(k, 2*2, 1, e1) )
sage: sr.state_array(e1) # note the column major ordering
[    0     a]
```

```
[    1 a + 1]
sage: sr.state_array(e2)
[    0     a]
[    1 a + 1]

sage: sr.state_array()
[0 0]
[0 0]
```

sub_byte(*b*)

Perform SubByte on a single byte/halfbyte b.

A ZeroDivision exception is raised if an attempt is made to perform an inversion on the zero element. This can be disabled by passing allow_zero_inversion=True to the constructor. A zero inversion can result in an inconsistent equation system.

INPUT:

- b - an element in self.base_ring()

EXAMPLE:

The S-Box table for $\mathbf{F}_{2^4}$:

```
sage: sr = mq.SR(1, 1, 1, 4, allow_zero_inversions=True)
sage: for e in sr.base_ring():
...     print '% 20s % 20s'%(e, sr.sub_byte(e))
                   0                a^2 + a
                   a                a^2 + 1
                 a^2                    a
                 a^3                a^3 + 1
               a + 1                    a^2
             a^2 + a            a^2 + a + 1
           a^3 + a^2                  a + 1
         a^3 + a + 1              a^3 + a^2
             a^2 + 1          a^3 + a^2 + a
             a^3 + a      a^3 + a^2 + a + 1
         a^2 + a + 1                a^3 + a
       a^3 + a^2 + a                    0
a^3 + a^2 + a + 1                   a^3
       a^3 + a^2 + 1                    1
             a^3 + 1          a^3 + a^2 + 1
                   1            a^3 + a + 1
```

sub_bytes(*d*)

Perform the non-linear transform on d.

INPUT:

- d - state array or something coercible to a state array

EXAMPLE:

```
sage: sr = mq.SR(2, 1, 2, 8, gf2=True)
sage: k = sr.base_ring()
sage: A = Matrix(k, 1, 2 , [k(1), k.gen()])
sage: sr.sub_bytes(A)
[  a^6 + a^5 + a^4 + a^3 + a^2 a^6 + a^5 + a^4 + a^2 + a + 1]
```

varformatstr(*name, n=None, rc=None, e=None*)

Return a format string which is understood by print et al.

If a numerical value is omitted, the default value of self is used. The numerical values (n, rc, e) are used to determine the width of the respective fields in the format string.

INPUT:

- name - name of the variable
- n - number of rounds (default: None)
- rc - number of rows * number of cols (default: None)
- e - exponent of base field (default: None)

EXAMPLE:

```
sage: sr = mq.SR(1, 2, 2, 4)
sage: sr.varformatstr('x')
'x%01d%01d%01d'
sage: sr.varformatstr('x', n=1000)
'x%03d%03d%03d'
```

variable_dict()

Return a dictionary to access variables in self.R by their names.

EXAMPLE:

```
sage: sr = mq.SR(1,1,1,4)
sage: sr.variable_dict()
{'x101': x101, 'x100': x100, 'x103': x103, 'x102': x102,
 's002': s002, 'w100': w100, 'w101': w101, 'w102': w102,
 'w103': w103, 'k100': k100, 'k101': k101, 'k102': k102,
 'k103': k103, 's003': s003, 's001': s001, 'k002': k002,
 'k001': k001, 'k000': k000, 'k003': k003, 's000': s000}

sage: sr = mq.SR(1,1,1,4,gf2=True)
sage: sr.variable_dict()
{'x101': x101, 'x100': x100, 'x103': x103, 'x102': x102,
 's002': s002, 'w100': w100, 'w101': w101, 'w102': w102,
 'w103': w103, 'k100': k100, 'k101': k101, 'k102': k102,
 'k103': k103, 's003': s003, 's001': s001, 'k002': k002,
 'k001': k001, 'k000': k000, 'k003': k003, 's000': s000}
```

vars(*name, nr, rc=None, e=None*)

Return a list of variables in self.

INPUT:

- name - variable name
- nr - number of round to create variable strings for
- rc - number of rounds * number of columns in the state array (default: None)
- e - exponent of base field (default: None)

EXAMPLE:

```
sage: sr = mq.SR(10, 1, 2, 4)
sage: sr.vars('x', 2)
(x200, x201, x202, x203, x210, x211, x212, x213)
```

varstr(*name, nr, rc, e*)

Return a string representing a variable for the small scale AES subject to the given constraints.

INPUT:

- name - variable name
- nr - number of round to create variable strings for
- rc - row*column index in state array
- e - exponent of base field

EXAMPLE:

```
sage: sr = mq.SR(10, 1, 2, 4)
sage: sr.varstr('x', 2, 1, 1)
'x211'
```

varstrs (*name, nr, rc=None, e=None*)

Return a list of strings representing variables in `self`.

INPUT:

- `name` - variable name
- `nr` - number of round to create variable strings for
- `rc` - number of rows * number of columns in the state array (default: `None`)
- `e` - exponent of base field (default: `None`)

EXAMPLE:

```
sage: sr = mq.SR(10, 1, 2, 4)
sage: sr.varstrs('x', 2)
('x200', 'x201', 'x202', 'x203', 'x210', 'x211', 'x212', 'x213')
```

class SR_gf2 (*n=1, r=1, c=1, e=4, star=False, **kwargs*)

antiphi (*l*)

The operation ϕ^{-1} from [MR02] or the inverse of `self.phi`.

INPUT:

- `l` - a vector in the sense of `self.is_vector`

EXAMPLE:

```
sage: sr = mq.SR(gf2=True)
sage: A = sr.random_state_array()
sage: A
[a^3 + a + 1]
sage: sr.antiphi(sr.phi(A)) == A
True
```

field_polynomials (*name, i, l=None*)

Return list of field polynomials for a given round `i` and name `name`.

INPUT:

- `name` - variable name
- `i` - round number
- `l` - length of variable list (default: `None` = r*c)

EXAMPLE:

```
sage: sr = mq.SR(3, 1, 1, 8, gf2=True)
sage: sr.field_polynomials('x', 2)
[x200^2 + x200, x201^2 + x201,
 x202^2 + x202, x203^2 + x203,
 x204^2 + x204, x205^2 + x205,
 x206^2 + x206, x207^2 + x207]

sage: sr = mq.SR(3, 1, 1, 8, gf2=True, polybori=True)
sage: sr.field_polynomials('x', 2)
[]
```

inversion_polynomials (*xi, wi, length*)

Return polynomials to represent the inversion in the AES S-Box.

INPUT:

- `xi` - output variables
- `wi` - input variables
- `length` - length of both lists

EXAMPLE:

```
sage: sr = mq.SR(1, 1, 1, 8, gf2=True)
sage: xi = sr.vars('x', 1)
sage: wi = sr.vars('w', 1)
sage: sr.inversion_polynomials(xi, wi, len(xi))[:3]
[x100*w100 + x102*w100 + x103*w100 + x107*w100 + x101*w101
+ x102*w101 + x106*w101 + x100*w102 + x101*w102 +
x105*w102 + x100*w103 + x104*w103 + x103*w104 + x102*w105
+ x101*w106 + x100*w107, x101*w100 + x103*w100 + x104*w100
+ x100*w101 + x102*w101 + x103*w101 + x107*w101 +
x101*w102 + x102*w102 + x106*w102 + x100*w103 + x101*w103
+ x105*w103 + x100*w104 + x104*w104 + x103*w105 +
x102*w106 + x101*w107, x102*w100 + x104*w100 + x105*w100 +
x101*w101 + x103*w101 + x104*w101 + x100*w102 + x102*w102
+ x103*w102 + x107*w102 + x101*w103 + x102*w103 +
x106*w103 + x100*w104 + x101*w104 + x105*w104 + x100*w105
+ x104*w105 + x103*w106 + x102*w107]
```

inversion_polynomials_single_sbox(*x=None, w=None, biaffine_only=None, correct_only=None*)

Return inversion polynomials of a single S-Box.

INPUT:

- `xi` - output variables
- `wi` - input variables
- `length` - length of both lists

EXAMPLES:

```
sage: sr = mq.SR(1, 1, 1, 8, gf2=True)
sage: len(sr.inversion_polynomials_single_sbox())
24
sage: len(sr.inversion_polynomials_single_sbox(correct_only=True))
23
sage: len(sr.inversion_polynomials_single_sbox(biaffine_only=False))
40
sage: len(sr.inversion_polynomials_single_sbox(biaffine_only=False, correct_only=True))

sage: set(l3) == set(sr._inversion_polynomials_single_sbox(biaffine_only=False, correct_only
True
```

is_vector(*d*)

Return `True` if the given matrix satisfies the conditions for a vector as it appears in the algebraic expression of `self`.

INPUT:

- `d` - matrix

EXAMPLE:

```
sage: sr = mq.SR(gf2=True)
sage: sr
SR(1,1,1,4)
sage: k = sr.base_ring()
sage: A = Matrix(k, 1, 1, [k.gen()])
sage: B = sr.vector(A)
sage: sr.is_vector(A)
False
sage: sr.is_vector(B)
True
```

lin_matrix(*length=None*)

Return the `Lin` matrix.

If no `length` is provided, the standard state space size is used. The key schedule calls this method with an explicit length argument because only `self.r` S-Box applications are performed in the key schedule.

INPUT:

- `length` - length of state space (default: `None`)

EXAMPLE:

```
sage: sr = mq.SR(1, 1, 1, 4, gf2=True)
sage: sr.lin_matrix()
[1 0 1 1]
[1 1 0 1]
[1 1 1 0]
[0 1 1 1]
```

mix_columns_matrix()

Return the `MixColumns` matrix.

EXAMPLE:

```
sage: sr = mq.SR(1, 2, 2, 4, gf2=True)
sage: s = sr.random_state_array()
sage: r1 = sr.mix_columns(s)
sage: r2 = sr.state_array(sr.mix_columns_matrix() * sr.vector(s))
sage: r1 == r2
True
```

phi (*l, diffusion_matrix=False*)

The operation ϕ from [MR02]

Given a list/matrix of elements in $\mathbf{F}_{2^e}$, return a matching list/matrix of elements in $\mathbf{F}_2$.

INPUT:

- `l` - element to perform ϕ on.
- `diffusion_matrix` - if `True`, the given matrix `l` is transformed to a matrix which performs the same operation over $\mathbf{F}_2$ as `l` over $\mathbf{F}_{2^n}$ (default: `False`).

EXAMPLE:

```
sage: sr = mq.SR(2, 1, 2, 4, gf2=True)
sage: k = sr.base_ring()
sage: A = matrix(k, 1, 2, [k.gen(), 0] )
sage: sr.phi(A)
[0 0]
[0 0]
[1 0]
[0 0]
```

shift_rows_matrix()

Return the `ShiftRows` matrix.

EXAMPLE:

```
sage: sr = mq.SR(1, 2, 2, 4, gf2=True)
sage: s = sr.random_state_array()
sage: r1 = sr.shift_rows(s)
sage: r2 = sr.state_array( sr.shift_rows_matrix() * sr.vector(s) )
sage: r1 == r2
True
```

vector (*d=None*)

Constructs a vector suitable for the algebraic representation of SR.

INPUT:

- `d` - values for vector (default: `None`)

EXAMPLE:

```
sage: sr = mq.SR(gf2=True)
sage: sr
SR(1,1,1,4)
sage: k = sr.base_ring()
sage: A = Matrix(k, 1, 1, [k.gen()])
sage: sr.vector(A)
[0]
[0]
[1]
[0]
```

class SR_gf2_2 (*n=1, r=1, c=1, e=4, star=False, **kwargs*)

This is an example how to customize the SR constructor.

In this example, we replace the S-Box inversion polynomials by the polynomials generated by the S-Box class.

inversion_polynomials_single_sbox(*x=None, w=None, biaffine_only=None, correct_only=None, groebner=False*)

Return inversion polynomials of a single S-Box.

INPUT:

- `x` - output variables (default: `None`)
- `w` - input variables (default: `None`)
- `biaffine_only` - ignored (always `False`)
- `correct_only` - ignored (always `True`)
- `groebner` - precompute the Groebner basis for this S-Box (default: `False`).

EXAMPLES:

```
sage: from sage.crypto.mq.sr import SR_gf2_2
sage: e = 4
sage: sr = SR_gf2_2(1, 1, 1, e)
sage: P = PolynomialRing(GF(2),['x%d'%i for i in range(e)] + ['w%d'%i for i in range(e)],orc
sage: X,W = P.gens()[:e],P.gens()[e:]
sage: sr.inversion_polynomials_single_sbox(X, W, groebner=True)
[x0 + w0*w1*w2 + w0*w1 + w0*w2 + w0*w3 + w0 + w1 + w2,
 x1 + w0*w1*w3 + w0*w3 + w0 + w1*w3 + w1 + w2*w3,
 x2 + w0*w2*w3 + w0*w2 + w0 + w1*w2 + w1*w3 + w2*w3,
 x3 + w0*w1*w2 + w0 + w1*w2*w3 + w1*w2 + w1*w3 + w1 + w2 + w3]

sage: from sage.crypto.mq.sr import SR_gf2_2
sage: e = 4
sage: sr = SR_gf2_2(1, 1, 1, e)
sage: sr.inversion_polynomials_single_sbox()
[w3*w1 + w3*w0 + w3*x2 + w3*x1 + w3 + w2*w1 + w1 + x3 + x2 + x1,
 w3*w2 + w3*w1 + w3*x3 + w2 + w1 + x3,
 w3*w2 + w3*w1 + w3*x2 + w3 + w2*x3 + x2 + x1,
 w3*w2 + w3*w1 + w3*x3 + w3*x2 + w3*x1 + w3 + w2*x2 + w0 + x3 + x2 + x1 + x0,
 w3*w2 + w3*w1 + w3*x1 + w3*x0 + w2*x1 + w0 + x3 + x0,
 w3*w2 + w3*w1 + w3*w0 + w3*x2 + w3*x1 + w2*w0 + w2*x0 + w0 + x3 + x2 + x1 + x0,
 w3*w2 + w3*x1 + w3 + w2*w0 + w1*w0 + w1 + x3 + x2,
 w3*w2 + w3*w1 + w3*x1 + w1*x3 + x3 + x2 + x1,
 w3*x3 + w3*x2 + w3*x0 + w3 + w1*x2 + w1 + w0 + x2 + x0,
 w3*w2 + w3*w1 + w3*x2 + w3*x1 + w1*x1 + w1 + w0 + x2 + x0,
 w3*w2 + w3*w1 + w3*w0 + w3*x3 + w3*x1 + w2*w0 + w1*x0 + x3 + x2,
 w3*w2 + w3*w1 + w3*x2 + w3*x1 + w3*x0 + w3 + w1 + w0*x3 + x3 + x2,
 w3*w2 + w3*w1 + w3*w0 + w3*x3 + w3 + w2*w0 + w1 + w0*x2 + x3 + x2,
 w3*w0 + w3*x2 + w2*w0 + w0*x1 + w0 + x3 + x1 + x0,
 w3*w0 + w3*x3 + w3*x0 + w2*w0 + w1 + w0*x0 + w0 + x3 + x2,
 w3*w2 + w3 + w1 + x3*x2 + x3 + x1,
 w3*w2 + w3*x3 + w1 + x3*x1 + x3 + x2,
 w3*w2 + w3*w0 + w3*x3 + w3*x2 + w3*x1 + w0 + x3*x0 + x1 + x0,
 w3*w2 + w3*w1 + w3*w0 + w3*x3 + w1 + w0 + x2*x1 + x2 + x0,
 w3*w2 + w2*w0 + w1 + x3 + x2*x0,
 w3*x3 + w3*x1 + w2*w0 + w1 + x3 + x2 + x1*x0 + x1]
```

class SR_gf2n(*n=1, r=1, c=1, e=4, star=False, **kwargs*)

Small Scale Variants of the AES polynomial system constructor over $\mathbf{F}_{2^n}$.

antiphi(*l*)

The operation ϕ^{-1} from [MR02] or the inverse of `self.phi`.

INPUT:

- `l` - a vector in the sense of `self.is_vector`

EXAMPLE:

```
sage: sr = mq.SR()
sage: A = sr.random_state_array()
sage: A
[a^3 + a + 1]
sage: sr.antiphi(sr.phi(A)) == A
True
```

field_polynomials(*name, i, l=None*)

Return list of conjugacy polynomials for a given round `i` and name `name`.

INPUT:

- `name` - variable name
- `i` - round number
- `l` - r*c (default: `None`)

EXAMPLE:

```
sage: sr = mq.SR(3, 1, 1, 8)
sage: sr.field_polynomials('x', 2)
[x200^2 + x201,
x201^2 + x202,
x202^2 + x203,
x203^2 + x204,
x204^2 + x205,
x205^2 + x206,
x206^2 + x207,
x207^2 + x200]
```

inversion_polynomials(*xi, wi, length*)

Return polynomials to represent the inversion in the AES S-Box.

INPUT:

- `xi` - output variables
- `wi` - input variables
- `length` - length of both lists

EXAMPLE:

```
sage: sr = mq.SR(1, 1, 1, 8)
sage: R = sr.ring()
sage: xi = Matrix(R, 8, 1, sr.vars('x', 1))
sage: wi = Matrix(R, 8, 1, sr.vars('w', 1))
sage: sr.inversion_polynomials(xi, wi, 8)
[x100*w100 + 1,
x101*w101 + 1,
x102*w102 + 1,
x103*w103 + 1,
x104*w104 + 1,
x105*w105 + 1,
x106*w106 + 1,
x107*w107 + 1]
```

is_vector(*d*)

Return `True` if `d` can be used as a vector for `self`.

EXAMPLE:

```
sage: sr = mq.SR()
sage: sr
SR(1,1,1,4)
sage: k = sr.base_ring()
```

```
sage: A = Matrix(k, 1, 1, [k.gen()])
sage: B = sr.vector(A)
sage: sr.is_vector(A)
False
sage: sr.is_vector(B)
True
```

lin_matrix(*length=None*)

Return the `Lin` matrix.

If no `length` is provided, the standard state space size is used. The key schedule calls this method with an explicit length argument because only `self.r` S-Box applications are performed in the key schedule.

INPUT:

- `length` - length of state space (default: `None`)

EXAMPLE:

```
sage: sr = mq.SR(1, 1, 1, 4)
sage: sr.lin_matrix()
[          a^2 + 1                 1         a^3 + a^2            a^2 + 1]
[               a                  a                 1 a^3 + a^2 + a + 1]
[          a^3 + a              a^2               a^2                  1]
[               1              a^3             a + 1              a + 1]
```

mix_columns_matrix()

Return the `MixColumns` matrix.

EXAMPLE:

```
sage: sr = mq.SR(1, 2, 2, 4)
sage: s = sr.random_state_array()
sage: r1 = sr.mix_columns(s)
sage: r2 = sr.state_array(sr.mix_columns_matrix() * sr.vector(s))
sage: r1 == r2
True
```

phi(*l*)

The operation ϕ from [MR02]

Projects state arrays to their algebraic representation.

INPUT:

- `l` - element to perform ϕ on.

EXAMPLE:

```
sage: sr = mq.SR(2, 1, 2, 4)
sage: k = sr.base_ring()
sage: A = matrix(k, 1, 2, [k.gen(), 0] )
sage: sr.phi(A)
[      a       0]
[    a^2       0]
[  a + 1       0]
[a^2 + 1       0]
```

shift_rows_matrix()

Return the `ShiftRows` matrix.

EXAMPLE:

```
sage: sr = mq.SR(1, 2, 2, 4)
sage: s = sr.random_state_array()
sage: r1 = sr.shift_rows(s)
```

```
sage: r2 = sr.state_array( sr.shift_rows_matrix() * sr.vector(s) )
sage: r1 == r2
True
```

vector(*d=None*)

Constructs a vector suitable for the algebraic representation of SR, i.e. BES.

INPUT:

- d - values for vector, must be understood by `self.phi` (default:None)

EXAMPLE:

```
sage: sr = mq.SR()
sage: sr
SR(1,1,1,4)
sage: k = sr.base_ring()
sage: A = Matrix(k, 1, 1, [k.gen()])
sage: sr.vector(A)
[      a]
[    a^2]
[  a + 1]
[a^2 + 1]
```

test_consistency(*max_n=2, **kwargs*)

Test all combinations of `r`, `c`, `e` and `n` in `(1, 2)` for consistency of random encryptions and their polynomial systems. $\mathbf{F}_2$ and $\mathbf{F}_{2^e}$ systems are tested. This test takes a while.

INPUT:

- max_n - maximal number of rounds to consider (default: 2)
- kwargs - are passed to the SR constructor

TESTS:

```
sage: from sage.crypto.mq.sr import test_consistency
sage: test_consistency(1) # long time -- calling w/ max_n = 2 requires a LOT of RAM (>> 2GB, evi
True
```

The above doctest used to fail on a machine with "only" 2GB RAM. Using `max_n = 1` appears to be a more reasonable memory usage.

16.9 Multivariate Polynomial Systems.

We call a finite set of multivariate polynomials an `MPolynomialSystem`.

In many other computer algebra systems (cf. Singular) this class would be called `Ideal` but an ideal is a very distinct object from its generators and thus this is not an ideal in Sage.

The idea of polynomial systems is specialized to systems which consist of several "rounds" in Sage. These kind of polynomial systems arise naturally in algebraic cryptanalysis of symmetric cryptographic primitives. The most prominent examples of these systems are: the small scale variants of the AES [CMR05] (cf. `mq.SR`) and Flurry/Curry [BPW06].

AUTHORS:

- Martin Albrecht (2007ff): initial version
- Martin Albrecht (2009): refactoring, clean-up, new functions

EXAMPLES:

As an example consider a small scale variant of the AES:

```
sage: sr = mq.SR(2,1,2,4,gf2=True,polybori=True)
sage: sr
SR(2,1,2,4)
```

We can construct a polynomial system for a random plaintext-ciphertext pair and study it:

```
sage: F,s = sr.polynomial_system()
sage: F
Polynomial System with 112 Polynomials in 64 Variables

sage: r2 = F.round(2); r2
(w200 + k100 + x100 + x102 + x103,
 w201 + k101 + x100 + x101 + x103 + 1,
 w202 + k102 + x100 + x101 + x102 + 1,
 w203 + k103 + x101 + x102 + x103,
 w210 + k110 + x110 + x112 + x113,
 w211 + k111 + x110 + x111 + x113 + 1,
 w212 + k112 + x110 + x111 + x112 + 1,
 w213 + k113 + x111 + x112 + x113,
 w100*x100 + w100*x103 + w101*x102 + w102*x101 + w103*x100,
 w100*x100 + w100*x101 + w101*x100 + w101*x103 + w102*x102 + w103*x101,
 w100*x101 + w100*x102 + w101*x100 + w101*x101 + w102*x100 + w102*x103 + w103*x102,
 w100*x100 + w100*x101 + w100*x103 + w101*x101 + w102*x100 + w102*x102 + w103*x100 + x100,
 w100*x102 + w101*x100 + w101*x101 + w101*x103 + w102*x101 + w103*x100 + w103*x102 + x101,
 w100*x100 + w100*x101 + w100*x102 + w101*x102 + w102*x100 + w102*x101 + w102*x103 + w103*x101 + x102
 w100*x101 + w101*x100 + w101*x102 + w102*x100 + w103*x101 + w103*x103 + x103,
 w100*x100 + w100*x102 + w100*x103 + w101*x100 + w101*x101 + w102*x102 + w103*x100 + w100,
 w100*x101 + w100*x103 + w101*x101 + w101*x102 + w102*x100 + w102*x103 + w103*x101 + w101,
 w100*x100 + w100*x102 + w101*x100 + w101*x102 + w101*x103 + w102*x100 + w102*x101 + w103*x102 + w102
 w100*x101 + w100*x102 + w101*x100 + w101*x103 + w102*x101 + w103*x103 + w103,
 w100*x102 + w101*x101 + w102*x100 + w103*x103 + 1,
 w110*x110 + w110*x113 + w111*x112 + w112*x111 + w113*x110,
 w110*x110 + w110*x111 + w111*x110 + w111*x113 + w112*x112 + w113*x111,
 w110*x111 + w110*x112 + w111*x110 + w111*x111 + w112*x110 + w112*x113 + w113*x112,
 w110*x110 + w110*x111 + w110*x113 + w111*x111 + w112*x110 + w112*x112 + w113*x110 + x110,
 w110*x112 + w111*x110 + w111*x111 + w111*x113 + w112*x111 + w113*x110 + w113*x112 + x111,
 w110*x110 + w110*x111 + w110*x112 + w111*x112 + w112*x110 + w112*x111 + w112*x113 + w113*x111 + x112
 w110*x111 + w111*x110 + w111*x112 + w112*x110 + w113*x111 + w113*x113 + x113,
 w110*x110 + w110*x112 + w110*x113 + w111*x110 + w111*x111 + w112*x112 + w113*x110 + w110,
 w110*x111 + w110*x113 + w111*x111 + w111*x112 + w112*x110 + w112*x113 + w113*x111 + w111,
 w110*x110 + w110*x112 + w111*x110 + w111*x112 + w111*x113 + w112*x110 + w112*x111 + w113*x112 + w112
 w110*x111 + w110*x112 + w111*x110 + w111*x113 + w112*x111 + w113*x113 + w113,
 w110*x112 + w111*x111 + w112*x110 + w113*x113 + 1)

 sage: type(r2)
 <class 'sage.crypto.mq.mpolynomialsystem.MPolynomialRoundSystem_generic'>
```

As an example, we separate the system in independent subsystems or compute the coefficient matrix:

```
sage: C = mq.MPolynomialSystem(r2).connected_components(); C
[Polynomial System with 16 Polynomials in 16 Variables,
 Polynomial System with 16 Polynomials in 16 Variables]

sage: C[0].groebner_basis()
```

```
[x111*x110 + w113*x110 + w113*x112 + w113*x113 + w113*w111 + w113*w112 + x111 + x113 + w110 + w111 +
 x112*x110 + w113*x112 + w113*x113 + w113*w110 + w113*w112 + x110 + x112 + 1,

 w110*x111 + w113*x112 + w113*w110 + w113*w111 + x110 + x112 + x113 + w113,
 w110*x112 + w113*x110 + w113*x112 + w113*x113 + x112 + x113 + w110 + w111 + w112,
 w110*x113 + w113*x110 + w113*x113 + x111 + x113 + w111 + w113 + 1,
 w111*x110 + w113*x110 + w113*x112 + x110 + x111 + w110 + w113 + 1,
 w111*x111 + w113*x110 + w113*x113 + w113*w110 + w113*w111 + x110 + x111 + x112 + x113,
 w111*x112 + w113*x110 + w113*x112 + w113*w110 + w113*w111 + x110 + x111 + x112 + w110 + w112,
 w111*x113 + w113*x113 + w113*w110 + w113*w111 + x111 + x112 + w110 + w111 + w112 + 1,
 w111*w110 + w113*x110 + w113*x112 + w113*x113 + w113*w111 + w113*w112 + x110 + x111 + x112 + x113 +
 w112*x110 + w113*x112 + w113*x113 + w113*w110 + w113*w111 + x110 + x111 + w110 + w111 + w112 + 1,
 w112*x111 + w113*x112 + w113*x113 + x112 + w110 + w113,
 w112*x112 + w113*x113 + x110 + x111 + w110 + w111 + 1,
 w112*x113 + w113*x110 + w113*x112 + w113*x113 + w113*w110 + w113*w111 + x111 + x112 + x113 + w110,
 w112*w110 + w113*x112 + w113*x113 + w113*w110 + w113*w112 + x110 + x111 + x112 + w111 + 1,
 w112*w111 + w113*x110 + w113*x112 + w113*w110 + w113*w111 + w113*w112 + x110 + w113 + 1,
 w113*x111 + w113*w110 + w113*w111 + x111 + w110 + w111,
 w210 + k110 + x110 + x112 + x113,
 w211 + k111 + x110 + x111 + x113 + 1,
 w212 + k112 + x110 + x111 + x112 + 1,
 w213 + k113 + x111 + x112 + x113]

sage: A,v = mq.MPolynomialSystem(r2).coefficient_matrix()
sage: A.rank()
32
```

Using these building blocks we can implement a simple XL algorithm easily:

```
sage: sr = mq.SR(1,1,1,4,gf2=True,polybori=True,order='lex')
sage: F,s = sr.polynomial_system()

sage: monomials = [a*b for a in F.variables() for b in F.variables() if a<b]
sage: len(monomials)
190
sage: F2 = mq.MPolynomialSystem(map(mul, cartesian_product_iterator((monomials, F))))
sage: A,v = F2.coefficient_matrix(sparse=False)
sage: A.echelonize()
sage: A
6840 x 4474 dense matrix over Finite Field of size 2
sage: A.rank()
4056
sage: A[4055]*v
(k002*k003)
```

The last output tells us that `k002` and `k003` can't both be 1.

TEST:

```
sage: P.<x,y> = PolynomialRing(QQ)
sage: I = [[x^2 + y^2], [x^2 - y^2]]
sage: F = mq.MPolynomialSystem(P,I)
sage: loads(dumps(F)) == F
True
```

REFERENCES:

MPolynomialRoundSystem(*R, gens*)

Construct an object representing the equations of a single round e.g. of a block cipher or however a "round" is defined.

INPUT:

- `R` - the base ring
- `gens` - list (default: `[]`)

EXAMPLE:

```
sage: P.<x,y,z> = PolynomialRing(GF(2),3)
sage: mq.MPolynomialRoundSystem(P,[x*y +1, z + 1])
(x*y + 1, z + 1)
```

class **MPolynomialRoundSystem_generic**(*R, gens*)

gens()

Return list of polynomials in in the system.

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True,gf2=True,order='block')
sage: F,s = sr.polynomial_system()
sage: R1 = F.round(1)
sage: l = R1.gens()
sage: l[0]
k000^2 + k000
```

monomials()

Return an unordered list of monomials appearing in polynomials in this system.

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True,gf2=True,order='block')
sage: F,s = sr.polynomial_system()
sage: R1 = F.round(1)
sage: sorted(R1.monomials())
[k003, k002, k001, k000, k003^2, k002^2, k001^2, k000^2]
```

ngens()

Return number of polynomials in the system.

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True,gf2=True,order='block')
sage: F,s = sr.polynomial_system()
sage: R0 = F.round(0)
sage: R0.ngens()
4
```

ring()

Return the polynomial ring the members of this system live in.

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True,gf2=True,order='block')
sage: F,s = sr.polynomial_system()
sage: R0 = F.round(0)
sage: print R0.ring().repr_long()
Polynomial Ring
```

```
Base Ring : Finite Field of size 2
     Size : 20 Variables
 Block  0 : Ordering : degrevlex
            Names    : k100, k101, k102, k103, x100, x101, x102, x103, w100, w101, w102, w1
 Block  1 : Ordering : degrevlex
            Names    : k000, k001, k002, k003
```

subs(**args, **kwargs*)

Substitute variables for every polynomial in this system and return a new system. See `MPolynomial.subs` for calling convention.

INPUT:

- `args` - arguments to be passed to `MPolynomial.subs`
- `kwargs` - keyword arguments to be passed to `MPolynomial.subs`

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True,gf2=True,order='block')
sage: F,s = sr.polynomial_system()
sage: R1 = F.round(1)
sage: R1 = R1.subs(s) # the solution
sage: R1
(0, 0, 0, 0)
```

variables()

Return an unordered list of variables appearing in polynomials in this system.

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True,gf2=True,order='block')
sage: F,s = sr.polynomial_system()
sage: R1 = F.round(1)
sage: sorted(R1.variables())
[k003, k002, k001, k000]
```

MPolynomialSystem(*arg1, arg2=None*)

Construct a new polynomial system object.

INPUT:

- `arg1` - a multivariate polynomial ring or an ideal
- `arg2` - an iterable object of rounds, preferable `MPolynomialRoundSystem`, or polynomials (default:`None`)

EXAMPLES:

```
sage: P.<a,b,c,d> = PolynomialRing(GF(127),4)
sage: I = sage.rings.ideal.Katsura(P)
```

If a list of MPolynomialRoundSystems is provided, those form the rounds:

```
sage: mq.MPolynomialSystem(I.ring(), [mq.MPolynomialRoundSystem(I.ring(),I.gens())])
Polynomial System with 4 Polynomials in 4 Variables
```

If an ideal is provided, the generators are used:

```
sage: mq.MPolynomialSystem(I)
Polynomial System with 4 Polynomials in 4 Variables
```

If a list of polynomials is provided, the system has only one round:

```
sage: mq.MPolynomialSystem(I.ring(), I.gens())
Polynomial System with 4 Polynomials in 4 Variables
```

class MPolynomialSystem_generic(*R, rounds*)

coefficient_matrix(*sparse=True*)

Return tuple `(A,v)` where `A` is the coefficient matrix of this system and `v` the matching monomial vector. Thus value of `A[i,j]` corresponds the coefficient of the monomial `v[j]` in the `i`-th polynomial in this system.

Monomials are order w.r.t. the term ordering of `self.ring()` in reverse order, i.e. such that the smallest entry comes last.

INPUT:

- `sparse` - construct a sparse matrix (default: `True`)

EXAMPLE:

```
sage: P.<a,b,c,d> = PolynomialRing(GF(127),4)
sage: I = sage.rings.ideal.Katsura(P)
sage: I.gens()
(a + 2*b + 2*c + 2*d - 1, a^2 + 2*b^2 + 2*c^2 + 2*d^2 - a, 2*a*b + 2*b*c
+ 2*c*d - b, b^2 + 2*a*c + 2*b*d - c)

sage: F = mq.MPolynomialSystem(I)
sage: A,v = F.coefficient_matrix()
sage: A
[  0   0   0   0   0   0   0   0   0   1   2   2   2 126]
[  1   0   2   0   0   2   0   0   2 126   0   0   0   0]
[  0   2   0   0   2   0   0   2   0   0 126   0   0   0]
[  0   0   1   2   0   0   2   0   0   0   0 126   0   0]

sage: v
[a^2]
[a*b]
[b^2]
[a*c]
[b*c]
[c^2]
[b*d]
[c*d]
[d^2]
[  a]
[  b]
[  c]
[  d]
[  1]

sage: A*v
[        a + 2*b + 2*c + 2*d - 1]
[a^2 + 2*b^2 + 2*c^2 + 2*d^2 - a]
[      2*a*b + 2*b*c + 2*c*d - b]
[        b^2 + 2*a*c + 2*b*d - c]
```

connected_components()

Split the polynomial system in systems which do not share any variables.

EXAMPLE:

As an example consider one round of AES, which naturally splits into four subsystems which are independent:

```
sage: sr = mq.SR(2,4,4,8,gf2=True,polybori=True)
sage: F,s = sr.polynomial_system()
sage: Fz = mq.MPolynomialSystem(F.round(2))
sage: Fz.connected_components()
[Polynomial System with 128 Polynomials in 128 Variables,
 Polynomial System with 128 Polynomials in 128 Variables,
 Polynomial System with 128 Polynomials in 128 Variables,
 Polynomial System with 128 Polynomials in 128 Variables]
```

connection_graph()

Return the graph which has the variables of this system as vertices and edges between two variables if they appear in the same polynomial.

EXAMPLE:

```
sage: B.<x,y,z> = BooleanPolynomialRing()
sage: F = mq.MPolynomialSystem([x*y + y + 1, z + 1])
sage: F.connection_graph()
Graph on 3 vertices
```

gen(*ij*)

Return an element in this system indexed by `ij`.

INPUT:

- `ij` - tuple, slice, integer

EXAMPLES:

```
sage: P.<a,b,c,d> = PolynomialRing(GF(127),4)
sage: F = mq.MPolynomialSystem(sage.rings.ideal.Katsura(P))
```

`ij`-th polynomial overall:

```
sage: F[0] # indirect doctest
a + 2*b + 2*c + 2*d - 1
```

`i`-th to `j`-th polynomial overall:

```
sage: F[0:2]
(a + 2*b + 2*c + 2*d - 1, a^2 + 2*b^2 + 2*c^2 + 2*d^2 - a)
```

`i`-th round, `j`-th polynomial:

```
sage: F[0,1]
a^2 + 2*b^2 + 2*c^2 + 2*d^2 - a
```

gens()

Return tuple of polynomials in this system.

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True)
sage: F,s = sr.polynomial_system()
sage: l = F.gens()
sage: len(l), type(l)
(40, <type 'tuple'>)
```

groebner_basis(**args, **kwargs*)

Compute and return a Groebner basis for the ideal spanned by the polynomials in this system (`self.gens()`).

INPUT:

- **`args` - list of arguments passed to** `MPolynomialIdeal.groebner_basis` call
- **`kwargs` - dictionary of arguments passed to** `MPolynomialIdeal.groebner_basis` call

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True)
sage: F,s = sr.polynomial_system()
sage: gb = F.groebner_basis()
sage: Ideal(gb).basis_is_groebner()
True
```

ideal()

Return Sage ideal spanned by the elements of this system.

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True)
sage: F,s = sr.polynomial_system()
sage: P = F.ring()
sage: I = F.ideal()
sage: I.elimination_ideal(P('s000*s001*s002*s003*w100*w101*w102*w103*x100*x101*x102*x103'))
Ideal (k002 + (a^2)*k003 + 1,
       k001 + (a^3)*k003 + (a + 1),
       k000 + (a^3 + a^2 + a)*k003 + (a^3 + a^2 + a),
       k103 + (a^3)*k003 + (a^2 + 1),
       k102 + (a^3 + a^2 + a)*k003 + (a^3 + 1),
       k101 + k003 + (a^2 + a),
       k100 + (a^2)*k003 + (a^2 + a),
       k003^2 + (a^3 + a^2 + a)*k003 + (a^3 + a^2 + a))
of Multivariate Polynomial Ring in k100, k101, k102, k103,
x100, x101, x102, x103, w100, w101, w102, w103, s000,
s001, s002, s003, k000, k001, k002, k003 over Finite Field
in a of size 2^4
```

monomials()

Return an unordered tuple of monomials in this polynomial system.

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True)
sage: F,s = sr.polynomial_system()
sage: len(F.monomials())
49
```

ngens()

Return number polynomials in this system.

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True,gf2=True,order='block')
sage: F,s = sr.polynomial_system()
sage: F.ngens()
56
```

nmonomials()

Return the number of monomials present in this system.

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True)
sage: F,s = sr.polynomial_system()
sage: F.nmonomials()
49
```

nrounds()

Return number of rounds of this system.

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True)
sage: F,s = sr.polynomial_system()
sage: F.nrounds()
4
```

nvariables()

Return number of variables present in this system.

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True)
sage: F,s = sr.polynomial_system()
sage: F.nvariables()
20
```

ring()

Return base ring.

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True,gf2=True,order='block')
sage: F,s = sr.polynomial_system()
sage: print F.ring().repr_long()
Polynomial Ring
 Base Ring : Finite Field of size 2
      Size : 20 Variables
  Block  0 : Ordering : degrevlex
             Names    : k100, k101, k102, k103, x100, x101, x102, x103, w100, w101, w102, w1
  Block  1 : Ordering : degrevlex
             Names    : k000, k001, k002, k003
```

round(*i*)

Return `i`-th round of this system.

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True)
sage: F,s = sr.polynomial_system()
sage: R0 = F.round(1)
sage: R0
(k000^2 + k001, k001^2 + k002, k002^2 + k003, k003^2 + k000)
```

rounds()

Return a tuple of rounds of this system.

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True)
sage: F,s = sr.polynomial_system()
sage: l = F.rounds()
sage: len(l)
4
```

subs(**args, **kwargs*)

Substitute variables for every polynomial in this system and return a new system. See `MPolynomial.subs` for calling convention.

INPUT:

- `args` - arguments to be passed to `MPolynomial.subs`
- `kwargs` - keyword arguments to be passed to `MPolynomial.subs`

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True)
sage: F,s = sr.polynomial_system(); F
Polynomial System with 40 Polynomials in 20 Variables
sage: F = F.subs(s); F
Polynomial System with 40 Polynomials in 16 Variables
```

variables()

Return all variables present in this system. This tuple may or may not be equal to the generators of the ring of this system.

EXAMPLE:

```
sage: sr = mq.SR(allow_zero_inversions=True)
sage: F,s = sr.polynomial_system()
sage: F.variables()[:10]
(k003, k002, k001, k000, s003, s002, s001, s000, w103, w102)
```

class MPolynomialSystem_gf2(*R, rounds*)

Polynomial Systems over $\mathbb{F}_2$.

eliminate_linear_variables(*maxlength=3, skip=<function <lambda> at 0x2dc9f50>*)

Return a new system where "linear variables" are eliminated.

In this function we call a variable "linear" if it appears as a leading term of a linear polynomial.

INPUT:

- `maxlength` - an optional upper bound on the number of monomials by which a variable is replaced.
- `skip` - an optional callable to skip eliminations. It must accept two parameters and return either `True` or `False`. The two parameters are the leading term and the tail of a polynomial (default: `lambda lm,tail: False`).

EXAMPLE:

```
sage: B.<a,b,c,d> = BooleanPolynomialRing()
sage: F = mq.MPolynomialSystem([c + d + b + 1, a + c + d, a*b + c, b*c*d + c])
sage: F.eliminate_linear_variables().gens() # everything vanishes
()
sage: F.eliminate_linear_variables(maxlength=2).gens()
(b + c + d + 1, b*c + b*d + c, b*c*d + c)
sage: F.eliminate_linear_variables(skip=lambda lm,tail: str(lm)=='a').gens()
(a + c + d, a*c + a*d + a + c, c*d + c)
```

Note: This is called "massaging" in [CB07].

REFERENCES:

class MPolynomialSystem_gf2e(*R, rounds*)

MPolynomialSystem over $\mathbb{F}_{2^e}$.

change_ring(*k*)

Project self onto `k` using the Weil restriction of scalars.

INPUT:

- `k` - GF(2) (parameter only for compatible syntax)

EXAMPLE:

```
sage: k.<a> = GF(2^2)
sage: P.<x,y> = PolynomialRing(k,2)
sage: a = P.base_ring().gen()
sage: F = mq.MPolynomialSystem(P,[x*y + 1, a*x + 1])
sage: F
Polynomial System with 2 Polynomials in 2 Variables
sage: F2 = F.change_ring(GF(2)); F2
```

```
doctest... DeprecationWarning: The use of this function is deprecated please use the weil_re
Polynomial System with 8 Polynomials in 4 Variables
sage: F2.gens()
(x1*y0 + x0*y1 + x1*y1,
x0*y0 + x1*y1 + 1,
x0 + x1,
x1 + 1,
x0^2 + x0,
x1^2 + x1,
y0^2 + y0,
y1^2 + y1)
```

Note: This function is deprecated use the `weil_restriction()` function instead.

weil_restriction()

Project this polynomial system to $\mathbb{F}_2$.

That is, compute the Weil restriction of scalars for the variety corresponding to this polynomial system and express it as a polynomial system over $\mathbb{F}_2$.

EXAMPLE:

```
sage: k.<a> = GF(2^2)
sage: P.<x,y> = PolynomialRing(k,2)
sage: a = P.base_ring().gen()
sage: F = mq.MPolynomialSystem(P,[x*y + 1, a*x + 1])
sage: F
Polynomial System with 2 Polynomials in 2 Variables
sage: F2 = F.weil_restriction(); F2
Polynomial System with 8 Polynomials in 4 Variables
sage: F2.gens()
(x1*y0 + x0*y1 + x1*y1,
x0*y0 + x1*y1 + 1,
x0 + x1,
x1 + 1,
x0^2 + x0,
x1^2 + x1,
y0^2 + y0,
y1^2 + y1)
```

Another bigger example for a small scale AES:

```
sage: sr = mq.SR(1,1,1,4,gf2=False)
sage: F,s = sr.polynomial_system(); F
Polynomial System with 40 Polynomials in 20 Variables
sage: F2 = F.weil_restriction(); F2
Polynomial System with 240 Polynomials in 80 Variables
```

is_MPolynomialRoundSystem(F)

Return `True` if `F` is an `MPolynomialRoundSystem`.

INPUT:

- `F` - anything

EXAMPLE:

```
sage: P.<x,y> = PolynomialRing(QQ)
sage: I = [[x^2 + y^2], [x^2 - y^2]]
sage: F = mq.MPolynomialSystem(P,I); F
Polynomial System with 2 Polynomials in 2 Variables
sage: mq.is_MPolynomialRoundSystem(F.round(0))
True
```

is_MPolynomialSystem(*F*)

Return `True` if `F` is an `MPolynomialSystem`.

INPUT:

- ``F`` - anything

EXAMPLE:

```
sage: P.<x,y> = PolynomialRing(QQ)
sage: I = [[x^2 + y^2], [x^2 - y^2]]
sage: F = mq.MPolynomialSystem(P,I); F
Polynomial System with 2 Polynomials in 2 Variables
sage: mq.is_MPolynomialSystem(F)
True
```

16.10 S-Boxes and Their Algebraic Representations

class SBox(**args, **kwargs*)

A substitution box or S-box is one of the basic components of symmetric key cryptography. In general, an S-box takes `m` input bits and transforms them into `n` output bits. This is called an `mxn` S-box and is often implemented as a lookup table. These S-boxes are carefully chosen to resist linear and differential cryptanalysis [Heys02].

This module implements an S-box class which allows an algebraic treatment.

EXAMPLE:

We consider the S-box of the block cipher PRESENT [PRESENT07]:

```
sage: S = mq.SBox(12,5,6,11,9,0,10,13,3,14,15,8,4,7,1,2); S
(12, 5, 6, 11, 9, 0, 10, 13, 3, 14, 15, 8, 4, 7, 1, 2)
sage: S(1)
5
```

Note that by default bits are interpreted in big endian order. This is not consistent with the rest of Sage, which has a strong bias towards little endian, but is consistent with most cryptographic literature:

```
sage: S([0,0,0,1])
[0, 1, 0, 1]

sage: S = mq.SBox(12,5,6,11,9,0,10,13,3,14,15,8,4,7,1,2, big_endian=False)
sage: S(1)
5
sage: S([0,0,0,1])
[1, 1, 0, 0]
```

Now we construct an `SBox` object for the 4-bit small scale AES S-Box (cf. `sage.crypto.mq.sr`):

```
sage: sr = mq.SR(1,1,1,4, allow_zero_inversions=True)
sage: S = mq.SBox([sr.sub_byte(e) for e in list(sr.k)])
sage: S
(6, 5, 2, 9, 4, 7, 3, 12, 14, 15, 10, 0, 8, 1, 13, 11)
```

REFERENCES:

difference_distribution_matrix()

Return difference distribution matrix `A` for this S-box.

The rows of `A` encode the differences `Delta I` of the input and the columns encode the difference `Delta O` for the output. The bits are ordered according to the endianess of this S-box. The value at `A[Delta`

I,Delta O] encodes how often Delta O is the actual output difference given Delta I as input difference.

See [Heys02] for an introduction to differential cryptanalysis.

EXAMPLE:

```
sage: S = mq.SBox(7,6,0,4,2,5,1,3)
sage: S.difference_distribution_matrix()
[8 0 0 0 0 0 0 0]
[0 2 2 0 2 0 0 2]
[0 0 2 2 0 0 2 2]
[0 2 0 2 2 0 2 0]
[0 2 0 2 0 2 0 2]
[0 0 2 2 2 2 0 0]
[0 2 2 0 0 2 2 0]
[0 0 0 0 2 2 2 2]
```

from_bits(*x*, *n=None*)

Return integer for bitstring x of length n.

INPUT:

- x - a bitstring
- n - bit length (optional)

EXAMPLE:

```
sage: S = mq.SBox(7,6,0,4,2,5,1,3)
sage: S.from_bits( [1,1,0])
6

sage: S( S.from_bits( [1,1,0] ) )
1
sage: S.from_bits( S( [1,1,0] ) )
1
```

interpolation_polynomial(*k=None*)

Return a univariate polynomial over an extension field representing this S-box.

If m is the input length of this S-box then the extension field is of degree m.

If the output length does not match the input length then a TypeError is raised.

INPUT:

- k - an instance of $\mathbf{F}_{2^m}$ (default: None)

EXAMPLE:

```
sage: S = mq.SBox(7,6,0,4,2,5,1,3)
sage: f = S.interpolation_polynomial()
sage: f
x^6 + a*x^5 + (a + 1)*x^4 + (a^2 + a + 1)*x^3
  + (a^2 + 1)*x^2 + (a + 1)*x + a^2 + a + 1

sage: a = f.base_ring().gen()

sage: f(0), S(0)
(a^2 + a + 1, 7)

sage: f(a^2 + 1), S(5)
(a^2 + 1, 5)
```

is_permutation()

Return True if this S-Box is a permutation.

EXAMPLE:

```
sage: S = mq.SBox(7,6,0,4,2,5,1,3)
sage: S.is_permutation()
True

sage: S = mq.SBox(3,2,0,0,2,1,1,3)
sage: S.is_permutation()
False
```

linear_approximation_matrix()

Return linear approximation matrix `A` for this S-box.

Let `i_b` be the `b`-th bit of `i` and `o_b` the `b`-th bit of `o`. Then `v = A[i,o]` encodes the bias of the equation `sum( i_b * x_i ) = sum( o_b * y_i )` if `x_i` and `y_i` represent the input and output variables of the S-box.

See [Heys02] for an introduction to linear cryptanalysis.

EXAMPLE:

```
sage: S = mq.SBox(7,6,0,4,2,5,1,3)
sage: S.linear_approximation_matrix()
[ 4  0  0  0  0  0  0  0]
[ 0  0  0  0  2  2  2 -2]
[ 0  0 -2 -2 -2  2  0  0]
[ 0  0 -2  2  0  0 -2 -2]
[ 0  2  0  2 -2  0  2  0]
[ 0 -2  0  2  0  2  0  2]
[ 0 -2 -2  0  0 -2  2  0]
[ 0 -2  2  0 -2  0  0 -2]
```

According to this matrix the first bit of the input is equal to the third bit of the output 6 out of 8 times:

```
sage: for i in srange(8): print S.to_bits(i)[0] == S.to_bits(S(i))[2]
False
True
True
True
False
True
True
True
```

maximal_difference_probability()

Return the difference probability of the difference with the highest probability in the range between 0.0 and 1.0 indicating 0% or 100% respectively.

EXAMPLE:

```
sage: S = mq.SBox(7,6,0,4,2,5,1,3)
sage: S.maximal_difference_probability()
0.25
```

maximal_difference_probability_absolute()

Return the difference probability of the difference with the highest probability in absolute terms, i.e. how often it occurs in total.

EXAMPLE:

```
sage: S = mq.SBox(7,6,0,4,2,5,1,3)
sage: S.maximal_difference_probability_absolute()
2
```

Note: This code is mainly called internally.

maximal_linear_bias_absolute()

Return maximal linear bias, i.e. how often the linear approximation with the highest bias is true or false minus 2^{n-1}.

EXAMPLE:

```
sage: S = mq.SBox(7,6,0,4,2,5,1,3)
sage: S.maximal_linear_bias_absolute()
2
```

maximal_linear_bias_relative()

Return maximal bias of all linear approximations of this S-box.

EXAMPLE:

```
sage: S = mq.SBox(7,6,0,4,2,5,1,3)
sage: S.maximal_linear_bias_relative()
0.25
```

polynomials(*X=None, Y=None, degree=2, groebner=False*)

Return a list of polynomials satisfying this S-box.

First, a simple linear fitting is performed for the given `degree` (cf. for example [BC03]). If `groebner=True` a Groebner basis is also computed for the result of that process.

INPUT:

- `X` - input variables
- `Y` - output variables
- `degree` - integer > 0 (default: `2`)
- `groebner` - calculate a reduced Groebner basis of the spanning polynomials to obtain more polynomials (default: `False`)

EXAMPLES:

```
sage: S = mq.SBox(7,6,0,4,2,5,1,3)
sage: P = S.ring()
```

By default, this method returns an indirect representation:

```
sage: S.polynomials()
[x0*x2 + x1 + y1 + 1,
 x0*x1 + x1 + x2 + y0 + y1 + y2 + 1,
 x0*y1 + x0 + x2 + y0 + y2,
 x0*y0 + x0*y2 + x1 + x2 + y0 + y1 + y2 + 1,
 x1*x2 + x0 + x1 + x2 + y2 + 1,
 x0*y0 + x1*y0 + x0 + x2 + y1 + y2,
 x0*y0 + x1*y1 + x1 + y1 + 1,
 x1*y2 + x1 + x2 + y0 + y1 + y2 + 1,
 x0*y0 + x2*y0 + x1 + x2 + y1 + 1,
 x2*y1 + x0 + y1 + y2,
 x2*y2 + x1 + y1 + 1,
 y0*y1 + x0 + x2 + y0 + y1 + y2,
 y0*y2 + x1 + x2 + y0 + y1 + 1,
 y1*y2 + x2 + y0]
```

We can get a direct representation by computing a lexicographical Groebner basis with respect to the right variable ordering, i.e. a variable ordering where the output bits are greater than the input bits:

```
sage: P.<y0,y1,y2,x0,x1,x2> = PolynomialRing(GF(2),6,order='lex')
sage: S.polynomials([x0,x1,x2],[y0,y1,y2], groebner=True)
[y0 + x0*x1 + x0*x2 + x0 + x1*x2 + x1 + 1,
 y1 + x0*x2 + x1 + 1,
 y2 + x0 + x1*x2 + x1 + x2 + 1]
```

REFERENCES:

ring()

Create, return and cache a polynomial ring for S-box polynomials.

EXAMPLE:

```
sage: S = mq.SBox(7,6,0,4,2,5,1,3)
sage: S.ring()
Multivariate Polynomial Ring in x0, x1, x2, y0, y1, y2 over Finite Field of size 2
```

solutions(*X=None, Y=None*)

Return a dictionary of solutions to this S-box.

INPUT:

- `X` - input variables (default: `None`)
- `Y` - output variables (default: `None`)

EXAMPLE:

```
sage: S = mq.SBox([7,6,0,4,2,5,1,3])
sage: F = S.polynomials()
sage: s = S.solutions()
sage: any(f.subs(_s) for f in F for _s in s)
False
```

to_bits(*x, n=None*)

Return bitstring of length `n` for integer `x`. The returned bitstring is guaranteed to have length `n`.

INPUT:

- `x` - an integer
- `n` - bit length (optional)

EXAMPLE:

```
sage: S = mq.SBox(7,6,0,4,2,5,1,3)
sage: S.to_bits(6)
[1, 1, 0]

sage: S.to_bits( S(6) )
[0, 0, 1]

sage: S( S.to_bits( 6 ) )
[0, 0, 1]
```

CHAPTER

SEVENTEEN

COMBINATORICS

17.1 Combinatorial Functions.

AUTHORS:

- David Joyner (2006-07): initial implementation.
- William Stein (2006-07): editing of docs and code; many optimizations, refinements, and bug fixes in corner cases
- David Joyner (2006-09): bug fix for combinations, added permutations_iterator, combinations_iterator from Python Cookbook, edited docs.
- David Joyner (2007-11): changed permutations, added hadamard_matrix
- Florent Hivert (2009-02): combinatorial class cleanup

This module implements some combinatorial functions, as listed below. For a more detailed description, see the relevant docstrings.

Sequences:

- Bell numbers, `bell_number`
- Bernoulli numbers, `bernoulli_number` (though PARI's bernoulli is better)
- Catalan numbers, `catalan_number` (not to be confused with the Catalan constant)
- Eulerian/Euler numbers, `euler_number` (Maxima)
- Fibonacci numbers, `fibonacci` (PARI) and `fibonacci_number` (GAP) The PARI version is better.
- Lucas numbers, `lucas_number1`, `lucas_number2`.
- Stirling numbers, `stirling_number1`, `stirling_number2`.

Set-theoretic constructions:

- Combinations of a multiset, `combinations`, `combinations_iterator`, and `number_of_combinations`. These are unordered selections without repetition of k objects from a multiset S.
- Arrangements of a multiset, `arrangements` and `number_of_arrangements` These are ordered selections without repetition of k objects from a multiset S.

- Derangements of a multiset, `derangements` and `number_of_derangements`.
- Tuples of a multiset, `tuples` and `number_of_tuples`. An ordered tuple of length k of set S is a ordered selection with repetitions of S and is represented by a sorted list of length k containing elements from S.
- Unordered tuples of a set, `unordered_tuple` and `number_of_unordered_tuples`. An unordered tuple of length k of set S is an unordered selection with repetitions of S and is represented by a sorted list of length k containing elements from S.
- Permutations of a multiset, `permutations`, `permutations_iterator`, `number_of_permutations`. A permutation is a list that contains exactly the same elements but possibly in different order.

Partitions:

- Partitions of a set, `partitions_set`, `number_of_partitions_set`. An unordered partition of set S is a set of pairwise disjoint nonempty sets with union S and is represented by a sorted list of such sets.
- Partitions of an integer, `partitions_list`, `number_of_partitions_list`. An unordered partition of n is an unordered sum $n = p_1 + p_2 + \ldots + p_k$ of positive integers and is represented by the list $p = [p_1, p_2, \ldots, p_k]$, in nonincreasing order, i.e., $p1 \geq p_2 ... \geq p_k$.
- Ordered partitions of an integer, `ordered_partitions`, `number_of_ordered_partitions`. An ordered partition of n is an ordered sum $n = p_1 + p_2 + \ldots + p_k$ of positive integers and is represented by the list $p = [p_1, p_2, \ldots, p_k]$, in nonincreasing order, i.e., $p1 \geq p_2 ... \geq p_k$.
- Restricted partitions of an integer, `partitions_restricted`, `number_of_partitions_restricted`. An unordered restricted partition of n is an unordered sum $n = p_1 + p_2 + \ldots + p_k$ of positive integers p_i belonging to a given set S, and is represented by the list $p = [p_1, p_2, \ldots, p_k]$, in nonincreasing order, i.e., $p1 \geq p_2 ... \geq p_k$.
- `partitions_greatest` implements a special type of restricted partition.
- `partitions_greatest_eq` is another type of restricted partition.
- Tuples of partitions, `partition_tuples`, `number_of_partition_tuples`. A k-tuple of partitions is represented by a list of all k-tuples of partitions which together form a partition of n.
- Powers of a partition, `partition_power(pi, k)`. The power of a partition corresponds to the k-th power of a permutation with cycle structure π.
- Sign of a partition, `partition_sign( pi )` This means the sign of a permutation with cycle structure given by the partition pi.
- Associated partition, `partition_associated( pi )` The "associated" (also called "conjugate" in the literature) partition of the partition pi which is obtained by transposing the corresponding Ferrers diagram.
- Ferrers diagram, `ferrers_diagram`. Analogous to the Young diagram of an irreducible representation of S_n.

Related functions:

- Bernoulli polynomials, `bernoulli_polynomial`

Implemented in other modules (listed for completeness):

The `sage.rings.arith` module contains the following combinatorial functions:

- binomial the binomial coefficient (wrapped from PARI)

- factorial (wrapped from PARI)
- partition (from the Python Cookbook) Generator of the list of all the partitions of the integer n.
- `number_of_partitions` (wrapped from PARI) the *number* of partitions:
- `falling_factorial` Definition: for integer $a \geq 0$ we have $x(x-1)\cdots(x-a+1)$. In all other cases we use the GAMMA-function: $\frac{\Gamma(x+1)}{\Gamma(x-a+1)}$.
- `rising_factorial` Definition: for integer $a \geq 0$ we have $x(x+1)\cdots(x+a-1)$. In all other cases we use the GAMMA-function: $\frac{\Gamma(x+a)}{\Gamma(x)}$.
- gaussian_binomial the gaussian binomial

$$\binom{n}{k}_q = \frac{(1-q^m)(1-q^{m-1})\cdots(1-q^{m-r+1})}{(1-q)(1-q^2)\cdots(1-q^r)}.$$

The `sage.groups.perm_gps.permgroup_elements` contains the following combinatorial functions:

- matrix method of PermutationGroupElement yielding the permutation matrix of the group element.

```
TODO:
   GUAVA commands:
    * MOLS returns a list of n Mutually Orthogonal Latin Squares (MOLS).
    * VandermondeMat
    * GrayMat returns a list of all different vectors of length n over
      the field F, using Gray ordering.
   Not in GAP:
    * Rencontres numbers
      http://en.wikipedia.org/wiki/Rencontres_number
```

REFERENCES:

- http://en.wikipedia.org/wiki/Twelvefold_way (general reference)

class CombinatorialClass()

cardinality()

Default implementation of cardinality which just goes through the iterator of the combinatorial class to count the number of objects.

EXAMPLES:

```
sage: class C(CombinatorialClass):
...     def __iter__(self):
...         return iter([1,2,3])
...
sage: C().cardinality() #indirect doctest
3
```

count()

Deprecated ! Please use `.cardinality` instead.

TEST:

```
sage: class C(CombinatorialClass):
...     def __iter__(self):
...         return iter([1,2,3])
...
sage: C().count() #indirect doctest
doctest:1: DeprecationWarning: The usage of count for combinatorial classes is deprecated. P
3
```

filter (*f*, *name=None*)

Returns the combinatorial subclass of f which consists of the elements x of self such that f(x) is True.

EXAMPLES:

```
sage: P = Permutations(3).filter(lambda x: x.avoids([1,2]))
sage: P.list()
[[3, 2, 1]]
```

first ()

Default implementation for first which uses iterator.

EXAMPLES:

```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.first() # indirect doctest
1
```

iterator ()

Iterator is deprecated for combinatorial classes.

EXAMPLES:

```
sage: p5 = Partitions(3)
sage: it = p5.iterator()
doctest:1: DeprecationWarning: The usage of iterator for combinatorial classes is deprecated
sage: [i for i in it]
[[3], [2, 1], [1, 1, 1]]
sage: [i for i in p5]
[[3], [2, 1], [1, 1, 1]]
```

last ()

Default implementation for first which uses iterator.

EXAMPLES:

```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.last() # indirect doctest
3
```

list ()

The default implementation of list which builds the list from the iterator.

EXAMPLES:

```
sage: class C(CombinatorialClass):
...     def __iter__(self):
...         return iter([1,2,3])
...
sage: C().list() #indirect doctest
[1, 2, 3]
```

map (*f*, *name=None*)

Returns the image $\{f(x) x in self f\}$ of this combinatorial class by f, as a combinatorial class.

f is supposed to be injective.

EXAMPLES:

```
sage: R = Permutations(3).map(attrcall('reduced_word')); R
Image of Standard permutations of 3 by *.reduced_word()
sage: R.cardinality()
6
sage: R.list()
[[], [2], [1], [1, 2], [2, 1], [2, 1, 2]]
sage: [ r for r in R]
[[], [2], [1], [1, 2], [2, 1], [2, 1, 2]]

If the function is not injective, then there may be repeated elements:
sage: P = Partitions(4)
sage: P.list()
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: P.map(len).list()
[1, 2, 2, 3, 4]
```

TESTS:

```
sage: R = Permutations(3).map(attrcall('reduced_word'))
sage: R == loads(dumps(R))
True
```

next(*obj*)

Default implementation for next which uses iterator.

EXAMPLES:

```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.next(2) # indirect doctest
3
```

object_class()

previous(*obj*)

Default implementation for next which uses iterator.

EXAMPLES:

```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.previous(2) # indirect doctest
1
```

random()

Deprecated. Use self.random_element() instead.

EXAMPLES:

```
sage: C = CombinatorialClass()
sage: C.random()
...
NotImplementedError: Deprecated: use random_element() instead
```

random_element()

Default implementation of random which uses unrank.

EXAMPLES:

```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
```

```
sage: C.random_element()
1
```

rank(*obj*)

Default implementation of rank which uses iterator.

EXAMPLES:

```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.rank(3) # indirect doctest
2
```

union(*right_cc*, *name=None*)

Returns the combinatorial class representing the union of self and right_cc.

EXAMPLES:

```
sage: P = Permutations(2).union(Permutations(1))
sage: P.list()
[[1, 2], [2, 1], [1]]
```

unrank(*r*)

Default implementation of unrank which goes through the iterator.

EXAMPLES:

```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.unrank(1) # indirect doctest
2
```

class **CombinatorialObject**(*l*)

index(*key*)

EXAMPLES:

```
sage: c = CombinatorialObject([1,2,3])
sage: c.index(1)
0
sage: c.index(3)
2
```

class **FilteredCombinatorialClass**(*combinatorial_class*, *f*, *name=None*)

cardinality()

EXAMPLES:

```
sage: P = Permutations(3).filter(lambda x: x.avoids([1,2]))
sage: P.cardinality()
1
```

class **InfiniteAbstractCombinatorialClass**()

This is an internal Class this should not be used directly. A class wich inerits from InfiniteAbstractCombinatorialClass inherits the standard methods list and count.

If self._infinite_cclass_slice exists then self.__iter__ returns an iterator for self, otherwise raise NotImplementedError. The method self._infinite_cclass_slice is supposed to accept any integer as an argument and return something which is iterable.

cardinality()

Counts the elements of the combinatorial class.

EXAMPLES: sage: R = InfiniteAbstractCombinatorialClass() sage: R.cardinality() +Infinity

list()

Returns an error since self is an infinite combinatorial class.

EXAMPLES: sage: R = InfiniteAbstractCombinatorialClass() sage: R.list() Traceback (most recent call last): ... NotImplementedError: infinite list

class MapCombinatorialClass(*cc, f, name=None*)

A MapCombinatorialClass models the image of a combinatorial class through a function which is assumed to be injective

See CombinatorialClass.map for examples

cardinality()

Returns the cardinality of this combinatorial class

EXAMPLES: sage: R = Permutations(10).map(attrcall('reduced_word')) sage: R.cardinality() 3628800

class UnionCombinatorialClass(*left_cc, right_cc, name=None*)

cardinality()

EXAMPLES:

```
sage: P = Permutations(3).union(Permutations(2))
sage: P.cardinality()
8
```

first()

EXAMPLES:

```
sage: P = Permutations(3).union(Permutations(2))
sage: P.first()
[1, 2, 3]
```

last()

EXAMPLES:

```
sage: P = Permutations(3).union(Permutations(2))
sage: P.last()
[2, 1]
```

list()

EXAMPLES:

```
sage: P = Permutations(3).union(Permutations(2))
sage: P.list()
[[1, 2, 3],
 [1, 3, 2],
 [2, 1, 3],
 [2, 3, 1],
 [3, 1, 2],
 [3, 2, 1],
 [1, 2],
 [2, 1]]
```

rank(*x*)

EXAMPLES:

```
sage: P = Permutations(3).union(Permutations(2))
sage: P.rank(Permutation([2,1]))
7
sage: P.rank(Permutation([1,2,3]))
0
```

unrank(*x*)

EXAMPLES:

```
sage: P = Permutations(3).union(Permutations(2))
sage: P.unrank(7)
[2, 1]
sage: P.unrank(0)
[1, 2, 3]
```

arrangements(*mset, k*)

An arrangement of mset is an ordered selection without repetitions and is represented by a list that contains only elements from mset, but maybe in a different order.

`arrangements` returns the set of arrangements of the multiset mset that contain k elements.

IMPLEMENTATION: Wraps GAP's Arrangements.

Warning: Wraps GAP - hence mset must be a list of objects that have string representations that can be interpreted by the GAP interpreter. If mset consists of at all complicated Sage objects, this function does *not* do what you expect. A proper function should be written! (TODO!)

EXAMPLES:

```
sage: mset = [1,1,2,3,4,4,5]
sage: arrangements(mset,2)
[[1, 1],
 [1, 2],
 [1, 3],
 [1, 4],
 [1, 5],
 [2, 1],
 [2, 3],
 [2, 4],
 [2, 5],
 [3, 1],
 [3, 2],
 [3, 4],
 [3, 5],
 [4, 1],
 [4, 2],
 [4, 3],
 [4, 4],
 [4, 5],
 [5, 1],
 [5, 2],
 [5, 3],
 [5, 4]]
 sage: arrangements( ["c","a","t"], 2 )
 ['ac', 'at', 'ca', 'ct', 'ta', 'tc']
 sage: arrangements( ["c","a","t"], 3 )
 ['act', 'atc', 'cat', 'cta', 'tac', 'tca']
```

bell_number(*n*)

Returns the n-th Bell number (the number of ways to partition a set of n elements into pairwise disjoint nonempty subsets).

If $n \leq 0$, returns 1.

Wraps GAP's Bell.

EXAMPLES:

```
sage: bell_number(10)
115975
sage: bell_number(2)
2
sage: bell_number(-10)
1
sage: bell_number(1)
1
sage: bell_number(1/3)
...
TypeError: no conversion of this rational to integer
```

bell_polynomial (*n, k*)

This function returns the Bell Polynomial

$$B_{n,k}(x_1, x_2, \ldots, x_{n-k+1}) = \sum_{\sum j_i = k, \sum i j_i = n} \frac{n!}{j_1! j_2! \ldots} \frac{x_1}{1!}^{j_1} \frac{x_2}{2!}^{j_2} \cdots$$

INPUT:

- n - integer
- k - integer

OUTPUT:

- polynomial expression (SymbolicArithmetic)

EXAMPLES:

```
sage: bell_polynomial(6,2)
10*x_3^2 + 15*x_2*x_4 + 6*x_1*x_5
sage: bell_polynomial(6,3)
15*x_2^3 + 60*x_1*x_2*x_3 + 15*x_1^2*x_4
```

REFERENCES:

- E.T. Bell, "Partition Polynomials"

AUTHORS:

- Blair Sutton (2009-01-26)

bernoulli_polynomial (*x, n*)

Return the nth Bernoulli polynomial as a polynomial in x. In particular, if x is anything other than a variable, this will simply be the nth Bernoulli polynomial evaluated at x.

The generating function for the Bernoulli polynomials is

$$\frac{te^{xt}}{e^t - 1} = \sum_{n=0}^{\infty} B_n(x) \frac{t^n}{n!},$$

and they are given directly by

$$B_n(x) = \sum_{i=0}^{n} \binom{n}{i} B_{n-i} x^i.$$

One has $B_n(x) = -n\zeta(1-n, x)$, where $\zeta(s, x)$ is the Hurwitz zeta function. Thus, in a certain sense, the Hurwitz zeta generalizes the Bernoulli polynomials to non-integer values of n.

EXAMPLES:

```
sage: y = QQ['y'].0
sage: bernoulli_polynomial(y,5)
y^5 - 5/2*y^4 + 5/3*y^3 - 1/6*y
sage: bernoulli_polynomial(y,5)(12)
199870
sage: bernoulli_polynomial(12,5)
199870
```

REFERENCES:

- http://en.wikipedia.org/wiki/Bernoulli_polynomials

catalan_number(n)

Returns the n-th Catalan number

Catalan numbers: The n-th Catalan number is given directly in terms of binomial coefficients by

$$C_n = \frac{1}{n+1}\binom{2n}{n} = \frac{(2n)!}{(n+1)!\,n!} \qquad \text{for } n \geq 0.$$

Consider the set $S = \{1, ..., n\}$. A noncrossing partition of S is a partition in which no two blocks "cross" each other, i.e., if a and b belong to one block and x and y to another, they are not arranged in the order axby. C_n is the number of noncrossing partitions of the set S. There are many other interpretations (see REFERENCES).

When $n = -1$, this function raises a ZeroDivisionError; for other $n < 0$ it returns 0.

EXAMPLES:

```
sage: [catalan_number(i) for i in range(7)]
[1, 1, 2, 5, 14, 42, 132]
sage: maxima.eval("-(1/2)*taylor (sqrt (1-4*x^2), x, 0, 15)")
'-1/2+x^2+x^4+2*x^6+5*x^8+14*x^10+42*x^12+132*x^14'
sage: [catalan_number(i) for i in range(-7,7) if i != -1]
[0, 0, 0, 0, 0, 0, 1, 1, 2, 5, 14, 42, 132]
sage: catalan_number(-1)
...
ZeroDivisionError: Rational division by zero
```

REFERENCES:

- http://en.wikipedia.org/wiki/Catalan_number
- http://www-history.mcs.st-andrews.ac.uk/~history/Miscellaneous/CatalanNumbers/catalan.html

combinations(*mset, k*)

A combination of a multiset (a list of objects which may contain the same object several times) mset is an unordered selection without repetitions and is represented by a sorted sublist of mset. Returns the set of all combinations of the multiset mset with k elements.

Warning: Wraps GAP's Combinations. Hence mset must be a list of objects that have string representations that can be interpreted by the GAP interpreter. If mset consists of at all complicated Sage objects, this function does *not* do what you expect. A proper function should be written! (TODO!)

EXAMPLES:

```
sage: mset = [1,1,2,3,4,4,5]
sage: combinations(mset,2)
[[1, 1],
 [1, 2],
 [1, 3],
```

```
 [1, 4],
 [1, 5],
 [2, 3],
 [2, 4],
 [2, 5],
 [3, 4],
 [3, 5],
 [4, 4],
 [4, 5]]
 sage: mset = ["d","a","v","i","d"]
 sage: combinations(mset,3)
 ['add', 'adi', 'adv', 'aiv', 'ddi', 'ddv', 'div']
```

Note: For large lists, this raises a string error.

combinations_iterator(*mset, n=None*)

Posted by Raymond Hettinger, 2006/03/23, to the Python Cookbook: http://aspn.activestate.com/ASPN/Cookbook/Python/Recipe/474124

Much faster than combinations.

EXAMPLES:

```
sage: X = combinations_iterator([1,2,3,4,5],3)
sage: [x for x in X]
[[1, 2, 3],
 [1, 2, 4],
 [1, 2, 5],
 [1, 3, 4],
 [1, 3, 5],
 [1, 4, 5],
 [2, 3, 4],
 [2, 3, 5],
 [2, 4, 5],
 [3, 4, 5]]
```

cyclic_permutations(*mset*)

Returns a list of all cyclic permutations of mset. Treats mset as a list, not a set, i.e. entries with the same value are distinct.

AUTHORS:

- Emily Kirkman

EXAMPLES:

```
sage: from sage.combinat.combinat import cyclic_permutations, cyclic_permutations_iterator
sage: cyclic_permutations(range(4))
[[0, 1, 2, 3], [0, 1, 3, 2], [0, 2, 1, 3], [0, 2, 3, 1], [0, 3, 1, 2], [0, 3, 2, 1]]
sage: for cycle in cyclic_permutations(['a', 'b', 'c']):
...       print cycle
['a', 'b', 'c']
['a', 'c', 'b']
```

Note that lists with repeats are not handled intuitively:

```
sage: cyclic_permutations([1,1,1])
[[1, 1, 1], [1, 1, 1]]
```

cyclic_permutations_iterator(*mset*)

Iterates over all cyclic permutations of mset in cycle notation. Treats mset as a list, not a set, i.e. entries with the same value are distinct.

AUTHORS:

- Emily Kirkman

EXAMPLES:

```
sage: from sage.combinat.combinat import cyclic_permutations, cyclic_permutations_iterator
sage: cyclic_permutations(range(4))
[[0, 1, 2, 3], [0, 1, 3, 2], [0, 2, 1, 3], [0, 2, 3, 1], [0, 3, 1, 2], [0, 3, 2, 1]]
sage: for cycle in cyclic_permutations(['a', 'b', 'c']):
...       print cycle
['a', 'b', 'c']
['a', 'c', 'b']
```

Note that lists with repeats are not handled intuitively:

```
sage: cyclic_permutations([1,1,1])
[[1, 1, 1], [1, 1, 1]]
```

derangements(*mset*)

A derangement is a fixed point free permutation of list and is represented by a list that contains exactly the same elements as mset, but possibly in different order. Derangements returns the set of all derangements of a multiset.

Wraps GAP's Derangements.

Warning: Wraps GAP - hence mset must be a list of objects that have string representations that can be interpreted by the GAP interpreter. If mset consists of at all complicated Sage objects, this function does *not* do what you expect. A proper function should be written! (TODO!)

EXAMPLES:

```
sage: mset = [1,2,3,4]
sage: derangements(mset)
[[2, 1, 4, 3],
 [2, 3, 4, 1],
 [2, 4, 1, 3],
 [3, 1, 4, 2],
 [3, 4, 1, 2],
 [3, 4, 2, 1],
 [4, 1, 2, 3],
 [4, 3, 1, 2],
 [4, 3, 2, 1]]
 sage: derangements(["c","a","t"])
 ['atc', 'tca']
```

euler_number(*n*)

Returns the n-th Euler number

IMPLEMENTATION: Wraps Maxima's euler.

EXAMPLES:

```
sage: [euler_number(i) for i in range(10)]
[1, 0, -1, 0, 5, 0, -61, 0, 1385, 0]
sage: maxima.eval("taylor (2/(exp(x)+exp(-x)), x, 0, 10)")
'1-x^2/2+5*x^4/24-61*x^6/720+277*x^8/8064-50521*x^10/3628800'
```

```
sage: [euler_number(i)/factorial(i) for i in range(11)]
[1, 0, -1/2, 0, 5/24, 0, -61/720, 0, 277/8064, 0, -50521/3628800]
sage: euler_number(-1)
...
ValueError: n (=-1) must be a nonnegative integer
```

REFERENCES:

- http://en.wikipedia.org/wiki/Euler_number

fibonacci(*n, algorithm='pari'*)

Returns the n-th Fibonacci number. The Fibonacci sequence F_n is defined by the initial conditions $F_1 = F_2 = 1$ and the recurrence relation $F_{n+2} = F_{n+1} + F_n$. For negative n we define $F_n = (-1)^{n+1}F_{-n}$, which is consistent with the recurrence relation.

INPUT:

- `algorithm` - string:
- `"pari"` - (default) - use the PARI C library's fibo function.
- `"gap"` - use GAP's Fibonacci function

Note: PARI is tens to hundreds of times faster than GAP here; moreover, PARI works for every large input whereas GAP doesn't.

EXAMPLES:

```
sage: fibonacci(10)
55
sage: fibonacci(10, algorithm='gap')
55
```

```
sage: fibonacci(-100)
-354224848179261915075
sage: fibonacci(100)
354224848179261915075
```

```
sage: fibonacci(0)
0
sage: fibonacci(1/2)
...
TypeError: no conversion of this rational to integer
```

fibonacci_sequence(*start, stop=None, algorithm=None*)

Returns an iterator over the Fibonacci sequence, for all fibonacci numbers f_n from `n = start` up to (but not including) `n = stop`

INPUT:

- `start` - starting value
- `stop` - stopping value
- `algorithm` - default (None) - passed on to fibonacci function (or not passed on if None, i.e., use the default).

EXAMPLES:

```
sage: fibs = [i for i in fibonacci_sequence(10, 20)]
sage: fibs
[55, 89, 144, 233, 377, 610, 987, 1597, 2584, 4181]
```

```
sage: sum([i for i in fibonacci_sequence(100, 110)])
699193769230753087300013
```

See Also:

fibonacci_xrange()

AUTHORS:

- Bobby Moretti

fibonacci_xrange(*start, stop=None, algorithm='pari'*)

Returns an iterator over all of the Fibonacci numbers in the given range, including `f_n = start` up to, but not including, `f_n = stop`.

EXAMPLES:

```
sage: fibs_in_some_range =  [i for i in fibonacci_xrange(10^7, 10^8)]
sage: len(fibs_in_some_range)
4
sage: fibs_in_some_range
[14930352, 24157817, 39088169, 63245986]
```

```
sage: fibs = [i for i in fibonacci_xrange(10, 100)]
sage: fibs
[13, 21, 34, 55, 89]
```

```
sage: list(fibonacci_xrange(13, 34))
[13, 21]
```

A solution to the second Project Euler problem:

```
sage: sum([i for i in fibonacci_xrange(10^6) if is_even(i)])
1089154
```

See Also:

fibonacci_sequence()

AUTHORS:

- Bobby Moretti

hadamard_matrix(*n*)

Returns an n x n Hadamard matrix of order n, if possible.

If the construction of this matrix is not implemented in GUAVA or there is no such matrix, raises a NotImplementedError.

EXAMPLES:

```
sage: hadamard_matrix(4)
[ 1  1  1  1]
[ 1 -1  1 -1]
[ 1  1 -1 -1]
[ 1 -1 -1  1]
sage: hadamard_matrix(6)
...
NotImplementedError: Hadamard matrix of order 6 does not exist or is not implemented yet.
```

hurwitz_zeta(*s, x, N*)

Returns the value of the $\zeta(s,x)$ to N decimals, where s and x are real.

The Hurwitz zeta function is one of the many zeta functions. It defined as

$$\zeta(s,x) = \sum_{k=0}^{\infty} (k+x)^{-s}.$$

When $x = 1$, this coincides with Riemann's zeta function. The Dirichlet L-functions may be expressed as a linear combination of Hurwitz zeta functions.

Note that if you use floting point inputs, then the results may be slightly off.

EXAMPLES:

```
sage: hurwitz_zeta(3,1/2,6)
8.41439000000000
sage: hurwitz_zeta(11/10,1/2,6)
12.1041000000000
sage: hurwitz_zeta(11/10,1/2,50)
12.103813495683755105709077412966680619033648618088
```

REFERENCES:

- http://en.wikipedia.org/wiki/Hurwitz_zeta_function

lucas_number1(*n, P, Q*)

Returns the n-th Lucas number "of the first kind" (this is not standard terminology). The Lucas sequence $L_n^{(1)}$ is defined by the initial conditions $L_1^{(1)} = 0$, $L_2^{(1)} = 1$ and the recurrence relation $L_{n+2}^{(1)} = P * L_{n+1}^{(1)} - Q * L_n^{(1)}$.

Wraps GAP's Lucas(...)[1].

P=1, Q=-1 gives the Fibonacci sequence.

INPUT:

- `n` - integer
- `P, Q` - integer or rational numbers

OUTPUT: integer or rational number

EXAMPLES:

```
sage: lucas_number1(5,1,-1)
5
sage: lucas_number1(6,1,-1)
8
sage: lucas_number1(7,1,-1)
13
sage: lucas_number1(7,1,-2)
43

sage: lucas_number1(5,2,3/5)
229/25
sage: lucas_number1(5,2,1.5)
...
TypeError: no canonical coercion from Real Field with 53 bits of precision to Rational Field
```

There was a conjecture that the sequence L_n defined by $L_{n+2} = L_{n+1} + L_n$, $L_1 = 1$, $L_2 = 3$, has the property that n prime implies that L_n is prime.

```
sage: lucas = lambda n:(5/2)*lucas_number1(n,1,-1)+(1/2)*lucas_number2(n,1,-1)
sage: [[lucas(n),is_prime(lucas(n)),n+1,is_prime(n+1)] for n in range(15)]
[[1, False, 1, False],
 [3, True, 2, True],
 [4, False, 3, True],
 [7, True, 4, False],
 [11, True, 5, True],
 [18, False, 6, False],
 [29, True, 7, True],
 [47, True, 8, False],
 [76, False, 9, False],
 [123, False, 10, False],
 [199, True, 11, True],
 [322, False, 12, False],
 [521, True, 13, True],
 [843, False, 14, False],
 [1364, False, 15, False]]
```

Can you use Sage to find a counterexample to the conjecture?

lucas_number2 (*n, P, Q*)

Returns the n-th Lucas number "of the second kind" (this is not standard terminology). The Lucas sequence $L_n^{(2)}$ is defined by the initial conditions $L_1^{(2)} = 2$, $L_2^{(2)} = P$ and the recurrence relation $L_{n+2}^{(2)} = P * L_{n+1}^{(2)} - Q * L_n^{(2)}$.

Wraps GAP's Lucas(...)[2].

INPUT:

- `n` - integer
- `P, Q` - integer or rational numbers

OUTPUT: integer or rational number

EXAMPLES:

```
sage: [lucas_number2(i,1,-1) for i in range(10)]
[2, 1, 3, 4, 7, 11, 18, 29, 47, 76]
sage: [fibonacci(i-1)+fibonacci(i+1) for i in range(10)]
[2, 1, 3, 4, 7, 11, 18, 29, 47, 76]

sage: n = lucas_number2(5,2,3); n
2
sage: type(n)
<type 'sage.rings.integer.Integer'>
sage: n = lucas_number2(5,2,-3/9); n
418/9
sage: type(n)
<type 'sage.rings.rational.Rational'>
```

The case P=1, Q=-1 is the Lucas sequence in Brualdi's Introductory Combinatorics, 4th ed., Prentice-Hall, 2004:

```
sage: [lucas_number2(n,1,-1) for n in range(10)]
[2, 1, 3, 4, 7, 11, 18, 29, 47, 76]
```

number_of_arrangements (*mset, k*)

Returns the size of arrangements(mset,k). Wraps GAP's NrArrangements.

EXAMPLES:

```
sage: mset = [1,1,2,3,4,4,5]
sage: number_of_arrangements(mset,2)
22
```

number_of_combinations(*mset, k*)

Returns the size of combinations(mset,k). IMPLEMENTATION: Wraps GAP's NrCombinations.

Note: `mset` must be a list of integers or strings (i.e., this is very restricted).

EXAMPLES:

```
sage: mset = [1,1,2,3,4,4,5]
sage: number_of_combinations(mset,2)
12
```

number_of_derangements(*mset*)

Returns the size of derangements(mset). Wraps GAP's NrDerangements.

EXAMPLES:

```
sage: mset = [1,2,3,4]
sage: number_of_derangements(mset)
9
```

number_of_permutations(*mset*)

Do not use this function. It will be deprecated in future version of Sage and eventually removed. Use Permutations instead; instead of

number_of_permutations(mset)

use

Permutations(mset).cardinality().

If you insist on using this now:

Returns the size of permutations(mset).

AUTHORS:

- Robert L. Miller

EXAMPLES:

```
sage: mset = [1,1,2,2,2]
sage: number_of_permutations(mset)
10
```

number_of_tuples(*S, k*)

Returns the size of tuples(S,k). Wraps GAP's NrTuples.

EXAMPLES:

```
sage: S = [1,2,3,4,5]
sage: number_of_tuples(S,2)
25
sage: S = [1,1,2,3,4,5]
sage: number_of_tuples(S,2)
25
```

number_of_unordered_tuples(*S, k*)

Returns the size of unordered_tuples(S,k). Wraps GAP's NrUnorderedTuples.

EXAMPLES:

```
sage: S = [1,2,3,4,5]
sage: number_of_unordered_tuples(S,2)
15
```

permutations(*mset*)

A permutation is represented by a list that contains exactly the same elements as mset, but possibly in different order. If mset is a proper set there are $|mset|!$ such permutations. Otherwise if the first elements appears k_1 times, the second element appears k_2 times and so on, the number of permutations is $|mset|!/(k_1!k_2!\ldots)$, which is sometimes called a multinomial coefficient.

permutations returns the set of all permutations of a multiset. Calls a function written by Mike Hansen, not GAP.

EXAMPLES:

```
sage: mset = [1,1,2,2,2]
sage: permutations(mset)
[[1, 1, 2, 2, 2],
 [1, 2, 1, 2, 2],
 [1, 2, 2, 1, 2],
 [1, 2, 2, 2, 1],
 [2, 1, 1, 2, 2],
 [2, 1, 2, 1, 2],
 [2, 1, 2, 2, 1],
 [2, 2, 1, 1, 2],
 [2, 2, 1, 2, 1],
 [2, 2, 2, 1, 1]]
sage: MS = MatrixSpace(GF(2),2,2)
sage: A = MS([1,0,1,1])
sage: permutations(A.rows())
[[(1, 0), (1, 1)], [(1, 1), (1, 0)]]
```

permutations_iterator(*mset, n=None*)

Do not use this function. It will be deprecated in future version of Sage and eventually removed. Use Permutations instead; instead of

for p in permutations_iterator(range(1, m+1), n)

use

for p in Permutations(m, n).

Note that Permutations, unlike this function, treats repeated elements as identical.

If you insist on using this now:

Returns an iterator (http://docs.python.org/lib/typeiter.html) which can be used in place of permutations(mset) if all you need it for is a 'for' loop.

Posted by Raymond Hettinger, 2006/03/23, to the Python Cookbook: http://aspn.activestate.com/ASPN/Cookbook/Python/Recipe/474124

Note- This function considers repeated elements as different entries, so for example:

```
sage: from sage.combinat.combinat import permutations, permutations_iterator
sage: mset = [1,2,2]
sage: permutations(mset)
[[1, 2, 2], [2, 1, 2], [2, 2, 1]]
sage: for p in permutations_iterator(mset): print p
[1, 2, 2]
[1, 2, 2]
[2, 1, 2]
```

```
[2, 2, 1]
[2, 1, 2]
[2, 2, 1]
```

EXAMPLES:

```
sage: X = permutations_iterator(range(3),2)
sage: [x for x in X]
[[0, 1], [0, 2], [1, 0], [1, 2], [2, 0], [2, 1]]
```

stirling_number1(*n, k*)

Returns the n-th Stilling number $S_1(n,k)$ of the first kind (the number of permutations of n points with k cycles). Wraps GAP's Stirling1.

EXAMPLES:

```
sage: stirling_number1(3,2)
3
sage: stirling_number1(5,2)
50
sage: 9*stirling_number1(9,5)+stirling_number1(9,4)
269325
sage: stirling_number1(10,5)
269325
```

Indeed, $S_1(n,k) = S_1(n-1,k-1) + (n-1)S_1(n-1,k)$.

stirling_number2(*n, k*)

Returns the n-th Stirling number $S_2(n,k)$ of the second kind (the number of ways to partition a set of n elements into k pairwise disjoint nonempty subsets). (The n-th Bell number is the sum of the $S_2(n,k)$'s, $k = 0, ..., n$.) Wraps GAP's Stirling2.

EXAMPLES: Stirling numbers satisfy $S_2(n,k) = S_2(n-1,k-1) + kS_2(n-1,k)$:

```
sage: 5*stirling_number2(9,5) + stirling_number2(9,4)
42525
sage: stirling_number2(10,5)
42525
```

```
sage: n = stirling_number2(20,11); n
1900842429486
sage: type(n)
<type 'sage.rings.integer.Integer'>
```

tuples(*S, k*)

An ordered tuple of length k of set is an ordered selection with repetition and is represented by a list of length k containing elements of set. tuples returns the set of all ordered tuples of length k of the set.

EXAMPLES:

```
sage: S = [1,2]
sage: tuples(S,3)
[[1, 1, 1], [2, 1, 1], [1, 2, 1], [2, 2, 1], [1, 1, 2], [2, 1, 2], [1, 2, 2], [2, 2, 2]]
sage: mset = ["s","t","e","i","n"]
sage: tuples(mset,2)
[['s', 's'], ['t', 's'], ['e', 's'], ['i', 's'], ['n', 's'], ['s', 't'], ['t', 't'],
 ['e', 't'], ['i', 't'], ['n', 't'], ['s', 'e'], ['t', 'e'], ['e', 'e'], ['i', 'e'],
 ['n', 'e'], ['s', 'i'], ['t', 'i'], ['e', 'i'], ['i', 'i'], ['n', 'i'], ['s', 'n'],
 ['t', 'n'], ['e', 'n'], ['i', 'n'], ['n', 'n']]
```

The Set(...) comparisons are necessary because finite fields are not enumerated in a standard order.

```
sage: K.<a> = GF(4, 'a')
sage: mset = [x for x in K if x!=0]
sage: tuples(mset,2)
[[a, a], [a + 1, a], [1, a], [a, a + 1], [a + 1, a + 1], [1, a + 1], [a, 1], [a + 1, 1], [1, 1]]
```

AUTHORS:

- Jon Hanke (2006-08)

unordered_tuples(*S*, *k*)

An unordered tuple of length k of set is a unordered selection with repetitions of set and is represented by a sorted list of length k containing elements from set.

unordered_tuples returns the set of all unordered tuples of length k of the set. Wraps GAP's UnorderedTuples.

Warning: Wraps GAP - hence mset must be a list of objects that have string representations that can be interpreted by the GAP intepreter. If mset consists of at all complicated Sage objects, this function does *not* do what you expect. A proper function should be written! (TODO!)

EXAMPLES:

```
sage: S = [1,2]
sage: unordered_tuples(S,3)
[[1, 1, 1], [1, 1, 2], [1, 2, 2], [2, 2, 2]]
sage: unordered_tuples(["a","b","c"],2)
['aa', 'ab', 'ac', 'bb', 'bc', 'cc']
```

17.2 Functions that compute some of the sequences in Sloane's tables

EXAMPLES:

Type sloane.[tab] to see a list of the sequences that are defined.

```
sage: a = sloane.A000005; a
 The integer sequence tau(n), which is the number of divisors of n.
 sage: a(1)
 1
 sage: a(6)
 4
 sage: a(100)
 9
```

Type `d._eval??` to see how the function that computes an individual term of the sequence is implemented.

The input must be a positive integer:

```
sage: a(0)
...
ValueError: input n (=0) must be a positive integer
sage: a(1/3)
...
TypeError: input must be an int, long, or Integer
```

You can also change how a sequence prints:

```
sage: a = sloane.A000005; a
The integer sequence tau(n), which is the number of divisors of n.
sage: a.rename('(..., tau(n), ...)')
sage: a
(..., tau(n), ...)
sage: a.reset_name()
sage: a
The integer sequence tau(n), which is the number of divisors of n.
```

TESTS:

```
sage: a = sloane.A000001;
sage: a == loads(dumps(a))
True
```

AUTHORS:

- William Stein: framework
- Jaap Spies: most sequences
- Nick Alexander: updated framework

class A000007()

class A000008()

class A000009()

cf()
EXAMPLES:

```
sage: it = sloane.A000009.cf()
sage: [it.next() for i in range(14)]
[1, 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, 12, 15, 18]
```

list(*n*)
EXAMPLES:

```
sage: sloane.A000009.list(14)
[1, 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, 12, 15, 18]
```

class A000010()

class A000012()

class A000015()

class A000016()

class A000027()

class A000030()

class A000032()

class A000035()

class A000040()

class A000041()

class A000043()

class A000045()

fib()
Returns a generator over all Fibonacci numbers, starting with 0.
EXAMPLES:

```
sage: it = sloane.A000045.fib()
sage: [it.next() for i in range(10)]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34]
```

list(*n*)
EXAMPLES:

```
sage: sloane.A000045.list(10)
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34]
```

class A000069()

class A000073()

list(*n*)
EXAMPLES:

```
sage: sloane.A000073.list(10)
[0, 0, 1, 1, 2, 4, 7, 13, 24, 44]
```

class A000079()

class A000085()

class A000100()

class A000108()

class A000110()

class A000120()

f(*n*)
EXAMPLES:

```
sage: [sloane.A000120.f(n) for n in range(10)]
[0, 1, 1, 2, 1, 2, 2, 3, 1, 2]
```

class A000124()

class A000129()

class A000142()

class A000153()

class A000165()

class A000166()

class A000169()

class **A000203**()

class **A000204**()

class **A000213**()

list(*n*)

EXAMPLES:

```
sage: sloane.A000213.list(10)
[1, 1, 1, 3, 5, 9, 17, 31, 57, 105]
```

class **A000217**()

class **A000225**()

class **A000244**()

class **A000255**()

class **A000261**()

class **A000272**()

class **A000290**()

class **A000292**()

class **A000302**()

class **A000312**()

class **A000326**()

class **A000330**()

class **A000396**()

class **A000578**()

class **A000583**()

class **A000587**()

class **A000668**()

class **A000670**()

class **A000720**()

class **A000796**()

list(*n*)

EXAMPLES:

```
sage: sloane.A000796.list(10)
[3, 1, 4, 1, 5, 9, 2, 6, 5, 3]
```

pi()

Based on an algorithm of Lambert Meertens The ABC-programming language!!!

EXAMPLES:

```
sage: it = sloane.A000796.pi()
sage: [it.next() for i in range(10)]
[3, 1, 4, 1, 5, 9, 2, 6, 5, 3]
```

class **A000961**()

list(*n*)
EXAMPLES:

```
sage: sloane.A000961.list(10)
[1, 2, 3, 4, 5, 7, 8, 9, 11, 13]
```

class A000984()

class A001006()

class A001045()

class A001055()

nwf(*n*, *m*)
EXAMPLES:

```
sage: sloane.A001055.nwf(4,1)
0
sage: sloane.A001055.nwf(4,2)
1
sage: sloane.A001055.nwf(4,3)
1
sage: sloane.A001055.nwf(4,4)
2
```

class A001109()

class A001110()

g(*k*)
EXAMPLES:

```
sage: sloane.A001110.g(2)
2
sage: sloane.A001110.g(1)
0
```

class A001147()

class A001157()

class A001189()

class A001221()

class A001222()

class A001227()

class A001333()

class A001358()

list(*n*)
EXAMPLES:

```
sage: sloane.A001358.list(9)
[4, 6, 9, 10, 14, 15, 21, 22, 25]
```

class A001405()

class A001477()

class A001694()

is_powerful(*n*)

This function returns True if and only if n is a Powerful Number:

A positive integer n is powerful if for every prime p dividing n, p^2 also divides n. See Sloane's OEIS A001694.

INPUT:

- n - integer

OUTPUT:

- True - if n is a Powerful number, else False

EXAMPLES:

```
sage: a = sloane.A001694
sage: a.is_powerful(2500)
True
sage: a.is_powerful(20)
False
```

AUTHORS:

- Jaap Spies (2006-12-07)

list(*n*)

EXAMPLES:

```
sage: sloane.A001694.list(9)
[1, 4, 8, 9, 16, 25, 27, 32, 36]
```

class A001836()

list(*n*)

EXAMPLES:

```
sage: sloane.A001836.list(9)
[53, 83, 158, 263, 293, 368, 578, 683, 743]
```

class A001906()

class A001909()

class A001910()

class A001969()

class A002110()

class A002113()

list(*n*)

EXAMPLES:

```
sage: sloane.A002113.list(15)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 22, 33, 44, 55]
```

class A002275()

class A002378()

class A002620()

class **A002808**()

list(*n*)
EXAMPLES:

```
sage: sloane.A002808.list(10)
[4, 6, 8, 9, 10, 12, 14, 15, 16, 18]
```

class **A003418**()

class **A004086**()

class **A004526**()

class **A005100**()

list(*n*)
EXAMPLES:

```
sage: sloane.A005100.list(10)
[1, 2, 3, 4, 5, 7, 8, 9, 10, 11]
```

class **A005101**()

list(*n*)
EXAMPLES:

```
sage: sloane.A005101.list(10)
[12, 18, 20, 24, 30, 36, 40, 42, 48, 54]
```

class **A005117**()

list(*n*)
EXAMPLES:

```
sage: sloane.A005117.list(10)
[1, 2, 3, 5, 6, 7, 10, 11, 13, 14]
```

class **A005408**()

class **A005843**()

class **A006318**()

class **A006530**()

class **A006882**()

df()
Double factorials n!!: a(n)=n*a(n-2).
EXAMPLES:

```
sage: it = sloane.A006882.df()
sage: [it.next() for i in range(10)]
[1, 1, 2, 3, 8, 15, 48, 105, 384, 945]
```

list(*n*)
EXAMPLES:

```
sage: sloane.A006882.list(10)
[1, 1, 2, 3, 8, 15, 48, 105, 384, 945]
```

class A007318()

class A008275()

s(*n*, *k*)

EXAMPLES:

```
sage: sloane.A008275.s(4,2)
11
sage: sloane.A008275.s(5,2)
-50
sage: sloane.A008275.s(5,3)
35
```

class A008277()

s2(*n*, *k*)

Returns the Stirling number S2(n,k) of the 2nd kind.

EXAMPLES:

```
sage: sloane.A008277.s2(4,2)
7
```

class A008683()

class A010060()

class A015521()

class A015523()

class A015530()

class A015531()

class A015551()

class A018252()

class A020639()

list(*n*)

EXAMPLES:

```
sage: sloane.A020639.list(10)
[1, 2, 3, 2, 5, 2, 7, 2, 3, 2]
```

class A046660(*offset=1*)

Excess of n = number of prime divisors (with multiplicity) - number of prime divisors (without multiplicity).

$\Omega(n) - \omega(n)$.

INPUT:

- `n` - positive integer

OUTPUT:

- `integer` - function value

EXAMPLES:

```
sage: a = sloane.A046660; a
Excess of n = Bigomega (with multiplicity) - omega (without multiplicity).
sage: a(0)
...
ValueError: input n (=0) must be a positive integer
sage: a(1)
0
sage: a(8)
2
sage: a(41)
0
sage: a(84792)
2
sage: a.list(12)
[0, 0, 0, 1, 0, 0, 0, 2, 1, 0, 0, 1]
```

AUTHORS:

- Jaap Spies (2007-01-19)

class A049310()

class A051959()

g(*k*)

EXAMPLES:

```
sage: sloane.A051959.g(2)
15
sage: sloane.A051959.g(1)
0
```

class A055790()

class A061084()

class A064553()

class A079922(*offset=1*)

function returns solutions to the Dancing School problem with n girls and $n+3$ boys.

The value is $per(B)$, the permanent of the (0,1)-matrix B of size $n \times n+3$ with $b(i,j) = 1$ if and only if $i \leq j \leq i+n$.

REFERENCES:

- Jaap Spies, Nieuw Archief voor Wiskunde, 5/7 nr 4, December 2006

INPUT:

- n - positive integer

OUTPUT:

- integer - function value

EXAMPLES:

```
sage: a = sloane.A079922; a
Solutions to the Dancing School problem with n girls and n+3 boys
sage: a.offset
1
sage: a(1)
4
sage: a(8)
2227
sage: a.list(8)
[4, 13, 36, 90, 212, 478, 1044, 2227]
```

Compare: Searching Sloane's online database... Solution to the Dancing School Problem with n girls and n+3 boys: f(n,3). [4, 13, 36, 90, 212, 478, 1044, 2227]

```
sage: a(-1)
...
ValueError: input n (=-1) must be a positive integer
```

AUTHORS:

- Jaap Spies (2007-01-14)

class A079923(*offset=1*)

function returns solutions to the Dancing School problem with n girls and $n + 4$ boys.

The value is $per(B)$, the permanent of the (0,1)-matrix B of size $n \times n + 3$ with $b(i, j) = 1$ if and only if $i \leq j \leq i + n$.

REFERENCES:

- Jaap Spies, Nieuw Archief voor Wiskunde, 5/7 nr 4, December 2006

INPUT:

- `n` - positive integer

OUTPUT:

- `integer` - function value

EXAMPLES:

```
sage: a = sloane.A079923; a
Solutions to the Dancing School problem with n girls and n+4 boys
sage: a.offset
1
sage: a(1)
5
sage: a(8)
15458
sage: a.list(8)
[5, 21, 76, 246, 738, 2108, 5794, 15458]
```

Compare: Searching Sloane's online database... Solution to the Dancing School Problem with n girls and n+4 boys: f(n,4). [5, 21, 76, 246, 738, 2108, 5794, 15458]

```
sage: a(0)
...
ValueError: input n (=0) must be a positive integer
```

is_number_of_the_third_kind(n)

This function returns True if and only if n is a number of the third kind.

A number is of the third kind if it can be written as a sum of at least three consecutive positive integers. Odd primes can only be written as a sum of two consecutive integers. Powers of 2 do not have a representation as a sum of k consecutive integers (other than the trivial $n = n$ for $k = 1$).

See: http://www.jaapspies.nl/mathfiles/problem2005-2C.pdf

INPUT:

•n - positive integer

OUTPUT:

•True - if n is not prime and not a power of 2 False -

EXAMPLES:

```
sage: a = sloane.A111774
sage: a.is_number_of_the_third_kind(6)
True
sage: a.is_number_of_the_third_kind(100)
True
sage: a.is_number_of_the_third_kind(16)
False
sage: a.is_number_of_the_third_kind(97)
False
```

AUTHORS:

•Jaap Spies (2006-12-09)

list(n)

EXAMPLES:

```
sage: sloane.A111774.list(12)
[6, 9, 10, 12, 14, 15, 18, 20, 21, 22, 24, 25]
```

class A111775()

class A111776()

class A111787()

class **ExponentialNumbers**(*a*)

class **ExtremesOfPermanentsSequence**(*offset=1*)

gen(*a0, a1, d*)
EXAMPLES:

```
sage: it = sloane.A000153.gen(0,1,2)
sage: [it.next() for i in range(5)]
[0, 1, 2, 7, 32]
```

list(*n*)
EXAMPLES:

```
sage: sloane.A000153.list(8)
[0, 1, 2, 7, 32, 181, 1214, 9403]
```

class **ExtremesOfPermanentsSequence2**(*offset=1*)

gen(*a0, a1, d*)
EXAMPLES:

```
sage: from sage.combinat.sloane_functions import ExtremesOfPermanentsSequence2
sage: e = ExtremesOfPermanentsSequence2()
sage: it = e.gen(6,43,6)
sage: [it.next() for i in range(5)]
[6, 43, 307, 2542, 23799]
```

class **RecurrenceSequence**(*offset=1*)

list(*n*)
EXAMPLES:

```
sage: sloane.A001110.list(8)
[0, 1, 36, 1225, 41616, 1413721, 48024900, 1631432881]
```

class **RecurrenceSequence2**(*offset=1*)

list(*n*)
EXAMPLES:

```
sage: sloane.A001906.list(10)
[0, 1, 3, 8, 21, 55, 144, 377, 987, 2584]
```

class **Sloane**()
A collection of Sloane generating functions.

This class inspects sage.combinat.sloane_functions, accumulating all the SloaneSequence classes starting with 'A'. These are listed for tab completion, but not instantiated until requested.

EXAMPLES: Ensure we have lots of entries:

```
sage: len(sloane.trait_names()) > 100
True
```

And ensure none are being incorrectly returned:

```
sage: [ None for n in sloane.trait_names() if not n.startswith('A') ]
[]
```

Ensure we can access dynamic constructions and cache correctly:

```
sage: s = sloane.A000587
sage: s is sloane.A000587
True
```

And that we can access other functions in parent classes:

```
sage: sloane.__class__
<class 'sage.combinat.sloane_functions.Sloane'>
```

AUTHORS:

- Nick Alexander

trait_names()

List Sloane generating functions for tab-completion. The member classes are inspected from module sage.combinat.sloane_functions.

They must be sub classes of SloaneSequence and must start with 'A'. These restrictions are only to prevent typos, incorrect inspecting, etc.

EXAMPLES:

```
sage: type(sloane.trait_names())
<type 'list'>
```

class SloaneSequence(*offset=1*)

Base class for a Sloane integer sequence.

EXAMPLES:

We create a dummy sequence:

list(*n*)

Return n terms of the sequence: sequence[offset], sequence[offset+1], ... , sequence[offset+n-1]. EXAMPLES:

```
sage: sloane.A000012.list(4)
[1, 1, 1, 1]
```

perm_mh(*m, h*)

This functions calculates $f(g,h)$ from Sloane's sequences A079908-A079928

INPUT:

- m - positive integer
- h - non negative integer

OUTPUT: permanent of the m x (m+h) matrix, etc.

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import perm_mh
sage: perm_mh(3,3)
36
sage: perm_mh(3,4)
76
```

AUTHORS:

- Jaap Spies (2006)

recur_gen2 (*a0, a1, a2, a3*)

homogenous general second-order linear recurrence generator with fixed coefficients

a(0) = a0, a(1) = a1, a(n) = a2*a(n-1) + a3*a(n-2)

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import recur_gen2
sage: it = recur_gen2(1,1,1,1)
sage: [it.next() for i in range(10)]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55]
```

recur_gen2b (*a0, a1, a2, a3, b*)

inhomogenous second-order linear recurrence generator with fixed coefficients and $b = f(n)$

$a(0) = a0$, $a(1) = a1$, $a(n) = a2 * a(n-1) + a3 * a(n-2) + f(n)$.

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import recur_gen2b
sage: it = recur_gen2b(1,1,1,1, lambda n: 0)
sage: [it.next() for i in range(10)]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55]
```

recur_gen3 (*a0, a1, a2, a3, a4, a5*)

homogenous general third-order linear recurrence generator with fixed coefficients

a(0) = a0, a(1) = a1, a(2) = a2, a(n) = a3*a(n-1) + a4*a(n-2) + a5*a(n-3)

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import recur_gen3
sage: it = recur_gen3(1,1,1,1,1,1)
sage: [it.next() for i in range(10)]
[1, 1, 1, 3, 5, 9, 17, 31, 57, 105]
```

17.3 Compute Bell and Uppuluri-Carpenter numbers.

AUTHORS:

- Nick Alexander

clear_mpz_globals()

expnums()

Compute the first n exponential numbers around aa, starting with the zero-th.

INPUT:

- `n` - C machine int
- `aa` - C machine int

OUTPUT: A list of length n.

ALGORITHM: We use the same integer addition algorithm as GAP. This is an extension of Bell's triangle to the general case of exponential numbers. The recursion performs $O(n^2)$ additions, but the running time is dominated by the cost of the last integer addition, because the growth of the integer results of partial computations is exponential in n. The algorithm stores $O(n)$ integers, but each is exponential in n.

EXAMPLES:

```
sage: expnums(10, 1)
[1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147]

sage: expnums(10, -1)
[1, -1, 0, 1, 1, -2, -9, -9, 50, 267]

sage: expnums(1, 1)
[1]
sage: expnums(0, 1)
[]
sage: expnums(-1, 0)
[]
```

AUTHORS:

- Nick Alexander

expnums2()

A vanilla python (but compiled via pyrex) implementation of expnums.

We Compute the first n exponential numbers around aa, starting with the zero-th.

EXAMPLES:

```
sage: from sage.combinat.expnums import expnums2
sage: expnums2(10, 1)
[1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147]
```

gmp_randrange()

init_mpz_globals()

17.4 Alternating Sign Matrices

AlternatingSignMatrices(n)

Returns the combinatorial class of alternating sign matrices of size n.

EXAMPLES:

```
sage: a2 = AlternatingSignMatrices(2); a2
Alternating sign matrices of size 2
sage: for a in a2: print a, "-\n"
[0 1]
[1 0]
-
[1 0]
[0 1]
-
```

class **AlternatingSignMatrices_n**(n)

cardinality()

TESTS:

```
sage: [ AlternatingSignMatrices(n).cardinality() for n in range(0, 11)]
[1, 1, 2, 7, 42, 429, 7436, 218348, 10850216, 911835460, 129534272700]
```

```
sage: asms = [ AlternatingSignMatrices(n) for n in range(6) ]
sage: all( [ asm.cardinality() == len(asm.list()) for asm in asms] )
True
```

ContreTableaux(*n*)

Returns the combinatorial class of contre tableaux of size n.

EXAMPLES:

```
sage: ct4 = ContreTableaux(4); ct4
Contre tableaux of size 4
sage: ct4.cardinality()
42
sage: ct4.first()
[[1, 2, 3, 4], [1, 2, 3], [1, 2], [1]]
sage: ct4.last()
[[1, 2, 3, 4], [2, 3, 4], [3, 4], [4]]
sage: ct4.random_element()
[[1, 2, 3, 4], [1, 2, 3], [1, 3], [3]]
```

class **ContreTableaux_n**(*n*)

cardinality()

TESTS:

```
sage: [ ContreTableaux(n).cardinality() for n in range(0, 11)]
[1, 1, 2, 7, 42, 429, 7436, 218348, 10850216, 911835460, 129534272700]
```

TruncatedStaircases(*n, last_column*)

Returns the combinatorial class of truncated staircases of size n with last column last_column.

EXAMPLES:

```
sage: t4 = TruncatedStaircases(4, [2,3]); t4
Truncated staircases of size 4 with last column [2, 3]
sage: t4.cardinality()
4
sage: t4.first()
[[4, 3, 2, 1], [3, 2, 1], [3, 2]]
sage: t4.list()
[[[4, 3, 2, 1], [3, 2, 1], [3, 2]], [[4, 3, 2, 1], [4, 2, 1], [3, 2]], [[4, 3, 2, 1], [4, 3, 1],
```

class **TruncatedStaircases_nlastcolumn**(*n, last_column*)

from_contre_tableau(*comps*)

Returns an alternating sign matrix from a contretableaux.

TESTS:

```
sage: import sage.combinat.alternating_sign_matrix as asm
sage: asm.from_contre_tableau([[1, 2, 3], [1, 2], [1]])
[0 0 1]
[0 1 0]
[1 0 0]
sage: asm.from_contre_tableau([[1, 2, 3], [2, 3], [3]])
[1 0 0]
[0 1 0]
[0 0 1]
```

17.5 Cartesian Products

CartesianProduct(**iters*)

Returns the combinatorial class of the cartesian product of *iters.

EXAMPLES:

```
sage: cp = CartesianProduct([1,2], [3,4]); cp
Cartesian product of [1, 2], [3, 4]
sage: cp.list()
[[1, 3], [1, 4], [2, 3], [2, 4]]
```

Note that if you have a generator-type object that is returned by a function, then you should use IterableFunctionCall class defined in sage.combinat.misc.

```
sage: def a(n): yield 1*n; yield 2*n
sage: def b(): yield 'a'; yield 'b'
sage: CartesianProduct(a(3), b()).list()
[[3, 'a'], [3, 'b']]
sage: from sage.combinat.misc import IterableFunctionCall
sage: CartesianProduct(IterableFunctionCall(a, 3), IterableFunctionCall(b)).list()
[[3, 'a'], [3, 'b'], [6, 'a'], [6, 'b']]
```

See the documentation for IterableFunctionCall for more information.

class **CartesianProduct_iters**(**iters*)

cardinality()

Returns the number of elements in the cartesian product of everything in *iters.

EXAMPLES:

```
sage: CartesianProduct(range(2), range(3)).cardinality()
6
sage: CartesianProduct(range(2), xrange(3)).cardinality()
6
sage: CartesianProduct(range(2), xrange(3), xrange(4)).cardinality()
24
```

list()

Returns

EXAMPLES:

```
sage: CartesianProduct(range(3), range(3)).list()
[[0, 0], [0, 1], [0, 2], [1, 0], [1, 1], [1, 2], [2, 0], [2, 1], [2, 2]]
sage: CartesianProduct('dog', 'cat').list()
[['d', 'c'],
 ['d', 'a'],
 ['d', 't'],
 ['o', 'c'],
 ['o', 'a'],
 ['o', 't'],
 ['g', 'c'],
 ['g', 'a'],
 ['g', 't']]
```

random_element()

Returns a random element from the cartesian product of *iters.

EXAMPLES:

```
sage: CartesianProduct('dog', 'cat').random_element()
['d', 'a']
```

17.6 Combinations

Combinations(*mset, k=None*)

Returns the combinatorial class of combinations of mset. If k is specified, then it returns the combinatorial class of combinations of mset of size k.

The combinatorial classes correctly handle the cases where mset has duplicate elements.

EXAMPLES:

```
sage: C = Combinations(range(4)); C
Combinations of [0, 1, 2, 3]
sage: C.list()
[[],
 [0],
 [1],
 [2],
 [3],
 [0, 1],
 [0, 2],
 [0, 3],
 [1, 2],
 [1, 3],
 [2, 3],
 [0, 1, 2],
 [0, 1, 3],
 [0, 2, 3],
 [1, 2, 3],
 [0, 1, 2, 3]]
 sage: C.cardinality()
 16
```

```
sage: C2 = Combinations(range(4),2); C2
Combinations of [0, 1, 2, 3] of length 2
sage: C2.list()
[[0, 1], [0, 2], [0, 3], [1, 2], [1, 3], [2, 3]]
sage: C2.cardinality()
6
```

```
sage: Combinations([1,2,2,3]).list()
[[],
 [1],
 [2],
 [3],
 [1, 2],
 [1, 3],
 [2, 2],
 [2, 3],
 [1, 2, 2],
 [1, 2, 3],
 [2, 2, 3],
 [1, 2, 2, 3]]
```

class **Combinations_mset**(*mset*)

cardinality()
TESTS:

```
sage: Combinations([1,2,3]).cardinality()
8
sage: Combinations(['a','a','b']).cardinality()
6
```

class **Combinations_msetk**(*mset, k*)

cardinality()
Returns the size of combinations(mset,k). IMPLEMENTATION: Wraps GAP's NrCombinations.
EXAMPLES:

```
sage: mset = [1,1,2,3,4,4,5]
sage: Combinations(mset,2).cardinality()
12
```

class **Combinations_set**(*mset*)

rank(*x*)
EXAMPLES:

```
sage: c = Combinations([1,2,3])
sage: range(c.cardinality()) == map(c.rank, c)
True
```

unrank(*r*)
EXAMPLES:

```
sage: c = Combinations([1,2,3])
sage: c.list() == map(c.unrank, range(c.cardinality()))
True
```

class **Combinations_setk**(*mset, k*)

list()
EXAMPLES:

```
sage: Combinations([1,2,3,4,5],3).list()
[[1, 2, 3],
 [1, 2, 4],
 [1, 2, 5],
 [1, 3, 4],
 [1, 3, 5],
 [1, 4, 5],
 [2, 3, 4],
 [2, 3, 5],
 [2, 4, 5],
 [3, 4, 5]]
```

rank(*x*)
EXAMPLES:

```
sage: c = Combinations([1,2,3], 2)
sage: range(c.cardinality()) == map(c.rank, c.list())
True
```

unrank(*r*)

EXAMPLES:

```
sage: c = Combinations([1,2,3], 2)
sage: c.list() == map(c.unrank, range(c.cardinality()))
True
```

17.7 Signed Compositions

SignedCompositions(*n*)

Returns the combinatorial class of signed compositions of n.

EXAMPLES:

```
sage: SC3 = SignedCompositions(3); SC3
Signed compositions of 3
sage: SC3.cardinality()
18
sage: len(SC3.list())
18
sage: SC3.first()
[1, 1, 1]
sage: SC3.last()
[-3]
sage: SC3.random_element()
[1, -1, 1]
sage: SC3.list()
[[1, 1, 1],
 [1, 1, -1],
 [1, -1, 1],
 [1, -1, -1],
 [-1, 1, 1],
 [-1, 1, -1],
 [-1, -1, 1],
 [-1, -1, -1],
 [1, 2],
 [1, -2],
 [-1, 2],
 [-1, -2],
 [2, 1],
 [2, -1],
 [-2, 1],
 [-2, -1],
 [3],
 [-3]]
```

class **SignedCompositions_n**(*n*)

cardinality()

TESTS:

```
sage: SC4 = SignedCompositions(4)
sage: SC4.cardinality() == len(SC4.list())
True
sage: SignedCompositions(3).cardinality()
18
```

17.8 Compositions

A composition c of a nonnegative integer n is a list of positive integers with total sum n.

EXAMPLES: There are 8 compositions of 4.

```
sage: Compositions(4).cardinality()
8
```

Here is the list of them:

```
sage: Compositions(4).list()
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1], [4]]
```

You can use the .first() method to get the 'first' composition of a number.

```
sage: Compositions(4).first()
[1, 1, 1, 1]
```

You can also calculate the 'next' composition given the current one.

```
sage: Compositions(4).next([1,1,2])
[1, 2, 1]
```

The following examples shows how to test whether or not an object is a composition.

```
sage: [3,4] in Compositions()
True
sage: [3,4] in Compositions(7)
True
sage: [3,4] in Compositions(5)
False
```

Similarly, one can check whether or not an object is a composition which satisfies further constraints.

```
sage: [4,2] in Compositions(6, inner=[2,2], min_part=2)
True
sage: [4,2] in Compositions(6, inner=[2,2], min_part=2)
True
sage: [4,2] in Compositions(6, inner=[2,2], min_part=3)
False
```

Note that the given constraints should compatible.

```
sage: [4,1] in Compositions(5, inner=[2,1], min_part=1)
True
```

The options length, min_length, and max_length can be used to set length constraints on the compositions. For example, the compositions of 4 of length equal to, at least, and at most 2 are given by:

```
sage: Compositions(4, length=2).list()
[[1, 3], [2, 2], [3, 1]]
sage: Compositions(4, min_length=2).list()
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1]]
```

```
sage: Compositions(4, max_length=2).list()
[[1, 3], [2, 2], [3, 1], [4]]
```

Setting both min_length and max_length to the same value is equivalent to setting length to this value.

```
sage: Compositions(4, min_length=2, max_length=2).list()
[[1, 3], [2, 2], [3, 1]]
```

The options inner and outer can be used to set part-by-part containment constraints. The list of compositions of 4 bounded above by [3,1,2] is given by:

```
sage: Compositions(4, outer=[3,1,2]).list()
[[1, 1, 2], [2, 1, 1], [3, 1]]
```

Outer sets max_length to the length of its argument. Moreover, the parts of outer may be infinite to clear the constraint on specific parts. This is the list of compositions of 4 of length at most 3 such that the first and third parts are at most 1:

```
sage: Compositions(4, outer=[1,oo,1]).list()
[[1, 2, 1], [1, 3]]
```

This is the list of compositions of 4 bounded below by [1,1,1].

```
sage: Compositions(4, inner=[1,1,1]).list()
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1]]
```

The options min_slope and max_slope can be used to set constraints on the slope, that is the difference p[i+1]-p[i] of two consecutive parts. The following is the list of weakly increasing compositions of 4.

```
sage: Compositions(4, min_slope=0).list()
[[1, 1, 1, 1], [1, 1, 2], [1, 3], [2, 2], [4]]
```

The following is the list of compositions of 4 such that two consecutive parts differ by at most one unit:

```
sage: Compositions(4, min_slope=-1, max_slope=1).list()
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [2, 2], [4]]
```

The constraints can be combinat together in all reasonable ways. This is the list of compositions of 5 of length between 2 and 4 such that the difference between consecutive parts is between -2 and 1.

```
sage: Compositions(5, max_slope=1, min_slope=-2, min_length=2, max_length=4).list()
[[1, 1, 1, 2],
 [1, 1, 2, 1],
 [1, 2, 1, 1],
 [1, 2, 2],
 [2, 1, 1, 1],
 [2, 1, 2],
 [2, 2, 1],
 [2, 3],
 [3, 1, 1],
 [3, 2]]
```

We can do the same thing with an outer constraint:

```
sage: Compositions(5, max_slope=1, min_slope=-2, min_length=2, max_length=4, outer=[2,5,2]).list()
[[1, 2, 2], [2, 1, 2], [2, 2, 1], [2, 3]]
```

However, providing incoherent constraints may yield strange results. It is up to the user to ensure that the inner and outer compositions themselves satisfy the parts and slope constraints.

AUTHORS:

- Mike Hansen

Composition(*co=None, descents=None, code=None*)

Returns a composition object.

EXAMPLES: The standard way to create a composition is by specifying it as a list.

```
sage: Composition([3,1,2])
[3, 1, 2]
```

You can create a composition from a list of its descents.

```
sage: Composition([1, 1, 3, 4, 3]).descents()
[0, 1, 4, 8, 11]
sage: Composition(descents=[1,0,4,8,11])
[1, 1, 3, 4, 3]
```

You can also create a composition from its code.

```
sage: Composition([4,1,2,3,5]).to_code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: Composition(code=_)
[4, 1, 2, 3, 5]
sage: Composition([3,1,2,3,5]).to_code()
[1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: Composition(code=_)
[3, 1, 2, 3, 5]
```

class **Composition_class**(*l*)

complement()

Returns the complement of the composition co. The complement is the reverse of co's conjugate composition.

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).conjugate()
[1, 1, 3, 3, 1, 3]
sage: Composition([1, 1, 3, 1, 2, 1, 3]).complement()
[3, 1, 3, 3, 1, 1]
```

conjugate()

Returns the conjugate of the composition comp.

Algorithm from mupad-combinat.

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).conjugate()
[1, 1, 3, 3, 1, 3]
```

descents(*final_descent=False*)

Returns the list of descents of the composition co.

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).descents()
[0, 1, 4, 5, 7, 8, 11]
```

is_finer(*co2*)

Returns True if the composition self is finer than the composition co2; otherwise, it returns False.

EXAMPLES:

```
sage: Composition([4,1,2]).is_finer([3,1,3])
False
sage: Composition([3,1,3]).is_finer([4,1,2])
False
sage: Composition([1,2,2,1,1,2]).is_finer([5,1,3])
True
sage: Composition([2,2,2]).is_finer([4,2])
True
```

major_index()

Returns the major index of the composition co. The major index is defined as the sum of the descents.

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).major_index()
31
```

peaks()

Returns a list of the peaks of the composition self. The peaks of a composition are the descents which do not immediately follow another descent.

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).peaks()
[4, 7]
```

refinement(*co2*)

Returns the refinement composition of self and co2.

EXAMPLES:

```
sage: Composition([1,2,2,1,1,2]).refinement([5,1,3])
[3, 1, 2]
```

to_code()

Returns the code of the composition self. The code of a composition is a list of length self.size() of 1s and 0s such that there is a 1 wherever a new part starts.

EXAMPLES:

```
sage: Composition([4,1,2,3,5]).to_code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
```

to_skew_partition(*overlap=1*)

Returns the skew partition obtained from the composition co. The parameter overlap indicates the number of boxes that are covered by boxes of the previous line.

EXAMPLES:

```
sage: Composition([3,4,1]).to_skew_partition()
[[6, 6, 3], [5, 2]]
sage: Composition([3,4,1]).to_skew_partition(overlap=0)
[[8, 7, 3], [7, 3]]
```

Compositions(*n=None, **kwargs*)

Returns the combinatorial class of compositions.

EXAMPLES: If n is not specified, it returns the combinatorial class of all (non-negative) integer compositions.

```
sage: Compositions()
Compositions of non-negative integers
sage: [] in Compositions()
True
sage: [2,3,1] in Compositions()
True
sage: [-2,3,1] in Compositions()
False
```

If n is specified, it returns the class of compositions of n.

```
sage: Compositions(3)
Compositions of 3
sage: Compositions(3).list()
[[1, 1, 1], [1, 2], [2, 1], [3]]
sage: Compositions(3).cardinality()
4
```

In addition, the following constraints can be put on the compositions: length, min_part, max_part, min_length, max_length, min_slope, max_slope, inner, and outer. For example,

```
sage: Compositions(3, length=2).list()
[[1, 2], [2, 1]]
sage: Compositions(4, max_slope=0).list()
[[1, 1, 1, 1], [2, 1, 1], [2, 2], [3, 1], [4]]
```

class **Compositions_all**()

object_class()

class **Compositions_constraints**(*n, **kwargs*)

cardinality()

EXAMPLES:

```
sage: Compositions(4, length=2).cardinality()
3
sage: Compositions(4, min_length=2).cardinality()
7
sage: Compositions(4, max_length=2).cardinality()
4
sage: Compositions(4, max_part=2).cardinality()
5
sage: Compositions(4, min_part=2).cardinality()
2
sage: Compositions(4, outer=[3,1,2]).cardinality()
3
```

list()

Returns a list of all the compositions of n.

EXAMPLES:

```
sage: Compositions(4, length=2).list()
[[1, 3], [2, 2], [3, 1]]
sage: Compositions(4, min_length=2).list()
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1]]
sage: Compositions(4, max_length=2).list()
[[1, 3], [2, 2], [3, 1], [4]]
sage: Compositions(4, max_part=2).list()
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [2, 2]]
sage: Compositions(4, min_part=2).list()
[[2, 2], [4]]
sage: Compositions(4, outer=[3,1,2]).list()
[[1, 1, 2], [2, 1, 1], [3, 1]]
sage: Compositions(4, outer=[1,'inf',1]).list()
[[1, 2, 1], [1, 3]]
sage: Compositions(4, inner=[1,1,1]).list()
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1]]
sage: Compositions(4, min_slope=0).list()
[[1, 1, 1, 1], [1, 1, 2], [1, 3], [2, 2], [4]]
sage: Compositions(4, min_slope=-1, max_slope=1).list()
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [2, 2], [4]]
sage: Compositions(5, max_slope=1, min_slope=-2, min_length=2, max_length=4).list()
[[1, 1, 1, 2],
 [1, 1, 2, 1],
 [1, 2, 1, 1],
 [1, 2, 2],
 [2, 1, 1, 1],
 [2, 1, 2],
 [2, 2, 1],
 [2, 3],
 [3, 1, 1],
 [3, 2]]
sage: Compositions(5, max_slope=1, min_slope=-2, min_length=2, max_length=4, outer=[2,5,2]).
[[1, 2, 2], [2, 1, 2], [2, 2, 1], [2, 3]]
```

object_class()

class **Compositions_n**(*n*)

cardinality()

TESTS:

```
sage: Compositions(3).cardinality()
4
sage: Compositions(0).cardinality()
1
```

list()

TESTS:

```
sage: Compositions(4).list()
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1], [4]]
sage: Compositions(0).list()
[[]]
```

from_code(*code*)

Return the composition from its code.The code of a composition is a list of length self.size() of 1s and 0s such that there is a 1 wherever a new part starts.

EXAMPLES:

```
sage: import sage.combinat.composition as composition
sage: Composition([4,1,2,3,5]).to_code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: composition.from_code(_)
[4, 1, 2, 3, 5]
sage: Composition([3,1,2,3,5]).to_code()
[1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: composition.from_code(_)
[3, 1, 2, 3, 5]
```

from_descents (*descents, nps=None*)

Returns a composition from the list of descents.

EXAMPLES:

```
sage: Composition([1, 1, 3, 4, 3]).descents()
[0, 1, 4, 8, 11]
sage: sage.combinat.composition.from_descents([1,0,4,8],12)
[1, 1, 3, 4, 3]
sage: sage.combinat.composition.from_descents([1,0,4,8,11])
[1, 1, 3, 4, 3]
```

17.9 Exact Cover Problem via Dancing Links

AllExactCovers (*M*)

Utilizes A. Ajanki's DLXMatrix class to solve the exact cover problem on the matrix M (treated as a dense binary matrix).

EXAMPLES:

```
sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]])  #no exact covers
sage: for cover in AllExactCovers(M):
...       print cover
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]]) #two exact covers
sage: for cover in AllExactCovers(M):
...       print cover
[(1, 1, 0), (0, 0, 1)]
[(1, 0, 1), (0, 1, 0)]
```

class DLXMatrix (*ones, initialsolution=None*)

next ()

Search for the first solution we can find, and return it.

Knuth describes the Dancing Links algorithm recursively, though actually implementing it as a recursive algorithm is permissible only for highly restricted problems. (for example, the original author implemented this for Sudoku, and it works beautifully there)

What follows is an iterative description of DLX:

```
stack <- [(NULL)]
level <- 0
while level >= 0:
    cur <- stack[level]
    if cur = NULL:
        if R[h] = h:
            level <- level - 1
```

```
                yield solution
            else:
                cover(best_column)
                stack[level] = best_column
        else if D[cur] != C[cur]:
            if cur != C[cur]:
                delete solution[level]
                for j in L[cur], L[L[cur]], ... , while j != cur:
                    uncover(C[j])
            cur <- D[cur]
            solution[level] <- cur
            stack[level] <- cur
            for j in R[cur], R[R[cur]], ... , while j != cur:
                cover(C[j])
            level <- level + 1
            stack[level] <- (NULL)
        else:
            if C[cur] != cur:
                delete solution[level]
                for j in L[cur], L[L[cur]], ... , while j != cur:
                    uncover(C[j])
            uncover(cur)
            level <- level - 1
```

TESTS:

```
sage: from sage.combinat.dlx import *
sage: M = DLXMatrix([[1,[1,2]],[2,[2,3]],[3,[1,3]]])
sage: while 1:
...     try:
...         C = M.next()
...     except StopIteration:
...         print "StopIteration"
...         break
...     print C
StopIteration
sage: M = DLXMatrix([[1,[1,2]],[2,[2,3]],[3,[3]]])
sage: for C in M:
...       print C
[1, 3]
sage: M = DLXMatrix([[1,[1]],[2,[2,3]],[3,[2]],[4,[3]]])
sage: for C in M:
...       print C
[1, 2]
[1, 3, 4]
```

OneExactCover(*M*)

Utilizes A. Ajanki's DLXMatrix class to solve the exact cover problem on the matrix M (treated as a dense binary matrix).

EXAMPLES:

```
sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]])  #no exact covers
sage: print OneExactCover(M)
None
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]]) #two exact covers
sage: print OneExactCover(M)
[(1, 1, 0), (0, 0, 1)]
```

17.10 Dancing links C++ wrapper

AllExactCovers(*M*)

Solves the exact cover problem on the matrix M (treated as a dense binary matrix).

EXAMPLES: No exact covers:

```
sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]])
sage: print [cover for cover in AllExactCovers(M)]
[]
```

Two exact covers:

```
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]])
sage: print [cover for cover in AllExactCovers(M)]
[[(1, 1, 0), (0, 0, 1)], [(1, 0, 1), (0, 1, 0)]]
```

DLXCPP(*rows*)

Solves the Exact Cover problem by using the Dancing Links algorithm described by Knuth.

Consider a matrix M with entries of 0 and 1, and compute a subset of the rows of this matrix which sum to the vector of all 1's.

The dancing links algorithm works particularly well for sparse matrices, so the input is a list of lists of the form:

```
[
 [i_11,i_12,...,i_1r]
 ...
 [i_m1,i_m2,...,i_ms]
]
```

where M[j][i_jk] = 1.

The first example below corresponds to the matrix:

```
1110
1010
0100
0001
```

which is exactly covered by:

```
1110
0001
```

and

```
1010
0100
0001
```

If soln is a solution given by DLXCPP(rows) then

[rows[soln[0]], rows[soln[1]], ... rows[soln[len(soln)-1]]]

is an exact cover.

Solutions are given as a list

EXAMPLES:

```
sage: rows = [[0,1,2]]
sage: rows+= [[0,2]]
sage: rows+= [[1]]
sage: rows+= [[3]]
sage: print [ x for x in DLXCPP(rows) ]
[[3, 0], [3, 1, 2]]
```

OneExactCover(*M*)

Solves the exact cover problem on the matrix M (treated as a dense binary matrix).

EXAMPLES:

```
sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]])  #no exact covers
sage: print OneExactCover(M)
None
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]]) #two exact covers
sage: print OneExactCover(M)
[(1, 1, 0), (0, 0, 1)]
```

17.11 Dyck Words

AUTHORS:

- Mike Hansen
- Dan Drake (2008-05-30): DyckWordBacktracker support

DyckWord(*dw=None, noncrossing_partition=None*)

Returns a Dyck word object

EXAMPLES:

```
sage: dw = DyckWord([1, 0, 1, 0]); dw
[1, 0, 1, 0]
sage: print dw
()()
sage: print dw.height()
1
sage: dw.to_noncrossing_partition()
[[1], [2]]
```

```
sage: DyckWord('()()')
[1, 0, 1, 0]
```

```
sage: DyckWord(noncrossing_partition=[[1],[2]])
[1, 0, 1, 0]
```

class DyckWordBacktracker(*k1, k2*)

DyckWordBacktracker: this class is an iterator for all Dyck words with n opening parentheses and n - endht closing parentheses using the backtracker class. It is used by the DyckWords_size class.

This is not really meant to be called directly, partially because it fails in a couple corner cases: DWB(0) yields [0], not the empty word, and DWB(k, k+1) yields something (it shouldn't yield anything). This could be fixed with a sanity check in _rec(), but then we'd be doing the sanity check *every time* we generate new objects; instead, we do *one* sanity check in DyckWords and assume here that the sanity check has already been made.

AUTHOR:

- Dan Drake (2008-05-30)

class DyckWord_class(l)

a_statistic()

Returns the a-statistic for the Dyck word.

One can view a balanced Dyck word as a lattice path from $(0,0)$ to (n,n) in the first quadrant by letting '1's represent steps in the direction $(1,0)$ and '0's represent steps in the direction $(0,1)$. The resulting path will remain weakly above the diagonal $y = x$.

The a-statistic, or area statistic, is the number of complete squares in the integer lattice which are below the path and above the line $y = x$. The 'half-squares' directly above the line $y = x$ do not contribute to this statistic.

EXAMPLES:

```
sage: dw = DyckWord([1,0,1,0])
sage: dw.a_statistic() # 2 half-squares, 0 complete squares
0

sage: dw = DyckWord([1,1,1,0,1,1,1,0,0,0,1,1,0,0,1,0,0,0])
sage: dw.a_statistic()
19

sage: DyckWord([1,1,1,1,0,0,0,0]).a_statistic()
6
sage: DyckWord([1,1,1,0,1,0,0,0]).a_statistic()
5
sage: DyckWord([1,1,1,0,0,1,0,0]).a_statistic()
4
sage: DyckWord([1,1,1,0,0,0,1,0]).a_statistic()
3
sage: DyckWord([1,0,1,1,0,1,0,0]).a_statistic()
2
sage: DyckWord([1,1,0,1,1,0,0,0]).a_statistic()
4
sage: DyckWord([1,1,0,0,1,1,0,0]).a_statistic()
2
sage: DyckWord([1,0,1,1,1,0,0,0]).a_statistic()
3
sage: DyckWord([1,0,1,1,0,0,1,0]).a_statistic()
1
sage: DyckWord([1,0,1,0,1,1,0,0]).a_statistic()
1
sage: DyckWord([1,1,0,0,1,0,1,0]).a_statistic()
1
sage: DyckWord([1,1,0,1,0,0,1,0]).a_statistic()
2
sage: DyckWord([1,1,0,1,0,1,0,0]).a_statistic()
3
sage: DyckWord([1,0,1,0,1,0,1,0]).a_statistic()
0
```

associated_parenthesis(pos)

EXAMPLES:

```
sage: DyckWord([1, 0]).associated_parenthesis(0)
1
```

```
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(0)
1
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(1)
0
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(2)
3
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(3)
2
sage: DyckWord([1, 1, 0]).associated_parenthesis(1)
2
sage: DyckWord([1, 1]).associated_parenthesis(0)
```

b_statistic()

Returns the b-statistic for the Dyck word.

One can view a balanced Dyck word as a lattice path from $(0, 0)$ to (n, n) in the first quadrant by letting '1's represent steps in the direction $(0, 1)$ and '0's represent steps in the direction $(1, 0)$. The resulting path will remain weakly above the diagonal $y = x$.

We describe the b-statistic of such a path in terms of what is known as the "bounce path".

We can think of our bounce path as describing the trail of a billiard ball shot West from (n, n), which "bounces" down whenever it encounters a vertical step and "bounces" left when it encounters the line y = x. The bouncing ball will strike the diagonal at places $(0, 0), (j_1, j_1), (j_2, j_2), ... , (j_r-1, j_r-1), (j_r, j_r) = (n, n)$. We define the b-statistic to be the sum $\sum_{i=1}^{r-1} j_i$.

(0, 0), (j_1, j_1), (j_2, j_2), ... , (j_r-1, j_r-1), (j_r, j_r) = (n, n).

We define the b-statistic to be the sum $\sum_{i=1}^{r-1} n - j_i$.

EXAMPLES:

```
sage: dw = DyckWord([1,1,1,0,1,1,1,0,0,0,1,1,0,0,1,0,0,0])
sage: dw.b_statistic()
7

sage: DyckWord([1,1,1,1,0,0,0,0]).b_statistic()
0
sage: DyckWord([1,1,1,0,1,0,0,0]).b_statistic()
1
sage: DyckWord([1,1,1,0,0,1,0,0]).b_statistic()
2
sage: DyckWord([1,1,1,0,0,0,1,0]).b_statistic()
3
sage: DyckWord([1,0,1,1,0,1,0,0]).b_statistic()
3
sage: DyckWord([1,1,0,1,1,0,0,0]).b_statistic()
1
sage: DyckWord([1,1,0,0,1,1,0,0]).b_statistic()
2
sage: DyckWord([1,0,1,1,1,0,0,0]).b_statistic()
1
sage: DyckWord([1,0,1,1,0,0,1,0]).b_statistic()
4
sage: DyckWord([1,0,1,0,1,1,0,0]).b_statistic()
3
sage: DyckWord([1,1,0,0,1,0,1,0]).b_statistic()
5
sage: DyckWord([1,1,0,1,0,0,1,0]).b_statistic()
4
sage: DyckWord([1,1,0,1,0,1,0,0]).b_statistic()
2
```

```
sage: DyckWord([1,0,1,0,1,0,1,0]).b_statistic()
6
```

REFERENCES:

- [1] The q,t-Catalan Numbers and the Space of Diagonal Harmonics: With an Appendix on the Combinatorics of Macdonald Polynomials - James Haglund, University of Pennsylvania, Philadelphia - AMS, 2008, 167 pp.

height()

Returns the height of the Dyck word.

We view the Dyck word as a Dyck path from $(0,0)$ to $(n,0)$ in the first quadrant by letting '1's represent steps in the direction $(1,1)$ and '0's represent steps in the direction $(1,-1)$.

The height is the maximum y-coordinate reached.

EXAMPLES:

```
sage: DyckWord([]).height()
0
sage: DyckWord([1,0]).height()
1
sage: DyckWord([1, 1, 0, 0]).height()
2
sage: DyckWord([1, 1, 0, 1, 0]).height()
2
sage: DyckWord([1, 1, 0, 0, 1, 0]).height()
2
sage: DyckWord([1, 0, 1, 0]).height()
1
sage: DyckWord([1, 1, 0, 0, 1, 1, 1, 0, 0, 0]).height()
3
```

peaks()

Returns a list of the positions of the peaks of a Dyck word. A peak is 1 followed by a 0. Note that this does not agree with the definition given by Haglund in: The q,t-Catalan Numbers and the Space of Diagonal Harmonics: With an Appendix on the Combinatorics of Macdonald Polynomials - James Haglund, University of Pennsylvania, Philadelphia - AMS, 2008, 167 pp.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).peaks()
[0, 2]
sage: DyckWord([1, 1, 0, 0]).peaks()
[1]
sage: DyckWord([1,1,0,1,0,1,0,0]).peaks() # Haglund's def gives 2
[1, 3, 5]
```

size()

Returns the size of the Dyck word, which is the number of opening parentheses in the Dyck word.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).size()
2
sage: DyckWord([1, 0, 1, 1, 0]).size()
3
```

to_noncrossing_partition()

Bijection of Biane from Dyck words to non crossing partitions Thanks to Mathieu Dutour for describing the bijection.

EXAMPLES:

```
sage: DyckWord([1, 0]).to_noncrossing_partition()
[[1]]
sage: DyckWord([1, 1, 0, 0]).to_noncrossing_partition()
[[1, 2]]
sage: DyckWord([1, 1, 1, 0, 0, 0]).to_noncrossing_partition()
[[1, 2, 3]]
sage: DyckWord([1, 0, 1, 0, 1, 0]).to_noncrossing_partition()
[[1], [2], [3]]
sage: DyckWord([1, 1, 0, 1, 0, 0]).to_noncrossing_partition()
[[2], [1, 3]]
```

to_ordered_tree()

TESTS:

```
sage: DyckWord([1, 1, 0, 0]).to_ordered_tree()
...
NotImplementedError: TODO
```

to_tableau()

EXAMPLES:

```
sage: DyckWord([]).to_tableau()
[]
sage: DyckWord([1, 0]).to_tableau()
[[2], [1]]
sage: DyckWord([1, 1, 0, 0]).to_tableau()
[[3, 4], [1, 2]]
sage: DyckWord([1, 0, 1, 0]).to_tableau()
[[2, 4], [1, 3]]
sage: DyckWord([1]).to_tableau()
[[1]]
sage: DyckWord([1, 0, 1]).to_tableau()
[[2], [1, 3]]
```

to_triangulation()

TESTS:

```
sage: DyckWord([1, 1, 0, 0]).to_triangulation()
...
NotImplementedError: TODO
```

DyckWords(*k1=None, k2=None*)

Returns the combinatorial class of Dyck words. A Dyck word is a sequence $(w_1, ..., w_n)$ consisting of '1's and '0's, with the property that for any i with $1 \leq i \leq n$, the sequence $(w_1, ..., w_i)$ contains at least as many 1 s as 0 .

A Dyck word is balanced if the total number of '1's is equal to the total number of '0's. The number of balanced Dyck words of length $2k$ is given by the Catalan number C_k.

EXAMPLES: If neither k1 nor k2 are specified, then DyckWords returns the combinatorial class of all balanced Dyck words.

```
sage: DW = DyckWords(); DW
Dyck words
sage: [] in DW
True
sage: [1, 0, 1, 0] in DW
True
sage: [1, 1, 0] in DW
False
```

If just k1 is specified, then it returns the combinatorial class of balanced Dyck words with k1 opening parentheses and k1 closing parentheses.

```
sage: DW2 = DyckWords(2); DW2
Dyck words with 2 opening parentheses and 2 closing parentheses
sage: DW2.first()
[1, 0, 1, 0]
sage: DW2.last()
[1, 1, 0, 0]
sage: DW2.cardinality()
2
sage: DyckWords(100).cardinality() == catalan_number(100)
True
```

If k2 is specified in addition to k1, then it returns the combinatorial class of Dyck words with k1 opening parentheses and k2 closing parentheses.

```
sage: DW32 = DyckWords(3,2); DW32
Dyck words with 3 opening parentheses and 2 closing parentheses
sage: DW32.list()
[[1, 0, 1, 0, 1],
 [1, 0, 1, 1, 0],
 [1, 1, 0, 0, 1],
 [1, 1, 0, 1, 0],
 [1, 1, 1, 0, 0]]
```

class DyckWords_all()

class DyckWords_size(*k1, k2=None*)

cardinality()

Returns the number of Dyck words of size n, i.e. the n-th Catalan number.

EXAMPLES:

```
sage: DyckWords(4).cardinality()
14
sage: ns = range(9)
sage: dws = [DyckWords(n) for n in ns]
sage: all([ dw.cardinality() == len(dw.list()) for dw in dws])
True
```

list()

Returns a list of all the Dyck words with k1 opening and k2 closing parentheses.

EXAMPLES:

```
sage: DyckWords(0).list()
[[]]
sage: DyckWords(1).list()
[[1, 0]]
sage: DyckWords(2).list()
[[1, 0, 1, 0], [1, 1, 0, 0]]
```

from_noncrossing_partition(*ncp*)

TESTS:

```
sage: DyckWord(noncrossing_partition=[[1,2]]) # indirect doctest
[1, 1, 0, 0]
sage: DyckWord(noncrossing_partition=[[1],[2]])
[1, 0, 1, 0]
```

```
sage: dws = DyckWords(5).list()
sage: ncps = map( lambda x: x.to_noncrossing_partition(), dws)
sage: dws2 = map( lambda x: DyckWord(noncrossing_partition=x), ncps)
sage: dws == dws2
True
```

from_ordered_tree(*tree*)

TESTS:

```
sage: sage.combinat.dyck_word.from_ordered_tree(1)
...
NotImplementedError: TODO
```

is_a(*obj, k1=None, k2=None*)

If k1 is specified, then the object must have exactly k1 open symbols. If k2 is also specified, then obj must have exactly k2 close symbols.

EXAMPLES:

```
sage: from sage.combinat.dyck_word import is_a
sage: is_a([1,1,0,0])
True
sage: is_a([1,0,1,0])
True
sage: is_a([1,1,0,0],2)
True
sage: is_a([1,1,0,0],3)
False
```

is_a_prefix(*obj, k1=None, k2=None*)

If k1 is specified, then the object must have exactly k1 open symbols. If k2 is also specified, then obj must have exactly k2 close symbols.

EXAMPLES:

```
sage: from sage.combinat.dyck_word import is_a_prefix
sage: is_a_prefix([1,1,0])
True
sage: is_a_prefix([0,1,0])
False
sage: is_a_prefix([1,1,0],2,1)
True
sage: is_a_prefix([1,1,0],1,1)
False
```

replace_parens(*x*)

EXAMPLES:

```
sage: from sage.combinat.dyck_word import replace_parens
sage: replace_parens('(')
1
sage: replace_parens(')')
0
sage: replace_parens(1)
...
ValueError
```

replace_symbols(*x*)
EXAMPLES:

```
sage: from sage.combinat.dyck_word import replace_symbols
sage: replace_symbols(1)
'('
sage: replace_symbols(0)
')'
sage: replace_symbols(3)
...
ValueError
```

17.12 Finite combinatorial classes

class **FiniteCombinatorialClass**(*l*)

INPUT: • l a list or iterable

Returns l, wrapped as a combinatorial class

EXAMPLES:

```
sage: F = FiniteCombinatorialClass([1,2,3])
sage: F.list()
[1, 2, 3]
sage: F.cardinality()
3
sage: F.random_element()
1
sage: F.first()
1
sage: F.last()
3
```

cardinality()
EXAMPLES:

```
sage: F = FiniteCombinatorialClass([1,2,3])
sage: F.cardinality()
3
```

keys()
EXAMPLES: sage: F = FiniteCombinatorialClass([1,2,3]) sage: F.keys() [0, 1, 2]

list()
TESTS:

```
sage: F = FiniteCombinatorialClass([1,2,3])
sage: F.list()
[1, 2, 3]
```

object_class(*x*)
EXAMPLES:

```
sage: F = FiniteCombinatorialClass([1,2,3])
sage: F.object_class(1)
1
```

class **FiniteCombinatorialClass_l**(*l*)

INPUT: • l a list or iterable

Returns l, wrapped as a combinatorial class

EXAMPLES:

```
sage: F = FiniteCombinatorialClass([1,2,3])
sage: F.list()
[1, 2, 3]
sage: F.cardinality()
3
sage: F.random_element()
1
sage: F.first()
1
sage: F.last()
3
```

cardinality()

EXAMPLES:

```
sage: F = FiniteCombinatorialClass([1,2,3])
sage: F.cardinality()
3
```

keys()

EXAMPLES: sage: F = FiniteCombinatorialClass([1,2,3]) sage: F.keys() [0, 1, 2]

list()

TESTS:

```
sage: F = FiniteCombinatorialClass([1,2,3])
sage: F.list()
[1, 2, 3]
```

object_class(*x*)

EXAMPLES:

```
sage: F = FiniteCombinatorialClass([1,2,3])
sage: F.object_class(1)
1
```

17.13 Tools for generating lists of integers in lexicographic order.

IMPORTANT NOTE (2009/02): The internal functions in this file will be deprecated soon. Please only use them through IntegerListsLex.

class IntegerListsLex(*n, length=None, min_length=0, max_length=+Infinity, floor=None, ceiling=None, min_part=0, max_part=+Infinity, min_slope=-Infinity, max_slope=+Infinity, name=None, element_constructor=None*)

A combinatorial class C for integer lists satisfying certain sum, length, upper/lower bound and regularity constraints. The purpose of this tool is mostly to provide a Constant Amortized Time iterator through those lists, in lexicographic order.

INPUT:

- `n` - a non negative integer
- `min_length` - a non negative integer
- `max_length` - an integer or ∞

- `length` - an integer; overrides min_length and max_length if specified
- `floor` - a function f (or list); defaults to `lambda i: 0`
- `ceiling` - a function f (or list); defaults to `lambda i: infinity`
- `min_slope` - an integer or $-\infty$; defaults to $-\infty$
- `max_slope` - an integer or $+\infty$; defaults to $+\infty$

An *integer list* is a list l of nonnegative integers, its *parts*. The *length* of l is the number of its parts; the *sum* of l is the sum of its parts.

Note: Two valid integer lists are considered equivalent if they only differ by trailing zeroes. In this case, only the list with the least number of trailing zeroes will be produced.

The constraints on the lists are as follow:

- Sum: $sum(l) == n$
- Length: $min\_length \leq len(l) \leq max\_length$
- Lower and upper bounds: $floor(i) \leq l[i] \leq ceiling(i)$, for $i = 0, \ldots, len(l)$
- Regularity condition: $minSlope \leq l[i+1] - l[i] \leq maxSlope$, for $i = 0, \ldots, len(l) - 1$

This is a generic low level tool. The interface has been designed with efficiency in mind. It is subject to incompatible changes in the future. More user friendly interfaces are provided by high level tools like Partitions or Compositions.

EXAMPLES:

We create the combinatorial class of lists of length 3 and sum 2:

```
sage: C = IntegerListsLex(2, length=3)
sage: C
Integer lists of sum 2 satisfying certain constraints
sage: C.cardinality()
6
sage: [p for p in C]
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]

sage: [2, 0, 0] in C
True
sage: [2, 0, 1] in C
False
sage: "a" in C
False
sage: ["a"] in C
False

sage: C.first()
[2, 0, 0]
```

One can specify lower and upper bound on each part:

```
sage: list(IntegerListsLex(5, length = 3, floor = [1,2,0], ceiling = [3,2,3]))
[[3, 2, 0], [2, 2, 1], [1, 2, 2]]
```

Using the slope condition, one can generate integer partitions (but see `sage.combinat.partition.Partitions`):

```
sage: list(IntegerListsLex(4, max_slope=0))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

This is the list of all partitions of 7 with parts at least 2:

```
sage: list(IntegerListsLex(7, max_slope = 0, min_part = 2))
[[7], [5, 2], [4, 3], [3, 2, 2]]
```

This is the list of all partitions of 5 and length at most 3 which are bounded below by [2,1,1]:

```
sage: list(IntegerListsLex(5, max_slope = 0, max_length = 3, floor = [2,1,1]))
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1]]
```

Note that [5] is considered valid, because the lower bound constraint only apply to existing positions in the list. To obtain instead the partitions containing [2,1,1], one need to use min_length:

```
sage: list(IntegerListsLex(5, max_slope = 0, min_length = 3, max_length = 3, floor = [2,1,1]))
[[3, 1, 1], [2, 2, 1]]
```

This is the list of all partitions of 5 which are contained in [3,2,2]:

```
sage: list(IntegerListsLex(5, max_slope = 0, max_length = 3, ceiling = [3,2,2]))
[[3, 2], [3, 1, 1], [2, 2, 1]]
```

This is the list of all compositions of 4 (but see Compositions):

```
sage: list(IntegerListsLex(4, min_part = 1))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

This is the list of all integer vectors of sum 4 and length 3:

```
sage: list(IntegerListsLex(4, length = 3))
[[4, 0, 0], [3, 1, 0], [3, 0, 1], [2, 2, 0], [2, 1, 1], [2, 0, 2], [1, 3, 0], [1, 2, 1], [1, 1,
```

There are all the lists of sum 4 and length 4 such that l[i] <= i:

```
sage: list(IntegerListsLex(4, length=4, ceiling=lambda i: i))
[[0, 1, 2, 1], [0, 1, 1, 2], [0, 1, 0, 3], [0, 0, 2, 2], [0, 0, 1, 3]]
```

This is the list of all monomials of degree 4 which divide the monomial $x^3y^1z^2$ (a monomial being identified with its exponent vector):

```
sage: R.<x,y,z> = QQ[]
sage: m = [3,1,2]
sage: def term(exponents):
...       return x^exponents[0] * y^exponents[1] * z^exponents[2]
...
sage: list( IntegerListsLex(4, length = len(m), ceiling = m, element_constructor = term) )
[x^3*y, x^3*z, x^2*y*z, x^2*z^2, x*y*z^2]
```

Note the use of the element_constructor feature.

In general, the complexity of the iteration algorithm is constant time amortized for each integer list produced. There is one degenerate case though where the algorithm may run forever without producing anything. If max_length is $+\infty$ and max_slope > 0, testing whether there exists a valid integer list of sum n may be only semi-decidable. In the following example, the algorithm will enter an infinite loop, because it needs to decide whether $ceiling(i)$ is nonzero for some i:

```
sage: list( IntegerListsLex(1, ceiling = lambda i: 0) ) # todo: not implemented
```

Note: Caveat: counting is done by brute force generation. In some special cases, it would be possible to do better by counting techniques for integral point in polytopes.

Note: Caveat: with the current implementation, the constraints should satisfy the following conditions:

- The upper and lower bounds themselves should satisfy the slope constraints.
- The maximal and minimal slopes values should not be equal.
- The maximal and minimal part values should not be equal.

Those conditions are not checked by the algorithm, and the result may be completely incorrect if they are not satisfied:

In the following example, the slope condition is not satisfied by the upper bound on the parts, and [3,3] is erroneously included in the result:

```
sage: list(IntegerListsLex(6, max_part=3,max_slope=-1))
[[3, 3], [3, 2, 1]]
```

With some work, this could be fixed withoug affecting the overall complexity and efficiency. Also, the generation algorithm could be extended to deal with non-constant slope constraints and with negative parts, as well as to accept a range parameter instead of a single integer for the sum n of the lists (the later was readilly implemented in MuPAD-Combinat). Encouragements, suggestions, and help are welcome.

TODO: integrate all remaining tests from http://mupad-combinat.svn.sourceforge.net/viewvc/mupad-combinat/trunk/MuPAD-Combinat/lib/COMBINAT/TEST/MachineIntegerListsLex.tst

TESTS:

```

build_args()

Returns a list of arguments that can be passed into the prexisting first,next,is_a, ... functions in this module. n is currently not included in this list.

EXAMPLES:

```
sage: C = IntegerListsLex(2, length=3)
sage: C.build_args()
[3,
 3,
 <function <lambda> at 0x...>,
 <function <lambda> at 0x...>,
 -Infinity,
```

```
 +Infinity]
```

ceiling(*i*)

Returns the maximum part that can appear in the $i^{th} position in any list produced.

EXAMPLES:

```
sage: C = IntegerListsLex(4, length=2, max_part=3)
sage: C.ceiling(0)
3
sage: C = IntegerListsLex(4, length=2, ceiling=[3,2])
sage: C.ceiling(0)
3
sage: C.ceiling(1)
2
```

count()

Default brute force implementation of count by iteration through all the objects.

Note that this skips the call to _element_constructor, unlike the default implementation from CombinatorialClass

TODO: do the iteration in place to save on copying time

first()

Returns the lexicographically maximal element in this combinatorial class.

EXAMPLES:

```
sage: C = IntegerListsLex(2, length=3)
sage: C.first()
[2, 0, 0]
```

floor(*i*)

Returns the minimum part that can appear in the i^{th} position in any list produced.

EXAMPLES:

```
sage: C = IntegerListsLex(4, length=2, min_part=1)
sage: C.floor(0)
1
sage: C = IntegerListsLex(4, length=2, floor=[1,2])
sage: C.floor(0)
1
sage: C.floor(1)
2
```

comp2ceil(*c, min_slope, max_slope*)

Given a composition, returns the lowest regular function N->N below it.

EXAMPLES:

```
sage: from sage.combinat.integer_list import comp2ceil
sage: f = comp2ceil([2, 1, 1],-1,0)
sage: [f(i) for i in range(10)]
[2, 1, 1, 1, 2, 3, 4, 5, 6, 7]
```

comp2floor(*f, min_slope, max_slope*)

Given a composition, returns the lowest regular function N->N above it.

EXAMPLES:

```
sage: from sage.combinat.integer_list import comp2floor
sage: f = comp2floor([2, 1, 1],-1,0)
```

```
sage: [f(i) for i in range(10)]
[2, 1, 1, 1, 2, 3, 4, 5, 6, 7]
```

first(*n, min_length, max_length, floor, ceiling, min_slope, max_slope*)

Returns the lexicographically smallest valid composition of n satisfying the conditions.

> **Warning:** INTERNAL FUNCTION! DO NOT USE DIRECTLY!

Preconditions:

- minslope < maxslope
- floor and ceiling need to satisfy the slope constraints, e.g. be obtained fromcomp2floor or comp2ceil
- floor must be below ceiling to ensure the existence a valid composition

TESTS:

```
sage: import sage.combinat.integer_list as integer_list
sage: f = lambda l: lambda i: l[i-1]
sage: f([0,1,2,3,4,5])(1)
0
sage: integer_list.first(12, 4, 4, f([0,0,0,0]), f([4,4,4,4]), -1, 1)
[4, 3, 3, 2]
sage: integer_list.first(36, 9, 9, f([3,3,3,2,1,1,0,0,0]), f([7,6,5,5,5,5,5,4,4]), -1, 1)
[7, 6, 5, 5, 4, 3, 3, 2, 1]
sage: integer_list.first(25, 9, 9, f([3,3,3,2,1,1,0,0,0]), f([7,6,5,5,5,5,5,4,4]), -2, 1)
[7, 6, 5, 4, 2, 1, 0, 0, 0]
sage: integer_list.first(36, 9, 9, f([3,3,3,2,1,4,2,0,0]), f([7,6,5,5,5,5,5,4,4]), -2, 1)
[7, 6, 5, 5, 5, 4, 3, 1, 0]
```

is_a(*comp, min_length, max_length, floor, ceiling, min_slope, max_slope*)

Returns True if comp meets the constraints imposed by the arguments.

> **Warning:** INTERNAL FUNCTION! DO NOT USE DIRECTLY!

EXAMPLES:

```
sage: from sage.combinat.integer_list import is_a
sage: IV = IntegerVectors(2,3,min_slope=0)
sage: params = IV._parameters()
sage: all([is_a(iv, *params) for iv in IV])
True
```

iterator(*n, min_length, max_length, floor, ceiling, min_slope, max_slope*)

> **Warning:** INTERNAL FUNCTION! DO NOT USE DIRECTLY!

EXAMPLES:

```
sage: from sage.combinat.integer_list import iterator
sage: IV = IntegerVectors(2,3,min_slope=0)
sage: params = IV._parameters()
sage: list(iterator(2,*params))
[[0, 1, 1], [0, 0, 2]]
```

list(*n, min_length, max_length, floor, ceiling, min_slope, max_slope*)

Warning: THIS FUNCTION IS DEPRECATED!

Please use IntegersListsLex(...) instead

EXAMPLES:

```
sage: import sage.combinat.integer_list as integer_list
sage: g = lambda x: lambda i: x

```

lower_regular (*comp, min_slope, max_slope*)

Returns the uppest regular composition below comp

TESTS:

```
sage: import sage.combinat.integer_list as integer_list
sage: integer_list.lower_regular([4,2,6], -1, 1)
[3, 2, 3]
sage: integer_list.lower_regular([4,2,6], -1, infinity)
[3, 2, 6]
sage: integer_list.lower_regular([1,4,2], -1, 1)
[1, 2, 2]
sage: integer_list.lower_regular([4,2,6,3,7], -2, 1)
[4, 2, 3, 3, 4]
sage: integer_list.lower_regular([4,2,infinity,3,7], -2, 1)
[4, 2, 3, 3, 4]
sage: integer_list.lower_regular([1, infinity, 2], -1, 1)
[1, 2, 2]
sage: integer_list.lower_regular([infinity, 4, 2], -1, 1)
[4, 3, 2]
```

next (*comp, min_length, max_length, floor, ceiling, min_slope, max_slope*)

Returns the next integer list after comp that satisfies the constraints.

> **Warning:** INTERNAL FUNCTION! DO NOT USE DIRECTLY!

EXAMPLES:

```
sage: from sage.combinat.integer_list import next
sage: IV = IntegerVectors(2,3,min_slope=0)
```

```
sage: params = IV._parameters()
sage: next([0,1,1], *params)
[0, 0, 2]
```

rightmost_pivot(*comp, min_length, max_length, floor, ceiling, min_slope, max_slope*)

TESTS:

```
sage: import sage.combinat.integer_list as integer_list
sage: f = lambda l: lambda i: l[i-1]
sage: integer_list.rightmost_pivot([7,6,5,5,4,3,3,2,1], 9, 9, f([3,3,3,2,1,1,0,0,0]), f([7,6,5,5
[7, 2]
sage: integer_list.rightmost_pivot([7,6,5,5,4,3,3,2,1], 9, 9,f([3,3,3,2,1,1,0,0,0]), f([7,6,5,5,
[7, 1]
sage: integer_list.rightmost_pivot([7,6,5,5,4,3,3,2,1], 9, 9,f([3,3,3,2,1,1,0,0,0]), f([7,6,5,5,
[8, 1]
sage: integer_list.rightmost_pivot([7,6,5,5,4,3,3,2,1], 9, 9,f([3,3,3,2,1,1,0,0,0]), f([7,6,5,5,
[8, 1]
sage: integer_list.rightmost_pivot([7,6,5,5,5,5,5,4,4], 9, 9,f([3,3,3,2,1,1,0,0,0]), f([7,6,5,5,
sage: integer_list.rightmost_pivot([3,3,3,2,1,1,0,0,0], 9, 9,f([3,3,3,2,1,1,0,0,0]), f([7,6,5,5,
sage: g = lambda x: lambda i: x
sage: integer_list.rightmost_pivot([1],1,1,g(0),g(2),-10, 10)

sage: integer_list.rightmost_pivot([3,2],2,3,g(2),g(2),-10,+10)
sage: integer_list.rightmost_pivot([3,3],2,3,g(2),g(2),-10,+10)
[1, 2]
sage: integer_list.rightmost_pivot([6],1,3,g(0),g(6),-1,0)
[1, 0]
sage: integer_list.rightmost_pivot([6],1,3,g(0),g(6),-2,0)
[1, 0]
sage: integer_list.rightmost_pivot([7,9,8,7],1,5,g(0),g(10),-1,10)
[2, 6]
sage: integer_list.rightmost_pivot([7,9,8,7],1,5,g(5),g(10),-10,10)
[3, 5]
sage: integer_list.rightmost_pivot([7,9,8,7],1,5,g(5),g(10),-1,10)
[2, 6]
sage: integer_list.rightmost_pivot([7,9,8,7],1,5,g(4),g(10),-2,10)
[3, 7]
sage: integer_list.rightmost_pivot([9,8,7],1,4,g(4),g(10),-2,0)
[1, 4]
sage: integer_list.rightmost_pivot([1,3],1,5,lambda i: i,g(10),-10,10)
sage: integer_list.rightmost_pivot([1,4],1,5,lambda i: i,g(10),-10,10)
sage: integer_list.rightmost_pivot([2,4],1,5,lambda i: i,g(10),-10,10)
[1, 1]
```

upper_bound(*min_length, max_length, floor, ceiling, min_slope, max_slope*)

Compute a coarse upper bound on the size of a vector satisfying the constraints.

TESTS:

```
sage: import sage.combinat.integer_list as integer_list
sage: f = lambda x: lambda i: x
sage: integer_list.upper_bound(0,4,f(0), f(1),-infinity,infinity)
4
```

```
sage: integer_list.upper_bound(0, infinity, f(0), f(1), -infinity, infinity)
+Infinity
sage: integer_list.upper_bound(0, infinity, f(0), f(1), -infinity, -1)
1
sage: integer_list.upper_bound(0, infinity, f(0), f(5), -infinity, -1)
15
sage: integer_list.upper_bound(0, infinity, f(0), f(5), -infinity, -2)
9
```

upper_regular (*comp, min_slope, max_slope*)

Returns the uppest regular composition above comp.

TESTS:

```
sage: import sage.combinat.integer_list as integer_list
sage: integer_list.upper_regular([4,2,6],-1,1)
[4, 5, 6]
sage: integer_list.upper_regular([4,2,6],-2, 1)
[4, 5, 6]
sage: integer_list.upper_regular([4,2,6,3,7],-2, 1)
[4, 5, 6, 6, 7]
sage: integer_list.upper_regular([4,2,6,1], -2, 1)
[4, 5, 6, 4]
```

17.14 Integer vectors

IntegerVectors (*n=None, k=None, **kwargs*)

Returns the combinatorial class of integer vectors.

EXAMPLES: If n is not specified, it returns the class of all integer vectors.

```
sage: IntegerVectors()
Integer vectors
sage: [] in IntegerVectors()
True
sage: [1,2,1] in IntegerVectors()
True
sage: [1, 0, 0] in IntegerVectors()
True
```

If n is specified, then it returns the class of all integer vectors which sum to n.

```
sage: IV3 = IntegerVectors(3); IV3
Integer vectors that sum to 3
```

Note that trailing zeros are ignored so that [3, 0] does not show up in the following list (since [3] does)

```
sage: IntegerVectors(3, max_length=2).list()
[[3], [2, 1], [1, 2], [0, 3]]
```

If n and k are both specified, then it returns the class of integer vectors that sum to n and are of length k.

```
sage: IV53 = IntegerVectors(5,3); IV53
Integer vectors of length 3 that sum to 5
sage: IV53.cardinality()
21
```

```
sage: IV53.first()
[5, 0, 0]
sage: IV53.last()
[0, 0, 5]
sage: IV53.random_element()
[4, 0, 1]
```

class **IntegerVectors_all**()

cardinality()
EXAMPLES:

```
sage: IntegerVectors().cardinality()
+Infinity
```

list()
EXAMPLES:

```
sage: IntegerVectors().list()
...
NotImplementedError: infinite list
```

class **IntegerVectors_nconstraints**(*n, constraints*)

cardinality()
EXAMPLES:

```
sage: IntegerVectors(3, max_length=2).cardinality()
4
sage: IntegerVectors(3).cardinality()
+Infinity
```

list()
EXAMPLES:

```
sage: IntegerVectors(3, max_length=2).list()
[[3], [2, 1], [1, 2], [0, 3]]
sage: IntegerVectors(3).list()
...
NotImplementedError: infinite list
```

class **IntegerVectors_nk**(*n, k*)

list()
EXAMPLE:

```
sage: IV = IntegerVectors(2,3)
sage: IV.list()
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
sage: IntegerVectors(3, 0).list()
[]
sage: IntegerVectors(3, 1).list()
[[3]]
sage: IntegerVectors(0, 1).list()
[[0]]
sage: IntegerVectors(0, 2).list()
[[0, 0]]
```

```
sage: IntegerVectors(2, 2).list()
[[2, 0], [1, 1], [0, 2]]
```

class IntegerVectors_nkconstraints(*n, k, constraints*)

cardinality()
EXAMPLES:

```
sage: IntegerVectors(3,3, min_part=1).cardinality()
1
sage: IntegerVectors(5,3, min_part=1).cardinality()
6
sage: IntegerVectors(13, 4, min_part=2, max_part=4).cardinality()
16
```

first()
EXAMPLES:

```
sage: IntegerVectors(2,3,min_slope=0).first()
[0, 1, 1]
```

next(*x*)
EXAMPLES:

```
sage: IntegerVectors(2,3,min_slope=0).last()
[0, 0, 2]
```

class IntegerVectors_nnondescents(*n, comp*)
The combinatorial class of integer vectors v graded by two parameters:

- n: the sum of the parts of v
- comp: the non descents composition of v

In other words: the length of v equals c[1]+...+c[k], and v is decreasing in the consecutive blocs of length c[1], ..., c[k]

Those are the integer vectors of sum n which are lexicographically maximal (for the natural left->right reading) in their orbit by the young subgroup S_c_1 x x S_c_k. In particular, they form a set of orbit representative of integer vectors w.r.t. this young subgroup.

constant_func(*i*)
Returns the constant function i.

EXAMPLES:

```
sage: f = sage.combinat.integer_vector.constant_func(3)
sage: f(-1)
3
sage: f('asf')
3
```

list2func(*l, default=None*)
Given a list l, return a function that takes in a value i and return l[i-1]. If default is not None, then the function will return the default value for out of range i's.

EXAMPLES:

```
sage: f = sage.combinat.integer_vector.list2func([1,2,3])
sage: f(1)
1
```

```
sage: f(2)
2
sage: f(3)
3
sage: f(4)
...
IndexError: list index out of range

sage: f = sage.combinat.integer_vector.list2func([1,2,3], 0)
sage: f(3)
3
sage: f(4)
0
```

17.15 Weighted Integer Vectors

WeightedIntegerVectors(*n, weight*)

Returns the combinatorial class of integer vectors of n weighted by weight.

EXAMPLES:

```
sage: WeightedIntegerVectors(8, [1,1,2])
Integer vectors of 8 weighted by [1, 1, 2]
sage: WeightedIntegerVectors(8, [1,1,2]).first()
[0, 0, 4]
sage: WeightedIntegerVectors(8, [1,1,2]).last()
[8, 0, 0]
sage: WeightedIntegerVectors(8, [1,1,2]).cardinality()
25
sage: WeightedIntegerVectors(8, [1,1,2]).random_element()
[1, 1, 3]
```

class **WeightedIntegerVectors_nweight**(*n, weight*)

list()

TESTS:

```
sage: WeightedIntegerVectors(7, [2,2]).list()
[]
sage: WeightedIntegerVectors(3, [2,1,1]).list()
[[1, 0, 1], [1, 1, 0], [0, 0, 3], [0, 1, 2], [0, 2, 1], [0, 3, 0]]

sage: ivw = [ WeightedIntegerVectors(k, [1,1,1]) for k in range(11) ]
sage: iv  = [ IntegerVectors(k, 3) for k in range(11) ]
sage: all( [ sorted(iv[k].list()) == sorted(ivw[k].list()) for k in range(11) ] )
True

sage: ivw = [ WeightedIntegerVectors(k, [2,3,7]) for k in range(11) ]
sage: all( [ i.cardinality() == len(i.list()) for i in ivw] )
True
```

17.16 Restricted growth arrays

class RestrictedGrowthArrays(*n*)

cardinality()
EXAMPLES:

```
sage: from sage.combinat.restricted_growth import RestrictedGrowthArrays
sage: R = RestrictedGrowthArrays(6)
sage: R.cardinality()
203
```

17.17 Yamanouchi Words

A right (respectively left) Yamanouchi word on a completely ordered alphabet, for instance [1,2,...,n], is a word math such that any right (respectively left) factor of math contains more entries math than math. For example, the word [2, 3, 2, 2, 1, 3, 1, 2, 1, 1] is a right Yamanouchi one.

The evaluation of a word math encodes the number of occurrences of each letter of math. In the case of Yamanouchi words, the evaluation is a partition. For example, the word [2, 3, 2, 2, 1, 3, 1, 2, 1, 1] has evaluation [4, 4, 2].

Yamanouchi words can be useful in the computation of Littlewood-Richardson coefficients $c^{\nu}_{\lambda,\mu}$. According to the Littlewood-Richardson rule, $c^{\nu}_{\lambda,\mu}$ is the number of skew tableaux of shape ν/λ and evaluation μ, whose row readings are Yamanouchi words.

17.18 Paths in Directed Acyclic Graphs

GraphPaths(*g, source=None, target=None*)
Returns the combinatorial class of paths in the directed acyclic graph g.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
```

If source and target are not given, then the returned class contains all paths (including trivial paths containing only one vertex).

```
sage: p = GraphPaths(G); p
Paths in Multi-digraph on 5 vertices
sage: p.cardinality()
37
sage: p.random_element()
[1, 2, 3, 4, 5]
```

If the source is specified, then the returned class contains all of the paths starting at the vertex source (including the trivial path).

```
sage: p = GraphPaths(G, source=3); p
Paths in Multi-digraph on 5 vertices starting at 3
sage: p.list()
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]
```

If the target is specified, then the returned class contains all of the paths ending at the vertex target (including the trivial path).

```
sage: p = GraphPaths(G, target=3); p
Paths in Multi-digraph on 5 vertices ending at 3
sage: p.cardinality()
5
sage: p.list()
[[3], [1, 3], [2, 3], [1, 2, 3], [1, 2, 3]]
```

If both the target and source are specified, then the returned class contains all of the paths from source to target.

```
sage: p = GraphPaths(G, source=1, target=3); p
Paths in Multi-digraph on 5 vertices starting at 1 and ending at 3
sage: p.cardinality()
3
sage: p.list()
[[1, 2, 3], [1, 2, 3], [1, 3]]
```

Note that G must be a directed acyclic graph.

```
sage: G = DiGraph({1:[2,2,3,5], 2:[3,4], 3:[4], 4:[2,5,7], 5:[6]}, multiedges=True)
sage: GraphPaths(G)
...
TypeError: g must be a directed acyclic graph
```

class GraphPaths_all(*g*)

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.cardinality()
37
```

list()

Returns a list of the paths of self.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: len(GraphPaths(G).list())
37
```

class GraphPaths_common()

incoming_edges(*v*)

Returns a list of v's incoming edges.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.incoming_edges(2)
[(1, 2, None), (1, 2, None)]
```

incoming_paths(*v*)

Returns a list of paths that end at v.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.incoming_paths(2)
[[2], [1, 2], [1, 2]]
```

outgoing_edges(*v*)
Returns a list of v's outgoing edges.
EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.outgoing_edges(2)
[(2, 3, None), (2, 4, None)]
```

outgoing_paths(*v*)
Returns a list of the paths that start at v.
EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.outgoing_paths(3)
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]
sage: gp.outgoing_paths(2)
[[2],
 [2, 3],
 [2, 3, 4],
 [2, 3, 4, 5],
 [2, 3, 4, 5],
 [2, 4],
 [2, 4, 5],
 [2, 4, 5]]
```

paths()
Returns a list of all the paths of self.
EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: len(gp.paths())
37
```

paths_from_source_to_target(*source, target*)
Returns a list of paths from source to target.
EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.paths_from_source_to_target(2,4)
[[2, 3, 4], [2, 4]]
```

class **GraphPaths_s**(*g, source*)

list()
EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G, 4)
sage: p.list()
[[4], [4, 5], [4, 5]]
```

class **GraphPaths_st**(*g, source, target*)
EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: GraphPaths(G,1,2).cardinality()
2
sage: GraphPaths(G,1,3).cardinality()
3
sage: GraphPaths(G,1,4).cardinality()
5
sage: GraphPaths(G,1,5).cardinality()
10
sage: GraphPaths(G,2,3).cardinality()
1
sage: GraphPaths(G,2,4).cardinality()
2
sage: GraphPaths(G,2,5).cardinality()
4
sage: GraphPaths(G,3,4).cardinality()
1
sage: GraphPaths(G,3,5).cardinality()
2
sage: GraphPaths(G,4,5).cardinality()
2
```

list()

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G,1,2)
sage: p.list()
[[1, 2], [1, 2]]
```

class GraphPaths_t(*g*, *target*)

list()

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G, target=4)
sage: p.list()
[[4],
 [2, 4],
 [1, 2, 4],
 [1, 2, 4],
 [3, 4],
 [1, 3, 4],
 [2, 3, 4],
 [1, 2, 3, 4],
 [1, 2, 3, 4]]
```

17.19 Latin Squares

A *latin square* of order n is an $n \times n$ array such that each symbol $s \in \{0, 1, \ldots, n-1\}$ appears precisely once in each row, and precisely once in each column. A *partial latin square* of order n is an $n \times n$ array such that each symbol $s \in \{0, 1, \ldots, n-1\}$ appears at most once in each row, and at most once in each column. Empty cells are denoted by -1. A latin square L is a *completion* of a partial latin square P if $P \subseteq L$. If P completes to just L then P *has unique completion*.

A *latin bitrade* (T_1, T_2) is a pair of partial latin squares such that:

1. $\{(i, j) \mid (i, j, k) \in T_1 \text{ for some symbol } k\} = \{(i, j) \mid (i, j, k') \in T_2 \text{ for some symbol } k'\}$;
2. for each $(i, j, k) \in T_1$ and $(i, j, k') \in T_2$, $k \neq k'$;
3. the symbols appearing in row i of T_1 are the same as those of row i of T_2; the symbols appearing in column j of T_1 are the same as those of column j of T_2.

Intuitively speaking, a bitrade gives the difference between two latin squares, so if (T_1, T_2) is a bitrade for the pair of latin squares (L_1, L_2), then $L1 = (L2 \setminus T_1) \cup T_2$ and $L2 = (L1 \setminus T_2) \cup T_1$.

This file contains

1. LatinSquare class definition;
2. some named latin squares (back circulant, forward circulant, abelian 2-group);
3. functions is_partial_latin_square and is_latin_square to test if a LatinSquare object satisfies the definition of a latin square or partial latin square, respectively;
4. tests for completion and unique completion (these use the C++ implementation of Knuth's dancing links algorithm to solve the problem as a instance of $0 - 1$ matrix exact cover);
5. functions for calculating the τ_i representation of a bitrade and the genus of the associated hypermap embedding;
6. Markov chain of Jacobson and Matthews (1996) for generating latin squares uniformly at random (provides a generator interface);
7. a few examples of τ_i representations of bitrades constructed from the action of a group on itself by right multiplication, functions for converting to a pair of LatinSquare objects.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(5)
sage: B
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
sage: B.is_latin_square()
True
sage: B[0, 1] = 0
sage: B.is_latin_square()
False

sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[ 0  2 -1  1]
[-1  0  1  3]
[ 3 -1  0  2]
[ 1  3  2 -1]
sage: T2
[ 1  0 -1  2]
[-1  3  0  1]
[ 0 -1  2  3]
```

```
[ 3  2  1 -1]
sage: T1.nr_filled_cells()
12
sage: genus(T1, T2)
1
```

To do:

1. Latin squares with symbols from a ring instead of the integers $\{0, 1, \ldots, n-1\}$.
2. Isotopism testing of latin squares and bitrades via graph isomorphism (nauty?).
3. Combinatorial constructions for bitrades.

AUTHORS:

- Carlo Hamalainen (2008-03-23): initial version

TESTS:

```
sage: L = elementary_abelian_2group(3)
sage: L == loads(dumps(L))
True
```

class LatinSquare(**args*)

actual_row_col_sym_sizes()

Bitrades sometimes end up in partial latin squares with unused rows, columns, or symbols. This function works out the actual number of used rows, columns, and symbols.

> **Warning:** We assume that the unused rows/columns occur in the lower right of self, and that the used symbols are in the range {0, 1, ..., m} (no holes in that list).

EXAMPLE:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(3)
sage: B[0,2] = B[1,2] = B[2,2] = -1
sage: B[0,0] = B[2,1] = -1
sage: B
[-1  1 -1]
[ 1  2 -1]
[ 2 -1 -1]
sage: B.actual_row_col_sym_sizes()
(3, 2, 2)
```

apply_isotopism(*row_perm, col_perm, sym_perm*)

An isotopism is a permutation of the rows, columns, and symbols of a partial latin square self. Use isotopism() to convert a tuple (indexed from 0) to a Permutation object.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(5)
sage: B
[0 1 2 3 4]
[1 2 3 4 0]
```

```
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
sage: alpha = isotopism((0,1,2,3,4))
sage: beta  = isotopism((1,0,2,3,4))
sage: gamma = isotopism((2,1,0,3,4))
sage: B.apply_isotopism(alpha, beta, gamma)
[3 4 2 0 1]
[0 2 3 1 4]
[1 3 0 4 2]
[4 0 1 2 3]
[2 1 4 3 0]
```

clear_cells()

Mark every cell in self as being empty.

EXAMPLES:

```
sage: A = LatinSquare(matrix(ZZ, [[0, 1], [2, 3]]))
sage: A.clear_cells()
sage: A
[-1 -1]
[-1 -1]
```

column(*x*)

Returns column x of the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(3).column(0)
(0, 1, 2)
```

contained_in(*Q*)

Returns True if self is a subset of Q?

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: P = elementary_abelian_2group(2)
sage: P[0, 0] = -1
sage: P.contained_in(elementary_abelian_2group(2))
True
sage: back_circulant(4).contained_in(elementary_abelian_2group(2))
False
```

copy()

To copy a latin square we must copy the underlying matrix.

EXAMPLES:

```
sage: A = LatinSquare(matrix(ZZ, [[0, 1], [2, 3]]))
sage: B = A.copy()
sage: A
[0 1]
[2 3]
```

disjoint_mate_dlxcpp_rows_and_map(*allow_subtrade*)

Internal function for find_disjoint_mates.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(4)
```

```
sage: B.disjoint_mate_dlxcpp_rows_and_map(allow_subtrade = True)
([[0, 16, 32], [1, 17, 32], [2, 18, 32], [3, 19, 32], [4, 16, 33], [5, 17, 33], [6, 18, 33],
```

dlxcpp_has_unique_completion()

Check if the partial latin square self of order n can be embedded in precisely one latin square of order n.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(2).dlxcpp_has_unique_completion()
True
sage: P = LatinSquare(2)
sage: P.dlxcpp_has_unique_completion()
False
sage: P[0, 0] = 0
sage: P.dlxcpp_has_unique_completion()
True
```

dumps()

Since the latin square class doesn't hold any other private variables we just call dumps on self.square:

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(2) == loads(dumps(back_circulant(2)))
True
```

filled_cells_map()

Number the filled cells of self with integers from {1, 2, 3, ...}

INPUT:

- `self` - Partial latin square self (empty cells have negative values)

OUTPUT: A dictionary cells_map where cells_map[(i,j)] = m means that (i,j) is the m-th filled cell in P, while cells_map[m] = (i,j).

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1.filled_cells_map()
{1: (0, 0), 2: (0, 1), 3: (0, 3), 4: (1, 1), 5: (1, 2), 6: (1, 3), 7: (2, 0), 8: (2, 2), 9:
```

find_disjoint_mates(*nr_to_find=None, allow_subtrade=False*)

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(4)
sage: g = B.find_disjoint_mates(allow_subtrade = True)
sage: B1 = g.next()
sage: B0, B1 = bitrade(B, B1)
sage: assert is_bitrade(B0, B1)
sage: print B0, "\n,\n", B1
[-1  1  2 -1]
[-1  2 -1  0]
[-1 -1 -1 -1]
[-1  0  1  2]
,
[-1  2  1 -1]
[-1  0 -1  2]
[-1 -1 -1 -1]
[-1  1  2  0]
```

gcs()

A greedy critical set of a latin square self is found by successively removing elements in a row-wise (bottom-up) manner, checking for unique completion at each step.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: A = elementary_abelian_2group(3)
sage: G = A.gcs()
sage: A
[0 1 2 3 4 5 6 7]
[1 0 3 2 5 4 7 6]
[2 3 0 1 6 7 4 5]
[3 2 1 0 7 6 5 4]
[4 5 6 7 0 1 2 3]
[5 4 7 6 1 0 3 2]
[6 7 4 5 2 3 0 1]
[7 6 5 4 3 2 1 0]
sage: G
[ 0  1  2  3  4  5  6 -1]
[ 1  0  3  2  5  4 -1 -1]
[ 2  3  0  1  6 -1  4 -1]
[ 3  2  1  0 -1 -1 -1 -1]
[ 4  5  6 -1  0  1  2 -1]
[ 5  4 -1 -1  1  0 -1 -1]
[ 6 -1  4 -1  2 -1  0 -1]
[-1 -1 -1 -1 -1 -1 -1 -1]
```

is_completable()

Returns True if the partial latin square can be completed to a latin square.

EXAMPLES:

The following partial latin square has no completion because there is nowhere that we can place the symbol 0 in the third row:

```
sage: B = LatinSquare(3)

sage: B[0, 0] = 0
sage: B[1, 1] = 0
sage: B[2, 2] = 1

sage: B
[ 0 -1 -1]
[-1  0 -1]
[-1 -1  1]

sage: B.is_completable()
False

sage: B[2, 2] = 0
sage: B.is_completable()
True
```

is_empty_column(*c*)

Checks if column c of the partial latin square self is empty.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(4)
sage: L.is_empty_column(0)
False
```

```
sage: L[0,0] = L[1,0] = L[2,0] = L[3,0] = -1
sage: L.is_empty_column(0)
True
```

is_empty_row(*r*)

Checks if row r of the partial latin square self is empty.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(4)
sage: L.is_empty_row(0)
False
sage: L[0,0] = L[0,1] = L[0,2] = L[0,3] = -1
sage: L.is_empty_row(0)
True
```

is_latin_square()

self is a latin square if it is an n by n matrix, and each symbol in [0, 1, ..., n-1] appears exactly once in each row, and exactly once in each column.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: elementary_abelian_2group(4).is_latin_square()
True

sage: forward_circulant(7).is_latin_square()
True
```

is_partial_latin_square()

self is a partial latin square if it is an n by n matrix, and each symbol in [0, 1, ..., n-1] appears at most once in each row, and at most once in each column.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: LatinSquare(4).is_partial_latin_square()
True
sage: back_circulant(3).gcs().is_partial_latin_square()
True
sage: back_circulant(6).is_partial_latin_square()
True
```

is_uniquely_completable()

Returns True if the partial latin square self has exactly one completion to a latin square. This is just a wrapper for the current best-known algorithm, Dancing Links by Knuth. See dancing_links.spyx

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(4).gcs().is_uniquely_completable()
True

sage: G = elementary_abelian_2group(3).gcs()
sage: G.is_uniquely_completable()
True

sage: G[0, 0] = -1
sage: G.is_uniquely_completable()
False
```

latex()

Returns LaTeX code for the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: print back_circulant(3).latex()
\begin{array}{|c|c|c|}\hline 0 & 1 & 2\\\hline 1 & 2 & 0\\\hline 2 & 0 & 1\\\hline\end{array
```

list()

Convert the latin square into a list, in a row-wise manner.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(3).list()
[0, 1, 2, 1, 2, 0, 2, 0, 1]
```

ncols()

Number of columns in the latin square.

EXAMPLES:

```
sage: LatinSquare(3).ncols()
3
```

nr_distinct_symbols()

Returns the number of distinct symbols in the partial latin square self.

EXAMPLE:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(5).nr_distinct_symbols()
5
sage: L = LatinSquare(10)
sage: L.nr_distinct_symbols()
0
sage: L[0, 0] = 0
sage: L[0, 1] = 1
sage: L.nr_distinct_symbols()
2
```

nr_filled_cells()

Returns the number of filled cells (i.e. cells with a positive value) in the partial latin square self.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: LatinSquare(matrix([[0, -1], [-1, 0]])).nr_filled_cells()
2
```

nrows()

Number of rows in the latin square.

EXAMPLES:

```
sage: LatinSquare(3).nrows()
3
```

permissable_values(*r*, *c*)

Find all values that do not appear in row r and column c of the latin square self. If self[r, c] is filled then we return the empty list.

INPUT:

- `self` - LatinSquare
- `r` - int; row of the latin square
- `c` - int; column of the latin square

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(5)
sage: L[0, 0] = -1
sage: L.permissable_values(0, 0)
[0]
```

random_empty_cell()

Find an empty cell of self, uniformly at random.

INPUT:

- `self` - LatinSquare

OUTPUT:

- `[r, c]` - cell such that self[r, c] is empty, or returns None if self is a (full) latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: P = back_circulant(2)
sage: P[1,1] = -1
sage: P.random_empty_cell()
[1, 1]
```

row(*x*)

Returns row x of the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(3).row(0)
(0, 1, 2)
```

set_immutable()

A latin square is immutable if the underlying matrix is immutable.

EXAMPLES:

```
sage: L = LatinSquare(matrix(ZZ, [[0, 1], [2, 3]]))
sage: L.set_immutable()
sage: {L : 0}   # this would fail without set_immutable()
{[0 1]
[2 3]: 0}
```

top_left_empty_cell()

Returns the least [r, c] such that self[r, c] is an empty cell. If all cells are filled then we return None.

INPUT:

- `self` - LatinSquare

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(5)
sage: B[3, 4] = -1
sage: B.top_left_empty_cell()
[3, 4]
```

vals_in_col(*c*)

Returns a dictionary with key e if and only if column c of self has the symbol e.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(3)
```

```
sage: B[0, 0] = -1
sage: back_circulant(3).vals_in_col(0)
{0: True, 1: True, 2: True}
```

vals_in_row(*r*)

Returns a dictionary with key e if and only if row r of self has the symbol e.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(3)
sage: B[0, 0] = -1
sage: back_circulant(3).vals_in_row(0)
{0: True, 1: True, 2: True}
```

LatinSquare_generator(*L_start, check_assertions=False*)

Generator for a sequence of uniformly distributed latin squares, given L_start as the initial latin square. This code implements the Markov chain algorithm of Jacobson and Matthews (1996), see below for the BibTex entry. This generator will never throw the StopIteration exception, so it provides an infinite sequence of latin squares.

EXAMPLES:

Use the back circulant latin square of order 4 as the initial square and print the next two latin squares given by the Markov chain:

```
sage: from sage.combinat.matrices.latin import *
sage: g = LatinSquare_generator(back_circulant(4))
sage: g.next().is_latin_square()
True
```

```

alternating_group_bitrade_generators(*m*)

Construct generators a, b, c for the alternating group on 3m+1 points, such that a*b*c = 1.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = alternating_group_bitrade_generators(1)
sage: (a, b, c, G)
((1,2,3), (1,4,2), (2,4,3), Permutation Group with generators [(1,2,3), (1,4,2)])
sage: a*b*c
()
```

```
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[ 0  2 -1  1]
[-1  0  1  3]
[ 3 -1  0  2]
[ 1  3  2 -1]
sage: T2
[ 1  0 -1  2]
[-1  3  0  1]
[ 0 -1  2  3]
[ 3  2  1 -1]
```

back_circulant(*n*)

The back-circulant latin square of order n is the Cayley table for (Z_n, +), the integers under addition modulo n.

INPUT:

- `n` - int; order of the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(5)
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
```

beta1(*rce, T1, T2*)

Find the unique (x, c, e) in T2 such that (r, c, e) is in T1.

INPUT:

- `rce` - tuple (or list) (r, c, e) in T1
- `T1, T2` - latin bitrade

OUTPUT: (x, c, e) in T2.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta1([0, 0, 0], T1, T2)
(1, 0, 0)
```

beta2(*rce, T1, T2*)

Find the unique (r, x, e) in T2 such that (r, c, e) is in T1.

INPUT:

- `rce` - tuple (or list) (r, c, e) in T1
- `T1, T2` - latin bitrade

OUTPUT:

- (r, x, e) in T2.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta2([0, 0, 0], T1, T2)
(0, 1, 0)
```

beta3 (*rce, T1, T2*)

Find the unique (r, c, x) in T2 such that (r, c, e) is in T1.

INPUT:

- `rce` - tuple (or list) (r, c, e) in T1
- `T1, T2` - latin bitrade

OUTPUT:

- (r, c, x) in T2.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta3([0, 0, 0], T1, T2)
(0, 0, 4)
```

bitrade (*T1, T2*)

Form the bitrade (Q1, Q2) from (T1, T2) by setting empty the cells (r, c) such that T1[r, c] == T2[r, c].

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B1 = back_circulant(5)
sage: alpha = isotopism((0,1,2,3,4))
sage: beta  = isotopism((1,0,2,3,4))
sage: gamma = isotopism((2,1,0,3,4))
sage: B2 = B1.apply_isotopism(alpha, beta, gamma)
sage: T1, T2 = bitrade(B1, B2)
sage: T1
[ 0  1 -1  3  4]
[ 1 -1 -1  4  0]
[ 2 -1  4  0  1]
[ 3  4  0  1  2]
[ 4  0  1  2  3]
```

```
sage: T2
[ 3  4 -1  0  1]
[ 0 -1 -1  1  4]
[ 1 -1  0  4  2]
[ 4  0  1  2  3]
[ 2  1  4  3  0]
```

bitrade_from_group(*a, b, c, G*)

Given group elements a, b, c in G such that abc = 1 and the subgroups a, b, c intersect (pairwise) only in the identity, construct a bitrade (T1, T2) where rows, columns, and symbols correspond to cosets of a, b, and c, respectively.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[ 0  2 -1  1]
[-1  0  1  3]
[ 3 -1  0  2]
[ 1  3  2 -1]
sage: T2
[ 1  0 -1  2]
[-1  3  0  1]
[ 0 -1  2  3]
[ 3  2  1 -1]
```

cells_map_as_square(*cells_map, n*)

Returns a LatinSquare with cells numbered from 1, 2, ... to given the dictionary cells_map.

Note: The value n should be the maximum of the number of rows and columns of the original partial latin square

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[ 0  2 -1  1]
[-1  0  1  3]
[ 3 -1  0  2]
[ 1  3  2 -1]
```

There are 12 filled cells in T:

```
sage: cells_map_as_square(T1.filled_cells_map(), max(T1.nrows(), T1.ncols()))
[ 1  2 -1  3]
[-1  4  5  6]
[ 7 -1  8  9]
[10 11 12 -1]
```

check_bitrade_generators(*a, b, c*)

Three group elements a, b, c will generate a bitrade if a*b*c = 1 and the subgroups a, b, c intersect (pairwise) in just the identity.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = p3_group_bitrade_generators(3)
sage: check_bitrade_generators(a, b, c)
True
sage: check_bitrade_generators(a, b, gap('()'))
False
```

coin()

Simulates a fair coin (returns True or False) using ZZ.random_element(2).

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: x = coin()
sage: x == 0 or x == 1
True
```

column_containing_sym(*L, r, x*)

Given an improper latin square L with L[r, c1] = L[r, c2] = x, return c1 or c2 with equal probability. This is an internal function and should only be used in LatinSquare_generator().

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = matrix([(1, 0, 2, 3), (0, 2, 3, 0), (2, 3, 0, 1), (3, 0, 1, 2)])
sage: L
[1 0 2 3]
[0 2 3 0]
[2 3 0 1]
[3 0 1 2]
sage: c = column_containing_sym(L, 1, 0)
sage: c == 0 or c == 3
True
```

direct_product(*L1, L2, L3, L4*)

The 'direct product' of four latin squares L1, L2, L3, L4 of order n is the latin square of order 2n consisting of

```
-----------
| L1 | L2 |
-----------
| L3 | L4 |
-----------
```

where the subsquares L2 and L3 have entries offset by n.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: direct_product(back_circulant(4), back_circulant(4), elementary_abelian_2group(2), element
[0 1 2 3 4 5 6 7]
[1 2 3 0 5 6 7 4]
[2 3 0 1 6 7 4 5]
[3 0 1 2 7 4 5 6]
[4 5 6 7 0 1 2 3]
[5 4 7 6 1 0 3 2]
[6 7 4 5 2 3 0 1]
[7 6 5 4 3 2 1 0]
```

dlxcpp_find_completions(*P, nr_to_find=None*)

Returns a list of all latin squares L of the same order as P such that P is contained in L. The optional parameter nr_to_find limits the number of latin squares that are found.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: dlxcpp_find_completions(LatinSquare(2))
[[0 1]
[1 0], [1 0]
[0 1]]

sage: dlxcpp_find_completions(LatinSquare(2), 1)
[[0 1]
[1 0]]
```

dlxcpp_rows_and_map(*P*)

Internal function for dlxcpp_find_completions. Given a partial latin square P we construct a list of rows of a 0-1 matrix M such that an exact cover of M corresponds to a completion of P to a latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: dlxcpp_rows_and_map(LatinSquare(2))
([[0, 4, 8], [1, 5, 8], [2, 4, 9], [3, 5, 9], [0, 6, 10], [1, 7, 10], [2, 6, 11], [3, 7, 11]], {
```

elementary_abelian_2group(*s*)

Returns the latin square based on the Cayley table for the elementary abelian 2-group of order 2s.

INPUT:

- s - int; order of the latin square will be 2s.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: elementary_abelian_2group(3)
[0 1 2 3 4 5 6 7]
[1 0 3 2 5 4 7 6]
[2 3 0 1 6 7 4 5]
[3 2 1 0 7 6 5 4]
[4 5 6 7 0 1 2 3]
[5 4 7 6 1 0 3 2]
[6 7 4 5 2 3 0 1]
[7 6 5 4 3 2 1 0]
```

forward_circulant(*n*)

The forward-circulant latin square of order n is the Cayley table for the operation r + c = (n-c+r) mod n.

INPUT:

- n - int; order of the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: forward_circulant(5)
[0 4 3 2 1]
[1 0 4 3 2]
[2 1 0 4 3]
```

```
[3 2 1 0 4]
[4 3 2 1 0]
```

genus(*T1, T2*)

Returns the genus of hypermap embedding associated with the bitrade (T1, T2). Informally, we compute the [tau_1, tau_2, tau_3] permutation representation of the bitrade. Each cycle of tau_1, tau_2, and tau_3 gives a rotation scheme for a black, white, and star vertex (respectively). The genus then comes from Euler's formula. For more details see Carlo Hamalainen: Partitioning 3-homogeneous latin bitrades. To appear in Geometriae Dedicata, available at http://arxiv.org/abs/0710.0938

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: genus(T1, T2)
1
sage: (a, b, c, G) = pq_group_bitrade_generators(3, 7)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: genus(T1, T2)
3
```

group_to_LatinSquare(*G*)

Construct a latin square on the symbols [0, 1, ..., n-1] for a group with an n by n Cayley table.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: group_to_LatinSquare(DihedralGroup(2))
[0 1 2 3]
[1 0 3 2]
[2 3 0 1]
[3 2 1 0]

sage: G = gap.Group(PermutationGroupElement((1,2,3)))
sage: group_to_LatinSquare(G)
[0 1 2]
[1 2 0]
[2 0 1]
```

is_bitrade(*T1, T2*)

Combinatorially, a pair (T1, T2) of partial latin squares is a bitrade if they are disjoint, have the same shape, and have row and column balance. For definitions of each of these terms see the relevant function in this file.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
```

is_disjoint(*T1, T2*)

The partial latin squares T1 and T2 are disjoint if T1[r, c] != T2[r, c] or T1[r, c] == T2[r, c] == -1 for each cell [r, c].

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import is_disjoint, back_circulant, isotopism
sage: is_disjoint(back_circulant(2), back_circulant(2))
False
```

```
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_disjoint(T1, T2)
True
```

is_primary_bitrade(*a, b, c, G*)

A bitrade generated from elements a, b, c is primary if a, b, c = G.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = p3_group_bitrade_generators(5)
sage: is_primary_bitrade(a, b, c, G)
True
```

is_row_and_col_balanced(*T1, T2*)

Partial latin squares T1 and T2 are balanced if the symbols appearing in row r of T1 are the same as the symbols appearing in row r of T2, for each r, and if the same condition holds on columns.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = matrix([[0,1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
sage: T2 = matrix([[0,1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
sage: is_row_and_col_balanced(T1, T2)
True
sage: T2 = matrix([[0,3,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
sage: is_row_and_col_balanced(T1, T2)
False
```

is_same_shape(*T1, T2*)

Two partial latin squares T1, T2 have the same shape if T1[r, c] = 0 if and only if T2[r, c] = 0.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: is_same_shape(elementary_abelian_2group(2), back_circulant(4))
True
sage: is_same_shape(LatinSquare(5), LatinSquare(5))
True
sage: is_same_shape(forward_circulant(5), LatinSquare(5))
False
```

isotopism(*p*)

Returns a Permutation object that represents an isotopism (for rows, columns or symbols of a partial latin square). Since matrices in Sage are indexed from 0, this function translates +1 to agree with the Permutation class. We also handle PermutationGroupElements.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: isotopism(5) # identity on 5 points
[1, 2, 3, 4, 5]

sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: g = G.gen(0)
sage: isotopism(g)
[2, 3, 1, 5, 4]

sage: isotopism([0,3,2,1]) # 0 goes to 0, 1 goes to 3, etc.
[1, 4, 3, 2]

sage: isotopism( (0,1,2) ) # single cycle, presented as a tuple
[2, 3, 1]

sage: x = isotopism( ((0,1,2), (3,4)) ) # tuple of cycles
sage: x
[2, 3, 1, 5, 4]
sage: x.to_cycles()
[(1, 2, 3), (4, 5)]
```

next_conjugate(*L*)

Permutes L[r, c] = e to the conjugate L[c, e] = r.

We assume that L is an n by n matrix and has values in the range 0, 1, ..., n-1.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(6)
sage: L
[0 1 2 3 4 5]
[1 2 3 4 5 0]
[2 3 4 5 0 1]
[3 4 5 0 1 2]
[4 5 0 1 2 3]
[5 0 1 2 3 4]
sage: next_conjugate(L)
[0 1 2 3 4 5]
[5 0 1 2 3 4]
[4 5 0 1 2 3]
[3 4 5 0 1 2]
[2 3 4 5 0 1]
[1 2 3 4 5 0]
sage: L == next_conjugate(next_conjugate(next_conjugate(L)))
True
```

p3_group_bitrade_generators(*p*)

Generators for a group of order p3 where p is a prime.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: p3_group_bitrade_generators(3)
((2,6,7)(3,8,9), (1,2,3)(4,7,8)(5,6,9), (1,9,2)(3,7,4)(5,8,6), Permutation Group with generators
```

pq_group_bitrade_generators(*p, q*)

Generators for a group of order pq where p and q are primes such that (q % p) == 1.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: pq_group_bitrade_generators(3,7)
((2,3,5)(4,7,6), (1,2,3,4,5,6,7), (1,4,2)(3,5,6), Permutation Group with generators [(2,3,5)(4,7
```

row_containing_sym(*L, c, x*)

Given an improper latin square L with L[r1, c] = L[r2, c] = x, return r1 or r2 with equal probability. This is an internal function and should only be used in LatinSquare_generator().

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = matrix([(0, 1, 0, 3), (3, 0, 2, 1), (1, 0, 3, 2), (2, 3, 1, 0)])
sage: L
[0 1 0 3]
[3 0 2 1]
[1 0 3 2]
[2 3 1 0]
sage: c = row_containing_sym(L, 1, 0)
sage: c == 1 or c == 2
True
```

tau1(*T1, T2, cells_map*)

The definition of τ_1 is

$$\tau_1 : T1 \to T1$$
$$\tau_1 = \beta_2^{-1}\beta_3$$

where the composition is left to right and $\beta_i : T2 \to T1$ changes just the i^{th} coordinate of a triple.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: (cells_map, t1, t2, t3) = tau123(T1, T2)
sage: t1 = tau1(T1, T2, cells_map)
sage: t1
[2, 3, 4, 5, 1, 7, 8, 9, 10, 6, 12, 13, 14, 15, 11, 17, 18, 19, 20, 16, 22, 23, 24, 25, 21]
sage: t1.to_cycles()
[(1, 2, 3, 4, 5), (6, 7, 8, 9, 10), (11, 12, 13, 14, 15), (16, 17, 18, 19, 20), (21, 22, 23, 24,
```

tau123(*T1, T2*)

Compute the tau_i representation for a bitrade (T1, T2). See the functions tau1, tau2, and tau3 for the mathematical definitions.

OUTPUT:

- (cells_map, t1, t2, t3)

where cells_map is a map to/from the filled cells of T1, and t1, t2, t3 are the tau1, tau2, tau3 permutations.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = pq_group_bitrade_generators(3, 7)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[ 0  1  2 -1 -1 -1 -1]
[ 2  4  3 -1 -1 -1 -1]
[ 4  0  5 -1 -1 -1 -1]
[ 3  5  1 -1 -1 -1 -1]
[ 6  3  0 -1 -1 -1 -1]
[ 1  6  4 -1 -1 -1 -1]
[ 5  2  6 -1 -1 -1 -1]
sage: T2
[ 2  0  1 -1 -1 -1 -1]
[ 3  2  4 -1 -1 -1 -1]
[ 5  4  0 -1 -1 -1 -1]
[ 1  3  5 -1 -1 -1 -1]
[ 0  6  3 -1 -1 -1 -1]
[ 4  1  6 -1 -1 -1 -1]
[ 6  5  2 -1 -1 -1 -1]
sage: (cells_map, t1, t2, t3) = tau123(T1, T2)
sage: cells_map
{1: (0, 0), 2: (0, 1), 3: (0, 2), 4: (1, 0), 5: (1, 1), 6: (1, 2), 7: (2, 0), 8: (2, 1), 9: (2,
sage: cells_map_as_square(cells_map, max(T1.nrows(), T1.ncols()))
[ 1  2  3 -1 -1 -1 -1]
[ 4  5  6 -1 -1 -1 -1]
[ 7  8  9 -1 -1 -1 -1]
[10 11 12 -1 -1 -1 -1]
[13 14 15 -1 -1 -1 -1]
[16 17 18 -1 -1 -1 -1]
[19 20 21 -1 -1 -1 -1]
sage: t1
[2, 3, 1, 5, 6, 4, 8, 9, 7, 11, 12, 10, 14, 15, 13, 17, 18, 16, 20, 21, 19]
sage: t2
[4, 8, 12, 10, 20, 18, 19, 5, 15, 16, 14, 9, 1, 17, 6, 7, 2, 21, 13, 11, 3]
sage: t3
[15, 16, 20, 3, 7, 14, 18, 1, 11, 6, 19, 2, 21, 10, 8, 12, 13, 5, 9, 4, 17]

sage: t1.to_cycles()
[(1, 2, 3), (4, 5, 6), (7, 8, 9), (10, 11, 12), (13, 14, 15), (16, 17, 18), (19, 20, 21)]
sage: t2.to_cycles()
[(1, 4, 10, 16, 7, 19, 13), (2, 8, 5, 20, 11, 14, 17), (3, 12, 9, 15, 6, 18, 21)]
sage: t3.to_cycles()
[(1, 15, 8), (2, 16, 12), (3, 20, 4), (5, 7, 18), (6, 14, 10), (9, 11, 19), (13, 21, 17)]
```

The product t1*t2*t3 is the identity, i.e. it fixes every point:

```
sage: len((t1*t2*t3).fixed_points()) == T1.nr_filled_cells()
True
```

tau2 (*T1, T2, cells_map*)

The definition of τ_2 is

$$\tau_2 : T1 \to T1$$
$$\tau_2 = \beta_3^{-1}\beta_1$$

where the composition is left to right and $\beta_i : T2 \to T1$ changes just the i^{th} coordinate of a triple.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: (cells_map, t1, t2, t3) = tau123(T1, T2)
sage: t2 = tau2(T1, T2, cells_map)
sage: t2
[21, 22, 23, 24, 25, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20]
sage: t2.to_cycles()
[(1, 21, 16, 11, 6), (2, 22, 17, 12, 7), (3, 23, 18, 13, 8), (4, 24, 19, 14, 9), (5, 25, 20, 15,
```

tau3 (*T1, T2, cells_map*)

The definition of τ_3 is

$$\tau_3 : T1 \to T1$$
$$\tau_3 = \beta_1^{-1}\beta_2$$

where the composition is left to right and $\beta_i : T2 \to T1$ changes just the i^{th} coordinate of a triple.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: (cells_map, t1, t2, t3) = tau123(T1, T2)
sage: t3 = tau3(T1, T2, cells_map)
sage: t3
[10, 6, 7, 8, 9, 15, 11, 12, 13, 14, 20, 16, 17, 18, 19, 25, 21, 22, 23, 24, 5, 1, 2, 3, 4]
sage: t3.to_cycles()
[(1, 10, 14, 18, 22), (2, 6, 15, 19, 23), (3, 7, 11, 20, 24), (4, 8, 12, 16, 25), (5, 9, 13, 17,
```

tau_to_bitrade (*t1, t2, t3*)

Given permutations t1, t2, t3 that represent a latin bitrade, convert them to an explicit latin bitrade (T1, T2). The result is unique up to isotopism.

EXAMPLE:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: _, t1, t2, t3 = tau123(T1, T2)
sage: U1, U2 = tau_to_bitrade(t1, t2, t3)
sage: assert is_bitrade(U1, U2)
```

```
sage: U1
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
sage: U2
[4 0 1 2 3]
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
```

17.20 Lyndon words

LyndonWords(*e, k=None*)

Returns the combinatorial class of Lyndon words.

EXAMPLES: If e is an integer, then e specifies the length of the alphabet; k must also be specified in this case.

```
sage: LW = LyndonWords(3,3); LW
Lyndon words from an alphabet of size 3 of length 3
sage: LW.first()
[1, 1, 2]
sage: LW.last()
[2, 3, 3]
sage: LW.random_element()
[1, 1, 2]
sage: LW.cardinality()
8
```

If e is a (weak) composition, then it returns the class of Lyndon words that have evaluation e.

```
sage: LyndonWords([2, 0, 1]).list()
[[1, 1, 3]]
sage: LyndonWords([2, 0, 1, 0, 1]).list()
[[1, 1, 3, 5], [1, 1, 5, 3], [1, 3, 1, 5]]
sage: LyndonWords([2, 1, 1]).list()
[[1, 1, 2, 3], [1, 1, 3, 2], [1, 2, 1, 3]]
```

class **LyndonWords_evaluation**(*e*)

cardinality()

Returns the number of Lyndon words with the evaluation e.

EXAMPLES:

```
sage: LyndonWords([]).cardinality()
0
sage: LyndonWords([2,2]).cardinality()
1
sage: LyndonWords([2,3,2]).cardinality()
30
```

Check to make sure that the count matches up with the number of Lyndon words generated.

```
sage: comps = [[],[2,2],[3,2,7],[4,2]]+Compositions(4).list()
sage: lws = [ LyndonWords(comp) for comp in comps]
sage: all( [ lw.cardinality() == len(lw.list()) for lw in lws] )
True
```

class LyndonWords_nk(*n, k*)

cardinality()
TESTS:

```
sage: [ LyndonWords(3,i).cardinality() for i in range(1, 11) ]
[3, 3, 8, 18, 48, 116, 312, 810, 2184, 5880]
```

StandardBracketedLyndonWords(*n, k*)
Returns the combinatorial class of standard bracketed Lyndon words from [1, ..., n] of length k. These are in one to one correspondence with the Lyndon words and form a basis for the subspace of degree k of the free Lie algebra of rank n.

EXAMPLES:

```
sage: SBLW33 = StandardBracketedLyndonWords(3,3); SBLW33
Standard bracketed Lyndon words from an alphabet of size 3 of length 3
sage: SBLW33.first()
[1, [1, 2]]
sage: SBLW33.last()
[[2, 3], 3]
sage: SBLW33.cardinality()
8
sage: SBLW33.random_element()
[1, [1, 2]]
```

class StandardBracketedLyndonWords_nk(*n, k*)

cardinality()
EXAMPLES:

```
sage: StandardBracketedLyndonWords(3, 3).cardinality()
8
sage: StandardBracketedLyndonWords(3, 4).cardinality()
18
```

standard_bracketing(*lw*)
Returns the standard bracketing of a Lyndon word lw.

EXAMPLES:

```
sage: import sage.combinat.lyndon_word as lyndon_word
sage: map( lyndon_word.standard_bracketing, LyndonWords(3,3) )
[[1, [1, 2]],
 [1, [1, 3]],
 [[1, 2], 2],
 [1, [2, 3]],
 [[1, 3], 2],
 [[1, 3], 3],
 [2, [2, 3]],
 [[2, 3], 3]]
```

17.21 Necklaces

The algorithm used in this file comes from

- Sawada, Joe. "A fast algorithm to generate necklaces with fixed content", Source Theoretical Computer Science archive Volume 301 , Issue 1-3 (May 2003)

Necklaces(*e*)
Returns the combinatorial class of necklaces with evaluation e.

EXAMPLES:

```
sage: Necklaces([2,1,1])
Necklaces with evaluation [2, 1, 1]
sage: Necklaces([2,1,1]).cardinality()
3
sage: Necklaces([2,1,1]).first()
[1, 1, 2, 3]
sage: Necklaces([2,1,1]).last()
[1, 2, 1, 3]
sage: Necklaces([2,1,1]).list()
[[1, 1, 2, 3], [1, 1, 3, 2], [1, 2, 1, 3]]
```

class Necklaces_evaluation(*e*)

cardinality()
Returns the number of integer necklaces with the evaluation e.

EXAMPLES:

```
sage: Necklaces([]).cardinality()
0
sage: Necklaces([2,2]).cardinality()
2
sage: Necklaces([2,3,2]).cardinality()
30
```

Check to make sure that the count matches up with the number of Lyndon words generated.

```
sage: comps = [[],[2,2],[3,2,7],[4,2]]+Compositions(4).list()
sage: ns = [ Necklaces(comp) for comp in comps]
sage: all( [ n.cardinality() == len(n.list()) for n in ns] )
True
```

17.22 Partitions

A partition p of a nonnegative integer n is a non-increasing list of positive integers (the *parts* of the partition) with total sum n.

A partition can be depicted by a diagram made of rows of boxes, where the number of boxes in the i^{th} row starting from the top is the i^{th} part of the partition.

The coordinate system related to a partition applies from the top to the bottom and from left to right. So, the corners of the partition are [[0,4], [1,2], [2,0]].

AUTHORS:

- Mike Hansen (2007): initial version

- Dan Drake (2009-03-28): deprecate RestrictedPartitions and implement Partitions_parts_in

EXAMPLES: There are 5 partitions of the integer 4.

```
sage: Partitions(4).cardinality()
5
sage: Partitions(4).list()
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

We can use the method .first() to get the 'first' partition of a number.

```
sage: Partitions(4).first()
[4]
```

Using the method .next(), we can calculate the 'next' partition. When we are at the last partition, None will be returned.

```
sage: Partitions(4).next([4])
[3, 1]
sage: Partitions(4).next([1,1,1,1]) is None
True
```

We can use `iter` to get an object which iterates over the partitions one by one to save memory. Note that when we do something like `for part in Partitions(4)` this iterator is used in the background.

```
sage: g = iter(Partitions(4))

sage: g.next()
[4]
sage: g.next()
[3, 1]
sage: g.next()
[2, 2]
sage: for p in Partitions(4): print p
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
```

We can add constraints to to the type of partitions we want. For example, to get all of the partitions of 4 of length 2, we'd do the following:

```
sage: Partitions(4, length=2).list()
[[3, 1], [2, 2]]
```

Here is the list of partitions of length at least 2 and the list of ones with length at most 2:

```
sage: Partitions(4, min_length=2).list()
[[3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: Partitions(4, max_length=2).list()
[[4], [3, 1], [2, 2]]
```

The options min_part and max_part can be used to set constraints on the sizes of all parts. Using max_part, we can select partitions having only 'small' entries. The following is the list of the partitions of 4 with parts at most 2:

```
sage: Partitions(4, max_part=2).list()
[[2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

The min_part options is complementary to max_part and selects partitions having only 'large' parts. Here is the list of all partitions of 4 with each part at least 2.

```
sage: Partitions(4, min_part=2).list()
[[4], [2, 2]]
```

The options inner and outer can be used to set part-by-part constraints. This is the list of partitions of 4 with [3, 1, 1] as an outer bound:

```
sage: Partitions(4, outer=[3,1,1]).list()
[[3, 1], [2, 1, 1]]
```

Outer sets max_length to the length of its argument. Moreover, the parts of outer may be infinite to clear constraints on specific parts. Here is the list of the partitions of 4 of length at most 3 such that the second and third part are 1 when they exist:

```
sage: Partitions(4, outer=[oo,1,1]).list()
[[4], [3, 1], [2, 1, 1]]
```

Finally, here are the partitions of 4 with [1,1,1] as an inner bound. Note that inner sets min_length to the length of its argument.

```
sage: Partitions(4, inner=[1,1,1]).list()
[[2, 1, 1], [1, 1, 1, 1]]
```

The options min_slope and max_slope can be used to set constraints on the slope, that is on the difference p[i+1]-p[i] of two consecutive parts. Here is the list of the strictly decreasing partitions of 4:

```
sage: Partitions(4, max_slope=-1).list()
[[4], [3, 1]]
```

The constraints can be combined together in all reasonable ways. Here are all the partitions of 11 of length between 2 and 4 such that the difference between two consecutive parts is between -3 and -1:

```
sage: Partitions(11,min_slope=-3,max_slope=-1,min_length=2,max_length=4).list()
[[7, 4], [6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2], [5, 3, 2, 1]]
```

Partition objects can also be created individually with the Partition function.

```
sage: Partition([2,1])
[2, 1]
```

Once we have a partition object, then there are a variety of methods that we can use. For example, we can get the conjugate of a partition. Geometrically, the conjugate of a partition is the reflection of that partition through its main diagonal. Of course, this operation is an involution.

```
sage: Partition([4,1]).conjugate()
[2, 1, 1, 1]
sage: Partition([4,1]).conjugate().conjugate()
[4, 1]
```

We can go back and forth between the exponential notations of a partition. The exponential notation can be padded with extra zeros.

```
sage: Partition([6,4,4,2,1]).to_exp()
[1, 1, 0, 2, 0, 1]
sage: Partition(exp=[1,1,0,2,0,1])
[6, 4, 4, 2, 1]
sage: Partition([6,4,4,2,1]).to_exp(5)
[1, 1, 0, 2, 0, 1]
sage: Partition([6,4,4,2,1]).to_exp(7)
[1, 1, 0, 2, 0, 1, 0]
sage: Partition([6,4,4,2,1]).to_exp(10)
[1, 1, 0, 2, 0, 1, 0, 0, 0, 0]
```

We can get the coordinates of the corners of a partition.

```
sage: Partition([4,3,1]).corners()
[[0, 3], [1, 2], [2, 0]]
```

We can compute the r-core and r-quotient of a partition and build the partition back up from them.

```
sage: Partition([6,3,2,2]).r_core(3)
[2, 1, 1]
sage: Partition([7,7,5,3,3,3,1]).r_quotient(3)
[[2], [1], [2, 2, 2]]
sage: p = Partition([11,5,5,3,2,2,2])
sage: p.r_core(3)
[]
sage: p.r_quotient(3)
[[2, 1], [4], [1, 1, 1]]
sage: Partition(core_and_quotient=([],[[2, 1], [4], [1, 1, 1]]))
[11, 5, 5, 3, 2, 2, 2]
```

OrderedPartitions(*n, k=None*)

Returns the combinatorial class of ordered partitions of n. If k is specified, then only the ordered partitions of length k are returned.

Note: It is recommended that you use Compositions instead as OrderedPartitions wraps GAP. See also ordered_partitions.

EXAMPLES:

```
sage: OrderedPartitions(3)
Ordered partitions of 3
sage: OrderedPartitions(3).list()
[[3], [2, 1], [1, 2], [1, 1, 1]]
sage: OrderedPartitions(3,2)
Ordered partitions of 3 of length 2
sage: OrderedPartitions(3,2).list()
[[2, 1], [1, 2]]
```

class OrderedPartitions_nk(*n, k=None*)

cardinality()

EXAMPLES:

```
sage: OrderedPartitions(3).cardinality()
4
sage: OrderedPartitions(3,2).cardinality()
2
```

list()

EXAMPLES:

```
sage: OrderedPartitions(3).list()
[[3], [2, 1], [1, 2], [1, 1, 1]]
sage: OrderedPartitions(3,2).list()
[[2, 1], [1, 2]]
```

Partition(*l=None, exp=None, core_and_quotient=None*)

Returns a partition object.

Note that Sage uses the English convention for partitions and tableaux.

EXAMPLES:

```
sage: Partition(exp=[2,1,1])
[3, 2, 1, 1]
sage: Partition(core_and_quotient=([2,1], [[2,1],[3],[1,1,1]]))
[11, 5, 5, 3, 2, 2, 2]
sage: Partition([3,2,1])
[3, 2, 1]
sage: [2,1] in Partitions()
True
sage: [2,1,0] in Partitions()
False
sage: Partition([2,1,0])
[2, 1]
sage: Partition([1,2,3])
...
ValueError: [1, 2, 3] is not a valid partition
```

PartitionTuples(*n, k*)

Returns the combinatorial class of k-tuples of partitions of n. These are are ordered list of k partitions whose sizes add up to

TODO: reimplement in term of species.ProductSpecies and Partitions

These describe the classes and the characters of wreath products of groups with k conjugacy classes with the symmetric group S_n.

EXAMPLES:

```
sage: PartitionTuples(4,2)
2-tuples of partitions of 4
sage: PartitionTuples(3,2).list()
[[[3], []],
 [[2, 1], []],
 [[1, 1, 1], []],
 [[2], [1]],
 [[1, 1], [1]],
 [[1], [2]],
 [[1], [1, 1]],
 [[], [3]],
 [[], [2, 1]],
 [[], [1, 1, 1]]]
```

class **PartitionTuples_nk**(*n, k*)

cardinality()

Returns the number of k-tuples of partitions which together form a partition of n.

Wraps GAP's NrPartitionTuples.

EXAMPLES:

```
sage: PartitionTuples(3,2).cardinality()
10
sage: PartitionTuples(8,2).cardinality()
185
```

Now we compare that with the result of the following GAP computation:

```
gap> S8:=Group((1,2,3,4,5,6,7,8),(1,2));
Group([ (1,2,3,4,5,6,7,8), (1,2) ])
gap> C2:=Group((1,2));
Group([ (1,2) ])
gap> W:=WreathProduct(C2,S8);
<permutation group of size 10321920 with 10 generators>
gap> Size(W);
10321920     ## = 2^8*Factorial(8), which is good:-)
gap> Size(ConjugacyClasses(W));
185
```

object_class()

class **Partition_class**(*l*)

add_box(*i, j=None*)

Returns a partition corresponding to self with a box added in row i. i and j are 0-based row and column indices. This does not change p.

Note that if you have coordinates in a list, you can call this function with python's * notation (see the examples below).

EXAMPLES:

```
sage: Partition([3, 2, 1, 1]).add_box(0)
[4, 2, 1, 1]
sage: cell = [4, 0]; Partition([3, 2, 1, 1]).add_box(*cell)
[3, 2, 1, 1, 1]
```

add_horizontal_border_strip(*k*)

Returns a list of all the partitions that can be obtained by adding a horizontal border strip of length k to self.

EXAMPLES:

```
sage: Partition([]).add_horizontal_border_strip(0)
[[]]
sage: Partition([]).add_horizontal_border_strip(2)
[[2]]
sage: Partition([2,2]).add_horizontal_border_strip(2)
[[2, 2, 2], [3, 2, 1], [4, 2]]
sage: Partition([3,2,2]).add_horizontal_border_strip(2)
[[3, 2, 2, 2], [3, 3, 2, 1], [4, 2, 2, 1], [4, 3, 2], [5, 2, 2]]
```

TODO: reimplement like remove_horizontal_border_strip using IntegerListsLex

add_vertical_border_strip(*k*)

Returns a list of all the partitions that can be obtained by adding a vertical border strip of length k to self.

EXAMPLES:

```
sage: Partition([]).add_vertical_border_strip(0)
[[]]
sage: Partition([]).add_vertical_border_strip(2)
[[1, 1]]
sage: Partition([2,2]).add_vertical_border_strip(2)
[[3, 3], [3, 2, 1], [2, 2, 1, 1]]
sage: Partition([3,2,2]).add_vertical_border_strip(2)
[[4, 3, 2], [4, 2, 2, 1], [3, 3, 3], [3, 3, 2, 1], [3, 2, 2, 1, 1]]
```

arm(*i, j*)

Returns the arm of cell (i,j) in partition p. The arm of cell (i,j) is the number of boxes that appear to the right of cell (i,j). Note that i and j are 0-based indices. If your coordinates are in the form [i,j], use Python's *-operator.

EXAMPLES:

```
sage: p = Partition([2,2,1])
sage: p.arm(0, 0)
1
sage: p.arm(0, 1)
0
sage: p.arm(2, 0)
0
sage: Partition([3,3]).arm(0, 0)
2
sage: Partition([3,3]).arm(*[0,0])
2
```

arm_lengths(*flat=False*)

Returns a tableau of shape p where each box is filled its arm. The optional boolean parameter flat provides the option of returning a flat list.

EXAMPLES:

```
sage: Partition([2,2,1]).arm_lengths()
[[1, 0], [1, 0], [0]]
sage: Partition([2,2,1]).arm_lengths(flat=True)
[1, 0, 1, 0, 0]
sage: Partition([3,3]).arm_lengths()
[[2, 1, 0], [2, 1, 0]]
sage: Partition([3,3]).arm_lengths(flat=True)
[2, 1, 0, 2, 1, 0]
```

arms_legs_coeff(*i, j*)

This is a statistic on a cell c=[i,j] in the diagram of partition p given by

$$[(1 - q^{arm(c)} * t^{leg(c)+1})]/[(1 - q^{arm(c)+1} * t^{leg(c)})]$$

EXAMPLES:

```
sage: Partition([3,2,1]).arms_legs_coeff(1,1)
(-t + 1)/(-q + 1)
sage: Partition([3,2,1]).arms_legs_coeff(0,0)
(-q^2*t^3 + 1)/(-q^3*t^2 + 1)
sage: Partition([3,2,1]).arms_legs_coeff(*[0,0])
(-q^2*t^3 + 1)/(-q^3*t^2 + 1)
```

associated()

An alias for partition.conjugate(p).

EXAMPLES:

```
sage: Partition([4,1,1]).associated()
[3, 1, 1, 1]
sage: Partition([4,1,1]).conjugate()
[3, 1, 1, 1]
sage: Partition([5,4,2,1,1,1]).associated().associated()
[5, 4, 2, 1, 1, 1]
```

atom()

Returns a list of the standard tableaux of size self.size() whose atom is equal to self.

EXAMPLES:

```
sage: Partition([2,1]).atom()
[[[1, 2], [3]]]
sage: Partition([3,2,1]).atom()
[[[1, 2, 3, 6], [4, 5]], [[1, 2, 3], [4, 5], [6]]]
```

aut()

Returns a factor for the number of permutations with cycle type self. self.aut() returns $1^{j_1} j_1! \cdots n^{j_n} j_n!$ where j_k is the number of parts in self equal to k.

The number of permutations having p as a cycle type is given by

$$\frac{n!}{1^{j_1} j_1! \cdots n^{j_n} j_n!}.$$

EXAMPLES:

```
sage: Partition([2,1]).aut()
2
```

boxes()

Return the coordinates of the boxes of self. Coordinates are given as (row-index, column-index) and are 0 based.

EXAMPLES:

```
sage: Partition([2,2]).boxes()
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: Partition([3,2]).boxes()
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1)]
```

centralizer_size(*t=0, q=0*)

Returns the size of the centralizer of any permutation of cycle type p. If m_i is the multiplicity of i as a part of p, this is given by $\prod_i (i^{m[i]}) * (m[i]!)$. Including the optional parameters t and q gives the q-t analog which is the former product times $\prod_{i=1}^{length(p)} (1 - q^{p[i]})/(1 - t^{p[i]})$.

EXAMPLES:

```
sage: Partition([2,2,1]).centralizer_size()
8
sage: Partition([2,2,2]).centralizer_size()
48
```

REFERENCES:

•Kerber, A. 'Algebraic Combinatorics via Finite Group Action', 1.3 p24

character_polynomial()

Returns the character polynomial associated to the partition self. The character polynomial q_μ is defined by

$$q_\mu(x_1, x_2, \ldots, x_k) =\downarrow \sum_{\alpha \vdash k} \frac{\chi^\mu_\alpha}{1^{a_1} 2^{a_2} \cdots k^{a_k} a_1! a_2! \cdots a_k!} \prod_{i=1}^{k} (i x_i - 1)^{a_i}$$

where a_i is the multiplicity of i in α.

It is computed in the following manner.

1.Expand the Schur function s_μ in the power-sum basis.

2.Replace each p_i with $ix_i - 1$

3.Apply the umbral operator $\downarrow$ to the resulting polynomial.

EXAMPLES:

```
sage: Partition([1]).character_polynomial()
x - 1
sage: Partition([1,1]).character_polynomial()
1/2*x0^2 - 3/2*x0 - x1 + 1
sage: Partition([2,1]).character_polynomial()
1/3*x0^3 - 2*x0^2 + 8/3*x0 - x2
```

conjugacy_class_size()

Returns the size of the conjugacy class of the symmetric group indexed by the partition p.

EXAMPLES:

```
sage: Partition([2,2,2]).conjugacy_class_size()
15
sage: Partition([2,2,1]).conjugacy_class_size()
15
sage: Partition([2,1,1]).conjugacy_class_size()
6
```

REFERENCES:

•Kerber, A. 'Algebraic Combinatorics via Finite Group Action' 1.3 p24

conjugate()

conjugate() returns the "conjugate" (also called "associated" in the literature) partition of the partition p which is obtained by transposing the corresponding Ferrers diagram.

EXAMPLES:

```
sage: Partition([2,2]).conjugate()
[2, 2]
sage: Partition([6,3,1]).conjugate()
[3, 2, 2, 1, 1, 1]
sage: print Partition([6,3,1]).ferrers_diagram()
******
***
*
sage: print Partition([6,3,1]).conjugate().ferrers_diagram()
***
**
**
*
*
*
```

contains(x)

Returns True if p2 is a partition whose Ferrers diagram is contained in the Ferrers diagram of self

EXAMPLES:

```
sage: p = Partition([3,2,1])
sage: p.contains([2,1])
True
sage: all(p.contains(mu) for mu in Partitions(3))
True
```

```
sage: all(p.contains(mu) for mu in Partitions(4))
False
```

content(*i, j*)

Returns the content statistic of the given cell, which is simply defined by j - i. This doesn't technically depend on the partition, but is included here because it is often useful in the context of partitions.

EXAMPLES:

```
sage: Partition([2,1]).content(0,1)
1
sage: p = Partition([3,2])
sage: sum([p.content(*c) for c in p.boxes()])
2
```

corners()

Returns a list of the corners of the partitions. These are the positions where we can remove a box. Indices are of the form [i,j] where i is the row-index and j is the column-index, and are 0-based.

EXAMPLES:

```
sage: Partition([3,2,1]).corners()
[[0, 2], [1, 1], [2, 0]]
sage: Partition([3,3,1]).corners()
[[1, 2], [2, 0]]
```

dominate(*rows=None*)

Returns a list of the partitions dominated by n. If n is specified, then it only returns the ones with = rows rows.

EXAMPLES:

```
sage: Partition([3,2,1]).dominate()
[[3, 2, 1], [3, 1, 1, 1], [2, 2, 2], [2, 2, 1, 1], [2, 1, 1, 1, 1], [1, 1, 1, 1, 1, 1]]
sage: Partition([3,2,1]).dominate(rows=3)
[[3, 2, 1], [2, 2, 2]]
```

dominates(*p2*)

Returns True if partition p1 dominates partitions p2. Otherwise, it returns False.

EXAMPLES:

```
sage: p = Partition([3,2])
sage: p.dominates([3,1])
True
sage: p.dominates([2,2])
True
sage: p.dominates([2,1,1])
True
sage: p.dominates([3,3])
False
sage: p.dominates([4])
False
sage: Partition([4]).dominates(p)
False
sage: Partition([]).dominates([1])
False
sage: Partition([]).dominates([])
True
sage: Partition([1]).dominates([])
True
```

down()

Returns a generator for partitions that can be obtained from p by removing a box.

EXAMPLES:

```
sage: [p for p in Partition([2,1,1]).down()]
[[1, 1, 1], [2, 1]]
sage: [p for p in Partition([3,2]).down()]
[[2, 2], [3, 1]]
sage: [p for p in Partition([3,2,1]).down()]
[[2, 2, 1], [3, 1, 1], [3, 2]]
```

down_list()

Returns a list of the partitions that can be obtained from the partition p by removing a box.

EXAMPLES:

```
sage: Partition([2,1,1]).down_list()
[[1, 1, 1], [2, 1]]
sage: Partition([3,2]).down_list()
[[2, 2], [3, 1]]
sage: Partition([3,2,1]).down_list()
[[2, 2, 1], [3, 1, 1], [3, 2]]
```

evaluation()

Returns the evaluation of the partition.

EXAMPLES:

```
sage: Partition([4,3,1,1]).evaluation()
[2, 0, 1, 1]
```

ferrers_diagram()

Return the Ferrers diagram of pi.

INPUT:

- pi - a partition, given as a list of integers.

EXAMPLES:

```
sage: print Partition([5,5,2,1]).ferrers_diagram()
*****
*****
**
*
sage: pi = Partitions(10).list()[11] ## [6,1,1,1,1]
sage: print pi.ferrers_diagram()
******
*
*
*
*
sage: pi = Partitions(10).list()[8] ## [6, 3, 1]
sage: print pi.ferrers_diagram()
******
***
*
```

generalized_pochhammer_symbol(*a*, *alpha*)

Returns the generalized Pochhammer symbol $(a)^{(\alpha)}_{self}$. This is the product over all cells (i,j) in p of $a-(i-1)/\alpha+j-1$.

EXAMPLES:

```
sage: Partition([2,2]).generalized_pochhammer_symbol(2,1)
12
```

hook(*i, j*)

Returns the hook of box (i,j) in the partition p. The hook of box (i,j) is defined to be one more than the sum of number of boxes to the right and the number of boxes below (in the English convention). Note that i and j are 0-based. If your coordinates are in the form [i,j], use Python's *-operator.

EXAMPLES:

```
sage: p = Partition([2,2,1])
sage: p.hook(0, 0)
4
sage: p.hook(0, 1)
2
sage: p.hook(2, 0)
1
sage: Partition([3,3]).hook(0, 0)
4
sage: cell = [0,0]; Partition([3,3]).hook(*cell)
4
```

hook_lengths()

Returns a tableau of shape p with the boxes filled in with the hook lengths.

In each box, put the sum of one plus the number of boxes horizontally to the right and vertically below the box (the hook length).

For example, consider the partition [3,2,1] of 6 with Ferrers Diagram:

```
# # #
# #
#
```

When we fill in the boxes with the hook lengths, we obtain:

```
5 3 1
3 1
1
```

EXAMPLES:

```
sage: Partition([2,2,1]).hook_lengths()
[[4, 2], [3, 1], [1]]
sage: Partition([3,3]).hook_lengths()
[[4, 3, 2], [3, 2, 1]]
sage: Partition([3,2,1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
sage: Partition([2,2]).hook_lengths()
[[3, 2], [2, 1]]
sage: Partition([5]).hook_lengths()
[[5, 4, 3, 2, 1]]
```

REFERENCES:

- http://mathworld.wolfram.com/HookLengthFormula.html

hook_polynomial(*q, t*)

Returns the two-variable hook polynomial.

EXAMPLES:

```
sage: R.<q,t> = PolynomialRing(QQ)
sage: a = Partition([2,2]).hook_polynomial(q,t)
sage: a == (1 - t)*(1 - q*t)*(1 - t^2)*(1 - q*t^2)
True
sage: a = Partition([3,2,1]).hook_polynomial(q,t)
sage: a == (1 - t)^3*(1 - q*t^2)^2*(1 - q^2*t^3)
True
```

hook_product(*a*)

Returns the Jack hook-product.

EXAMPLES:

```
sage: Partition([3,2,1]).hook_product(x)
(x + 2)^2*(2*x + 3)
sage: Partition([2,2]).hook_product(x)
2*(x + 1)*(x + 2)
```

hooks()

Returns a sorted list of the hook lengths in self.

EXAMPLES:

```
sage: Partition([3,2,1]).hooks()
[5, 3, 3, 1, 1, 1]
```

jacobi_trudi()

EXAMPLES:

```
sage: part = Partition([3,2,1])
sage: jt = part.jacobi_trudi(); jt
[h[3] h[1]    0]
[h[4] h[2]  h[]]
[h[5] h[3] h[1]]
sage: s = SFASchur(QQ)
sage: h = SFAHomogeneous(QQ)
sage: h( s(part) )
h[3, 2, 1] - h[3, 3] - h[4, 1, 1] + h[5, 1]
sage: jt.det()
h[3, 2, 1] - h[3, 3] - h[4, 1, 1] + h[5, 1]
```

k_atom(*k*)

EXAMPLES:

```
sage: p = Partition([3,2,1])
sage: p.k_atom(1)
[]
sage: p.k_atom(3)
[[[1, 1, 1], [2, 2], [3]],
 [[1, 1, 1, 2], [2], [3]],
 [[1, 1, 1, 3], [2, 2]],
 [[1, 1, 1, 2, 3], [2]]]
sage: Partition([3,2,1]).k_atom(4)
[[[1, 1, 1], [2, 2], [3]], [[1, 1, 1, 3], [2, 2]]]
```

TESTS:

```
sage: Partition([1]).k_atom(1)
[[[1]]]
sage: Partition([1]).k_atom(2)
[[[1]]]
sage: Partition([]).k_atom(1)
[[]]
```

k_conjugate(*k*)

Returns the k-conjugate of the partition.

The k-conjugate is the partition that is given by the columns of the k-skew diagram of the partition.

EXAMPLES:

```
sage: p = Partition([4,3,2,2,1,1])
sage: p.k_conjugate(4)
[3, 2, 2, 1, 1, 1, 1, 1, 1]
```

k_skew(*k*)

Returns the k-skew partition.

The k-skew diagram of a k-bounded partition is the skew diagram denoted $\lambda/^k$ satisfying the conditions:

1.row i of $\lambda/^k$ has length λ_i

2.no cell in $\lambda/^k$ has hook-length exceeding k

3.every square above the diagram of $\lambda/^k$ has hook length exceeding k.

REFERENCES:

•Lapointe, L. and Morse, J. 'Order Ideals in Weak Subposets of Young's Lattice and Associated Unimodality Conjectures'

EXAMPLES:

```
sage: p = Partition([4,3,2,2,1,1])
sage: p.k_skew(4)
[[9, 5, 3, 2, 1, 1], [5, 2, 1]]
```

k_split(*k*)

Returns the k-split of self.

EXAMPLES:

```
sage: Partition([4,3,2,1]).k_split(3)
[]
sage: Partition([4,3,2,1]).k_split(4)
[[4], [3, 2], [1]]
sage: Partition([4,3,2,1]).k_split(5)
[[4, 3], [2, 1]]
sage: Partition([4,3,2,1]).k_split(6)
[[4, 3, 2], [1]]
sage: Partition([4,3,2,1]).k_split(7)
[[4, 3, 2, 1]]
sage: Partition([4,3,2,1]).k_split(8)
[[4, 3, 2, 1]]
```

leg(*i, j*)

Returns the leg of box (i,j) in partition p. The leg of box (i,j) is defined to be the number of boxes below it in partition p. Note that i and j are 0-based. If your coordinates are in the form [i,j], use Python's *-operator.

EXAMPLES:

```
sage: p = Partition([2,2,1])
sage: p.leg(0, 0)
2
sage: p.leg(0,1)
1
sage: p.leg(2,0)
0
sage: Partition([3,3]).leg(0, 0)
1
sage: cell = [0,0]; Partition([3,3]).leg(*cell)
1
```

leg_lengths(*flat=False*)

Returns a tableau of shape p with each box filled in with its leg. The optional boolean parameter flat provides the option of returning a flat list.

EXAMPLES:

```
sage: Partition([2,2,1]).leg_lengths()
[[2, 1], [1, 0], [0]]
sage: Partition([2,2,1]).leg_lengths(flat=True)
[2, 1, 1, 0, 0]
sage: Partition([3,3]).leg_lengths()
[[1, 1, 1], [0, 0, 0]]
sage: Partition([3,3]).leg_lengths(flat=True)
[1, 1, 1, 0, 0, 0]
```

length()

Returns the number of parts in self.

EXAMPLES:

```
sage: Partition([3,2]).length()
2
sage: Partition([2,2,1]).length()
3
sage: Partition([]).length()
0
```

lower_hook(*i, j, alpha*)

Returns the lower hook length of the box (i,j) in self. When alpha == 1, this is just the normal hook length. Indices are 0-based.

The lower hook length of a box (i,j) in a partition κ is defined by

$$h^\kappa_*(i,j) = \kappa'_j - i + 1 + \alpha(\kappa_i - j).$$

EXAMPLES:

```
sage: p = Partition([2,1])
sage: p.lower_hook(0,0,1)
3
sage: p.hook(0,0)
3
sage: [ p.lower_hook(i,j,x) for i,j in p.boxes() ]
[x + 2, 1, 1]
```

lower_hook_lengths(*alpha*)

Returns the lower hook lengths of the partition. When alpha == 1, these are just the normal hook lengths.

The lower hook length of a box (i,j) in a partition κ is defined by

$$h^*_\kappa(i,j) = \kappa'_j - i + \alpha(\kappa_i - j + 1).$$

EXAMPLES:

```
sage: Partition([3,2,1]).lower_hook_lengths(x)
[[2*x + 3, x + 2, 1], [x + 2, 1], [1]]
sage: Partition([3,2,1]).lower_hook_lengths(1)
[[5, 3, 1], [3, 1], [1]]
sage: Partition([3,2,1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
```

next()

Returns the partition that lexicographically follows the partition p. If p is the last partition, then it returns False.

EXAMPLES:

```
sage: Partition([4]).next()
[3, 1]
sage: Partition([1,1,1,1]).next()
False
```

outside_corners()

Returns a list of the positions where we can add a box so that the shape is still a partition. Indices are of the form [i,j] where i is the row-index and j is the column-index, and are 0-based.

EXAMPLES:

```
sage: Partition([2,2,1]).outside_corners()
[[0, 2], [2, 1], [3, 0]]
sage: Partition([2,2]).outside_corners()
[[0, 2], [2, 0]]
sage: Partition([6,3,3,1,1,1]).outside_corners()
[[0, 6], [1, 3], [3, 1], [6, 0]]
sage: Partition([]).outside_corners()
[[0, 0]]
```

parent()

Returns the combinatorial class of partitions of sum(self).

EXAMPLES:

```
sage: Partition([3,2,1]).parent()
Partitions of the integer 6
```

power(k)

partition_power(pi, k) returns the partition corresponding to the k-th power of a permutation with cycle structure pi (thus describes the powermap of symmetric groups).

Wraps GAP's PowerPartition.

EXAMPLES:

```
sage: p = Partition([5,3])
sage: p.power(1)
[5, 3]
sage: p.power(2)
[5, 3]
sage: p.power(3)
[5, 1, 1, 1]
sage: p.power(4)
[5, 3]
sage: Partition([3,2,1]).power(3)
[2, 1, 1, 1, 1]
```

Now let us compare this to the power map on S_8:

```
sage: G = SymmetricGroup(8)
sage: g = G([(1,2,3,4,5),(6,7,8)])
sage: g
(1,2,3,4,5)(6,7,8)
sage: g^2
(1,3,5,2,4)(6,8,7)
sage: g^3
(1,4,2,5,3)
sage: g^4
(1,5,4,3,2)(6,7,8)
```

pp()

EXAMPLES:

```
sage: Partition([5,5,2,1]).pp()
*****
*****
**
*
```

r_core(*length*)

Returns the r-core of the partition p. The construction of the r-core can be visualized by repeatedly removing border strips of size r from p until this is no longer possible. The remaining partition is the r-core.

EXAMPLES:

```
sage: Partition([6,3,2,2]).r_core(3)
[2, 1, 1]
sage: Partition([]).r_core(3)
[]
sage: Partition([8,7,7,4,1,1,1,1,1]).r_core(3)
[2, 1, 1]
```

TESTS:

```
sage: Partition([3,3,3,2,1]).r_core(3)
[]
sage: Partition([10,8,7,7]).r_core(4)
[]
sage: Partition([21,15,15,9,6,6,6,3,3]).r_core(3)
[]
```

r_quotient(*length*)

Returns the r-quotient of the partition p. The r-quotient is a list of r partitions, constructed in the following way. Label each cell in p with its content, modulo r. Let R_i be the set of rows ending in a box labelled i, and C_i be the set of columns ending in a box labelled i. Then the jth component of the r-quotient of p is the partition defined by intersecting R_j with C_j+1.

EXAMPLES:

```
sage: Partition([7,7,5,3,3,3,1]).r_quotient(3)
[[2], [1], [2, 2, 2]]
```

TESTS:

```
sage: Partition([8,7,7,4,1,1,1,1,1]).r_quotient(3)
[[2, 1], [2, 2], [2]]
sage: Partition([10,8,7,7]).r_quotient(4)
[[2], [3], [2], [1]]
sage: Partition([6,3,3]).r_quotient(3)
[[1], [1], [2]]
sage: Partition([3,3,3,2,1]).r_quotient(3)
[[1], [1, 1], [1]]
sage: Partition([6,6,6,3,3,3]).r_quotient(3)
[[2, 1], [2, 1], [2, 1]]
sage: Partition([21,15,15,9,6,6,6,3,3]).r_quotient(3)
[[5, 2, 1], [5, 2, 1], [7, 3, 2]]
sage: Partition([21,15,15,9,6,6,3,3]).r_quotient(3)
[[5, 2], [5, 2, 1], [7, 3, 1]]
sage: Partition([14,12,11,10,10,10,10,9,6,4,3,3,2,1]).r_quotient(5)
[[3, 3], [2, 2, 1], [], [3, 3, 3], [1]]
```

reading_tableau()

EXAMPLES:

```
sage: Partition([3,2,1]).reading_tableau()
[[1, 3, 6], [2, 5], [4]]
```

remove_box(*i, j=None*)

Returns the partition obtained by removing a box at the end of row i.

EXAMPLES:

```
sage: Partition([2,2]).remove_box(1)
[2, 1]
sage: Partition([2,2,1]).remove_box(2)
[2, 2]
sage: #Partition([2,2]).remove_box(0)

sage: Partition([2,2]).remove_box(1,1)
[2, 1]
sage: #Partition([2,2]).remove_box(1,0)
```

remove_horizontal_border_strip(*k*)

Returns the partitions obtained from self by removing an horizontal border strip of length k

EXAMPLES:

```
sage: Partition([5,3,1]).remove_horizontal_border_strip(0).list()
[[5, 3, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(1).list()
[[5, 3], [5, 2, 1], [4, 3, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(2).list()
[[5, 2], [5, 1, 1], [4, 3], [4, 2, 1], [3, 3, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(3).list()
[[5, 1], [4, 2], [4, 1, 1], [3, 3], [3, 2, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(4).list()
[[4, 1], [3, 2], [3, 1, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(5).list()
[[3, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(6).list()
[]
```

The result is returned as a combinatorial class:

```
sage: Partition([5,3,1]).remove_horizontal_border_strip(5)
The subpartitions of [5, 3, 1] obtained by removing an horizontal border strip of length 5
```

TESTS:

```
sage: Partition([3,2,2]).remove_horizontal_border_strip(2).list()
[[3, 2], [2, 2, 1]]
sage: Partition([3,2,2]).remove_horizontal_border_strip(2).first().parent()
Partitions...
sage: Partition([]).remove_horizontal_border_strip(0).list()
[[]]
sage: Partition([]).remove_horizontal_border_strip(6).list()
[]
```

sign()

partition_sign(pi) returns the sign of a permutation with cycle structure given by the partition pi.

This function corresponds to a homomorphism from the symmetric group S_n into the cyclic group of order 2, whose kernel is exactly the alternating group A_n. Partitions of sign 1 are called even partitions while partitions of sign -1 are called odd.

Wraps GAP's SignPartition.

EXAMPLES:

```
sage: Partition([5,3]).sign()
1
sage: Partition([5,2]).sign()
-1
```

Zolotarev's lemma states that the Legendre symbol $\left(\frac{a}{p}\right)$ for an integer $a \pmod p$ (p a prime number), can be computed as sign(p_a), where sign denotes the sign of a permutation and p_a the permutation of the residue classes $\pmod p$ induced by modular multiplication by a, provided p does not divide a.

We verify this in some examples.

```
sage: F = GF(11)
sage: a = F.multiplicative_generator();a
2
sage: plist = [int(a*F(x)) for x in range(1,11)]; plist
[2, 4, 6, 8, 10, 1, 3, 5, 7, 9]
```

This corresponds ot the permutation (1, 2, 4, 8, 5, 10, 9, 7, 3, 6) (acting the set $\{1, 2, ..., 10\}$) and to the partition [10].

```
sage: p = PermutationGroupElement('(1, 2, 4, 8, 5, 10, 9, 7, 3, 6)')
sage: p.sign()
-1
sage: Partition([10]).sign()
-1
sage: kronecker_symbol(11,2)
-1
```

Now replace 2 by 3:

```
sage: plist = [int(F(3*x)) for x in range(1,11)]; plist
[3, 6, 9, 1, 4, 7, 10, 2, 5, 8]
sage: range(1,11)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
sage: p = PermutationGroupElement('(3,4,8,7,9)')
sage: p.sign()
1
sage: kronecker_symbol(3,11)
1
sage: Partition([5,1,1,1,1,1]).sign()
1
```

In both cases, Zolotarev holds.

REFERENCES:

- http://en.wikipedia.org/wiki/Zolotarev's_lemma

size()

Returns the size of partition p.

EXAMPLES:

```
sage: Partition([2,2]).size()
4
sage: Partition([3,2,1]).size()
6
```

to_exp(*k=0*)

Return a list of the multiplicities of the parts of a partition. Use the optional parameter k to get a return list of length at least k.

EXAMPLES:

```
sage: Partition([3,2,2,1]).to_exp()
[1, 2, 1]
sage: Partition([3,2,2,1]).to_exp(5)
[1, 2, 1, 0, 0]
```

to_exp_dict()

Returns a dictionary containing the multiplicities of the parts of this partition.

EXAMPLES:

```
sage: p = Partition([4,2,2,1])
sage: d = p.to_exp_dict()
sage: d[4]
1
sage: d[2]
2
sage: d[1]
1
sage: 5 in d
False
```

to_list()

Return self as a list.

EXAMPLES:

```
sage: p = Partition([2,1]).to_list(); p
[2, 1]
sage: type(p)
<type 'list'>
```

TESTS:

```
sage: p = Partition([2,1])
sage: pl = p.to_list()
sage: pl[0] = 0; p
[2, 1]
```

up()

Returns a generator for partitions that can be obtained from pi by adding a box.

EXAMPLES:

```
sage: [p for p in Partition([2,1,1]).up()]
[[3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]
sage: [p for p in Partition([3,2]).up()]
[[4, 2], [3, 3], [3, 2, 1]]
```

up_list()

Returns a list of the partitions that can be formed from the partition p by adding a box.

EXAMPLES:

```
sage: Partition([2,1,1]).up_list()
[[3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]
sage: Partition([3,2]).up_list()
[[4, 2], [3, 3], [3, 2, 1]]
```

upper_hook(*i, j, alpha*)

Returns the upper hook length of the box (i,j) in self. When alpha == 1, this is just the normal hook length. As usual, indices are 0 based.

The upper hook length of a box (i,j) in a partition κ is defined by

$$h_*^\kappa(i,j) = \kappa'_j - i + \alpha(\kappa_i - j + 1).$$

EXAMPLES:

```
sage: p = Partition([2,1])
sage: p.upper_hook(0,0,1)
3
sage: p.hook(0,0)
3
sage: [ p.upper_hook(i,j,x) for i,j in p.boxes() ]
[2*x + 1, x, x]
```

upper_hook_lengths(*alpha*)

Returns the upper hook lengths of the partition. When alpha == 1, these are just the normal hook lengths. The upper hook length of a box (i,j) in a partition κ is defined by

$$h_*^\kappa(i,j) = \kappa'_j - i + 1 + \alpha(\kappa_i - j).$$

EXAMPLES:

```
sage: Partition([3,2,1]).upper_hook_lengths(x)
[[3*x + 2, 2*x + 1, x], [2*x + 1, x], [x]]
sage: Partition([3,2,1]).upper_hook_lengths(1)
[[5, 3, 1], [3, 1], [1]]
sage: Partition([3,2,1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
```

weighted_size()

Returns sum([i*p[i] for i in range(len(p))]). It is also the sum of the leg of every cell in b, or the sum of binomial(s[i],2) for s the conjugate partition of p.

EXAMPLES:

```
sage: Partition([2,2]).weighted_size()
2
sage: Partition([3,3,3]).weighted_size()
9
sage: Partition([5,2]).weighted_size()
2
```

Partitions(*n=None, **kwargs*)

Partitions(n, **kwargs) returns the combinatorial class of integer partitions of n, subject to the constraints given by the keywords.

Valid keywords are: `starting`, `ending`, `min_part`, `max_part`, `max_length`, `min_length`, `length`, `max_slope`, `min_slope`, `inner`, `outer`, and `parts_in`. They have the following meanings:

- `starting=p` specifies that the partitions should all be greater than or equal to p in reverse lex order.
- `length=k` specifies that the partitions have exactly k parts.
- `min_length=k` specifies that the partitions have at least k parts.
- `min_part=k` specifies that all parts of the partitions are at least k.
- `outer=p` specifies that the partitions be contained inside the partition p.
- `min_slope=k` specifies that the partitions have slope at least k; the slope is the difference between successive parts.
- `parts_in=S` specifies that the partitions have parts in the set S, which can be any sequence of positive integers.

The `max_*` versions, along with `inner` and `ending`, work analogously.

Right now, the `parts_in`, `starting`, and `ending` keyword arguments are mutually exclusive, both of each other and of other keyword arguments. If you specify, say, `parts_in`, all other keyword arguments will be ignored; `starting` and `ending` work the same way.

EXAMPLES: If no arguments are passed, then the combinatorial class of all integer partitions is returned.

```
sage: Partitions()
Partitions
sage: [2,1] in Partitions()
True
```

If an integer n is passed, then the combinatorial class of integer partitions of n is returned.

```
sage: Partitions(3)
Partitions of the integer 3
sage: Partitions(3).list()
[[3], [2, 1], [1, 1, 1]]
```

If `starting=p` is passed, then the combinatorial class of partitions greater than or equal to p in lexicographic order is returned.

```
sage: Partitions(3, starting=[2,1])
Partitions of the integer 3 starting with [2, 1]
sage: Partitions(3, starting=[2,1]).list()
[[2, 1], [1, 1, 1]]
```

If `ending=p` is passed, then the combinatorial class of partitions at most p in lexicographic order is returned.

```
sage: Partitions(3, ending=[2,1])
Partitions of the integer 3 ending with [2, 1]
sage: Partitions(3, ending=[2,1]).list()
[[3], [2, 1]]
```

Using `max_slope=-1` yields partitions into distinct parts – each part differs from the next by at least 1. Use a different `max_slope` to get parts that differ by, say, 2.

```
sage: Partitions(7, max_slope=-1).list()
[[7], [6, 1], [5, 2], [4, 3], [4, 2, 1]]
sage: Partitions(15, max_slope=-1).cardinality()
27
```

The number of partitions of n into odd parts equals the number of partitions into distinct parts. Let's test that for n from 10 to 20.

```
sage: test = lambda n: Partitions(n, max_slope=-1).cardinality() == Partitions(n, parts_in=[1,3.
sage: all(test(n) for n in [10..20])
True
```

The number of partitions of n into distinct parts that differ by at least 2 equals the number of partitions into parts that equal 1 or 4 modulo 5; this is one of the Rogers-Ramanujan identities.

```
sage: test = lambda n: Partitions(n, max_slope=-2).cardinality() == Partitions(n, parts_in=([1,6
sage: all(test(n) for n in [10..20])
True
```

Here are some more examples illustrating `min_part`, `max_part`, and `length`.

```
sage: Partitions(5,min_part=2)
Partitions of the integer 5 satisfying constraints min_part=2
sage: Partitions(5,min_part=2).list()
[[5], [3, 2]]
```

```
sage: Partitions(3,max_length=2).list()
[[3], [2, 1]]

sage: Partitions(10, min_part=2, length=3).list()
[[6, 2, 2], [5, 3, 2], [4, 4, 2], [4, 3, 3]]
```

Here are some further examples using various constraints:

```
  sage: [x for x in Partitions(4)]
  [[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
  sage: [x for x in Partitions(4, length=2)]
  [[3, 1], [2, 2]]
  sage: [x for x in Partitions(4, min_length=2)]
  [[3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
  sage: [x for x in Partitions(4, max_length=2)]
  [[4], [3, 1], [2, 2]]
  sage: [x for x in Partitions(4, min_length=2, max_length=2)]
  [[3, 1], [2, 2]]
  sage: [x for x in Partitions(4, max_part=2)]
  [[2, 2], [2, 1, 1], [1, 1, 1, 1]]
  sage: [x for x in Partitions(4, min_part=2)]
  [[4], [2, 2]]
  sage: [x for x in Partitions(4, outer=[3,1,1])]
  [[3, 1], [2, 1, 1]]
  sage: [x for x in Partitions(4, outer=[infinity, 1, 1])]
  [[4], [3, 1], [2, 1, 1]]
  sage: [x for x in Partitions(4, inner=[1,1,1])]
  [[2, 1, 1], [1, 1, 1, 1]]
  sage: [x for x in Partitions(4, max_slope=-1)]
  [[4], [3, 1]]
  sage: [x for x in Partitions(4, min_slope=-1)]
  [[4], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
  sage: [x for x in Partitions(11, max_slope=-1, min_slope=-3, min_length=2, max_length=4)]
  [[7, 4], [6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2], [5, 3, 2, 1]]
  sage: [x for x in Partitions(11, max_slope=-1, min_slope=-3, min_length=2, max_length=4, outer
  [[6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2]]
```

```
Note that if you specify min_part=0, then the objects produced
will have parts equal to zero which violates some internal
assumptions that the Partition class makes.

::
```

```
  sage: [x for x in Partitions(4, length=3, min_part=0)]
  doctest:... RuntimeWarning: Currently, setting min_part=0 produces Partition objects which vic
  [[4, 0, 0], [3, 1, 0], [2, 2, 0], [2, 1, 1]]
  sage: [x for x in Partitions(4, min_length=3, min_part=0)]
  [[4, 0, 0], [3, 1, 0], [2, 2, 0], [2, 1, 1], [1, 1, 1, 1]]
```

```
Except for very special cases, counting is done by brute force
iteration through all the partitions. However the iteration
itself has a reasonnable complexity (constant memory, constant
amortized time), which allow for manipulating large partitions::
```

```
  sage: Partitions(1000, max_length=1).list()
  [[1000]]
```

In particular, getting the first element is also constant time::

```
sage: Partitions(30, max_part=29).first()
[29, 1]
```

TESTS:

```
sage: P = Partitions(5, min_part=2)
sage: P == loads(dumps(P))
True

sage: repr( Partitions(5, min_part=2) )
'Partitions of the integer 5 satisfying constraints min_part=2'

sage: P = Partitions(5, min_part=2)
sage: P.first().parent()
Partitions...
sage: [2,1] in P
False
sage: [2,2,1] in P
False
sage: [3,2] in P
True
```

class PartitionsGreatestEQ(*n, k*)

Returns combinatorial class of all (unordered) "restricted" partitions of the integer n having its greatest part equal to the integer k.

EXAMPLES:

```
sage: PartitionsGreatestEQ(10,2)
Partitions of 10 having greatest part equal to 2
sage: PartitionsGreatestEQ(10,2).list()
[[2, 2, 2, 2, 2],
 [2, 2, 2, 2, 1, 1],
 [2, 2, 2, 1, 1, 1, 1],
 [2, 2, 1, 1, 1, 1, 1, 1],
 [2, 1, 1, 1, 1, 1, 1, 1, 1]]

sage: [4,3,2,1] in PartitionsGreatestEQ(10,2)
False
sage: [2,2,2,2,2] in PartitionsGreatestEQ(10,2)
True
sage: [1]*10 in PartitionsGreatestEQ(10,2)
False

sage: PartitionsGreatestEQ(10,2).first().parent()
Partitions...
```

TESTS:

```
sage: p = PartitionsGreatestEQ(10,2)
sage: p == loads(dumps(p))
True
```

class PartitionsGreatestEQ_nk(*n, k*)

class PartitionsGreatestLE(*n, k*)

Returns the combinatorial class of all (unordered) "restricted" partitions of the integer n having parts less than or equal to the integer k.

EXAMPLES:

```
sage: PartitionsGreatestLE(10,2)
Partitions of 10 having parts less than or equal to 2
sage: PartitionsGreatestLE(10,2).list()
[[2, 2, 2, 2, 2],
 [2, 2, 2, 2, 1, 1],
 [2, 2, 2, 1, 1, 1, 1],
 [2, 2, 1, 1, 1, 1, 1, 1],
 [2, 1, 1, 1, 1, 1, 1, 1, 1],
 [1, 1, 1, 1, 1, 1, 1, 1, 1, 1]]

sage: [4,3,2,1] in PartitionsGreatestLE(10,2)
False
sage: [2,2,2,2,2] in PartitionsGreatestLE(10,2)
True
sage: PartitionsGreatestLE(10,2).first().parent()
Partitions...
```

TESTS:

```
sage: p = PartitionsGreatestLE(10,2)
sage: p == loads(dumps(p))
True
```

class PartitionsGreatestLE_nk(*n, k*)

PartitionsInBox(*h, w*)

Returns the combinatorial class of partitions that fit in a h by w box.

EXAMPLES:

```
sage: PartitionsInBox(2,2)
Integer partitions which fit in a 2 x 2 box
sage: PartitionsInBox(2,2).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2]]
```

class PartitionsInBox_hw(*h, w*)

list()

Returns a list of all the partitions inside a box of height h and width w.

EXAMPLES:

```
sage: PartitionsInBox(2,2).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2]]
```

class Partitions_all()

cardinality()

Returns the number of integer partitions.

EXAMPLES:

```
sage: Partitions().cardinality()
+Infinity
```

object_class()

class Partitions_constraints(*n, length=None, min_length=0, max_length=+Infinity, floor=None, ceiling=None, min_part=0, max_part=+Infinity, min_slope=-Infinity, max_slope=+Infinity, name=None, element_constructor=None*)

class Partitions_ending(*n, ending_partition*)

first()

EXAMPLES:

```
sage: Partitions(4, ending=[1,1,1,1]).first()
[4]
```

next(*part*)

EXAMPLES:

```
sage: Partitions(4, ending=[1,1,1,1]).next(Partition([4]))
[3, 1]
sage: Partitions(4, ending=[1,1,1,1]).next(Partition([1,1,1,1])) is None
True
```

class Partitions_n(*n*)

cardinality(*algorithm='default'*)

INPUT:

- `algorithm`
  - (default: `default`)
  - `'bober'` - use Jonathan Bober's implementation (*very* fast, but relatively new)
  - `'gap'` - use GAP (VERY *slow*)
  - `'pari'` - use PARI. Speed seems the same as GAP until n is in the thousands, in which case PARI is faster. *But* PARI has a bug, e.g., on 64-bit Linux PARI-2.3.2 outputs numbpart(147007)%1000 as 536, but it should be 533!. So do not use this option.
  - `'default'` - `'bober'` when k is not specified; otherwise use `'gap'`.

Use the function `partitions(n)` to return a generator over all partitions of n.

It is possible to associate with every partition of the integer n a conjugacy class of permutations in the symmetric group on n points and vice versa. Therefore p(n) = NrPartitions(n) is the number of conjugacy classes of the symmetric group on n points.

EXAMPLES:

```
sage: v = Partitions(5).list(); v
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: len(v)
7
sage: Partitions(5).cardinality(algorithm='gap')
7
sage: Partitions(5).cardinality(algorithm='pari')
7
sage: Partitions(5).cardinality(algorithm='bober')
7
```

The input must be a nonnegative integer or a ValueError is raised.

```
sage: Partitions(10).cardinality()
42
sage: Partitions(3).cardinality()
3
```

```
sage: Partitions(10).cardinality()
42
sage: Partitions(3).cardinality(algorithm='pari')
3
sage: Partitions(10).cardinality(algorithm='pari')
42
sage: Partitions(40).cardinality()
37338
sage: Partitions(100).cardinality()
190569292
```

A generating function for p(n) is given by the reciprocal of Euler's function:

$$\sum_{n=0}^{\infty} p(n)x^n = \prod_{k=1}^{\infty}\left(\frac{1}{1-x^k}\right).$$

We use Sage to verify that the first several coefficients do instead agree:

```
sage: q = PowerSeriesRing(QQ, 'q', default_prec=9).gen()
sage: prod([(1-q^k)^(-1) for k in range(1,9)])  ## partial product of
1 + q + 2*q^2 + 3*q^3 + 5*q^4 + 7*q^5 + 11*q^6 + 15*q^7 + 22*q^8 + O(q^9)
sage: [Partitions(k) .cardinality()for k in range(2,10)]
[2, 3, 5, 7, 11, 15, 22, 30]
```

REFERENCES:

- http://en.wikipedia.org/wiki/Partition_(number_theory)

first()

Returns the lexicographically first partition of a positive integer n. This is the partition [n].

EXAMPLES:

```
sage: Partitions(4).first()
[4]
```

last()

Returns the lexicographically last partition of the positive integer n. This is the all-ones partition.

EXAMPLES:

```
sage: Partitions(4).last()
[1, 1, 1, 1]
```

object_class()

class **Partitions_parts_in**(*n, parts*)

cardinality()

Return the number of partitions with parts in S. Wraps GAP's `NrRestrictedPartitions`.

EXAMPLES:

```
sage: Partitions(15, parts_in=[2,3,7]).cardinality()
5
```

If you can use all parts 1 through n, we'd better get $p(n)$:

```
sage: Partitions(20, parts_in=[1..20]).cardinality() == Partitions(20).cardinality()
True
```

TESTS:

Let's check the consistency of GAP's function and our own algorithm that actually generates the partitions.

```
sage: ps = Partitions(15, parts_in=[1,2,3])
sage: ps.cardinality() == len(ps.list())
True
sage: ps = Partitions(15, parts_in=[])
sage: ps.cardinality() == len(ps.list())
True
sage: ps = Partitions(3000, parts_in=[50,100,500,1000])
sage: ps.cardinality() == len(ps.list())
True
sage: ps = Partitions(10, parts_in=[3,6,9])
sage: ps.cardinality() == len(ps.list())
True
sage: ps = Partitions(0, parts_in=[1,2])
sage: ps.cardinality() == len(ps.list())
True
```

first()

Return the lexicographically first partition of a positive integer n with the specified parts, or None if no such partition exists.

EXAMPLES:

```
sage: Partitions(9, parts_in=[3,4]).first()
[3, 3, 3]
sage: Partitions(6, parts_in=[1..6]).first()
[6]
sage: Partitions(30, parts_in=[4,7,8,10,11]).first()
[11, 11, 8]
```

last()

Returns the lexicographically last partition of the positive integer n with the specified parts, or None if no such partition exists.

EXAMPLES:

```
sage: Partitions(15, parts_in=[2,3]).last()
[3, 2, 2, 2, 2, 2, 2]
sage: Partitions(30, parts_in=[4,7,8,10,11]).last()
[7, 7, 4, 4, 4, 4]
sage: Partitions(10, parts_in=[3,6]).last() is None
True
sage: Partitions(50, parts_in=[11,12,13]).last()
[13, 13, 12, 12]
sage: Partitions(30, parts_in=[4,7,8,10,11]).last()
[7, 7, 4, 4, 4, 4]
```

TESTS:

```
sage: Partitions(6, parts_in=[1..6]).last()
[1, 1, 1, 1, 1, 1]
sage: Partitions(0, parts_in=[]).last()
[]
sage: Partitions(50, parts_in=[11,12]).last() is None
True
```

object_class()

class **Partitions_starting**(*n, starting_partition*)

first()

EXAMPLES:

```
sage: Partitions(3, starting=[2,1]).first()
[2, 1]
```

next(*part*)

EXAMPLES:

```
sage: Partitions(3, starting=[2,1]).next(Partition([2,1]))
[1, 1, 1]
```

RestrictedPartitions(*n, S, k=None*)

This function has been deprecated and will be removed in a future version of Sage; use Partitions() with the `parts_in` keyword.

Original docstring follows.

A restricted partition is, like an ordinary partition, an unordered sum $n = p_1 + p_2 + \ldots + p_k$ of positive integers and is represented by the list $p = [p_1, p_2, \ldots, p_k]$, in nonincreasing order. The difference is that here the p_i must be elements from the set S, while for ordinary partitions they may be elements from $[1..n]$.

Returns the list of all restricted partitions of the positive integer n into sums with k summands with the summands of the partition coming from the set S. If k is not given all restricted partitions for all k are returned.

Wraps GAP's RestrictedPartitions.

EXAMPLES:

```
sage: RestrictedPartitions(5,[3,2,1])
doctest:...: DeprecationWarning: RestrictedPartitions is deprecated; use Partitions with the par
doctest:...: DeprecationWarning: RestrictedPartitions_nsk is deprecated; use Partitions with the
Partitions of 5 restricted to the values [1, 2, 3]
sage: RestrictedPartitions(5,[3,2,1]).list()
[[3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: RestrictedPartitions(5,[3,2,1],4)
Partitions of 5 restricted to the values [1, 2, 3] of length 4
sage: RestrictedPartitions(5,[3,2,1],4).list()
[[2, 1, 1, 1]]
```

class **RestrictedPartitions_nsk**(*n, S, k=None*)

We are deprecating RestrictedPartitions, so this class should be deprecated too.

cardinality()

Returns the size of RestrictedPartitions(n,S,k). Wraps GAP's NrRestrictedPartitions.

EXAMPLES:

```
sage: RestrictedPartitions(8,[1,3,5,7]).cardinality()
doctest:...: DeprecationWarning: RestrictedPartitions is deprecated; use Partitions with the
6
sage: RestrictedPartitions(8,[1,3,5,7],2).cardinality()
2
```

list()

Returns the list of all restricted partitions of the positive integer n into sums with k summands with the summands of the partition coming from the set S. If k is not given all restricted partitions for all k are returned.

Wraps GAP's RestrictedPartitions.

EXAMPLES:

```
sage: RestrictedPartitions(8,[1,3,5,7]).list()
doctest:...: DeprecationWarning: RestrictedPartitions is deprecated; use Partitions with the
[[7, 1], [5, 3], [5, 1, 1, 1], [3, 3, 1, 1], [3, 1, 1, 1, 1, 1], [1, 1, 1, 1, 1, 1, 1]]
```

```
sage: RestrictedPartitions(8,[1,3,5,7],2).list()
[[7, 1], [5, 3]]
```

cyclic_permutations_of_partition(*partition*)

Returns all combinations of cyclic permutations of each cell of the partition.

AUTHORS:

- Robert L. Miller

EXAMPLES:

```
sage: from sage.combinat.partition import cyclic_permutations_of_partition
sage: cyclic_permutations_of_partition([[1,2,3,4],[5,6,7]])
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```

Note that repeated elements are not considered equal:

```
sage: cyclic_permutations_of_partition([[1,2,3],[4,4,4]])
[[[1, 2, 3], [4, 4, 4]],
 [[1, 3, 2], [4, 4, 4]],
 [[1, 2, 3], [4, 4, 4]],
 [[1, 3, 2], [4, 4, 4]]]
```

cyclic_permutations_of_partition_iterator(*partition*)

Iterates over all combinations of cyclic permutations of each cell of the partition.

AUTHORS:

- Robert L. Miller

EXAMPLES:

```
sage: from sage.combinat.partition import cyclic_permutations_of_partition
sage: list(cyclic_permutations_of_partition_iterator([[1,2,3,4],[5,6,7]]))
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```

Note that repeated elements are not considered equal:

```
sage: list(cyclic_permutations_of_partition_iterator([[1,2,3],[4,4,4]]))
[[[1, 2, 3], [4, 4, 4]],
 [[1, 3, 2], [4, 4, 4]],
 [[1, 2, 3], [4, 4, 4]],
 [[1, 3, 2], [4, 4, 4]]]
```

ferrers_diagram(*pi*)

Return the Ferrers diagram of pi.

INPUT:

- `pi` - a partition, given as a list of integers.

EXAMPLES:

```
sage: print ferrers_diagram([5,5,2,1])
*****
*****
**
*
sage: pi = partitions_list(10)[30] ## [6,1,1,1,1]
sage: print ferrers_diagram(pi)
******
*
*
*
*
sage: pi = partitions_list(10)[33] ## [6, 3, 1]
sage: print ferrers_diagram(pi)
******
***
*
```

from_core_and_quotient(*core, quotient*)

Returns a partition from its r-core and r-quotient.

Algorithm from mupad-combinat.

EXAMPLES:

```
sage: partition.from_core_and_quotient([2,1], [[2,1],[3],[1,1,1]])
[11, 5, 5, 3, 2, 2, 2]
```

from_exp(*a*)

Returns a partition from its list of multiplicities.

EXAMPLES:

```
sage: partition.from_exp([1,2,1])
[3, 2, 2, 1]
```

number_of_ordered_partitions(*n, k=None*)

Returns the size of ordered_partitions(n,k). Wraps GAP's NrOrderedPartitions.

It is possible to associate with every partition of the integer n a conjugacy class of permutations in the symmetric group on n points and vice versa. Therefore p(n) = NrPartitions(n) is the number of conjugacy classes of the symmetric group on n points.

EXAMPLES:

```
sage: number_of_ordered_partitions(10,2)
9
sage: number_of_ordered_partitions(15)
16384
```

number_of_partitions(*n, k=None, algorithm='default'*)

Returns the size of partitions_list(n,k).

INPUT:

- `n` - an integer
- `k` - (default: None); if specified, instead returns the cardinality of the set of all (unordered) partitions of the positive integer n into sums with k summands.
- `algorithm` - (default: 'default')
- `'default'` - If k is not None, then use Gap (very slow). If k is None, use Jonathan Bober's highly optimized implementation (this is the fastest code in the world for this problem).
- `'bober'` - use Jonathan Bober's implementation
- `'gap'` - use GAP (VERY *slow*)
- `'pari'` - use PARI. Speed seems the same as GAP until n is in the thousands, in which case PARI is faster. *But* PARI has a bug, e.g., on 64-bit Linux PARI-2.3.2 outputs numbpart(147007)%1000 as 536 when it should be 533!. So do not use this option.

IMPLEMENTATION: Wraps GAP's NrPartitions or PARI's numbpart function.

Use the function `partitions(n)` to return a generator over all partitions of n.

It is possible to associate with every partition of the integer n a conjugacy class of permutations in the symmetric group on n points and vice versa. Therefore p(n) = NrPartitions(n) is the number of conjugacy classes of the symmetric group on n points.

EXAMPLES:

```
sage: v = list(partitions(5)); v
[(1, 1, 1, 1, 1), (1, 1, 1, 2), (1, 2, 2), (1, 1, 3), (2, 3), (1, 4), (5,)]
sage: len(v)
7
sage: number_of_partitions(5, algorithm='gap')
7
sage: number_of_partitions(5, algorithm='pari')
7
sage: number_of_partitions(5, algorithm='bober')
7
```

The input must be a nonnegative integer or a ValueError is raised.

```
sage: number_of_partitions(-5)
...
ValueError: n (=-5) must be a nonnegative integer
```

```
sage: number_of_partitions(10,2)
5
sage: number_of_partitions(10)
42
sage: number_of_partitions(3)
3
sage: number_of_partitions(10)
42
```

```
sage: number_of_partitions(3, algorithm='pari')
3
sage: number_of_partitions(10, algorithm='pari')
42
sage: number_of_partitions(40)
37338
sage: number_of_partitions(100)
190569292
sage: number_of_partitions(100000)
2749351056977569651267751632098635268817342931598005475820312598430214732811496417305550507416607
```

A generating function for p(n) is given by the reciprocal of Euler's function:

$$\sum_{n=0}^{\infty} p(n)x^n = \prod_{k=1}^{\infty} \left(\frac{1}{1-x^k}\right).$$

We use Sage to verify that the first several coefficients do instead agree:

```
sage: q = PowerSeriesRing(QQ, 'q', default_prec=9).gen()
sage: prod([(1-q^k)^(-1) for k in range(1,9)])  ## partial product of
1 + q + 2*q^2 + 3*q^3 + 5*q^4 + 7*q^5 + 11*q^6 + 15*q^7 + 22*q^8 + O(q^9)
sage: [number_of_partitions(k) for k in range(2,10)]
[2, 3, 5, 7, 11, 15, 22, 30]
```

REFERENCES:

- http://en.wikipedia.org/wiki/Partition_(number_theory)

TESTS:

```
sage: n = 500 + randint(0,500)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 1500 + randint(0,1500)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 1000000 + randint(0,1000000)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 1000000 + randint(0,1000000)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 1000000 + randint(0,1000000)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 1000000 + randint(0,1000000)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 1000000 + randint(0,1000000)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 1000000 + randint(0,1000000)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 100000000 + randint(0,100000000)
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0
True
sage: n = 1000000000 + randint(0,1000000000)
```

```
sage: number_of_partitions( n - (n % 385) + 369) % 385 == 0       # takes a long time
True
```

Another consistency test for n up to 500:

```
sage: len([n for n in [1..500] if number_of_partitions(n) != number_of_partitions(n,algorithm='p
0
```

number_of_partitions_list(*n, k=None*)

This function will be deprecated in a future version of Sage and eventually removed. Use Partitions(n).cardinality() or Partitions(n, length=k).cardinality() instead.

Original docstring follows.

Returns the size of partitions_list(n,k).

Wraps GAP's NrPartitions.

It is possible to associate with every partition of the integer n a conjugacy class of permutations in the symmetric group on n points and vice versa. Therefore p(n) = NrPartitions(n) is the number of conjugacy classes of the symmetric group on n points.

`number_of_partitions(n)` is also available in PARI, however the speed seems the same until n is in the thousands (in which case PARI is faster).

EXAMPLES:

```
sage: partition.number_of_partitions_list(10,2)
5
sage: partition.number_of_partitions_list(10)
42
```

A generating function for p(n) is given by the reciprocal of Euler's function:

$$\sum_{n=0}^{\infty} p(n)x^n = \prod_{k=1}^{\infty}\left(\frac{1}{1-x^k}\right).$$

Sage verifies that the first several coefficients do instead agree:

```
sage: q = PowerSeriesRing(QQ, 'q', default_prec=9).gen()
sage: prod([(1-q^k)^(-1) for k in range(1,9)])  ## partial product of
1 + q + 2*q^2 + 3*q^3 + 5*q^4 + 7*q^5 + 11*q^6 + 15*q^7 + 22*q^8 + O(q^9)
sage: [partition.number_of_partitions_list(k) for k in range(2,10)]
[2, 3, 5, 7, 11, 15, 22, 30]
```

REFERENCES:

- http://en.wikipedia.org/wiki/Partition_(number_theory)

number_of_partitions_restricted(*n, S, k=None*)

This function will be deprecated in a future version of Sage and eventually removed. Use RestrictedPartitions(n, S, k).cardinality() instead.

Original docstring follows.

Returns the size of partitions_restricted(n,S,k). Wraps GAP's NrRestrictedPartitions.

EXAMPLES:

```
sage: number_of_partitions_restricted(8,[1,3,5,7])
6
sage: number_of_partitions_restricted(8,[1,3,5,7],2)
2
```

number_of_partitions_set(*S, k*)

Returns the size of `partitions_set(S,k)`. Wraps GAP's NrPartitionsSet.

The Stirling number of the second kind is the number of partitions of a set of size n into k blocks.

EXAMPLES:

```
sage: mset = [1,2,3,4]
sage: number_of_partitions_set(mset,2)
7
sage: stirling_number2(4,2)
7
```

REFERENCES

- http://en.wikipedia.org/wiki/Partition_of_a_set

number_of_partitions_tuples(*n, k*)

number_of_partition_tuples(n, k) returns the number of partition_tuples(n,k).

Wraps GAP's NrPartitionTuples.

EXAMPLES:

```
sage: number_of_partitions_tuples(3,2)
10
sage: number_of_partitions_tuples(8,2)
185
```

Now we compare that with the result of the following GAP computation:

```
gap> S8:=Group((1,2,3,4,5,6,7,8),(1,2));
Group([ (1,2,3,4,5,6,7,8), (1,2) ])
gap> C2:=Group((1,2));
Group([ (1,2) ])
gap> W:=WreathProduct(C2,S8);
<permutation group of size 10321920 with 10 generators>
gap> Size(W);
10321920     ## = 2^8*Factorial(8), which is good:-)
gap> Size(ConjugacyClasses(W));
185
```

ordered_partitions(*n, k=None*)

An ordered partition of n is an ordered sum

$$n = p_1 + p_2 + \cdots + p_k$$

of positive integers and is represented by the list $p = [p_1, p_2, \cdots, p_k]$. If k is omitted then all ordered partitions are returned.

`ordered_partitions(n,k)` returns the list of all (ordered) partitions of the positive integer n into sums with k summands.

Do not call `ordered_partitions` with an n much larger than 15, since the list will simply become too large.

Wraps GAP's OrderedPartitions.

The number of ordered partitions T_n of $\{1, 2, ..., n\}$ has the generating function is

$$\sum_n \frac{T_n}{n!} x^n = \frac{1}{2 - e^x}.$$

EXAMPLES:

```
sage: ordered_partitions(10,2)
[[1, 9], [2, 8], [3, 7], [4, 6], [5, 5], [6, 4], [7, 3], [8, 2], [9, 1]]

sage: ordered_partitions(4)
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1], [4]]
```

REFERENCES:

- http://en.wikipedia.org/wiki/Ordered_partition_of_a_set

partition_associated(*pi*)

partition_associated(pi) returns the "associated" (also called "conjugate" in the literature) partition of the partition pi which is obtained by transposing the corresponding Ferrers diagram.

EXAMPLES:

```
sage: partition_associated([2,2])
[2, 2]
sage: partition_associated([6,3,1])
[3, 2, 2, 1, 1, 1]
sage: print ferrers_diagram([6,3,1])
******
***
*
sage: print ferrers_diagram([3,2,2,1,1,1])
***
**
**
*
*
*
```

partition_power(*pi, k*)

partition_power(pi, k) returns the partition corresponding to the k-th power of a permutation with cycle structure pi (thus describes the powermap of symmetric groups).

Wraps GAP's PowerPartition.

EXAMPLES:

```
sage: partition_power([5,3],1)
[5, 3]
sage: partition_power([5,3],2)
[5, 3]
sage: partition_power([5,3],3)
[5, 1, 1, 1]
sage: partition_power([5,3],4)
[5, 3]
```

Now let us compare this to the power map on S_8:

```
sage: G = SymmetricGroup(8)
sage: g = G([(1,2,3,4,5),(6,7,8)])
sage: g
(1,2,3,4,5)(6,7,8)
sage: g^2
(1,3,5,2,4)(6,8,7)
sage: g^3
(1,4,2,5,3)
```

```
sage: g^4
(1,5,4,3,2)(6,7,8)
```

partition_sign(*pi*)

partition_sign(pi) returns the sign of a permutation with cycle structure given by the partition pi.

This function corresponds to a homomorphism from the symmetric group S_n into the cyclic group of order 2, whose kernel is exactly the alternating group A_n. Partitions of sign 1 are called even partitions while partitions of sign -1 are called odd.

Wraps GAP's SignPartition.

EXAMPLES:

```
sage: partition_sign([5,3])
1
sage: partition_sign([5,2])
-1
```

Zolotarev's lemma states that the Legendre symbol $\left(\frac{a}{p}\right)$ for an integer $a \pmod p$ (p a prime number), can be computed as sign(p_a), where sign denotes the sign of a permutation and p_a the permutation of the residue classes $\pmod p$ induced by modular multiplication by a, provided p does not divide a.

We verify this in some examples.

```
sage: F = GF(11)
sage: a = F.multiplicative_generator();a
2
sage: plist = [int(a*F(x)) for x in range(1,11)]; plist
[2, 4, 6, 8, 10, 1, 3, 5, 7, 9]
```

This corresponds ot the permutation (1, 2, 4, 8, 5, 10, 9, 7, 3, 6) (acting the set $\{1, 2, ..., 10\}$) and to the partition [10].

```
sage: p = PermutationGroupElement('(1, 2, 4, 8, 5, 10, 9, 7, 3, 6)')
sage: p.sign()
-1
sage: partition_sign([10])
-1
sage: kronecker_symbol(11,2)
-1
```

Now replace 2 by 3:

```
sage: plist = [int(F(3*x)) for x in range(1,11)]; plist
[3, 6, 9, 1, 4, 7, 10, 2, 5, 8]
sage: range(1,11)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
sage: p = PermutationGroupElement('(3,4,8,7,9)')
sage: p.sign()
1
sage: kronecker_symbol(3,11)
1
sage: partition_sign([5,1,1,1,1,1])
1
```

In both cases, Zolotarev holds.

REFERENCES:

- http://en.wikipedia.org/wiki/Zolotarev's_lemma

partitions(*n*)
Generator of all the partitions of the integer n.

INPUT:

- n - int

To compute the number of partitions of n use number_of_partitions(n).

EXAMPLES:

```
sage: partitions(3)
<generator object at 0x...>
sage: list(partitions(3))
[(1, 1, 1), (1, 2), (3,)]
```

AUTHORS:

- Adapted from David Eppstein, Jan Van lent, George Yoshida; Python Cookbook 2, Recipe 19.16.

partitions_greatest(*n, k*)
Returns the list of all (unordered) "restricted" partitions of the integer n having parts less than or equal to the integer k.

Wraps GAP's PartitionsGreatestLE.

EXAMPLES:

```
sage: partitions_greatest(10,2)
[[1, 1, 1, 1, 1, 1, 1, 1, 1, 1],
 [2, 1, 1, 1, 1, 1, 1, 1, 1],
 [2, 2, 1, 1, 1, 1, 1, 1],
 [2, 2, 2, 1, 1, 1, 1],
 [2, 2, 2, 2, 1, 1],
 [2, 2, 2, 2, 2]]
```

partitions_greatest_eq(*n, k*)
Returns the list of all (unordered) "restricted" partitions of the integer n having at least one part equal to the integer k.

Wraps GAP's PartitionsGreatestEQ.

EXAMPLES:

```
sage: partitions_greatest_eq(10,2)
[[2, 1, 1, 1, 1, 1, 1, 1, 1],
 [2, 2, 1, 1, 1, 1, 1, 1],
 [2, 2, 2, 1, 1, 1, 1],
 [2, 2, 2, 2, 1, 1],
 [2, 2, 2, 2, 2]]
```

partitions_list(*n, k=None*)
This function will be deprecated in a future version of Sage and eventually removed. Use Partitions(n).list() or Partitions(n, length=k).list() instead.

Original docstring follows.

An unordered partition of n is an unordered sum $n = p_1 + p_2 + \ldots + p_k$ of positive integers and is represented by the list $p = [p_1, p_2, \ldots, p_k]$, in nonincreasing order, i.e., $p1 \geq p_2 ... \geq p_k$.

INPUT:

- n, k - positive integer

partitions_list(n,k) returns the list of all (unordered) partitions of the positive integer n into sums with k summands. If k is omitted then all partitions are returned.

Do not call partitions_list with an n much larger than 40, in which case there are 37338 partitions, since the list will simply become too large.

Wraps GAP's Partitions.

EXAMPLES:

```
sage: partitions_list(10,2)
[[5, 5], [6, 4], [7, 3], [8, 2], [9, 1]]
sage: partitions_list(5)
[[1, 1, 1, 1, 1], [2, 1, 1, 1], [2, 2, 1], [3, 1, 1], [3, 2], [4, 1], [5]]
```

partitions_restricted(*n, S, k=None*)

This function will be deprecated in a future version of Sage and eventually removed. Use RestrictedPartitions(n, S, k).list() instead.

Original docstring follows.

A restricted partition is, like an ordinary partition, an unordered sum $n = p_1 + p_2 + \ldots + p_k$ of positive integers and is represented by the list $p = [p_1, p_2, \ldots, p_k]$, in nonincreasing order. The difference is that here the p_i must be elements from the set S, while for ordinary partitions they may be elements from $[1..n]$.

Returns the list of all restricted partitions of the positive integer n into sums with k summands with the summands of the partition coming from the set S. If k is not given all restricted partitions for all k are returned.

Wraps GAP's RestrictedPartitions.

EXAMPLES:

```
sage: partitions_restricted(8,[1,3,5,7])
[[1, 1, 1, 1, 1, 1, 1, 1],
 [3, 1, 1, 1, 1, 1],
 [3, 3, 1, 1],
 [5, 1, 1, 1],
 [5, 3],
 [7, 1]]
sage: partitions_restricted(8,[1,3,5,7],2)
[[5, 3], [7, 1]]
```

partitions_set(*S, k=None, use_file=True*)

An unordered partition of a set S is a set of pairwise disjoint nonempty subsets with union S and is represented by a sorted list of such subsets.

partitions_set returns the list of all unordered partitions of the list S of increasing positive integers into k pairwise disjoint nonempty sets. If k is omitted then all partitions are returned.

The Bell number B_n, named in honor of Eric Temple Bell, is the number of different partitions of a set with n elements.

Warning: Wraps GAP - hence S must be a list of objects that have string representations that can be interpreted by the GAP interpreter. If mset consists of at all complicated Sage objects, this function does *not* do what you expect. See SetPartitions in `combinat/set_partition`.

Warning: This function is inefficient. The runtime is dominated by parsing the output from GAP.

Wraps GAP's PartitionsSet.

EXAMPLES:

```
sage: S = [1,2,3,4]
sage: partitions_set(S,2)
[[[1], [2, 3, 4]],
 [[1, 2], [3, 4]],
 [[1, 2, 3], [4]],
 [[1, 2, 4], [3]],
 [[1, 3], [2, 4]],
 [[1, 3, 4], [2]],
 [[1, 4], [2, 3]]]
```

- http://en.wikipedia.org/wiki/Partition_of_a_set

partitions_tuples(*n, k*)

partition_tuples(n, k) returns the list of all k-tuples of partitions which together form a partition of n.

k-tuples of partitions describe the classes and the characters of wreath products of groups with k conjugacy classes with the symmetric group S_n.

Wraps GAP's PartitionTuples.

EXAMPLES:

```
sage: partitions_tuples(3,2)
[[[1, 1, 1], []],
 [[1, 1], [1]],
 [[1], [1, 1]],
 [[], [1, 1, 1]],
 [[2, 1], []],
 [[1], [2]],
 [[2], [1]],
 [[], [2, 1]],
 [[3], []],
 [[], [3]]]
```

17.23 Permutations

The Permutations module. Use Permutation? to get information about the Permutation class, and Permutations? to get information about the combinatorial class of permutations.

AUTHORS:

- Mike Hansen
- Dan Drake (2008-04-07): allow Permutation() to take lists of tuples
- Sebastien Labbe (2009-03-17): added robinson_schensted_inverse

Arrangements(*mset, k*)

An arrangement of mset is an ordered selection without repetitions and is represented by a list that contains only elements from mset, but maybe in a different order.

`Arrangements` returns the combinatorial class of arrangements of the multiset mset that contain k elements.

EXAMPLES:

```
sage: mset = [1,1,2,3,4,4,5]
sage: Arrangements(mset,2).list()
[[1, 1],
 [1, 2],
 [1, 3],
 [1, 4],
 [1, 5],
 [2, 1],
 [2, 3],
 [2, 4],
 [2, 5],
 [3, 1],
 [3, 2],
 [3, 4],
 [3, 5],
 [4, 1],
 [4, 2],
 [4, 3],
 [4, 4],
 [4, 5],
 [5, 1],
 [5, 2],
 [5, 3],
 [5, 4]]
 sage: Arrangements(mset,2).cardinality()
 22
 sage: Arrangements( ["c","a","t"], 2 ).list()
 [['c', 'a'], ['c', 't'], ['a', 'c'], ['a', 't'], ['t', 'c'], ['t', 'a']]
 sage: Arrangements( ["c","a","t"], 3 ).list()
 [['c', 'a', 't'],
  ['c', 't', 'a'],
  ['a', 'c', 't'],
  ['a', 't', 'c'],
  ['t', 'c', 'a'],
  ['t', 'a', 'c']]
```

class **Arrangements_msetk**(*mset, k*)

class **Arrangements_setk**(*s, k*)

CyclicPermutations(*mset*)

Returns the combinatorial class of all cyclic permutations of mset in cycle notation. These are the same as necklaces.

EXAMPLES:

```
sage: CyclicPermutations(range(4)).list()
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]
sage: CyclicPermutations([1,1,1]).list()
[[1, 1, 1]]
```

CyclicPermutationsOfPartition(*partition*)

Returns the combinatorial class of all combinations of cyclic permutations of each cell of the partition. This is the same as a Cartesian product of necklaces.

EXAMPLES:

```
sage: CyclicPermutationsOfPartition([[1,2,3,4],[5,6,7]]).list()
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]

sage: CyclicPermutationsOfPartition([[1,2,3,4],[4,4,4]]).list()
[[[1, 2, 3, 4], [4, 4, 4]],
 [[1, 2, 4, 3], [4, 4, 4]],
 [[1, 3, 2, 4], [4, 4, 4]],
 [[1, 3, 4, 2], [4, 4, 4]],
 [[1, 4, 2, 3], [4, 4, 4]],
 [[1, 4, 3, 2], [4, 4, 4]]]

sage: CyclicPermutationsOfPartition([[1,2,3],[4,4,4]]).list()
[[[1, 2, 3], [4, 4, 4]], [[1, 3, 2], [4, 4, 4]]]

sage: CyclicPermutationsOfPartition([[1,2,3],[4,4,4]]).list(distinct=True)
[[[1, 2, 3], [4, 4, 4]],
 [[1, 3, 2], [4, 4, 4]],
 [[1, 2, 3], [4, 4, 4]],
 [[1, 3, 2], [4, 4, 4]]]
```

class **CyclicPermutationsOfPartition_partition**(*partition*)

iterator(*distinct=False*)

AUTHORS:

- Robert Miller

EXAMPLES:

```
sage: CyclicPermutationsOfPartition([[1,2,3,4],[5,6,7]]).list() # indirect doctest
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```

```
sage: CyclicPermutationsOfPartition([[1,2,3,4],[4,4,4]]).list()
[[[1, 2, 3, 4], [4, 4, 4]],
 [[1, 2, 4, 3], [4, 4, 4]],
 [[1, 3, 2, 4], [4, 4, 4]],
 [[1, 3, 4, 2], [4, 4, 4]],
 [[1, 4, 2, 3], [4, 4, 4]],
 [[1, 4, 3, 2], [4, 4, 4]]]

sage: CyclicPermutationsOfPartition([[1,2,3],[4,4,4]]).list()
[[[1, 2, 3], [4, 4, 4]], [[1, 3, 2], [4, 4, 4]]]

sage: CyclicPermutationsOfPartition([[1,2,3],[4,4,4]]).list(distinct=True)
[[[1, 2, 3], [4, 4, 4]],
 [[1, 3, 2], [4, 4, 4]],
 [[1, 2, 3], [4, 4, 4]],
 [[1, 3, 2], [4, 4, 4]]]
```

list(*distinct=False*)

EXAMPLES:

```
sage: CyclicPermutationsOfPartition([[1,2,3],[4,4,4]]).list()
[[[1, 2, 3], [4, 4, 4]], [[1, 3, 2], [4, 4, 4]]]
sage: CyclicPermutationsOfPartition([[1,2,3],[4,4,4]]).list(distinct=True)
[[[1, 2, 3], [4, 4, 4]],
 [[1, 3, 2], [4, 4, 4]],
 [[1, 2, 3], [4, 4, 4]],
 [[1, 3, 2], [4, 4, 4]]]
```

class **CyclicPermutations_mset**(*mset*)

iterator(*distinct=False*)

EXAMPLES:

```
sage: CyclicPermutations(range(4)).list() # indirect doctest
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]
 sage: CyclicPermutations([1,1,1]).list()
 [[1, 1, 1]]
 sage: CyclicPermutations([1,1,1]).list(distinct=True)
 [[1, 1, 1], [1, 1, 1]]
```

list(*distinct=False*)

EXAMPLES:

```
sage: CyclicPermutations(range(4)).list()
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]
```

class **PatternAvoider**(*n, patterns*)

Permutation(*l*)

Converts l to a permutation.

INPUT:

- an instance of Permutation_class,
- list of integers, viewed as one-line permutation notation,
- string, expressing the permutation in cycle notation,
- list of tuples of integers, the permutation in cycle notation.
- a PermutationGroupElement
- a pair of two tableaux of the same shape, where the second one is standard. This uses the inverse of Robinson Schensted algorithm.

OUTPUT:

- `Permutation_class` object.

EXAMPLES:

```
sage: Permutation([2,1])
[2, 1]
sage: Permutation([2, 1, 4, 5, 3])
[2, 1, 4, 5, 3]
sage: Permutation('(1,2)')
[2, 1]
sage: Permutation('(1,2)(3,4,5)')
[2, 1, 4, 5, 3]
sage: Permutation( ((1,2),(3,4,5)) )
[2, 1, 4, 5, 3]
sage: Permutation( [(1,2),(3,4,5)] )
[2, 1, 4, 5, 3]
sage: Permutation( ((1,2)) )
[2, 1]
sage: Permutation( (1,2) )
[2, 1]
sage: Permutation( ((1,2),) )
[2, 1]
sage: p = Permutation((1, 2, 5)); p
[2, 5, 3, 4, 1]
sage: type(p)
<class 'sage.combinat.permutation.Permutation_class'>
```

Construction from a string in cycle notation

```
sage: p = Permutation( '(4,5)' ); p
[1, 2, 3, 5, 4]
```

The length of the permutation is the maximum integer appearing; add a 1-cycle to increase this:

```
sage: p2 = Permutation( '(4,5)(10)' ); p2
[1, 2, 3, 5, 4, 6, 7, 8, 9, 10]
sage: len(p); len(p2)
5
10
```

We construct a Permutation from a PermutationGroupElement:

```
sage: g = PermutationGroupElement([2,1,3])
sage: Permutation(g)
[2, 1, 3]
```

From a pair of tableaux of the same shape. This uses the inverse of Robinson Schensted algorithm:

```
sage: p = [[1, 4, 7], [2, 5], [3], [6]]
sage: q = [[1, 2, 5], [3, 6], [4], [7]]
sage: P = Tableau(p)
sage: Q = Tableau(q)
sage: Permutation( (p, q) )
[3, 6, 5, 2, 7, 4, 1]
sage: Permutation( [p, q] )
[3, 6, 5, 2, 7, 4, 1]
sage: Permutation( (P, Q) )
[3, 6, 5, 2, 7, 4, 1]
sage: Permutation( [P, Q] )
[3, 6, 5, 2, 7, 4, 1]
```

TESTS:

```
sage: Permutation([()])
[1]
sage: Permutation('()')
[1]
sage: Permutation(())
[1]
```

From a pair of empty tableaux

```
sage: Permutation( ([], []) )
[]
sage: Permutation( [[], []] )
[]
```

PermutationOptions(***kwargs*)

Sets the global options for elements of the permutation class. The defaults are for permutations to be displayed in list notation and the multiplication done from left to right (like in GAP).

display: 'list' - the permutations are displayed in list notation 'cycle' - the permutations are displayed in cycle notation 'singleton' - the permutations are displayed in cycle notation with singleton cycles shown as well.

mult: 'l2r' - the multiplication of permutations is done like composition of functions from left to right. That is, if we think of the permutations p1 and p2 as functions, then (p1*p2)(x) = p2(p1(x)). This is the default in multiplication in GAP. 'r2l' - the multiplication of permutations is done right to left so that (p1*p2)(x) = p1(p2(x))

If no parameters are set, then the function returns a copy of the options dictionary.

Note that these options have no effect on PermutationGroupElements.

EXAMPLES:

```
sage: p213 = Permutation([2,1,3])
sage: p312 = Permutation([3,1,2])
sage: PermutationOptions(mult='l2r', display='list')
sage: po = PermutationOptions()
sage: po['display']
'list'
sage: p213
[2, 1, 3]
sage: PermutationOptions(display='cycle')
sage: p213
(1,2)
sage: PermutationOptions(display='singleton')
```

```
sage: p213
(1,2)(3)
sage: PermutationOptions(display='list')

sage: po['mult']
'l2r'
sage: p213*p312
[1, 3, 2]
sage: PermutationOptions(mult='r2l')
sage: p213*p312
[3, 2, 1]
sage: PermutationOptions(mult='l2r')
```

class **Permutation_class**(*l*)

action(*a*)

Returns the action of the permutation on a list.

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: a = range(3)
sage: p.action(a)
[1, 0, 2]
sage: b = [1,2,3,4]
sage: p.action(b)
...
ValueError: len(a) must equal len(self)
```

avoids(*patt*)

Returns True if the permutation avoid the pattern patt and False otherwise.

EXAMPLES:

```
sage: Permutation([6,2,5,4,3,1]).avoids([4,2,3,1])
False
sage: Permutation([6,1,2,5,4,3]).avoids([4,2,3,1])
True
sage: Permutation([6,1,2,5,4,3]).avoids([3,4,1,2])
True
```

bruhat_greater()

Returns the combinatorial class of permutations greater than or equal to p in the Bruhat order.

EXAMPLES:

```
sage: Permutation([4,1,2,3]).bruhat_greater().list()
[[4, 1, 2, 3],
 [4, 1, 3, 2],
 [4, 2, 1, 3],
 [4, 2, 3, 1],
 [4, 3, 1, 2],
 [4, 3, 2, 1]]
```

bruhat_inversions()

Returns the list of inversions of p such that the application of this inversion to p decrements its number of inversions.

Equivalently, it returns the list of pairs (i,j), i < j such that p[i] < p[j] and such that there exists no k between i and j satisfying p[i] < p[k].

EXAMPLES:

```
sage: Permutation([5,2,3,4,1]).bruhat_inversions()
[[0, 1], [0, 2], [0, 3], [1, 4], [2, 4], [3, 4]]
sage: Permutation([6,1,4,5,2,3]).bruhat_inversions()
[[0, 1], [0, 2], [0, 3], [2, 4], [2, 5], [3, 4], [3, 5]]
```

bruhat_inversions_iterator()

Returns the iterator for the inversions of p such that the application of this inversion to p decrements its number of inversions.

EXAMPLES:

```
sage: list(Permutation([5,2,3,4,1]).bruhat_inversions_iterator())
[[0, 1], [0, 2], [0, 3], [1, 4], [2, 4], [3, 4]]
sage: list(Permutation([6,1,4,5,2,3]).bruhat_inversions_iterator())
[[0, 1], [0, 2], [0, 3], [2, 4], [2, 5], [3, 4], [3, 5]]
```

bruhat_lequal(*p2*)

Returns True if self is less than p2 in the Bruhat order.

EXAMPLES:

```
sage: Permutation([2,4,3,1]).bruhat_lequal(Permutation([3,4,2,1]))
True
```

bruhat_pred()

Returns a list of the permutations strictly smaller than p in the Bruhat order such that there is no permutation between one of those and p.

EXAMPLES:

```
sage: Permutation([6,1,4,5,2,3]).bruhat_pred()
[[1, 6, 4, 5, 2, 3],
 [4, 1, 6, 5, 2, 3],
 [5, 1, 4, 6, 2, 3],
 [6, 1, 2, 5, 4, 3],
 [6, 1, 3, 5, 2, 4],
 [6, 1, 4, 2, 5, 3],
 [6, 1, 4, 3, 2, 5]]
```

bruhat_pred_iterator()

An iterator for the permutations strictly smaller than p in the Bruhat order such that there is no permutation between one of those and p.

EXAMPLES:

```
sage: [x for x in Permutation([6,1,4,5,2,3]).bruhat_pred_iterator()]
[[1, 6, 4, 5, 2, 3],
 [4, 1, 6, 5, 2, 3],
 [5, 1, 4, 6, 2, 3],
 [6, 1, 2, 5, 4, 3],
 [6, 1, 3, 5, 2, 4],
 [6, 1, 4, 2, 5, 3],
 [6, 1, 4, 3, 2, 5]]
```

bruhat_smaller()

Returns a the combinatorial class of permutations smaller than or equal to p in the Bruhat order.

EXAMPLES:

```
sage: Permutation([4,1,2,3]).bruhat_smaller().list()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 3, 2, 4],
 [1, 4, 2, 3],
```

```
 [2, 1, 3, 4],
 [2, 1, 4, 3],
 [3, 1, 2, 4],
 [4, 1, 2, 3]]
```

bruhat_succ()

Returns a list of the permutations strictly greater than p in the Bruhat order such that there is no permutation between one of those and p.

EXAMPLES:

```
sage: Permutation([6,1,4,5,2,3]).bruhat_succ()
[[6, 4, 1, 5, 2, 3],
 [6, 2, 4, 5, 1, 3],
 [6, 1, 5, 4, 2, 3],
 [6, 1, 4, 5, 3, 2]]
```

bruhat_succ_iterator()

An iterator for the permutations that are strictly greater than p in the Bruhat order such that there is no permutation between one of those and p.

EXAMPLES:

```
sage: [x for x in Permutation([6,1,4,5,2,3]).bruhat_succ_iterator()]
[[6, 4, 1, 5, 2, 3],
 [6, 2, 4, 5, 1, 3],
 [6, 1, 5, 4, 2, 3],
 [6, 1, 4, 5, 3, 2]]
```

complement()

Returns the complement of the permutation which is obtained by replacing each value x in the list with n - x + 1.

EXAMPLES:

```
sage: Permutation([1,2,3]).complement()
[3, 2, 1]
sage: Permutation([1, 3, 2]).complement()
[3, 1, 2]
```

cycle_string(*singletons=False*)

Returns a string of the permutation in cycle notation.

If singletons=True, it includes 1-cycles in the string.

EXAMPLES:

```
sage: Permutation([1,2,3]).cycle_string()
'()'
sage: Permutation([2,1,3]).cycle_string()
'(1,2)'
sage: Permutation([2,3,1]).cycle_string()
'(1,2,3)'
sage: Permutation([2,1,3]).cycle_string(singletons=True)
'(1,2)(3)'
```

cycle_type()

Returns a partition of len(p) corresponding to the cycle type of p. This is a non-increasing sequence of the cycle lengths of p.

EXAMPLES:

```
sage: Permutation([3,1,2,4]).cycle_type()
[3, 1]
```

descent_polynomial()

Returns the descent polynomial of the permutation p.

The descent polynomial of p is the product of all the z[p[i]] where i ranges over the descents of p.

REFERENCES:

•Garsia and Stanton 1984

EXAMPLES:

```
sage: Permutation([2,1,3]).descent_polynomial()
z1
sage: Permutation([4,3,2,1]).descent_polynomial()
z1*z2^2*z3^3
```

descents(*final_descent=False*)

Returns the list of the descents of the permutation p.

A descent of a permutation is an integer i such that p[i] > p[i+1]. With the final_descent option, the last position of a non empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).descents()
[1, 2]
sage: Permutation([1,4,3,2]).descents(final_descent=True)
[1, 2, 3]
```

descents_composition()

Returns the composition corresponding to the descents of the permutation.

EXAMPLES:

```
sage: Permutation([1,3,2,4]).descents_composition()
[2, 2]
```

dict()

Returns a dictionary corresponding to the permutation.

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: d = p.dict()
sage: d[1]
2
sage: d[2]
1
sage: d[3]
3
```

fixed_points()

Returns a list of the fixed points of the permutation p.

EXAMPLES:

```
sage: Permutation([1,3,2,4]).fixed_points()
[1, 4]
sage: Permutation([1,2,3,4]).fixed_points()
[1, 2, 3, 4]
```

has_pattern(*patt*)

Returns the boolean answering the question 'Is patt a pattern appearing in permutation p?'

EXAMPLES:

```
sage: Permutation([3,5,1,4,6,2]).has_pattern([1,3,2])
True
```

idescents(*final_descent=False*)

Returns a list of the idescents of self, that is the list of the descents of self's inverse.

With the final_descent option, the last position of a non empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).idescents()
[1, 2]
sage: Permutation([1,4,3,2]).idescents(final_descent=True)
[1, 2, 3]
```

idescents_signature(*final_descent=False*)

Each position in self is mapped to -1 if it is an idescent and 1 if it is not an idescent.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).idescents()
[1, 2]
sage: Permutation([1,4,3,2]).idescents_signature()
[1, -1, -1, 1]
```

imajor_index(*final_descent=False*)

Returns the inverse major index of the permutation self, which is the major index of the inverse of self.

The major index is the sum of the descents of p. Since our permutation indices are 0-based, we need to add one the number of descents.

EXAMPLES:

```
sage: Permutation([2,1,3]).imajor_index()
1
sage: Permutation([3,4,1,2]).imajor_index()
2
sage: Permutation([4,3,2,1]).imajor_index()
6
```

inverse()

Returns the inverse of a permutation

EXAMPLES:

```
sage: Permutation([3,8,5,10,9,4,6,1,7,2]).inverse()
[8, 10, 1, 6, 3, 7, 9, 2, 5, 4]
sage: Permutation([2, 4, 1, 5, 3]).inverse()
[3, 1, 5, 2, 4]
```

inversions()

Returns a list of the inversions of permutation p.

EXAMPLES:

```
sage: Permutation([3,2,4,1,5]).inversions()
[[0, 1], [0, 3], [1, 3], [2, 3]]
```

is_even()

Returns True if the permutation p is even and false otherwise.

EXAMPLES:

```
sage: Permutation([1,2,3]).is_even()
True
sage: Permutation([2,1,3]).is_even()
False
```

ishift(*i*)

Returns an the i-shift of self. If an i-shift of self can't be performed, then None is returned.

An i-shift can be applied when i is not in between i-1 and i+1. The i-shift moves i to the other side, and leaves the relative positions of i-1 and i+1 in place.

EXAMPLES: Here, 2 is to the left of both 1 and 3. A 2-shift can be applied which moves the 2 to the right and leaves 1 and 3 in their same relative order.

```
sage: Permutation([2,1,3]).ishift(2)
[1, 3, 2]
```

Note that the movement is done in place:

```
sage: Permutation([2,4,1,3]).ishift(2)
[1, 4, 3, 2]
```

Since 2 is between 1 and 3 in [1,2,3], an 2-shift cannot be applied.

```
sage: Permutation([1,2,3]).ishift(2)
[1, 2, 3]
```

iswitch(*i*)

Returns an the i-switch of self. If an i-switch of self can't be performed, then self is returned.

An i-shift can be applied when i is not in between i-1 and i+1. The i-shift moves i to the other side, and switches the relative positions of i-1 and i+1 in place.

EXAMPLES: Here, 2 is to the left of both 1 and 3. A 2-switch can be applied which moves the 2 to the right and switches the relative order between 1 and 3.

```
sage: Permutation([2,1,3]).iswitch(2)
[3, 1, 2]
```

Note that the movement is done in place:

```
sage: Permutation([2,4,1,3]).iswitch(2)
[3, 4, 1, 2]
```

Since 2 is between 1 and 3 in [1,2,3], an 2-switch cannot be applied.

```
sage: Permutation([1,2,3]).iswitch(2)
[1, 2, 3]
```

left_tableau()

Returns the right standard tableau after performing the RSK algorithm on self.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).left_tableau()
[[1, 2], [3], [4]]
```

length()

Returns the length of a permutation p. The length is given by the number of inversions of p.

EXAMPLES:

```
sage: Permutation([5, 1, 3, 2, 4]).length()
5
```

longest_increasing_subsequence()

Returns a list of the longest increasing subsequences of the permutation p.

EXAMPLES:

```
sage: Permutation([2,3,4,1]).longest_increasing_subsequence()
[[2, 3, 4]]
```

major_index(*final_descent=False*)

Returns the major index of the permutation p.

The major index is the sum of the descents of p. Since our permutation indices are 0-based, we need to add one the number of descents.

EXAMPLES:

```
sage: Permutation([2,1,3]).major_index()
1
sage: Permutation([3,4,1,2]).major_index()
2
sage: Permutation([4,3,2,1]).major_index()
6
```

next()

Returns the permutation that follows p in lexicographic order. If p is the last permutation, then next returns false.

EXAMPLES:

```
sage: p = Permutation([1, 3, 2])
sage: p.next()
[2, 1, 3]
sage: p = Permutation([4,3,2,1])
sage: p.next()
False
```

number_of_descents(*final_descent=False*)

Returns the number of descents of the permutation p.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).number_of_descents()
2
sage: Permutation([1,4,3,2]).number_of_descents(final_descent=True)
3
```

number_of_fixed_points()

Returns the number of fixed points of the permutation p.

EXAMPLES:

```
sage: Permutation([1,3,2,4]).number_of_fixed_points()
2
sage: Permutation([1,2,3,4]).number_of_fixed_points()
4
```

number_of_idescents(*final_descent=False*)

Returns the number of descents of the permutation p.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).number_of_idescents()
2
sage: Permutation([1,4,3,2]).number_of_idescents(final_descent=True)
3
```

number_of_inversions()

Returns the number of inversions in the permutation p.

An inversion of a permutation is a pair of elements (p[i],p[j]) with i < j and p[i] > p[j].

REFERENCES:

- http://mathworld.wolfram.com/PermutationInversion.html

EXAMPLES:

```
sage: Permutation([3,2,4,1,5]).number_of_inversions()
4
sage: Permutation([1, 2, 6, 4, 7, 3, 5]).number_of_inversions()
6
```

number_of_peaks()

Returns the number of peaks of the permutation p.

A peak of a permutation is an integer i such that p[i-1] < p[i] and p[i] > p[i+1].

EXAMPLES:

```
sage: Permutation([1,3,2,4,5]).number_of_peaks()
1
sage: Permutation([4,1,3,2,6,5]).number_of_peaks()
2
```

number_of_recoils()

Returns the number of recoils of the permutation p.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).number_of_recoils()
2
```

number_of_saliances()

Returns the number of saliances of the permutation p.

EXAMPLES:

```
sage: Permutation([2,3,1,5,4]).number_of_saliances()
2
sage: Permutation([5,4,3,2,1]).number_of_saliances()
5
```

pattern_positions(*patt*)

Returns the list of positions where the pattern patt appears in p.

EXAMPLES:

```
sage: Permutation([3,5,1,4,6,2]).pattern_positions([1,3,2])
[[0, 1, 3], [2, 3, 5], [2, 4, 5]]
```

peaks()

Returns a list of the peaks of the permutation p.

A peak of a permutation is an integer i such that p[i-1] < p[i] and p[i] > p[i+1].

EXAMPLES:

```
sage: Permutation([1,3,2,4,5]).peaks()
[1]
sage: Permutation([4,1,3,2,6,5]).peaks()
[2, 4]
```

permutohedron_greater(*side='right'*)

Returns a list of permutations greater than or equal to p in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option side='left', then they will be done in the left permutohedron.

EXAMPLES:

```
sage: Permutation([4,2,1,3]).permutohedron_greater()
[[4, 2, 1, 3], [4, 2, 3, 1], [4, 3, 2, 1]]
sage: Permutation([4,2,1,3]).permutohedron_greater(side='left')
[[4, 2, 1, 3], [4, 3, 1, 2], [4, 3, 2, 1]]
```

permutohedron_lequal(*p2, side='right'*)

Returns True if self is less than p2 in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option side='left', then they will be done in the left permutohedron.

EXAMPLES:

```
sage: p = Permutation([3,2,1,4])
sage: p.permutohedron_lequal(Permutation([4,2,1,3]))
False
sage: p.permutohedron_lequal(Permutation([4,2,1,3]), side='left')
True
```

permutohedron_pred(*side='right'*)

Returns a list of the permutations strictly smaller than p in the permutohedron order such that there is no permutation between one of those and p.

By default, the computations are done in the right permutohedron. If you pass the option side='left', then they will be done in the left permutohedron.

EXAMPLES:

```
sage: p = Permutation([4,2,1,3])
sage: p.permutohedron_pred()
[[2, 4, 1, 3], [4, 1, 2, 3]]
sage: p.permutohedron_pred(side='left')
[[4, 1, 2, 3], [3, 2, 1, 4]]
```

permutohedron_smaller(*side='right'*)

Returns a list of permutations smaller than or equal to p in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option side='left', then they will be done in the left permutohedron.

EXAMPLES:

```
sage: Permutation([4,2,1,3]).permutohedron_smaller()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 4, 2, 3],
 [2, 1, 3, 4],
 [2, 1, 4, 3],
 [2, 4, 1, 3],
 [4, 1, 2, 3],
 [4, 2, 1, 3]]

sage: Permutation([4,2,1,3]).permutohedron_smaller(side='left')
[[1, 2, 3, 4],
 [1, 3, 2, 4],
 [2, 1, 3, 4],
 [2, 3, 1, 4],
 [3, 1, 2, 4],
 [3, 2, 1, 4],
 [4, 1, 2, 3],
 [4, 2, 1, 3]]
```

permutohedron_succ(*side='right'*)

Returns a list of the permutations strictly greater than p in the permutohedron order such that there is no permutation between one of those and p.

By default, the computations are done in the right permutohedron. If you pass the option side='left', then they will be done in the left permutohedron.

EXAMPLES:

```
sage: p = Permutation([4,2,1,3])
sage: p.permutohedron_succ()
[[4, 2, 3, 1]]
sage: p.permutohedron_succ(side='left')
[[4, 3, 1, 2]]
```

prev()

Returns the permutation that comes directly before p in lexicographic order. If p is the first permutation, then it returns False.

EXAMPLES:

```
sage: p = Permutation([1,2,3])
sage: p.prev()
False
sage: p = Permutation([1,3,2])
sage: p.prev()
[1, 2, 3]
```

rank()

Returns the rank of a permutation in lexicographic ordering.

EXAMPLES:

```
sage: Permutation([1,2,3]).rank()
0
sage: Permutation([1, 2, 4, 6, 3, 5]).rank()
10
sage: perms = Permutations(6).list()
sage: [p.rank() for p in perms ] == range(factorial(6))
True
```

recoils()

Returns the list of the positions of the recoils of the permutation p.

A recoil of a permutation is an integer i such that i+1 is to the left of it.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).recoils()
[2, 3]
```

recoils_composition()

Returns the composition corresponding to recoils of the permutation.

EXAMPLES:

```
sage: Permutation([1,3,2,4]).recoils_composition()
[3]
```

reduced_word()

Returns the reduced word of a permutation.

EXAMPLES:

```
sage: Permutation([3,5,4,6,2,1]).reduced_word()
[2, 1, 4, 3, 2, 4, 3, 5, 4, 5]
```

reduced_word_lexmin()

Returns a lexicographically minimal reduced word of a permutation.

EXAMPLES:

```
sage: Permutation([3,4,2,1]).reduced_word_lexmin()
[1, 2, 1, 3, 2]
```

reduced_words()

Returns a list of the reduced words of the permutation p.

EXAMPLES:

```
sage: Permutation([2,1,3]).reduced_words()
[[1]]
sage: Permutation([3,1,2]).reduced_words()
[[2, 1]]
sage: Permutation([3,2,1]).reduced_words()
[[1, 2, 1], [2, 1, 2]]
sage: Permutation([3,2,4,1]).reduced_words()
[[1, 2, 3, 1], [1, 2, 1, 3], [2, 1, 2, 3]]
```

remove_extra_fixed_points()

Returns the permutation obtained by removing any fixed points at the end of self.

EXAMPLES:

```
sage: Permutation([2,1,3]).remove_extra_fixed_points()
[2, 1]
sage: Permutation([1,2,3,4]).remove_extra_fixed_points()
[1]
```

reverse()

Returns the permutation obtained by reversing the list.

EXAMPLES:

```
sage: Permutation([3,4,1,2]).reverse()
[2, 1, 4, 3]
sage: Permutation([1,2,3,4,5]).reverse()
[5, 4, 3, 2, 1]
```

right_tableau()

Returns the right standard tableau after performing the RSK algorithm on self.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).right_tableau()
[[1, 2], [3], [4]]
```

robinson_schensted()

Returns the pair of standard tableau obtained by running the Robinson-Schensted Algorithm on self.

EXAMPLES:

```
sage: p = Permutation([6,2,3,1,7,5,4])
sage: p.robinson_schensted()
[[[1, 3, 4], [2, 5], [6, 7]], [[1, 3, 5], [2, 6], [4, 7]]]
```

TESTS:

The empty permutation:

```
sage: p = Permutation([])
sage: p.robinson_schensted()
[[], []]
```

runs()

Returns a list of the runs in the permutation p.

REFERENCES:

- http://mathworld.wolfram.com/PermutationRun.html

EXAMPLES:

```
sage: Permutation([1,2,3,4]).runs()
[[1, 2, 3, 4]]
sage: Permutation([4,3,2,1]).runs()
[[4], [3], [2], [1]]
sage: Permutation([2,4,1,3]).runs()
[[2, 4], [1, 3]]
```

saliances()

Returns a list of the saliances of the permutation p.

A saliance of a permutation p is an integer i such that p[i] > p[j] for all j > i.

EXAMPLES:

```
sage: Permutation([2,3,1,5,4]).saliances()
[3, 4]
sage: Permutation([5,4,3,2,1]).saliances()
[0, 1, 2, 3, 4]
```

signature(*p*)

Returns the signature of a permutation.

EXAMPLES:

```
sage: Permutation([4, 2, 3, 1, 5]).signature()
-1
```

to_cycles(*singletons=True*)

Returns the permutation p as a list of disjoint cycles.

EXAMPLES:

```
sage: Permutation([2,1,3,4]).to_cycles()
[(1, 2), (3,), (4,)]
sage: Permutation([2,1,3,4]).to_cycles(singletons=False)
[(1, 2)]
```

to_inversion_vector()

Returns the inversion vector of a permutation p.

If iv is the inversion vector, then iv[i] is the number of elements larger than i that appear to the left of i in the permutation.

EXAMPLES:

```
sage: Permutation([5,9,1,8,2,6,4,7,3]).to_inversion_vector()
[2, 3, 6, 4, 0, 2, 2, 1, 0]
sage: Permutation([8,7,2,1,9,4,6,5,10,3]).to_inversion_vector()
[3, 2, 7, 3, 4, 3, 1, 0, 0, 0]
sage: Permutation([3,2,4,1,5]).to_inversion_vector()
[3, 1, 0, 0, 0]
```

to_lehmer_cocode()

Returns the Lehmer cocode of p.

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: p.to_lehmer_cocode()
[0, 1, 0]
sage: q = Permutation([3,1,2])
sage: q.to_lehmer_cocode()
[0, 1, 1]
```

to_lehmer_code()

Returns the Lehmer code of the permutation p.

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: p.to_lehmer_code()
[1, 0, 0]
sage: q = Permutation([3,1,2])
sage: q.to_lehmer_code()
[2, 0, 0]
```

to_major_code(*final_descent=False*)

Returns the major code of the permutation p, which is defined as the list [m1-m2, m2-m3,..,mn] where mi := maj(pi) is the major indices of the permutation math obtained by erasing the letters smaller than math in p.

REFERENCES:

- Carlitz, L. 'q-Bernoulli and Eulerian Numbers' Trans. Amer. Math. Soc. 76 (1954) 332-350 Skandera, M. 'An Eulerian Partner for Inversions', Sem. Lothar. Combin. 46 (2001) B46d.

EXAMPLES:

```
sage: Permutation([9,3,5,7,2,1,4,6,8]).to_major_code()
[5, 0, 1, 0, 1, 2, 0, 1, 0]
sage: Permutation([2,8,4,3,6,7,9,5,1]).to_major_code()
[8, 3, 3, 1, 4, 0, 1, 0, 0]
```

to_matrix()

Returns a matrix representing the permutation.

EXAMPLES:

```
sage: Permutation([1,2,3]).to_matrix()
[1 0 0]
[0 1 0]
[0 0 1]

sage: Permutation([1,3,2]).to_matrix()
[1 0 0]
[0 0 1]
[0 1 0]
```

Notice that matrix multiplication corresponds to permutation multiplication only when the permutation option mult='r2l'

```
sage: PermutationOptions(mult='r2l')
sage: p = Permutation([2,1,3])
sage: q = Permutation([3,1,2])
sage: (p*q).to_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
sage: p.to_matrix()*q.to_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
sage: PermutationOptions(mult='l2r')
sage: (p*q).to_matrix()
[1 0 0]
[0 0 1]
[0 1 0]
```

to_permutation_group_element()

Returns a PermutationGroupElement equal to self.

EXAMPLES:

```
sage: Permutation([2,1,4,3]).to_permutation_group_element()
(1,2)(3,4)
sage: Permutation([1,2,3]).to_permutation_group_element()
()
```

to_tableau_by_shape(*shape*)

Returns a tableau of shape shape with the entries in self.

EXAMPLES:

```
sage: Permutation([3,4,1,2,5]).to_tableau_by_shape([3,2])
[[1, 2, 5], [3, 4]]
sage: Permutation([3,4,1,2,5]).to_tableau_by_shape([3,2]).to_permutation()
[3, 4, 1, 2, 5]
```

weak_excedences()

Returns all the numbers self[i] such that self[i] = i+1.

EXAMPLES:

```
sage: Permutation([1,4,3,2,5]).weak_excedences()
[1, 4, 3, 5]
```

Permutations(*n=None, k=None, **kwargs*)

Returns a combinatorial class of permutations.

Permutations(n) returns the class of permutations of n, if n is an integer, list, set, or string.

Permutations(n, k) returns the class of permutations of n (where n is any of the above things) of length k; k must be an integer.

Valid keyword arguments are: 'descents', 'bruhat_smaller', 'bruhat_greater', 'recoils_finer', 'recoils_fatter', 'recoils', and 'avoiding'. With the exception of 'avoiding', you cannot specify n or k along with a keyword.

Permutations(descents=list) returns the class of permutations with descents in the positions specified by 'list'.

Permutations(bruhat_smaller,greater=p) returns the class of permutations smaller or greater, respectively, than the given permutation in Bruhat order.

Permutations(recoils=p) returns the class of permutations whose recoils composition is p.

Permutations(recoils_fatter,finer=p) returns the class of permutations whose recoils composition is fatter or finer, respectively, than the given permutation.

Permutations(n, avoiding=P) returns the class of permutations of n avoiding P. Here P may be a single permutation or a list of permutations; the returned class will avoid all patterns in P.

EXAMPLES:

```
sage: p = Permutations(3); p
Standard permutations of 3
sage: p.list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]

sage: p = Permutations(3, 2); p
Permutations of {1,...,3} of length 2
sage: p.list()
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]

sage: p = Permutations(['c', 'a', 't']); p
Permutations of the set ['c', 'a', 't']
sage: p.list()
[['c', 'a', 't'],
```

```
 ['c', 't', 'a'],
 ['a', 'c', 't'],
 ['a', 't', 'c'],
 ['t', 'c', 'a'],
 ['t', 'a', 'c']]

sage: p = Permutations(['c', 'a', 't'], 2); p
Permutations of the set ['c', 'a', 't'] of length 2
sage: p.list()
[['c', 'a'], ['c', 't'], ['a', 'c'], ['a', 't'], ['t', 'c'], ['t', 'a']]

sage: p = Permutations([1,1,2]); p
Permutations of the multi-set [1, 1, 2]
sage: p.list()
[[1, 1, 2], [1, 2, 1], [2, 1, 1]]

sage: p = Permutations([1,1,2], 2); p
Permutations of the multi-set [1, 1, 2] of length 2
sage: p.list()
[[1, 1], [1, 2], [2, 1]]

sage: p = Permutations(descents=[1,3]); p
Standard permutations of 4 with descents [1, 3]
sage: p.list()
[[1, 3, 2, 4], [1, 4, 2, 3], [2, 3, 1, 4], [2, 4, 1, 3], [3, 4, 1, 2]]

sage: p = Permutations(bruhat_smaller=[1,3,2,4]); p
Standard permutations that are less than or equal to [1, 3, 2, 4] in the Bruhat order
sage: p.list()
[[1, 2, 3, 4], [1, 3, 2, 4]]

sage: p = Permutations(bruhat_greater=[4,2,3,1]); p
Standard permutations that are greater than or equal to [4, 2, 3, 1] in the Bruhat order
sage: p.list()
[[4, 2, 3, 1], [4, 3, 2, 1]]

sage: p = Permutations(recoils_finer=[2,1]); p
Standard permutations whose recoils composition is finer than [2, 1]
sage: p.list()
[[1, 2, 3], [1, 3, 2], [3, 1, 2]]

sage: p = Permutations(recoils_fatter=[2,1]); p
Standard permutations whose recoils composition is fatter than [2, 1]
sage: p.list()
[[1, 3, 2], [3, 1, 2], [3, 2, 1]]

sage: p = Permutations(recoils=[2,1]); p
Standard permutations whose recoils composition is [2, 1]
sage: p.list()
[[1, 3, 2], [3, 1, 2]]
```

```
sage: p = Permutations(4, avoiding=[1,3,2]); p
Standard permutations of 4 avoiding [1, 3, 2]
sage: p.list()
[[4, 1, 2, 3],
 [4, 2, 1, 3],
 [4, 2, 3, 1],
 [4, 3, 1, 2],
 [4, 3, 2, 1],
 [3, 4, 1, 2],
 [3, 4, 2, 1],
 [2, 3, 4, 1],
 [3, 2, 4, 1],
 [1, 2, 3, 4],
 [2, 1, 3, 4],
 [2, 3, 1, 4],
 [3, 1, 2, 4],
 [3, 2, 1, 4]]

sage: p = Permutations(5, avoiding=[[3,4,1,2], [4,2,3,1]]); p
Standard permutations of 5 avoiding [[3, 4, 1, 2], [4, 2, 3, 1]]
sage: p.cardinality()
88
sage: p.random_element()
[5, 1, 2, 4, 3]
```

class **Permutations_mset**(*mset*)

cardinality()
EXAMPLES:

```
sage: Permutations([1,2,2]).cardinality()
3
```

class **Permutations_msetk**(*mset, k*)

list()
EXAMPLES:

```
sage: Permutations([1,2,2],2).list()
[[1, 2], [2, 1], [2, 2]]
```

class **Permutations_nk**(*n, k*)

cardinality()
EXAMPLES:

```
sage: Permutations(3,0).cardinality()
1
sage: Permutations(3,1).cardinality()
3
sage: Permutations(3,2).cardinality()
6
sage: Permutations(3,3).cardinality()
6
sage: Permutations(3,4).cardinality()
0
```

random_element()
EXAMPLES:

```
sage: Permutations(3,2).random_element()
[0, 1]
```

class **Permutations_set**(*s*)

cardinality()
EXAMPLES:

```
sage: Permutations([1,2,3]).cardinality()
6
```

random_element()
EXAMPLES:

```
sage: Permutations([1,2,3]).random_element()
[1, 2, 3]
```

class **Permutations_setk**(*s*, *k*)

random_element()
EXAMPLES:

```
sage: Permutations([1,2,3],2).random_element()
[1, 2]
```

class **StandardPermutations_all**()

class **StandardPermutations_avoiding_12**(*n*)

list()
EXAMPLES:

```
sage: Permutations(3, avoiding=[1,2]).list()
[[3, 2, 1]]
```

class **StandardPermutations_avoiding_123**(*n*)

cardinality()
EXAMPLES:

```
sage: Permutations(5, avoiding=[1, 2, 3]).cardinality()
42
sage: len( Permutations(5, avoiding=[1, 2, 3]).list() )
42
```

class **StandardPermutations_avoiding_132**(*n*)

cardinality()
EXAMPLES:

```
sage: Permutations(5, avoiding=[1, 3, 2]).cardinality()
42
sage: len( Permutations(5, avoiding=[1, 3, 2]).list() )
42
```

class **StandardPermutations_avoiding_21**(*n*)

list()
EXAMPLES:

```
sage: Permutations(3, avoiding=[2,1]).list()
[[1, 2, 3]]
```

class **StandardPermutations_avoiding_213**(*n*)

cardinality()
EXAMPLES:

```
sage: Permutations(5, avoiding=[2, 1, 3]).cardinality()
42
sage: len( Permutations(5, avoiding=[2, 1, 3]).list() )
42
```

class **StandardPermutations_avoiding_231**(*n*)

cardinality()
EXAMPLES:

```
sage: Permutations(5, avoiding=[2, 3, 1]).cardinality()
42
sage: len( Permutations(5, avoiding=[2, 3, 1]).list() )
42
```

class **StandardPermutations_avoiding_312**(*n*)

cardinality()
EXAMPLES:

```
sage: Permutations(5, avoiding=[3, 1, 2]).cardinality()
42
sage: len( Permutations(5, avoiding=[3, 1, 2]).list() )
42
```

class **StandardPermutations_avoiding_321**(*n*)

cardinality()
EXAMPLES:

```
sage: Permutations(5, avoiding=[3, 2, 1]).cardinality()
42
sage: len( Permutations(5, avoiding=[3, 2, 1]).list() )
42
```

class **StandardPermutations_avoiding_generic**(*n*, *a*)

class **StandardPermutations_bruhat_greater**(*p*)

list()
Returns a list of permutations greater than or equal to p in the Bruhat order.
EXAMPLES:

```
sage: Permutations(bruhat_greater=[4,1,2,3]).list()
[[4, 1, 2, 3],
 [4, 1, 3, 2],
```

```
 [4, 2, 1, 3],
 [4, 2, 3, 1],
 [4, 3, 1, 2],
 [4, 3, 2, 1]]
```

class StandardPermutations_bruhat_smaller(*p*)

list()

Returns a list of permutations smaller than or equal to p in the Bruhat order.

EXAMPLES:

```
sage: Permutations(bruhat_smaller=[4,1,2,3]).list()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 3, 2, 4],
 [1, 4, 2, 3],
 [2, 1, 3, 4],
 [2, 1, 4, 3],
 [3, 1, 2, 4],
 [4, 1, 2, 3]]
```

class StandardPermutations_descents(*d, n*)

first()

Returns the first permutation with descents d.

EXAMPLES:

```
sage: Permutations(descents=([1,0,4,8],12)).first()
[3, 2, 1, 4, 6, 5, 7, 8, 10, 9, 11, 12]
```

last()

Returns the last permutation with descents d.

EXAMPLES:

```
sage: Permutations(descents=([1,0,4,8],12)).last()
[12, 11, 8, 9, 10, 4, 5, 6, 7, 1, 2, 3]
```

list()

Returns a list of all the permutations that have the descents d.

EXAMPLES:

```
sage: Permutations(descents=([2,4,0],5)).list()
[[2, 1, 4, 3, 5],
 [2, 1, 5, 3, 4],
 [3, 1, 4, 2, 5],
 [3, 1, 5, 2, 4],
 [4, 1, 3, 2, 5],
 [5, 1, 3, 2, 4],
 [4, 1, 5, 2, 3],
 [5, 1, 4, 2, 3],
 [3, 2, 4, 1, 5],
 [3, 2, 5, 1, 4],
 [4, 2, 3, 1, 5],
 [5, 2, 3, 1, 4],
 [4, 2, 5, 1, 3],
 [5, 2, 4, 1, 3],
 [4, 3, 5, 1, 2],
 [5, 3, 4, 1, 2]]
```

object_class()

class **StandardPermutations_n**(*n*)

cardinality()
EXAMPLES:

```
sage: Permutations(0).cardinality()
1
sage: Permutations(3).cardinality()
6
sage: Permutations(4).cardinality()
24
```

identity()
Returns the identity permutation of length n.
EXAMPLES:

```
sage: Permutations(4).identity()
[1, 2, 3, 4]
sage: Permutations(0).identity()
[]
```

random_element()
EXAMPLES:

```
sage: Permutations(4).random_element()
[1, 3, 2, 4]
```

rank(*p*)
EXAMPLES:

```
sage: SP3 = Permutations(3)
sage: map(SP3.rank, SP3)
[0, 1, 2, 3, 4, 5]
sage: SP0 = Permutations(0)
sage: map(SP0.rank, SP0)
[0]
```

unrank(*r*)
EXAMPLES:

```
sage: SP3 = Permutations(3)
sage: l = map(SP3.unrank, range(6))
sage: l == SP3.list()
True
sage: SP0 = Permutations(0)
sage: l = map(SP0.unrank, range(1))
sage: l == SP0.list()
True
```

class **StandardPermutations_recoils**(*recoils*)

list()
Returns a list of all of the permutations whose recoils composition is equal to recoils.
EXAMPLES:

```
sage: Permutations(recoils=[2,2]).list()
[[1, 3, 2, 4], [1, 3, 4, 2], [3, 1, 2, 4], [3, 1, 4, 2], [3, 4, 1, 2]]
```

object_class()

class StandardPermutations_recoilsfatter(*recoils*)

list()

Returns a list of all of the permutations whose recoils composition is fatter than recoils.

EXAMPLES:

```
sage: Permutations(recoils_fatter=[2,2]).list()
[[1, 3, 2, 4],
 [1, 3, 4, 2],
 [1, 4, 3, 2],
 [3, 1, 2, 4],
 [3, 1, 4, 2],
 [3, 2, 1, 4],
 [3, 2, 4, 1],
 [3, 4, 1, 2],
 [3, 4, 2, 1],
 [4, 1, 3, 2],
 [4, 3, 1, 2],
 [4, 3, 2, 1]]
```

object_class()

class StandardPermutations_recoilsfiner(*recoils*)

list()

Returns a list of all of the permutations whose recoils composition is finer than recoils.

EXAMPLES:

```
sage: Permutations(recoils_finer=[2,2]).list()
[[1, 2, 3, 4],
 [1, 3, 2, 4],
 [1, 3, 4, 2],
 [3, 1, 2, 4],
 [3, 1, 4, 2],
 [3, 4, 1, 2]]
```

object_class()

bruhat_lequal(*p1*, *p2*)

Returns True if p1 is less than p2 in the Bruhat order.

Algorithm from mupad-combinat.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.bruhat_lequal([2,4,3,1],[3,4,2,1])
True
```

descents_composition_first(*dc*)

Computes the smallest element of a descent class having a descent decomposition dc.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.descents_composition_first([1,1,3,4,3])
[3, 2, 1, 4, 6, 5, 7, 8, 10, 9, 11, 12]
```

descents_composition_last(*dc*)
Returns the largest element of a descent class having a descent decomposition dc.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.descents_composition_last([1,1,3,4,3])
[12, 11, 8, 9, 10, 4, 5, 6, 7, 1, 2, 3]
```

descents_composition_list(*dc*)
Returns a list of all the permutations that have a descent compositions dc.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.descents_composition_list([1,2,2])
[[2, 1, 4, 3, 5],
 [2, 1, 5, 3, 4],
 [3, 1, 4, 2, 5],
 [3, 1, 5, 2, 4],
 [4, 1, 3, 2, 5],
 [5, 1, 3, 2, 4],
 [4, 1, 5, 2, 3],
 [5, 1, 4, 2, 3],
 [3, 2, 4, 1, 5],
 [3, 2, 5, 1, 4],
 [4, 2, 3, 1, 5],
 [5, 2, 3, 1, 4],
 [4, 2, 5, 1, 3],
 [5, 2, 4, 1, 3],
 [4, 3, 5, 1, 2],
 [5, 3, 4, 1, 2]]
```

from_cycles(*n*, *cycles*)
Returns the permutation corresponding to cycles.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.from_cycles(4, [[1,2]])
[2, 1, 3, 4]
```

from_inversion_vector(*iv*)
Returns the permutation corresponding to inversion vector iv.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.from_inversion_vector([3,1,0,0,0])
[3, 2, 4, 1, 5]
sage: permutation.from_inversion_vector([2,3,6,4,0,2,2,1,0])
[5, 9, 1, 8, 2, 6, 4, 7, 3]
```

from_lehmer_code(*lehmer*)
Returns the permutation with Lehmer code lehmer.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: Permutation([2,1,5,4,3]).to_lehmer_code()
[1, 0, 2, 1, 0]
sage: permutation.from_lehmer_code(_)
[2, 1, 5, 4, 3]
```

from_major_code(*mc, final_descent=False*)

Returns the permutation corresponding to major code mc.

REFERENCES:

- Skandera, M. 'An Eulerian Partner for Inversions', Sem. Lothar. Combin. 46 (2001) B46d.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.from_major_code([5, 0, 1, 0, 1, 2, 0, 1, 0])
[9, 3, 5, 7, 2, 1, 4, 6, 8]
sage: permutation.from_major_code([8, 3, 3, 1, 4, 0, 1, 0, 0])
[2, 8, 4, 3, 6, 7, 9, 5, 1]
sage: Permutation([2,1,6,4,7,3,5]).to_major_code()
[3, 2, 0, 2, 2, 0, 0]
sage: permutation.from_major_code([3, 2, 0, 2, 2, 0, 0])
[2, 1, 6, 4, 7, 3, 5]
```

from_permutation_group_element(*pge*)

Returns a Permutation give a PermutationGroupElement pge.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: pge = PermutationGroupElement([(1,2),(3,4)])
sage: permutation.from_permutation_group_element(pge)
[2, 1, 4, 3]
```

from_rank(*n, rank*)

Returns the permutation with the specified lexicographic rank. The permutation is of the set [1,...,n].

The permutation is computed without iterating through all of the permutations with lower rank. This makes it efficient for large permutations.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: Permutation([3, 6, 5, 4, 2, 1]).rank()
359
sage: [permutation.from_rank(3, i) for i in range(6)]
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
sage: Permutations(6)[10]
[1, 2, 4, 6, 3, 5]
sage: permutation.from_rank(6,10)
[1, 2, 4, 6, 3, 5]
```

from_reduced_word(*rw*)

Returns the permutation corresponding to the reduced word rw.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.from_reduced_word([3,2,3,1,2,3,1])
[3, 4, 2, 1]
sage: permutation.from_reduced_word([])
[]
```

permutohedron_lequal(*p1, p2, side='right'*)

Returns True if p1 is less than p2in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option side='left', then they will be done in the left permutohedron.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.permutohedron_lequal(Permutation([3,2,1,4]),Permutation([4,2,1,3]))
False
sage: permutation.permutohedron_lequal(Permutation([3,2,1,4]),Permutation([4,2,1,3]), side='left
True
```

robinson_schensted_inverse(*p, q*)

Returns the permutation corresponding to the pair of tableaux (p, q) using the inverse of Robinson-Schensted algorithm.

INPUT:

- p, q: two tableaux of the same shape and where q is standard.

EXAMPLES:

```
sage: from sage.combinat.permutation import robinson_schensted_inverse
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: robinson_schensted_inverse(t1, t2)
[1, 4, 5, 3, 2]
sage: robinson_schensted_inverse(t1, t1)
[1, 4, 3, 2, 5]
sage: robinson_schensted_inverse(t2, t2)
[1, 2, 5, 4, 3]
sage: robinson_schensted_inverse(t2, t1)
[1, 5, 4, 2, 3]
```

If the first tableau is semistandard:

```
sage: p = Tableau([[1,2,2]]); q = Tableau([[1,2,3]])
sage: robinson_schensted_inverse(p, q)
[1, 2, 2]
sage: _.robinson_schensted()
[[[1, 2, 2]], [[1, 2, 3]]]
```

Note that currently the constructor of Tableau accept as input lists that are not even tableaux but only filling of a parition diagram. This feature should not be used with robinson_schensted_inverse.

TESTS:

From empty tableaux:

```
sage: robinson_schensted_inverse(Tableau([]), Tableau([]))
[]
```

This function is the inverse of robinson_shensted:

```
sage: f = lambda p: robinson_schensted_inverse(*p.robinson_schensted())
sage: all(p == f(p) for n in range(7) for p in Permutations(n))
True

sage: n = ZZ.random_element(200)
sage: p = Permutations(n).random_element()
sage: is_fine = True if p == f(p) else p ; is_fine
True
```

Both tableaux must be of the same shape:

```
sage: robinson_schensted_inverse(Tableau([[1,2,3]]), Tableau([[1,2]]))
...
ValueError: p(=[[1, 2, 3]]) and q(=[[1, 2]]) must have the same shape
```

The second tableau must be standard:

```
sage: robinson_schensted_inverse(Tableau([[1,2,3]]), Tableau([[1,3,2]]))
...
ValueError: q(=[[1, 3, 2]]) must be standard
```

to_standard(*p*)

Returns a standard permutation corresponding to the permutation p.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.to_standard([4,2,7])
[2, 1, 3]
sage: permutation.to_standard([1,2,3])
[1, 2, 3]
```

17.24 q-Analogues

q_binomial(*n, k, p=None*)

Returns the q-binomial coefficient.

If p is unspecified, then it defaults to using the generator q for a univariate polynomial ring over the integers.

EXAMPLES:

```
sage: import sage.combinat.q_analogues as q_analogues
sage: q_analogues.q_binomial(4,2)
q^4 + q^3 + 2*q^2 + q + 1
sage: p = ZZ['p'].0
sage: q_analogues.q_binomial(4,2,p)
p^4 + p^3 + 2*p^2 + p + 1
```

q_factorial(*n, p=None*)

Returns the q-analogue of the n!.

If p is unspecified, then it defaults to using the generator q for a univariate polynomial ring over the integers.

EXAMPLES:

```
sage: import sage.combinat.q_analogues as q_analogues
sage: q_analogues.q_factorial(3)
q^3 + 2*q^2 + 2*q + 1
sage: p = ZZ['p'].0
sage: q_analogues.q_factorial(3, p)
p^3 + 2*p^2 + 2*p + 1
```

q_int(*n, p=None*)

Returns the q-analogue of the integer n.

If p is unspecified, then it defaults to using the generator q for a univariate polynomial ring over the integers.

EXAMPLES:

```
sage: import sage.combinat.q_analogues as q_analogues
sage: q_analogues.q_int(3)
q^2 + q + 1
sage: p = ZZ['p'].0
sage: q_analogues.q_int(3,p)
p^2 + p + 1
```

qt_catalan_number(*n*)

Returns the q,t-Catalan number.

EXAMPLES:

```
sage: import sage.combinat.q_analogues as q_analogues
sage: q_analogues.qt_catalan_number(1)
1
sage: q_analogues.qt_catalan_number(2)
q + t
sage: q_analogues.qt_catalan_number(3)
q^3 + q^2*t + q*t^2 + t^3 + q*t
sage: q_analogues.qt_catalan_number(4)
q^6 + q^5*t + q^4*t^2 + q^3*t^3 + q^2*t^4 + q*t^5 + t^6 + q^4*t + q^3*t^2 + q^2*t^3 + q*t^4 + q^
```

17.25 Ordered Set Partitions

An ordered set partition p of a set s is a partition of s, into subsets called parts and represented as a list of sets. By extension, an ordered set partition of a nonnegative integer n is the set partition of the integers from 1 to n. The number of ordered set partitions of n is called the n-th ordered Bell number.

There is a natural integer composition associated with an ordered set partition, that is the sequence of sizes of all its parts in order.

EXAMPLES: There are 13 ordered set partitions of {1,2,3}.

```
sage: OrderedSetPartitions(3).cardinality()
13
```

Here is the list of them:

```
sage: OrderedSetPartitions(3).list() #random due to the sets
[[{1}, {2}, {3}],
 [{1}, {3}, {2}],
 [{2}, {1}, {3}],
```

```
 [{3}, {1}, {2}],
 [{2}, {3}, {1}],
 [{3}, {2}, {1}],
 [{1}, {2, 3}],
 [{2}, {1, 3}],
 [{3}, {1, 2}],
 [{1, 2}, {3}],
 [{1, 3}, {2}],
 [{2, 3}, {1}],
 [{1, 2, 3}]]
```

There are 12 ordered set partitions of {1,2,3,4} whose underlying composition is [1,2,1].

```
sage: OrderedSetPartitions(4,[1,2,1]).list() #random due to the sets
[[{1}, {2, 3}, {4}],
 [{1}, {2, 4}, {3}],
 [{1}, {3, 4}, {2}],
 [{2}, {1, 3}, {4}],
 [{2}, {1, 4}, {3}],
 [{3}, {1, 2}, {4}],
 [{4}, {1, 2}, {3}],
 [{3}, {1, 4}, {2}],
 [{4}, {1, 3}, {2}],
 [{2}, {3, 4}, {1}],
 [{3}, {2, 4}, {1}],
 [{4}, {2, 3}, {1}]]
```

AUTHORS:

- Mike Hansen
- MuPAD-Combinat developers (for algorithms and design inspiration)

OrderedSetPartitions(*s, c=None*)

Returns the combinatorial class of ordered set partitions of s.

EXAMPLES:

```
sage: OS = OrderedSetPartitions([1,2,3,4]); OS
Ordered set partitions of {1, 2, 3, 4}
sage: OS.cardinality()
75
sage: OS.first()
[{1}, {2}, {3}, {4}]
sage: OS.last()
[{1, 2, 3, 4}]
sage: OS.random_element()
[{3}, {1}, {2}, {4}]
```

```
sage: OS = OrderedSetPartitions([1,2,3,4], [2,2]); OS
Ordered set partitions of {1, 2, 3, 4} into parts of size [2, 2]
sage: OS.cardinality()
6
sage: OS.first()
[{1, 2}, {3, 4}]
sage: OS.last()
[{3, 4}, {1, 2}]
```

```
sage: OS.list()
[[{1, 2}, {3, 4}],
 [{1, 3}, {2, 4}],
 [{1, 4}, {2, 3}],
 [{2, 3}, {1, 4}],
 [{2, 4}, {1, 3}],
 [{3, 4}, {1, 2}]]

sage: OS = OrderedSetPartitions("cat"); OS
Ordered set partitions of ['c', 'a', 't']
sage: OS.list()
[[{'a'}, {'c'}, {'t'}],
 [{'a'}, {'t'}, {'c'}],
 [{'c'}, {'a'}, {'t'}],
 [{'t'}, {'a'}, {'c'}],
 [{'c'}, {'t'}, {'a'}],
 [{'t'}, {'c'}, {'a'}],
 [{'a'}, {'c', 't'}],
 [{'c'}, {'a', 't'}],
 [{'t'}, {'a', 'c'}],
 [{'a', 'c'}, {'t'}],
 [{'a', 't'}, {'c'}],
 [{'c', 't'}, {'a'}],
 [{'a', 'c', 't'}]]
```

class **OrderedSetPartitions_s**(*s*)

cardinality()

EXAMPLES:

```
sage: OrderedSetPartitions(0).cardinality()
1
sage: OrderedSetPartitions(1).cardinality()
1
sage: OrderedSetPartitions(2).cardinality()
3
sage: OrderedSetPartitions(3).cardinality()
13
sage: OrderedSetPartitions([1,2,3]).cardinality()
13
sage: OrderedSetPartitions(4).cardinality()
75
sage: OrderedSetPartitions(5).cardinality()
541
```

class **OrderedSetPartitions_scomp**(*s*, *comp*)

cardinality()

EXAMPLES:

```
sage: OrderedSetPartitions(5,[2,3]).cardinality()
10
sage: OrderedSetPartitions(0, []).cardinality()
1
sage: OrderedSetPartitions(0, [0]).cardinality()
1
sage: OrderedSetPartitions(0, [0,0]).cardinality()
```

```
1
sage: OrderedSetPartitions(5, [2,0,3]).cardinality()
10
```

class **OrderedSetPartitions_sn**(*s*, *n*)

cardinality()
EXAMPLES:

```
sage: OrderedSetPartitions(4,2).cardinality()
14
sage: OrderedSetPartitions(4,1).cardinality()
1
```

17.26 Set Partitions

A set partition s of a set set is a partition of set, into subsets called parts and represented as a set of sets. By extension, a set partition of a nonnegative integer n is the set partition of the integers from 1 to n. The number of set partitions of n is called the n-th Bell number.

There is a natural integer partition associated with a set partition, that is the non-decreasing sequence of sizes of all its parts.

There is a classical lattice associated with all set partitions of n. The infimum of two set partitions is the set partition obtained by intersecting all the parts of both set partitions. The supremum is obtained by transitive closure of the relation i related to j iff they are in the same part in at least one of the set partitions.

EXAMPLES: There are 5 set partitions of the set 1,2,3.

```
sage: SetPartitions(3).cardinality()
5
```

Here is the list of them

```
sage: SetPartitions(3).list() #random due to the sets
[{{1, 2, 3}}, {{2, 3}, {1}}, {{1, 3}, {2}}, {{1, 2}, {3}}, {{2}, {3}, {1}}]
```

There are 6 set partitions of 1,2,3,4 whose underlying partition is [2, 1, 1]:

```
sage: SetPartitions(4, [2,1,1]).list() #random due to the sets
[{{3, 4}, {2}, {1}},
 {{2, 4}, {3}, {1}},
 {{4}, {2, 3}, {1}},
 {{1, 4}, {2}, {3}},
 {{1, 3}, {4}, {2}},
 {{1, 2}, {4}, {3}}]
```

AUTHORS:

- Mike Hansen
- MuPAD-Combinat developers (for algorithms and design inspiration).

SetPartitions(*s, part=None*)

An unordered partition of a set S is a set of pairwise disjoint nonempty subsets with union S and is represented by a sorted list of such subsets.

SetPartitions(s) returns the class of all set partitions of the set s, which can be a set or a string; if a string, each character is considered an element.

SetPartitions(n), where n is an integer, returns the class of all set partitions of the set [1, 2,..., n].

You may specify a second argument k. If k is an integer, SetPartitions returns the class of set partitions into k parts; if it is an integer partition, SetPartitions returns the class of set partitions whose block sizes correspond to that integer partition.

The Bell number B_n, named in honor of Eric Temple Bell, is the number of different partitions of a set with n elements.

EXAMPLES:

```
sage: S = [1,2,3,4]
sage: SetPartitions(S,2)
Set partitions of [1, 2, 3, 4] with 2 parts
sage: SetPartitions([1,2,3,4], [3,1]).list()
[{{2, 3, 4}, {1}}, {{1, 3, 4}, {2}}, {{3}, {1, 2, 4}}, {{4}, {1, 2, 3}}]
sage: SetPartitions(7, [3,3,1]).cardinality()
70
```

In strings, repeated letters are considered distinct:

```
sage: SetPartitions('aabcd').cardinality()
52
sage: SetPartitions('abcde').cardinality()
52
```

REFERENCES:

- http://en.wikipedia.org/wiki/Partition_of_a_set

class SetPartitions_set(*set*)

cardinality()

EXAMPLES:

```
sage: SetPartitions(4).cardinality()
15
sage: bell_number(4)
15
```

class SetPartitions_setn(*set, n*)

cardinality()

The Stirling number of the second kind is the number of partitions of a set of size n into k blocks.

EXAMPLES:

```
sage: SetPartitions(5, 3).cardinality()
25
sage: stirling_number2(5,3)
25
```

class SetPartitions_setparts(*set, parts*)

cardinality()

Returns the number of set partitions of set. This number is given by the n-th Bell number where n is the number of elements in the set.

If a partition or partition length is specified, then count will generate all of the set partitions.

EXAMPLES:

```
sage: SetPartitions([1,2,3,4]).cardinality()
15
sage: SetPartitions(3).cardinality()
5
sage: SetPartitions(3,2).cardinality()
3
sage: SetPartitions([]).cardinality()
1
```

object_class()

A finite enumerated set.

inf(*s*, *t*)

Returns the infimum of the two set partitions s and t.

EXAMPLES:

```
sage: sp1 = Set([Set([2,3,4]),Set([1])])
sage: sp2 = Set([Set([1,3]), Set([2,4])])
sage: s = Set([ Set([2,4]), Set([3]), Set([1])]) #{{2, 4}, {3}, {1}}
sage: sage.combinat.set_partition.inf(sp1, sp2) == s
True
```

less(*s*, *t*)

Returns True if s < t otherwise it returns False.

EXAMPLES:

```
sage: z = SetPartitions(3).list()
sage: sage.combinat.set_partition.less(z[0], z[1])
False
sage: sage.combinat.set_partition.less(z[4], z[1])
True
sage: sage.combinat.set_partition.less(z[4], z[0])
True
sage: sage.combinat.set_partition.less(z[3], z[0])
True
sage: sage.combinat.set_partition.less(z[2], z[0])
True
sage: sage.combinat.set_partition.less(z[1], z[0])
True
sage: sage.combinat.set_partition.less(z[0], z[0])
False
```

standard_form(*sp*)

Returns the set partition as a list of lists.

EXAMPLES:

```
sage: map(sage.combinat.set_partition.standard_form, SetPartitions(4, [2,2]))
[[[3, 4], [1, 2]], [[2, 4], [1, 3]], [[2, 3], [1, 4]]]
```

sup(*s*, *t*)

Returns the supremum of the two set partitions s and t.

EXAMPLES:

```
sage: sp1 = Set([Set([2,3,4]),Set([1])])
sage: sp2 = Set([Set([1,3]), Set([2,4])])
sage: s = Set([ Set([1,2,3,4]) ])
sage: sage.combinat.set_partition.sup(sp1, sp2) == s
True
```

17.27 Skew Partitions

A skew partition skp of size n is a pair of partitions $[p_1, p_2]$ where p_1 is a partition of the integer n_1, p_2 is a partition of the integer n_2, p_2 is an inner partition of p_1, and $n = n_1 - n_2$. We say that p_1 and p_2 are respectively the *inner* and *outer* partitions of skp.

A skew partition can be depicted by a diagram made of rows of boxes, in the same way as a partition. Only the boxes of the outer partition p_1 which are not in the inner partition p_2 appear in the picture. For example, this is the diagram of the skew partition [[5,4,3,1],[3,3,1]].

```
sage: print SkewPartition([[5,4,3,1],[3,3,1]]).diagram()
   ##
   #
 ##
#
```

A skew partition can be *connected*, which can easily be described in graphic terms: for each pair of consecutive rows, there are at least two boxes (one in each row) which have a common edge. This is the diagram of the connected skew partition [[5,4,3,1],[3,1]]:

```
sage: print SkewPartition([[5,4,3,1],[3,1]]).diagram()
   ##
 ###
###
#
sage: SkewPartition([[5,4,3,1],[3,1]]).is_connected()
True
```

The first example of a skew partition is not a connected one.

Applying a reflection with respect to the main diagonal yields the diagram of the *conjugate skew partition*, here [[4,3,3,2,1],[3,3,2]]:

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).conjugate()
[[4, 3, 3, 2, 1], [3, 2, 2]]
sage: print SkewPartition([[5,4,3,1],[3,3,1]]).conjugate().diagram()
   #
  #
  #
##
#
```

The *outer corners* of a skew partition are the corners of its outer partition. The *inner corners* are the internal corners of the outer partition when the inner partition is taken off. Shown below are the coordinates of the inner and outer corners.

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).outer_corners()
[[0, 4], [1, 3], [2, 2], [3, 0]]
sage: SkewPartition([[5,4,3,1],[3,3,1]]).inner_corners()
[[0, 3], [2, 1], [3, 0]]
```

EXAMPLES: There are 9 skew partitions of size 3.

```
sage: SkewPartitions(3).cardinality()
9
sage: SkewPartitions(3).list()
[[[1, 1, 1], []],
 [[2, 2, 1], [1, 1]],
 [[2, 1, 1], [1]],
 [[3, 2, 1], [2, 1]],
 [[2, 2], [1]],
 [[3, 2], [2]],
 [[2, 1], []],
 [[3, 1], [1]],
 [[3], []]]
```

There are 4 connected skew partitions of size 3.

```
sage: SkewPartitions(3, overlap=1).cardinality()
4
sage: SkewPartitions(3, overlap=1).list()
[[[1, 1, 1], []], [[2, 2], [1]], [[2, 1], []], [[3], []]]
```

This is the conjugate of the skew partition [[4,3,1],[2]]

```
sage: SkewPartition([[4,3,1],[2]]).conjugate()
[[3, 2, 2, 1], [1, 1]]
```

Geometrically, we just applied a reflection with respect to the main diagonal on the diagram of the partition. Of course, this operation is an involution:

```
sage: SkewPartition([[4,3,1],[2]]).conjugate().conjugate()
[[4, 3, 1], [2]]
```

The jacobi_trudy() method computes the Jacobi-Trudi matrix. See Macdonald I.-G., (1995), "Symmetric Functions and Hall Polynomials", Oxford Science Publication for a definition and discussion.

```
sage: SkewPartition([[4,3,1],[2]]).jacobi_trudi()
[h[2]  h[]    0]
[h[5] h[3]  h[]]
[h[6] h[4] h[1]]
```

This example shows how to compute the corners of a skew partition.

```
sage: SkewPartition([[4,3,1],[2]]).inner_corners()
[[0, 2], [1, 0]]
sage: SkewPartition([[4,3,1],[2]]).outer_corners()
[[0, 3], [1, 2], [2, 0]]
```

SkewPartition(*skp*)

Returns the skew partition object corresponding to skp.

EXAMPLES:

```
sage: skp = SkewPartition([[3,2,1],[2,1]]); skp
[[3, 2, 1], [2, 1]]
sage: skp.inner()
[2, 1]
sage: skp.outer()
[3, 2, 1]
```

class **SkewPartition_class**(*skp*)

column_lengths()

Returns the column lengths of the skew partition.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).column_lengths()
[1, 2, 1]
sage: SkewPartition([[5,2,2,2],[2,1]]).column_lengths()
[2, 3, 1, 1, 1]
```

columns_intersection_set()

Returns the set of boxes in the lines of lambda which intersect the skew partition.

EXAMPLES:

```
sage: skp = SkewPartition([[3,2,1],[2,1]])
sage: boxes = Set([ (0,0), (0, 1), (0,2), (1, 0), (1, 1), (2, 0)])
sage: skp.columns_intersection_set() == boxes
True
```

conjugate()

Returns the conjugate of the skew partition skp.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2]]).conjugate()
[[3, 2, 1], [1, 1]]
```

diagram()

Return the Ferrers diagram of self.

EXAMPLES:

```
sage: print SkewPartition([[5,4,3,1],[3,3,1]]).ferrers_diagram()
   ##
   #
 ##
#
sage: print SkewPartition([[5,4,3,1],[3,1]]).diagram()
   ##
 ###
###
#
```

ferrers_diagram()

Return the Ferrers diagram of self.

EXAMPLES:

```
sage: print SkewPartition([[5,4,3,1],[3,3,1]]).ferrers_diagram()
   ##
    #
 ##
#
sage: print SkewPartition([[5,4,3,1],[3,1]]).diagram()
   ##
 ###
###
#
```

inner()

Returns the inner partition of the skew partition.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).inner()
[1, 1]
```

inner_corners()

Returns a list of the inner corners of the skew partition skp.

EXAMPLES:

```
sage: SkewPartition([[4, 3, 1], [2]]).inner_corners()
[[0, 2], [1, 0]]
```

is_connected()

Returns True if self is a connected skew partition.

A skew partition is said to be *connected* if for each pair of consecutive rows, there are at least two boxes (one in each row) which have a common edge.

EXAMPLES:

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).is_connected()
False
sage: SkewPartition([[5,4,3,1],[3,1]]).is_connected()
True
```

is_overlap(*n*)

Returns True if n = self.overlap()

See Also:

overlap()

EXAMPLES:

```
sage: SkewPartition([[5,4,3,1],[3,1]]).is_overlap(1)
True
```

jacobi_trudi()

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2,1]]).jacobi_trudi()
[h[1]    0    0]
[h[3] h[1]    0]
[h[5] h[3] h[1]]
sage: SkewPartition([[4,3,2],[2,1]]).jacobi_trudi()
[h[2]  h[]    0]
[h[4] h[2]  h[]]
[h[6] h[4] h[2]]
```

k_conjugate(*k*)

Returns the k-conjugate of the skew partition.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(3)
[[2, 1, 1, 1, 1], [2, 1]]
sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(4)
[[2, 2, 1, 1], [2, 1]]
sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(5)
[[3, 2, 1], [2, 1]]
```

outer()

Returns the outer partition of the skew partition.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).outer()
[3, 2, 1]
```

outer_corners()

Returns a list of the outer corners of the skew partition skp.

EXAMPLES:

```
sage: SkewPartition([[4, 3, 1], [2]]).outer_corners()
[[0, 3], [1, 2], [2, 0]]
```

overlap()

Returns the overlap of self.

The overlap of two consecutive rows in a skew partition is the number of pairs of boxes (one in each row) that share a common edge. This number can be positive, zero, or negative.

The overlap of a skew partition is the minimum of the overlap of the consecutive rows, or infinity in the case of at most one row. If the overlap is positive, then the skew partition is called *connected*.

EXAMPLES:

```
sage: SkewPartition([[],[]]).overlap()
+Infinity
sage: SkewPartition([[1],[]]).overlap()
+Infinity
sage: SkewPartition([[10],[]]).overlap()
+Infinity
sage: SkewPartition([[10],[2]]).overlap()
+Infinity
sage: SkewPartition([[10,1],[2]]).overlap()
-1
sage: SkewPartition([[10,10],[1]]).overlap()
9
```

pieri_macdonald_coeffs()

Computation of the coefficients which appear in the Pieri formula for Macdonald polynomails given in his book (Chapter 6.6 formula 6.24(ii))

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2,1]]).pieri_macdonald_coeffs()
1
sage: SkewPartition([[3,2,1],[2,2]]).pieri_macdonald_coeffs()
(q^2*t^3 - q^2*t - t^2 + 1)/(q^2*t^3 - q*t^2 - q*t + 1)
sage: SkewPartition([[3,2,1],[2,2,1]]).pieri_macdonald_coeffs()
(q^6*t^8 - q^6*t^6 - q^4*t^7 - q^5*t^5 + q^4*t^5 - q^3*t^6 + q^5*t^3 + 2*q^3*t^4 + q*t^5 - q
sage: SkewPartition([[3,3,2,2],[3,2,2,1]]).pieri_macdonald_coeffs()
(q^5*t^6 - q^5*t^5 + q^4*t^6 - q^4*t^5 - q^4*t^3 + q^4*t^2 - q^3*t^3 - q^2*t^4 + q^3*t^2 + q
```

r_quotient(k)

The quotient map extended to skew partitions.

EXAMPLES:

```
sage: SkewPartition([[3, 3, 2, 1], [2, 1]]).r_quotient(2)
[[[3], []], [[], []]]
```

row_lengths()

Returns the row lengths of the skew partition.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).row_lengths()
[2, 1, 1]
```

rows_intersection_set()

Returns the set of boxes in the lines of lambda which intersect the skew partition.

EXAMPLES:

```
sage: skp = SkewPartition([[3,2,1],[2,1]])
sage: boxes = Set([ (0,0), (0, 1), (0,2), (1, 0), (1, 1), (2, 0)])
sage: skp.rows_intersection_set() == boxes
True
```

size()

Returns the size of the skew partition.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).size()
4
```

to_dag()

Returns a directed acyclic graph corresponding to the skew partition.

EXAMPLES:

```
sage: dag = SkewPartition([[3, 2, 1], [1, 1]]).to_dag()
sage: dag.edges()
[('0,1', '0,2', None), ('0,1', '1,1', None)]
sage: dag.vertices()
['0,1', '0,2', '1,1', '2,0']
```

to_list()

Returns self as a list of lists.

EXAMPLES:

```
sage: s = SkewPartition([[4,3,1],[2]])
sage: s.to_list()
[[4, 3, 1], [2]]
sage: type(s.to_list())
<type 'list'>
```

SkewPartitions(*n=None, row_lengths=None, overlap=0*)

Returns the combinatorial class of skew partitions.

EXAMPLES:

```
sage: SkewPartitions(4)
Skew partitions of 4
sage: SkewPartitions(4).cardinality()
28
sage: SkewPartitions(row_lengths=[2,1,2])
Skew partitions with row lengths [2, 1, 2]
sage: SkewPartitions(4, overlap=2)
```

```
Skew partitions of 4 with overlap of 2
sage: SkewPartitions(4, overlap=2).list()
[[[2, 2], []], [[4], []]]
```

class SkewPartitions_all()

list()
TESTS:

```
sage: SkewPartitions().list()
...
NotImplementedError
```

object_class()

class SkewPartitions_n(*n*, *overlap=0*)

cardinality()
Returns the number of skew partitions of the integer n.
EXAMPLES:

```
sage: SkewPartitions(0).cardinality()
1
sage: SkewPartitions(4).cardinality()
28
sage: SkewPartitions(5).cardinality()
87
sage: SkewPartitions(4, overlap=1).cardinality()
9
sage: SkewPartitions(5, overlap=1).cardinality()
20
sage: s = SkewPartitions(5, overlap=-1)
sage: s.cardinality() == len(s.list())
True
```

list()
Returns a list of the skew partitions of n.
EXAMPLES:

```
sage: SkewPartitions(3).list()
[[[1, 1, 1], []],
 [[2, 2, 1], [1, 1]],
 [[2, 1, 1], [1]],
 [[3, 2, 1], [2, 1]],
 [[2, 2], [1]],
 [[3, 2], [2]],
 [[2, 1], []],
 [[3, 1], [1]],
 [[3], []]]
sage: SkewPartitions(3, overlap=0).list()
[[[1, 1, 1], []],
 [[2, 2, 1], [1, 1]],
 [[2, 1, 1], [1]],
 [[3, 2, 1], [2, 1]],
 [[2, 2], [1]],
 [[3, 2], [2]],
 [[2, 1], []],
 [[3, 1], [1]],
```

```
 [[3], []]]
sage: SkewPartitions(3, overlap=1).list()
[[[1, 1, 1], []], [[2, 2], [1]], [[2, 1], []], [[3], []]]
sage: SkewPartitions(3, overlap=2).list()
[[[3], []]]
sage: SkewPartitions(3, overlap=3).list()
[[[3], []]]
sage: SkewPartitions(3, overlap=4).list()
[]
```

object_class()

class SkewPartitions_rowlengths(*co, overlap=0*)

The combinatorial class of all skew partitions with given row lengths.

list()

Returns a list of all the skew partitions that have row lengths given by the composition self.co.

EXAMPLES:

```
sage: SkewPartitions(row_lengths=[2,2]).list()
[[[2, 2], []], [[3, 2], [1]], [[4, 2], [2]]]
sage: SkewPartitions(row_lengths=[2,2], overlap=1).list()
[[[2, 2], []], [[3, 2], [1]]]
```

object_class()

row_lengths_aux(*skp*)

EXAMPLES:

```
sage: from sage.combinat.skew_partition import row_lengths_aux
sage: row_lengths_aux([[5,4,3,1],[3,3,1]])
[2, 1, 2]
sage: row_lengths_aux([[5,4,3,1],[3,1]])
[2, 3]
```

17.28 Subsets

The combinatorial class of the subsets of a finite set. The set can be given as a list or a Set or else as an integer n which encodes the set $\{1, 2, ..., n\}$. See the `Subsets` for more informations and examples.

AUTHORS:

- Mike Hansen: initial version
- Florent Hivert (2009/02/06): doc improvements + new methods

class SubMultiset_s(*s*)

The combinatorial class of the sub multisets of s.

EXAMPLES:

```
sage: S = Subsets([1,2,2,3], submultiset=True)
sage: S._s
[1, 2, 2, 3]
```

The positions of the unique elements in s are stored in:

```
sage: S._indices
[0, 1, 3]
```

and their multiplicities in:

```
sage: S._multiplicities
[1, 2, 1]
sage: Subsets([1,2,3,3], submultiset=True).cardinality()
12
sage: S == loads(dumps(S))
True
```

class SubMultiset_sk(*s, k*)

The combinatorial class of the subsets of size k of a multiset s. Note that each subset is represented by a list of the elements rather than a set since we can have multiplicities (no multiset data structure yet in sage).

EXAMPLES:

```
sage: S = Subsets([1,2,3,3],2, submultiset=True)
sage: S._k
2
sage: S.cardinality()
4
sage: S.first()
[1, 2]
sage: S.last()
[3, 3]
sage: [sub for sub in S]
[[1, 2], [1, 3], [2, 3], [3, 3]]
sage: S == loads(dumps(S))
True
```

Subsets(*s, k=None, submultiset=False*)

Returns the combinatorial class of the subsets of the finite set s. The set can be given as a list, Set or any iterable convertible to a set. It can alternatively be given a non-negative integer n which encode the set $\{1, 2, \ldots, n\}$ (i.e. the Sage `range(1,s+1)`).

A second optional parameter k can be given. In this case, Subsets returns the combinatorial class of subsets of s of size k.

Finally the option `submultiset` allows one to deal with sets with repeated elements usually called multisets.

EXAMPLES:

```
sage: S = Subsets([1, 2, 3]); S
Subsets of {1, 2, 3}
sage: S.cardinality()
8
sage: S.first()
{}
sage: S.last()
{1, 2, 3}
sage: S.random_element()
{2}
sage: S.list()
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
```

Here is the same example where the set is given as an integer:

```
sage: S = Subsets(3)
sage: S.list()
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
```

We demonstrate various the effect of the various options:

```
sage: S = Subsets(3, 2); S
Subsets of {1, 2, 3} of size 2
sage: S.list()
[{1, 2}, {1, 3}, {2, 3}]

sage: S = Subsets([1, 2, 2], submultiset=True); S
SubMultiset of [1, 2, 2]
sage: S.list()
[[], [1], [2], [1, 2], [2, 2], [1, 2, 2]]

sage: S = Subsets([1, 2, 2, 3], 3, submultiset=True); S
SubMultiset of [1, 2, 2, 3] of size 3
sage: S.list()
[[1, 2, 2], [1, 2, 3], [2, 2, 3]]
```

class Subsets_s (s)

cardinality()

Returns the number of subsets of the set s.

This is given by $2^{|s|}$.

EXAMPLES:

```
sage: Subsets(Set([1,2,3])).cardinality()
8
sage: Subsets([1,2,3,3]).cardinality()
8
sage: Subsets(3).cardinality()
8
```

first()

Returns the first subset of s. Since we aren't restricted to subsets of a certain size, this is always the empty set.

EXAMPLES:

```
sage: Subsets([1,2,3]).first()
{}
sage: Subsets(3).first()
{}
```

last()

Returns the last subset of s. Since we aren't restricted to subsets of a certain size, this is always the set s itself.

EXAMPLES:

```
sage: Subsets([1,2,3]).last()
{1, 2, 3}
sage: Subsets(3).last()
{1, 2, 3}
```

random_element()

Returns a random element of the class of subsets of s (in other words, a random subset of s).

EXAMPLES:

```
sage: Subsets(3).random_element()
{2}
sage: Subsets([4,5,6]).random_element()
{5}
```

rank(*sub*)

Returns the rank of sub as a subset of s.

EXAMPLES:

```
sage: Subsets(3).rank([])
0
sage: Subsets(3).rank([1,2])
4
sage: Subsets(3).rank([1,2,3])
7
sage: Subsets(3).rank([2,3,4]) == None
True
```

unrank(*r*)

Returns the subset of s that has rank k.

EXAMPLES:

```
sage: Subsets(3).unrank(0)
{}
sage: Subsets([2,4,5]).unrank(1)
{2}
sage: s = Subsets([2,4,5])
```

class **Subsets_sk**(*s*, *k*)

cardinality()

EXAMPLES:

```
sage: Subsets(Set([1,2,3]), 2).cardinality()
3
sage: Subsets([1,2,3,3], 2).cardinality()
3
sage: Subsets([1,2,3], 1).cardinality()
3
sage: Subsets([1,2,3], 3).cardinality()
1
sage: Subsets([1,2,3], 0).cardinality()
1
sage: Subsets([1,2,3], 4).cardinality()
0
sage: Subsets(3,2).cardinality()
3
sage: Subsets(3,4).cardinality()
0
```

first()

Returns the first subset of s of size k.

EXAMPLES:

```
sage: Subsets(Set([1,2,3]), 2).first()
{1, 2}
sage: Subsets([1,2,3,3], 2).first()
{1, 2}
```

```
sage: Subsets(3,2).first()
{1, 2}
sage: Subsets(3,4).first()
```

last()
Returns the last subset of s of size k.
EXAMPLES:

```
sage: Subsets(Set([1,2,3]), 2).last()
{2, 3}
sage: Subsets([1,2,3,3], 2).last()
{2, 3}
sage: Subsets(3,2).last()
{2, 3}
sage: Subsets(3,4).last()
```

random_element()
Returns a random element of the class of subsets of s of size k (in other words, a random subset of s of size k).
EXAMPLES:

```
sage: Subsets(3, 2).random_element()
{1, 2}
sage: Subsets(3,4).random_element() is None
True
```

rank(*sub*)
Returns the rank of sub as a subset of s of size k.
EXAMPLES:

```
sage: Subsets(3,2).rank([1,2])
0
sage: Subsets([2,3,4],2).rank([3,4])
2
sage: Subsets([2,3,4],2).rank([2])
sage: Subsets([2,3,4],4).rank([2,3,4,5])
```

unrank(*r*)
Returns the subset of s that has rank k.
EXAMPLES:

```
sage: Subsets(3,2).unrank(0)
{1, 2}
sage: Subsets([2,4,5],2).unrank(0)
{2, 4}
```

17.29 Subwords

A subword of a word w is a word obtained by deleting the letters at some (non necessarily adjacent) positions in w. It is not to be confused with the notion of factor where one keeps adjacent positions in w. Sometimes it is useful to allow repeated uses of the same letter of w in a "generalized" subword. We call this a subword with repetitions.

For example:

- "bnjr" is a subword of the word "bonjour" but not a factor;
- "njo" is both a factor and a subword of the word "bonjour";

- “nr” is a subword of “bonjour”;
- “rn” is not a subword of “bonjour”;
- “nnu” is not a subword of “bonjour”;
- “nnu” is a subword with repetitions of “bonjour”;

A word can be given either as a string or as a list.

AUTHORS:

- Mike Hansen: initial version

Subwords(*w, k=None*)

Returns the combinatorial class of subwords of w. The word w can be given by either a string or a list.

If k is specified, then it returns the combinatorial class of subwords of w of length k.

EXAMPLES:

```
sage: S = Subwords(['a','b','c']); S
Subwords of ['a', 'b', 'c']
sage: S.first()
[]
sage: S.last()
['a', 'b', 'c']
sage: S.list()
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]
```

```
sage: S = Subwords(['a','b','c'], 2); S
Subwords of ['a', 'b', 'c'] of length 2
sage: S.list()
[['a', 'b'], ['a', 'c'], ['b', 'c']]
```

class Subwords_w(*w*)

cardinality()

EXAMPLES:

```
sage: Subwords([1,2,3]).cardinality()
8
```

first()

EXAMPLES:

```
sage: Subwords([1,2,3]).first()
[]
```

last()

EXAMPLES:

```
sage: Subwords([1,2,3]).last()
[1, 2, 3]
```

class Subwords_wk(*w, k*)

cardinality()
Returns the number of subwords of w of length k.
EXAMPLES:

```
sage: Subwords([1,2,3], 2).cardinality()
3
```

first()
EXAMPLES:

```
sage: Subwords([1,2,3],2).first()
[1, 2]
sage: Subwords([1,2,3],0).first()
[]
```

last()
EXAMPLES:

```
sage: Subwords([1,2,3],2).last()
[2, 3]
```

smallest_positions(*word, subword, pos=0*)
Returns the smallest positions for which subword appears as a subword of word. If pos is specified, then it returns the positions of the first appearance of subword starting at pos.

If subword is not found in word, then it returns False.

EXAMPLES:

```
sage: sage.combinat.subword.smallest_positions([1,2,3,4], [2,4])
[1, 3]
sage: sage.combinat.subword.smallest_positions([1,2,3,4,4], [2,4])
[1, 3]
sage: sage.combinat.subword.smallest_positions([1,2,3,3,4,4], [3,4])
[2, 4]
sage: sage.combinat.subword.smallest_positions([1,2,3,3,4,4], [3,4],2)
[2, 4]
sage: sage.combinat.subword.smallest_positions([1,2,3,3,4,4], [3,4],3)
[3, 4]
sage: sage.combinat.subword.smallest_positions([1,2,3,4], [2,3])
[1, 2]
sage: sage.combinat.subword.smallest_positions([1,2,3,4], [5,5])
False
sage: sage.combinat.subword.smallest_positions([1,3,3,4,5],[3,5])
[1, 4]
sage: sage.combinat.subword.smallest_positions([1,3,3,5,4,5,3,5],[3,5,3])
[1, 3, 6]
sage: sage.combinat.subword.smallest_positions([1,3,3,5,4,5,3,5],[3,5,3],2)
[2, 3, 6]
sage: sage.combinat.subword.smallest_positions([1,2,3,4,3,4,4],[2,3,3,1])
False
sage: sage.combinat.subword.smallest_positions([1,3,3,5,4,5,3,5],[3,5,3],3)
False
```

TEST:

```
sage: w = ["a", "b", "c", "d"]; ww = ["b", "d"]
sage: x = sage.combinat.subword.smallest_positions(w, ww); ww # Trac #5534
['b', 'd']
```

17.30 Tuples

Tuples(*S*, *k*)

Returns the combinatorial class of ordered tuples of S of length k.

An ordered tuple of length k of set is an ordered selection with repetition and is represented by a list of length k containing elements of set.

EXAMPLES:

```
sage: S = [1,2]
sage: Tuples(S,3).list()
[[1, 1, 1], [2, 1, 1], [1, 2, 1], [2, 2, 1], [1, 1, 2], [2, 1, 2], [1, 2, 2], [2, 2, 2]]
sage: mset = ["s","t","e","i","n"]
sage: Tuples(mset,2).list()
[['s', 's'], ['t', 's'], ['e', 's'], ['i', 's'], ['n', 's'], ['s', 't'], ['t', 't'],
 ['e', 't'], ['i', 't'], ['n', 't'], ['s', 'e'], ['t', 'e'], ['e', 'e'], ['i', 'e'],
 ['n', 'e'], ['s', 'i'], ['t', 'i'], ['e', 'i'], ['i', 'i'], ['n', 'i'], ['s', 'n'],
 ['t', 'n'], ['e', 'n'], ['i', 'n'], ['n', 'n']]

sage: K.<a> = GF(4, 'a')
sage: mset = [x for x in K if x!=0]
sage: Tuples(mset,2).list()
[[a, a], [a + 1, a], [1, a], [a, a + 1], [a + 1, a + 1], [1, a + 1], [a, 1], [a + 1, 1], [1, 1]]
```

class Tuples_sk(*S*, *k*)

cardinality()

EXAMPLES:

```
sage: S = [1,2,3,4,5]
sage: Tuples(S,2).cardinality()
25
sage: S = [1,1,2,3,4,5]
sage: Tuples(S,2).cardinality()
25
```

UnorderedTuples(*S*, *k*)

Returns the combinatorial class of unordered tuples of S of length k.

An unordered tuple of length k of set is a unordered selection with repetitions of set and is represented by a sorted list of length k containing elements from set.

EXAMPLES:

```
sage: S = [1,2]
sage: UnorderedTuples(S,3).list()
[[1, 1, 1], [1, 1, 2], [1, 2, 2], [2, 2, 2]]
sage: UnorderedTuples(["a","b","c"],2).list()
[['a', 'a'], ['a', 'b'], ['a', 'c'], ['b', 'b'], ['b', 'c'], ['c', 'c']]
```

class UnorderedTuples_sk(*S*, *k*)

cardinality()

EXAMPLES:

```
sage: S = [1,2,3,4,5]
sage: UnorderedTuples(S,2).cardinality()
15
```

list()
EXAMPLES:

```
sage: S = [1,2]
sage: UnorderedTuples(S,3).list()
[[1, 1, 1], [1, 1, 2], [1, 2, 2], [2, 2, 2]]
sage: UnorderedTuples(["a","b","c"],2).list()
[['a', 'a'], ['a', 'b'], ['a', 'c'], ['b', 'b'], ['b', 'c'], ['c', 'c']]
```

17.31 Combinatorial Algebras

17.31.1 Free modules

class CombinatorialFreeModule(*R, cc, element_class=<class 'sage.combinat.free_module.CombinatorialFreeModuleElement'>*, *prefix='B'*)
EXAMPLES: We construct a free module whose basis is indexed by the letters a,b,c:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: F
Free module generated by ['a', 'b', 'c'] over Rational Field
```

Its basis is a family, indexed by a,b,c: Caveat in family: the order of the indices is not preserved

```
sage: e = F.basis()
```

```
sage: list(sorted(e.keys()))
['a', 'b', 'c']
sage: list(sorted(e))
[B['a'], B['b'], B['c']]
```

Let us construct some elements, and compute with them:

```
sage: e['a']
B['a']
sage: 2*e['a']
2*B['a']
sage: e['a'] + 3*e['b']
B['a'] + 3*B['b']
```

class CombinatorialFreeModuleElement(*M, x*)

coefficient(*m*)
EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: z = s([4]) - 2*s([2,1]) + s([1,1,1]) + s([1])
sage: z.coefficient([4])
1
sage: z.coefficient([2,1])
-2
```

coefficients()
Returns a list of the coefficients appearing on the basiselements in self.
EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] - 3*B['c']
sage: f.coefficients()
[1, -3]

sage: s = SFASchur(QQ)
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.coefficients()
[1, 1, 1, 1]
```

is_zero()

Returns True if and only self == 0.

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] - 3*B['c']
sage: f.is_zero()
False
sage: F(0).is_zero()
True

sage: s = SFASchur(QQ)
sage: s([2,1]).is_zero()
False
sage: s(0).is_zero()
True
sage: (s([2,1]) - s([2,1])).is_zero()
True
```

length()

Returns the number of basis elements of self with nonzero coefficients.

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] - 3*B['c']
sage: f.length()
2

sage: s = SFASchur(QQ)
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.length()
4
```

map_coefficients(*f*)

Returns a new element of self.parent() obtained by applying the function f to all of the coefficients of self.

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] - 3*B['c']
sage: f.map_coefficients(lambda x: x+5)
6*B['a'] + 2*B['c']

sage: s = SFASchur(QQ)
sage: a = s([2,1])+2*s([3,2])
```

```
sage: a.map_coefficients(lambda x: x*2)
2*s[2, 1] + 4*s[3, 2]
```

map_mc(*f*)

Returns a new element of self.parent() obtained by applying the function f to a monomial coefficient (m,c) pair. f returns a (new_m, new_c) pair.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: f = lambda m,c: (m.conjugate(), 2*c)
sage: a = s([2,1]) + s([1,1,1])
sage: a.map_monomial(f)
2*s[2, 1] + 2*s[3]
```

map_monomial(*f*)

Returns a new element of self.parent() obtained by applying the function f to a monomial coefficient (m,c) pair. f returns a (new_m, new_c) pair.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: f = lambda m,c: (m.conjugate(), 2*c)
sage: a = s([2,1]) + s([1,1,1])
sage: a.map_monomial(f)
2*s[2, 1] + 2*s[3]
```

map_support(*f*)

Returns a new element of self.parent() obtained by applying the function f to all of the combinatorial objects indexing the basis elements.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: a = s([2,1])+2*s([3,2])
sage: a.map_support(lambda x: x.conjugate())
s[2, 1] + 2*s[2, 2, 1]
```

monomial_coefficients()

Return the internal dictionary which has the combinatorial objects indexing the basis as keys and their corresponding coefficients as values.

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 3*B['c']
sage: d = f.monomial_coefficients()
sage: d['a']
1
sage: d['c']
3
```

```
sage: s = SFASchur(QQ)
sage: a = s([2,1])+2*s([3,2])
sage: d = a.monomial_coefficients()
sage: type(d)
<type 'dict'>
sage: d[ Partition([2,1]) ]
1
sage: d[ Partition([3,2]) ]
2
```

monomials()
EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 2*B['c']
sage: f.monomials()
[B['a'], B['c']]
```

support()
Returns a list of the combinatorial objects indexing the basis elements of self which non-zero coefficients.
EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] - 3*B['c']
sage: f.support()
['a', 'c']

sage: s = SFASchur(QQ)
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.support()
[[1], [1, 1, 1], [2, 1], [4]]
```

terms()
EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] + 2*B['c']
sage: f.terms()
[B['a'], 2*B['c']]
```

to_vector()
Returns a vector version of self.
EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: B = F.basis()
sage: f = B['a'] - 3*B['c']
sage: f.to_vector()
(1, 0, -3)

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: a = 2*QS3([1,2,3])+4*QS3([3,2,1])
sage: a.to_vector()
(2, 0, 0, 0, 0, 4)
```

class **CombinatorialFreeModuleInterface**(*R*, *element_class*)

basis()
Returns the basis of self.
EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: F.basis()
Finite family {'a': B['a'], 'c': B['c'], 'b': B['b']}
```

```
sage: QS3 = SymmetricGroupAlgebra(QQ,3)
sage: list(QS3.basis())
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

combinatorial_class()

Returns the combinatorial class that indexes the basis elements.

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.combinatorial_class()
Combinatorial class with elements in ['a', 'b', 'c']

sage: s = SFASchur(QQ)
sage: s.combinatorial_class()
Partitions
```

dimension()

Returns the dimension of the combinatorial algebra (which is given by the number of elements in the associated combinatorial class).

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.dimension()
3

sage: s = SFASchur(QQ)
sage: s.dimension()
+Infinity
```

get_order()

Returns the order of the elements in the basis.

EXAMPLES:

```
sage: QS2 = SymmetricGroupAlgebra(QQ,2)
sage: QS2.get_order()
[[1, 2], [2, 1]]
```

prefix()

Returns the prefix used when displaying elements of self.

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.prefix()
'B'

sage: X = SchubertPolynomialRing(QQ)
sage: X.prefix()
'X'
```

set_order(*order*)

Sets the order of the elements of the combinatorial class.

If .set_order() has not been called, then the ordering is the one used in the generation of the elements of self's associated combinatorial class.

EXAMPLES:

```
sage: QS2 = SymmetricGroupAlgebra(QQ,2)
sage: b = list(QS2.basis().keys())
sage: b.reverse()
sage: QS2.set_order(b)
```

```
sage: QS2.get_order()
[[2, 1], [1, 2]]
```

sum(*operands*)

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, [1,2,3,4])
sage: F.sum(F.term(i) for i in [1,2,3])
B[1] + B[2] + B[3]
```

term(*i*)

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.term('a')
B['a']
```

zero()

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.zero()
0
```

17.31.2 Combinatorial Algebras

A combinatorial algebra is an algebra whose basis elements are indexed by a combinatorial class. Some examples of combinatorial algebras are the symmetric group algebra of order n (indexed by permutations of size n) and the algebra of symmetric functions (indexed by integer partitions).

The CombinatorialAlgebra base class makes it easy to define and work with new combinatorial algebras in Sage. For example, the following code constructs an algebra which models the power-sum symmetric functions.

```
sage: class PowerSums(CombinatorialAlgebra):
...       def __init__(self, R):
...           self._combinatorial_class = Partitions()
...           self._one = Partition([])
...           self._name = 'Power-sum symmetric functions'
...           self._prefix = 'p'
...           CombinatorialAlgebra.__init__(self, R)
...       def _multiply_basis(self, a, b):
...           l = list(a)+list(b)
...           l.sort(reverse=True)
...           return Partition(l)
...

sage: ps = PowerSums(QQ); ps
Power-sum symmetric functions over Rational Field
sage: ps([2,1])^2
p[2, 2, 1, 1]
sage: ps([2,1])+2*ps([1,1,1])
2*p[1, 1, 1] + p[2, 1]
sage: ps(2)
2*p[]
```

The important things to define are ._combinatorial_class which specifies the combinatorial class that indexes the basis elements, ._one which specifies the identity element in the algebra, ._name which specifies the name of the algebra,

._prefix which is the string put in front of each basis element, and finally a _multiply or _multiply basis method that defines the multiplication in the algebra.

class CombinatorialAlgebra(*R, element_class=None*)

multiply(*left, right*)

Returns left*right where left and right are elements of self. multiply() uses either _multiply or _multiply basis to carry out the actual multiplication.

EXAMPLES:

```
sage: s = SFASchur(QQ)
sage: a = s([2])
sage: s.multiply(a,a)
s[2, 2] + s[3, 1] + s[4]
sage: ZS3 = SymmetricGroupAlgebra(ZZ, 3)
sage: a = 2 + ZS3([2,1,3])
sage: a*a
5*[1, 2, 3] + 4*[2, 1, 3]
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ,3)
sage: j2 = H3.jucys_murphy(2)
sage: j2*j2
(q^3-q^2+q)*T[1, 2, 3] + (q^3-q^2+q-1)*T[2, 1, 3]
sage: X = SchubertPolynomialRing(ZZ)
sage: X([1,2,3])*X([2,1,3])
X[2, 1]
```

class CombinatorialAlgebraElement(*A, x*)

to_matrix()

Returns a matrix version of self obtained by the action of self on the left. If new_BR is specified, then the matrix will be over new_BR.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: a = QS3([2,1,3])
sage: a._matrix_() # indirect doctest
[0 0 1 0 0 0]
[0 0 0 0 1 0]
[1 0 0 0 0 0]
[0 0 0 0 0 1]
[0 1 0 0 0 0]
[0 0 0 1 0 0]
sage: a._matrix_(RDF)
[0.0 0.0 1.0 0.0 0.0 0.0]
[0.0 0.0 0.0 0.0 1.0 0.0]
[1.0 0.0 0.0 0.0 0.0 0.0]
[0.0 0.0 0.0 0.0 0.0 1.0]
[0.0 1.0 0.0 0.0 0.0 0.0]
[0.0 0.0 0.0 1.0 0.0 0.0]
```

17.31.3 Symmetric Group Algebra

class HeckeAlgebraSymmetricGroupElement_t(*A, x*)

HeckeAlgebraSymmetricGroupT(*R, n, q=None*)

Returns the Hecke algebra of the symmetric group on the T basis.

EXAMPLES:

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3)
Hecke algebra of the symmetric group of order 3 on the T basis over Univariate Polynomial Ring i

sage: HeckeAlgebraSymmetricGroupT(QQ, 3, 2)
Hecke algebra of the symmetric group of order 3 with q=2 on the T basis over Rational Field
```

class HeckeAlgebraSymmetricGroup_generic(*R, n, q=None*)

q()

EXAMPLES:

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3).q()
q
sage: HeckeAlgebraSymmetricGroupT(QQ, 3, 2).q()
2
```

class HeckeAlgebraSymmetricGroup_t(*R, n, q=None*)

algebra_generators()

Return the generators of the algebra.

EXAMPLES:

```
sage: HeckeAlgebraSymmetricGroupT(QQ,3).algebra_generators()
[T[2, 1, 3], T[1, 3, 2]]
```

jucys_murphy(*k*)

Returns the Jucys-Murphy element J_k of the Hecke algebra. The Jucys-Murphy elements generate the maximal commutative sub-algebra of the Hecke algebra.

EXAMPLES:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ,3)
sage: j2 = H3.jucys_murphy(2); j2
q*T[1, 2, 3] + (q-1)*T[2, 1, 3]
sage: j3 = H3.jucys_murphy(3); j3
q^2*T[1, 2, 3] + (q^2-q)*T[1, 3, 2] + (q-1)*T[3, 2, 1]
sage: j2*j3 == j3*j2
True
sage: H3.jucys_murphy(1)
...
ValueError: k must be between 2 and n (= 3)
```

t(*i*)

EXAMPLES:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ,3)
sage: H3.t(1)
T[2, 1, 3]
sage: H3.t(2)
T[1, 3, 2]
sage: H3.t(0)
...
ValueError: i must be between 1 and n-1 (= 2)
```

t_action(*a, i*)

Return the action of T_i on a.

EXAMPLES:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: a = H3([2,1,3])+2*H3([1,2,3])
sage: H3.t_action(a, 1)
q*T[1, 2, 3] + (q+1)*T[2, 1, 3]
sage: H3.t(1)*a
q*T[1, 2, 3] + (q+1)*T[2, 1, 3]
```

t_action_on_basis(*perm*, *i*)

EXAMPLES:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: H3.t_action_on_basis(Permutation([2,1,3]), 1)
q*T[1, 2, 3] + (q-1)*T[2, 1, 3]
sage: H3.t_action_on_basis(Permutation([1,2,3]), 1)
T[2, 1, 3]
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3, 1)
sage: H3.t_action_on_basis(Permutation([2,1,3]), 1)
T[1, 2, 3]
