

Elliptic Curves over $\mathbf{Q}(\sqrt{5})$

William Stein, University of Washington

(This is part of the NSF-funded AIM FRG project on Databases of L -functions)

February 2011

1. Finding Curves

Problem 1: Finding Elliptic Curves

Curves Over
 $\mathbf{Q}(\sqrt{5})$

Stein

Tables of Elliptic Curves over $\mathbf{Q}(\sqrt{5})$

- 1 Table 1: All (modular) elliptic curves over $\mathbf{Q}(\sqrt{5})$ with *norm conductor* up to some bound.
- 2 Table 2: A few hundred million elliptic curves over $\mathbf{Q}(\sqrt{5})$ with norm conductor $\leq 10^8$ (say).
- 3 Table 3: Rank records. See Noam Elkies.

Finding Curves via Modular Forms

Curves Over
 $\mathbf{Q}(\sqrt{5})$

Stein

- 1 **Standard Conjecture:** *Rational newforms over $\mathbf{Q}(\sqrt{5})$ correspond to the isogeny classes of elliptic curves over $\mathbf{Q}(\sqrt{5})$.* So we expect to get *all* curves of given conductor by enumerating modular forms over $\mathbf{Q}(\sqrt{5})$.
- 2 There is an approach of Dembele to compute sparse Hecke operators on modular forms over $\mathbf{Q}(\sqrt{5})$. (I have designed and implemented the fastest practical implementation.)
Table got by computing space:
<http://wstein.org/Tables/hmf/sqrt5/dimensions.txt>
- 3 Combine with linear algebra over finite fields and the Hasse bound to get all rational eigenvectors. (Not optimized yet. Requires fast sparse linear algebra – Gonzalo Tornaria has been working on this in Sage lately.)
- 4 Resulting table of eigenforms: http://wstein.org/Tables/hmf/sqrt5/ellcurve_aplists.txt

Computing Modular Forms over $\mathbf{Q}(\sqrt{5})$

Curves Over
 $\mathbf{Q}(\sqrt{5})$

Stein

Overview of Dembele's Algorithm to Compute Forms of level n

- 1 Let $R =$ maximal order in Hamilton quaternion algebra B over $F = \mathbf{Q}(\sqrt{5})$.
- 2 Let $X =$ free abelian group on $S = R^* \setminus \mathbf{P}^1(\mathcal{O}_F/\mathfrak{n})$.
- 3 To compute the Hecke operator T_p on X , compute (and store once and for all) certain $\#\mathbf{F}_p + 1$ elements $\alpha_{p,i} \in B$ with norm p , then compute $T_p(x) = \sum \alpha_{p,i}(x)$.

That's it! Making this *really fast* took thousands of lines of tightly written Cython code, treatment of special cases, etc.

http://code.google.com/p/purplesage/source/browse/psage/modform/hilbert/sqrt5/sqrt5_fast.pyx

Rational Newforms over $\mathbb{Q}(\sqrt{5})$

Curves Over

Implementation in Sage: Uses C_{ython}=(C+Python)/2

Curves Over
 $\mathbb{Q}(\sqrt{5})$

Stein

Install PSAGE: <http://code.google.com/p/purplesage/>.

Hecke Operators over $\mathbb{Q}(\sqrt{5})$ in Sage

```
sage: import psage.modform.hilbert.sqrt5 as H
sage: N = H.tables.F.factor(100019)[0][0]; N
Fractional ideal (65*a + 292)

sage: time S = H.HilbertModularForms(N); S
Time: CPU 0.31 s, Wall: 0.34 s
Hilbert modular forms of dimension 1667, level 65*a+292
(of norm 100019=100019) over QQ(sqrt(5))

sage: time T5 = S.hecke_matrix(H.tables.F.factor(5)[0][0])
Time: CPU 0.07 s, Wall: 0.09 s
```

(Yes, that just took much less than a second!)

See <http://nt.sagenb.org/home/pub/30/> for all code.

Magma?

Curves Over
 $\mathbb{Q}(\sqrt{5})$

Stein

Why not just use Magma, which already has modular forms over totally real fields in it, due to the general work of John Voight, Lassina Dembele, and Steve Donnelly:

```
[wstein ]$ magma
Magma V2.16-13      Fri Nov  5 2010 18:09:32
> F<w> := QuadraticField(5);
> M := HilbertCuspForms(F,
      Factorization(Integers(F)*100019)[1][1]);
> time T5 := HeckeOperator(M,
      Factorization(Integers(F)*5)[1][1]);
Time: 235.730      # 4 minutes
```

Thousand times slower than my implementation in Sage.

Magma's implementation is *very* general. And the above was just one Hecke operator. We'll need many, and Magma gets *much* slower as the subscript of the Hecke operator grows.

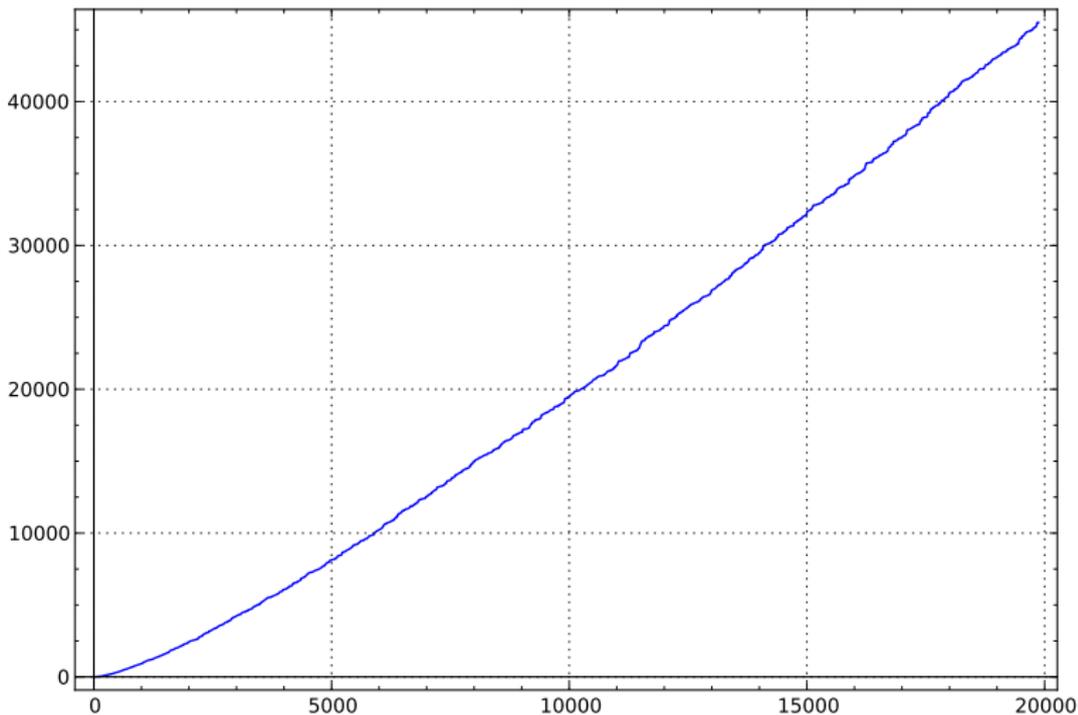

(REMARK: After the talk, John Voight and I decided that with the newest Magma V2.17, and with very careful use of Magma (diving into the source code), one could do the above computation with it only taking 100 times longer than Sage.)

How Many Isogeny Classes of Curves?

Curves Over
 $\mathbf{Q}(\sqrt{5})$

Stein

Rational Newforms over $\mathbf{Q}(\sqrt{5})$ of level up to N

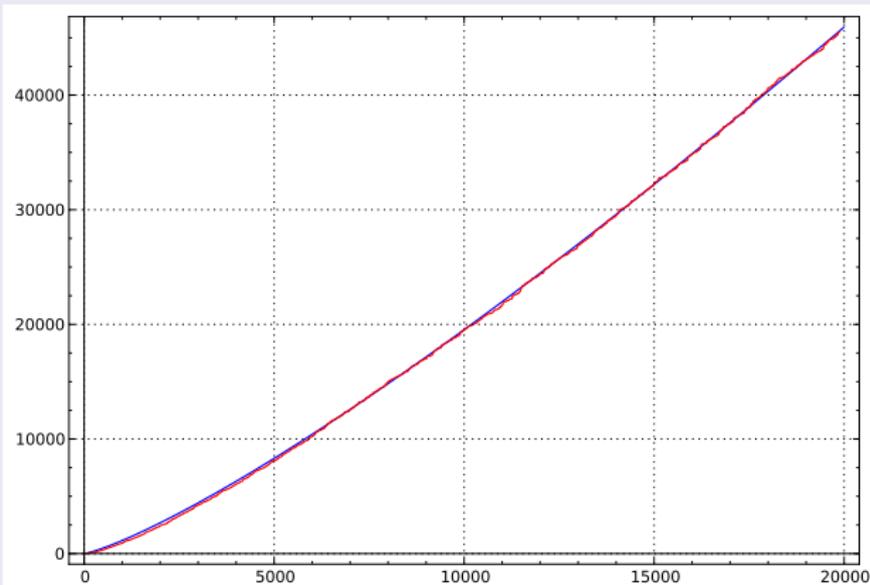

How Many Isogeny Classes of Curves?

Curves Over
 $\mathbf{Q}(\sqrt{5})$

Stein

Rational Newforms over $\mathbf{Q}(\sqrt{5})$ of level $\leq X$ (Least Squares)

$$\#\{\text{newforms with norm level up to } X\} \sim 0.227X^{1.234}$$

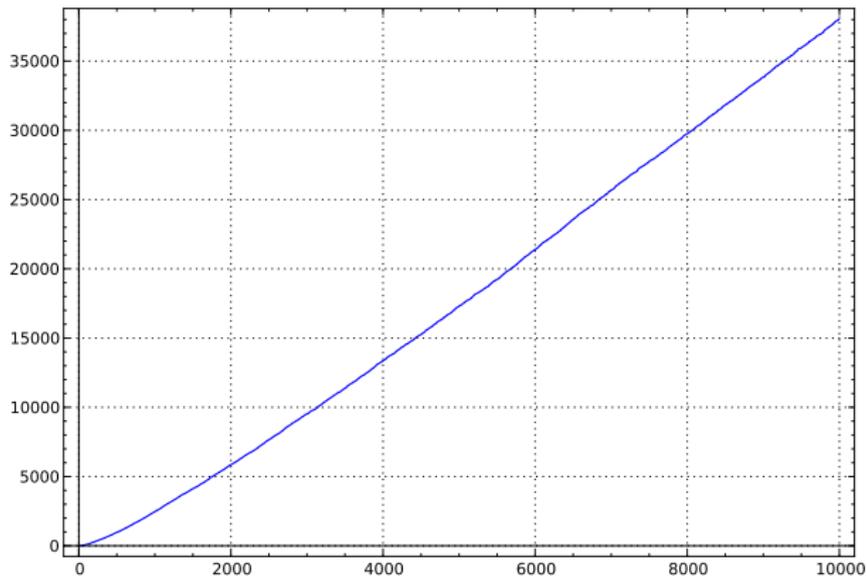

For comparison, Cremona's tables up to 10,000

Curves Over
 $\mathbb{Q}(\sqrt{5})$

Stein

Cremona's tables

Conjecture (Watkins): Number of elliptic curves over \mathbb{Q} with level up to X is $\sim cX^{5/6}$.

Rational Newforms \mapsto Curves over $\mathbb{Q}(\sqrt{5})$

Curves Over
 $\mathbb{Q}(\sqrt{5})$

Stein

- 1 Big search through equations, compute corresponding modular form by a point count, and look up in table. (Joanna Gaski and Alyson Deines doing this now:
http://wstein.org/Tables/hmf/sqrt5/finding_weierstrass_equations/)
- 2 Or, apply Dembele's paper *An Algorithm For Modular Elliptic Curves Over Real Quadratic Fields* (I haven't implemented this yet; how good in practice?)
- 3 Or, apply the method of Cremona-Lingham to find the curves by finding S -integral points over number fields. (Not implemented in Sage.)
- 4 Enumerate the curves in an isogeny class.
 - 1 For a specific curve, bound the degrees of isogenies using the Galois representation. (Don't know how to do this yet.)
 - 2 Explicitly compute all possible isogenies, e.g., using Cremona's student Kimi Tsukazaki's Ph.D. thesis full of isogeny formulas. (I'm not sure how to do this.)

Comment from Noam Elkies about previous Slide

Curves Over
 $\mathbb{Q}(\sqrt{5})$

Stein

Noam Elkies: “Apropos Cremona-Lingham: remember that at Sage Days 22 I suggested a way to reduce this to solving S -unit equations (via the lambda-invariant), which is effective, unlike finding S -integral points on $y^2 = x^3 + k$.

Also, see my Atkin paper

<http://www.math.harvard.edu/~elkies/xisog.pdf>?”

Elliptic Curves over $\mathbb{Q}(\sqrt{5})$

Joanna Gaski and Alyson Deines make tables like this ($a = (1 + \sqrt{5})/2$)

Canonical Minimal Weierstrass Model?

Curves Over
 $\mathbf{Q}(\sqrt{5})$

Stein

Canonical Minimal Weierstrass Models over \mathbf{Q}

Fact: Every elliptic curve over \mathbf{Q} has a unique minimal Weierstrass equation $[a_1, a_2, a_3, a_4, a_6]$ with $a_1, a_3 \in \{0, 1\}$ and $a_2 \in \{0, -1, 1\}$?

What about $\mathbf{Q}(\sqrt{5})$

Cremona: Something similar is true for number fields, for appropriate choices of conventions. ...

“Let me know what ideas you come up with for the unit scalings, since we need to set a convention for the rest of the world to use!” – Cremona, email, 2010-10-28

(Not worked out yet.)

Huge Table: Like Stein-Watkins over $\mathbf{Q}(\sqrt{5})$

Curves Over
 $\mathbf{Q}(\sqrt{5})$

Stein

- 1 Enumerate over pairs (c_4, c_6) that satisfy certain congruence conditions so they define a minimal curve, with bounded discriminant and conductor. (Details being worked out by Joanni and Aly; they estimate that there are about 3 million pairs c_4, c_6 modulo 1728 to consider.)
- 2 Compute first few a_p for each curve; use these a_p as a key, and keep only one curve from each isogeny class.
- 3 Get a table of hundreds of millions of curves over $\mathbf{Q}(\sqrt{5})$.
- 4 Compute data, e.g., analytic rank, about each.

2. What to do with 'em

Problem 2: Computing With Curves

Curves Over
 $\mathbf{Q}(\sqrt{5})$

Stein

Some Invariants of an Elliptic Curve over $\mathbf{Q}(\sqrt{5})$

- 1 Torsion subgroup
- 2 Tamagawa numbers and Kodaira symbols
- 3 Rank and generators for $E(\mathbf{Q}(\sqrt{5}))$: Simon 2-descent is relevant
- 4 Regulator
- 5 $L(E, s)$: analytic rank, leading coefficient, zeroes in critical strip
- 6 $\#\text{III}(E)_{\text{an}}$: conjectural order of III.

BSD Challenges

Curves Over
 $\mathbf{Q}(\sqrt{5})$

Stein

Some Challenges

- 1 Verify that $\#\text{III}(E)_{\text{an}}$ is approx. perfect square for curves with norm conductor up to some bound.
- 2 Prove the full BSD conjecture for a curve over $\mathbf{Q}(\sqrt{5})$.
- 3 Prove the full BSD conjecture for a curve over $\mathbf{Q}(\sqrt{5})$ that doesn't come by base change from a curve over \mathbf{Q} .
- 4 Verify Kolyvagin's conjecture for a curve of rank ≥ 2 .

Nothing done at all yet! Proving BSD for specific curves will likely require explicit computation with Heegner points, the Gross-Zagier formula, etc., following Zhang. It also likely requires proving something new using Euler systems.

Other Interesting things to compute

Curves Over
 $\mathbf{Q}(\sqrt{5})$

Stein

Other invariants...

- 1 **All integral points:** a recent student (Nook) of Cremona did this in Magma, so port it. (See next slide.)
- 2 Compute **Heegner points**, as defined by Zhang. Find their height using his generalization of the Gross-Zagier formula. (Requires level is not a square.)
- 3 **Congruence number:**
 - 1 define using quaternion ideal Hecke module,
 - 2 or define via congruences between q -expansions.
- 4 **Galois representations:** Images of Galois (like Sutherland did for elliptic curves over \mathbf{Q})
- 5 **Congruence graph:** between all elliptic curves up to some conductor, where two curves are connected if they have the same mod p representations.

Integral Points over Number Fields

Curves Over
 $\mathbb{Q}(\sqrt{5})$

Stein

Hi William,

I saw the slides for your talk on elliptic curves over $\mathbb{Q}(\sqrt{5})$. You mention translating Nook's Magma code for integral points as a future project. That's exactly what Jackie Anderson and I did at Sagedays 22. If someone is interested in that, make sure they look our work first (code attached).

The translation is done. There is a speed up against Magma version by using python generators. What needs to be done is a bit more testing (against Magma version). John Cremona warned us to be careful with this algorithm because it produces an upper bound and exhaustively searches up to it. If the bound is a bit lower it might fail on rare occasions.

Rado Kirov

Rank Records

Curves Over
 $\mathbf{Q}(\sqrt{5})$

Stein

The Rank Challenge Problem

What is the “simplest” (smallest norm conductor) elliptic curve over $\mathbf{Q}(\sqrt{5})$ of rank 0, 1, 2, 3, 4, 5,...? Best known records:

| Rank | Norm(N) | Equation | Person |
|------|-----------------|------------------------------|---------|
| 0 | 31 (prime) | $[1, a+1, a, a, 0]$ | Dembele |
| 1 | 199 (prime) | $[0, -a-1, 1, a, 0]$ | Dembele |
| 2 | 1831 (prime) | $[0, -a, 1, -a-1, 2a+1]$ | Dembele |
| 3 | $26569 = 163^2$ | $[0, 0, 1, -2, 1]$ | Elkies |
| 4 | 1209079 (prime) | $[1, -1, 0, -8-12a, 19+30a]$ | Elkies |
| 5 | 64004329 | $[0, -1, 1, -9-2a, 15+4a]$ | Elkies |

Best possible? (Over \mathbf{Q} the corresponding best known conductors are 11, 37, 389, 5077, 234446, and 19047851.)

Examples: Curves of rank 0,1,2 in detail

Curves Over
 $\mathbb{Q}(\sqrt{5})$

Stein

I computed all BSD invariants and solved for III_{an} for the first curves of rank 0,1,2.

Bit of a disaster...

Example: Rank 0 Curve of Norm Conductor 31

$$E : y^2 + xy + ay = x^3 + (a + 1)x^2 + ax$$

| | |
|------------------|------------------------------------|
| Conductor | $5a - 2$ |
| Torsion | $\mathbf{Z}/8\mathbf{Z}$ |
| Tamagawa Numbers | $c_p = 1$ (l1) |
| Rank and gens | 0 |
| Regulator | 1 |
| $L^*(E, 1)$ | 0.359928959498039 |
| Real Periods | 3.05217315335726, 8.43805988789973 |

$$\begin{aligned}\text{III}(E)_{\text{an}} &= \frac{\sqrt{D} \cdot L^*(E, 1) \cdot T^2}{\Omega_E \cdot \text{Reg}_E \cdot \prod c_p} \\ &= \sqrt{5} \cdot 0.35992 \cdot 8^2 / (3.05217 \cdot 8.43805) = 2.0000000 \dots\end{aligned}$$

Why is this wrong? Guess: Ω_E is somehow wrong...?

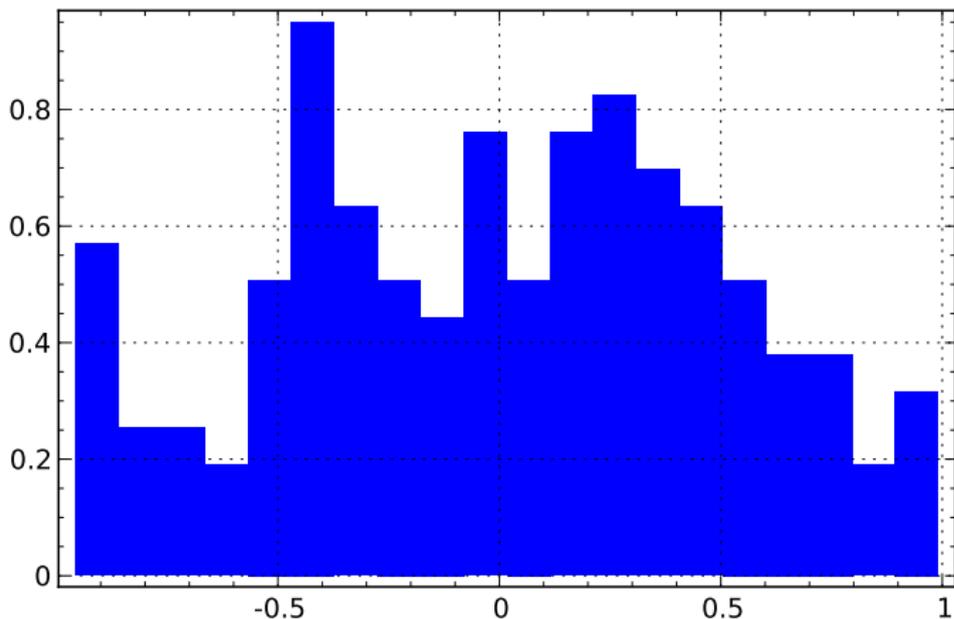

Example: Rank 0 Curve of Norm Conductor 31

Curves Over
 $\mathbb{Q}(\sqrt{5})$

Stein

$$E : y^2 + xy + ay = x^3 + (a + 1)x^2 + ax$$

Sato-Tate Distribution: Primes up to Norm 1000

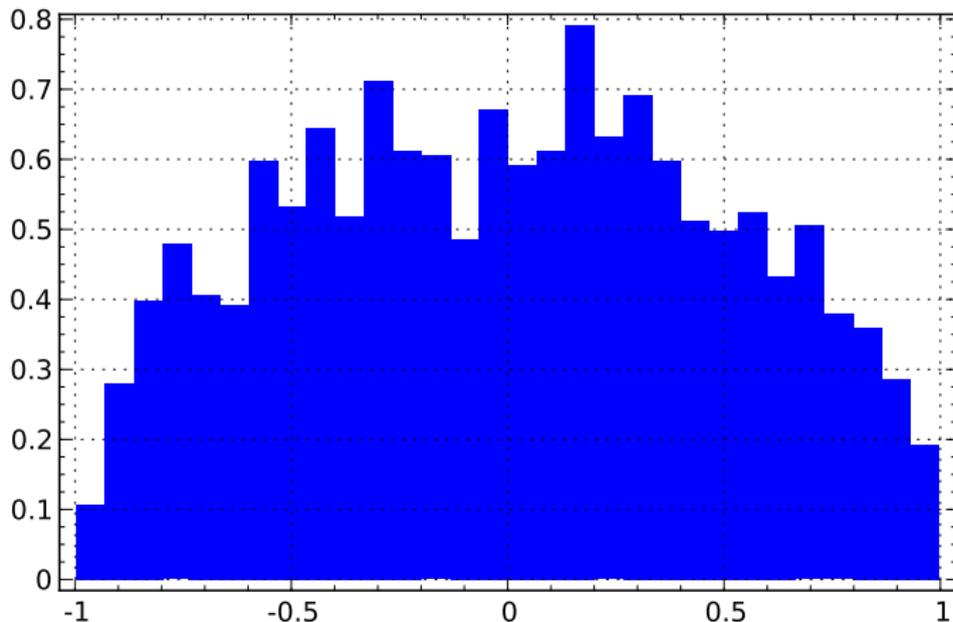

Example: Rank 0 Curve of Norm Conductor 31

Curves Over
 $\mathbb{Q}(\sqrt{5})$

Curves Over
 $\mathbb{Q}(\sqrt{5})$

Stein

$$E : y^2 + y = x^3 + (-a - 1)x^2 + ax$$

Table for the curve 199

| | |
|------------------|------------------------------------|
| Conductor | $3a + 13$ |
| Torsion | $\mathbf{Z}/3\mathbf{Z}$ |
| Tamagawa Numbers | $c_p = 1$ (I1) |
| Rank and gens | 1, gen (0, 0) |
| Regulator | 0.154308568543030 |
| $L^*(E, 1)$ | 0.657814883009960 |
| Real Periods | 3.53489274657737, 6.06743219455559 |

$$\begin{aligned} \text{III}(E)_{\text{an}} &= \frac{\sqrt{D} \cdot L^*(E, 1) \cdot T^2}{\Omega_E \cdot \text{Reg}_E \cdot \prod c_p} \\ &= \sqrt{5} \cdot 0.657 \cdot 3^2 / (3.53 \cdot 6.067 \cdot 0.154 \cdot 1) = 4.00000 \dots \end{aligned}$$

Integral Points for curve 199

Curves Over
 $\mathbb{Q}(\sqrt{5})$

Stein

Rado Kirov and Jackie Anderson's Code...

```
sage: E = EllipticCurve([0,-a-1,1,a,0]); show(E)
sage: integral_points(E, E.gens())
[(a : -1 : 1), (a + 1 : a : 1), (2*a + 2 : -4*a - 3 : 1),
(-a + 3 : 3*a - 5 : 1), (-a + 2 : -2*a + 2 : 1),
(6*a + 3 : 18*a + 11 : 1),
(-42*a + 70 : -420*a + 678 : 1),
(1 : 0 : 1), (0 : 0 : 1)]
```

Example: Rank 2 Curve of Norm Conductor 1831

Curves Over
 $\mathbb{Q}(\sqrt{5})$

Stein

$$E : y^2 + y = x^3 + (-a)x^2 + (-a - 1)x + (2a + 1)$$

Table for the curve 1831

| | |
|------------------|---------------------------------------------------------------------------------------------------|
| Conductor | $7a + 40$ |
| Torsion | 1 |
| Tamagawa Numbers | $c_p = 1$ (11) |
| Rank and gens | 2, gens $(0 : -a - 1 : 1)$, $(-\frac{3}{4}a + \frac{1}{4} : -\frac{5}{4}a - \frac{5}{8} : 1)$ |
| Regulator | 0.191946627694056 |
| $L^*(E, 1)$ | 2.88288222151816 |
| Real Periods | 3.75830925418163, 5.02645072067941 |

$$\text{III}(E)_{\text{an}} = \frac{\sqrt{D} \cdot L^*(E, 1) \cdot T^2}{\Omega_E \cdot \text{Reg}_E \cdot \prod c_p} = 0.888888888888 \dots \sim \frac{8}{9}$$

Wrong again. Why? Probably the regulator is wrong (saturation).

Remark About Sha Orders

Curves Over
 $\mathbb{Q}(\sqrt{5})$

Stein

Some remarks about Sha being wrong. E.g., Dan Kane and Henri Cohen both pointed out that “there may be a factor of 2^r coming from inconsistent normalizations of the height/regulator.”

Noam Elkies: “Finally, for your two examples where $\#III$ seems to be 2 or $8/9$, the discriminant in each case has negative norm, so one positive and one negative conjugate; I think this means the real locus has two components, so indeed Ω_E should be doubled. This will fix the first $\#III$. The second one is still the bizarre $4/9$. So we must also explore your suggestion about saturation. Indeed a naive search quickly returns a point $(1, -a)$, and then 3 times this point plus 6 times your generator $(0, -a-1)$ gives your second generator. So indeed we find a group containing the span of your two generators with index 3.”

The rank 1 example has a factor of 2 coming from Elkies's remark, and a factor coming from the rank, so there is still something amiss!

Summary

Curves Over
 $\mathbb{Q}(\sqrt{5})$

Stein

- 1 Three kinds of tables: all curves up to given conductor (like Cremona), large number of curves (like Stein-Watkins), rank records (like Elkies)
- 2 Compute all BSD invariants: much work remains
- 3 L -functions: zeros, Sato-Tate data, etc.
- 4 Integral points
- 5 For everything, much work remains.
